Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

```matlab
1   In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

classdef Parameter < Simulink.Parameter
    methods
        function setupCoderInfo(obj)
            useLocalCustomStorageClasses(obj, 'mypkg');
            obj.CoderInfo.StorageClass = 'Custom';
    end
end % classdef
```
Open the Custom Storage Class Designer for your package.

cscdesigner('mypkg')

Define storage classes.

Optional: Define custom attributes for storage classes

Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs` folder, where `+mypkg` is the folder containing the @Parameter and @Signal folders.

Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```matlab
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        AlternateName = '';
    end
end % classdef
```

Override the default implementation of the `isAddressable` method to determine whether the storage class is writable.

```matlab
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'logical scalar')
        IsAlternateNameInstanceSpecific = true;
    end
    methods
        function retVal = isAddressable(hObj, hCSCDefn, hData)
            retVal = false;
        end
    end % methods
end % classdef
```

Override the default implementation of the `getInstanceSpecificProps` method.

For examples, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\Simulink\@CSCTypeAttributes_FlatStructure` and `CSCTypeAttributes_Unstructed.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\Simulink\@CSCTypeAttributes_Unstructed`.
Note This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

Note In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        GetFunction = '';
        SetFunction = '';
    end

    methods
        function retVal = getIdentifiersForInstance(hCSCAttrib,...
            hCSCDefn, hData, identifier)
            retVal = struct('GetFunction',...
                hData.CoderInfo.CustomAttributes.GetFunction, ...'
            'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
        end%
    end % methods
end % classdef

6 If you are using grouped storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.
For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

Determine Where to Store Variables and Objects for Simulink Models

Model data are objects and variables that you create in workspaces such as the base workspace or a data dictionary. Model data include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Data types
- Model configuration sets
- Simulation input and output data

You can store, partition, and share model data in a location that is appropriate for your design. The storage locations that you choose can depend on:

- Your modeling goals.
- The model architecture (referenced models, subsystems, and other partitioning strategies) and component structure.
- The types of data that you use.

Types of Data

- **Simulation data** is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation acquires through Inport blocks. A simulation can export output data through, for example, Outport blocks, To Workspace blocks, and logged signals.

You can store simulation data for your current MATLAB session in the base workspace. To permanently store this simulation data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Comparison of Signal Loading Techniques” on page 68-124 and “Export Simulation Data” on page 68-3.

- **Design data** is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, parameter and signal data objects, data type objects, and bus objects.
You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To permanently store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- Configuration sets are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

**Store Data for Your Design**

The table shows the techniques you can use to store, partition, and manage design data and configuration sets.

### Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
• A model workspace. Use a model workspace to permanently store data that is local to a model.

• A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 66-174.

**Temporary Data: Base Workspace**

Use the base workspace to temporarily store data:

• While you learn to use Simulink

• When you need to quickly create variables while experimenting with modeling techniques
• When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

**Local Data: Model Workspace**

Use a model workspace to store data that you use only in the associated model. This data can include:

• Constant parameters, for example, numeric variables that you use to specify block parameter values.

• Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, signal objects in a model workspace can use only the Auto storage class. If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

• `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `IsAlias` property to false.

• Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.
You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 66-162.

**Global and Shared Data: Data Dictionary**

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, you can still use variables in the base workspace by configuring access from either the model or the dictionary.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects, including signal objects (such as `Simulink.Signal`) that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.Bus` objects that you use to define signal interfaces between referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.
You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

**Considerations for Code Generation**

If you intend to generate C code from a model (Simulink Coder), take these considerations into account.

- If you apply a storage class other than `Auto` to a signal object (such as `Simulink.Signal`) to control the appearance of a signal or block state in the generated code, you cannot store the object in a model workspace. Store the object in the base workspace or a data dictionary. For more information about storage classes for signals and states, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

- If you apply a storage class other than `Auto` to a parameter object (such as `Simulink.Parameter`), you can store the object in the base workspace, a model workspace, or a data dictionary. However, if you store the object in a model workspace, the code generator assumes that the containing model owns the parameter. For more information, see “Code Generation Impact of Storage Location for Parameter Objects” (Simulink Coder).

Create, Edit, and Manage Workspace Variables

To share information such as parameter values and signal data types between separate blocks and models, you use workspace variables. For example, you can create a numeric MATLAB variable in the base workspace and use the variable to set the value of the Gain parameter in multiple Gain blocks simultaneously (see “Share and Reuse Block Parameter Values by Creating Variables” on page 38-13). You can create a Simulink.Bus object to explicitly define the structure of a bus signal.

You can store workspace variables in the base workspace, model workspaces, or data dictionaries. To decide where to store variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 66-134.

Tools for Managing Variables

Use one or more of these techniques to create, modify, store, and migrate workspace variables:

- To share block parameter values and create Simulink.Parameter and Simulink.Signal objects (for example, in preparation for code generation), you can use the Model Data Editor. You can interact with all of the block parameters, signal lines, and block states in a model at once. You can also inspect tunable block parameters in a list that you can search, sort, and filter.

- To create a variable, in the data table, begin editing the cell that corresponds to a block parameter value (in the Value column) or a signal or state name (in the Name column). Enter the name of the variable you want to create and click the action button in the right side of the cell.

  If a block parameter value is already set to a simple numeric expression, you can create a variable for that expression. Click in the right side of the cell that corresponds to the value, then select Create variable. In the Create New Data dialog box, set the name and location for the new variable, then click Create. The cell now displays the new variable.

- To modify variables by using the columns in the data table, click the Show/refresh additional information button. Then, the data table contains rows that correspond to the variables and objects that the model uses.

- To interact with one variable at a time (for example, to inspect all of the variable properties at once), open the Property Inspector (on the Modeling tab, under
Design, click Property Inspector) and select the relevant row in the data table. The Property Inspector shows the properties of the selected variable.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

- To interact with a small number of parameters, signals, or states at a time, use individual block parameter dialog boxes or the Property Inspector to create variables for sharing block parameter values and create and configure parameter and signal objects for code generation.

In the dialog box or the Property Inspector, click the action button next to the value of a block parameter, signal name, or state name.

- To create and edit any type or class of variable or object, move variables between workspaces, and inspect all of the variables in a workspace at once, use the Model Explorer. You can also rename variables and precisely analyze the way that an entire model or an individual block uses variables. See “Search and Edit Using Model Explorer” on page 13-2 and “Edit and Manage Workspace Variables by Using Model Explorer” on page 66-149.

**Edit Variable Value or Property From Block Parameter**

This example shows how to change the value of a Gain parameter (Gain block) whose value is set by a numeric variable. Modify the variable, not the block parameter.

1. Open the model f14. The model loads variables into the base workspace.
3. In the model, select the Gain block that uses the variable Mw.
4. In the Property Inspector, click the button next to the value of the Gain parameter. Select Open.
5. In the Data properties dialog box, type a new value for the variable in the Value box and click OK.

**Modify Structure and Array Variables Interactively**

To inspect and modify a variable whose value is a structure or array, you can launch the Variable Editor by clicking the nearby button. Choose one of these techniques:
• In the Model Explorer, select the variable in the Contents pane. In the Dialog pane (the right pane), the button appears.

• In the Model Data Editor (on the Modeling tab, click Model Data Editor), on the Parameters tab, click the Show/refresh additional information button. In the data table, find the row that corresponds to the variable and, in the Value column, begin editing the value of the variable. The button appears in the right side of the cell.

• In a block dialog box or the Property Inspector, the button appears next to the value of a block parameter that uses the variable. Click the button and use the menu options to open the property dialog box for the variable. Then, in the property dialog box, click the button again to launch the Variable Editor. You can use this technique only for parameter objects such as Simulink.Parameter.

### Ramifications of Modifying or Deleting a Variable

When you modify or delete a variable, the change can impact multiple blocks and models that use the variable. To assess the impact by determining where the variable is used, use the Model Explorer (see “Analyze Variable Usage in a Model” on page 66-146). However, you can analyze variable usage only for models that are open at the time of the analysis. Before you perform the analysis, open any models that you suspect use the variable.

Models and blocks use variables through name resolution (see “Symbol Resolution” on page 66-174). When you change the name of a variable without making corresponding changes to dependent blocks and models, the blocks and models generate errors. Instead, to rename a variable in the context of one or more models, see “Rename a Variable Throughout a Model” on page 66-146.

When a block or model cannot access a variable that it needs, it generates an error in the Diagnostic Viewer. In some cases, you can use buttons in the Diagnostic Viewer to fix the error (for example, by restoring a deleted variable). To increase the likelihood that you can use the Diagnostic Viewer to recover from the absence of a variable, use these techniques:

• Store variables in a data dictionary instead of the base workspace. With a data dictionary, you gain additional options for recovery. For information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

• For every model, keep the corresponding Simulink cache file available. For example, when you share the model with someone else, share the cache file, too. When you fetch the latest model design files from a source control system, fetch the cache file from the continuous integration system or latest build folder. The cache file preserves
information that Simulink Coder can use to help you recover from the absence of a variable. For more information about Simulink cache files, see “Share Build Artifacts for Faster Simulation and Code Generation” on page 8-77.

### Analyze Variable Usage in a Model

To analyze the ways in which a model uses variables, use the Model Explorer. You can:

- Determine where a variable is used in a model.
- Determine whether a model uses a variable.
- Determine which variables in a workspace are not used by a model.

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 66-149.

### Rename a Variable Throughout a Model

This example shows how to rename a variable in the Model Data Editor:

1. Open the model `f14`. The model loads variables into the base workspace.
2. In the model, on the Modeling tab, click Model Data Editor. In the Model Data Editor, inspect the Parameters tab.
3. In the model, click the Gain block labeled `Mw`.
   
   In the Model Data Editor, the Value column shows that the block uses the variable `Mw`. Suppose you want to rename this variable.
4. In the Model Data Editor, click the Show/refresh additional information button.
   
   Now, the data table contains rows that correspond to workspace variables that the model uses.
5. Activate the Change scope button.
   
   Now, the data table shows information about data items in subsystems.
6. In the Filter contents box, enter `Mw`.
   
   The data table shows rows that correspond to the variable and to blocks that use the variable.
7. In the row that represents `Mw`, right-click and select Rename All.
8 In the **Select a system** dialog box, click the name of the model `f14` to select it as the context for renaming the variable `Mw`.

9 Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

10 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.

11 Click **Show/refresh additional information** again. Because the renaming operation changed the name of the variable and the values of some block parameters, for more accurate information in the Model Data Editor, you must click **Show/refresh additional information**.

### Interact With Variables Programmatically

At the command prompt, you can create and modify variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create, modify, and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

<table>
<thead>
<tr>
<th>Target Workspace</th>
<th>Technique or Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base workspace</td>
<td>Enter commands at the command prompt.</td>
</tr>
<tr>
<td>Model workspace</td>
<td>See <code>Simulink.ModelWorkspace</code></td>
</tr>
<tr>
<td>Data dictionary</td>
<td>See “Store Data in Dictionary Programmatically” on page 70-48.</td>
</tr>
</tbody>
</table>

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the
variables through the programmatic workspace interfaces. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 38-52.

“Export Workspace Variables” on page 66-158
“Importing Workspace Variables” on page 66-160

To learn all of the techniques you can use to create, edit, and manage workspace variables, see “Create, Edit, and Manage Workspace Variables” on page 66-143.

Finding Variables That Are Used by a Model or Block

In the Model Explorer, you can get a list of variables that a model or block uses. The following approach is one way to get that list of variables:

1. In the Contents pane, right-click the block for which you want to find the variables that it uses.
2. Select the Find Referenced Variables menu item.
Model Explorer returns results similar to these:

For performance, Model Explorer uses cached information from the last compiled version of the model. If you want to recompile the model, either do so manually or, in the Model Explorer, set the **Update diagram** field to **yes** and repeat the search.
You can also use the following approaches to find variables that a model or block uses:

- In the Model Explorer, in the **Model Hierarchy** pane, right-click a block or model node and select the **Find Referenced Variables** menu item.
- In the Model Explorer, in the search bar, use the **for Referenced Variables** search type option.
- In the Simulink Editor, right-click a block, subsystem, or in the canvas and select the **Find Referenced Variables** menu item. Clicking the canvas returns results for the whole model.

The `Simulink.findVars` function provides additional options for returning information about workspace variables that is not available from the Model Explorer or Simulink Editor.

For information about limitations when finding referenced variables, see the `Simulink.findVars` documentation.

**Using the Set of Returned Variables**

For a variable in the set of returned variables, you can find the blocks that use that variable (for details, see “Finding Blocks That Use a Specific Variable” on page 66-151). Also, you can export variables from the returned set of variables. For details, see “Export Workspace Variables” on page 66-158.

**Finding Blocks That Use a Specific Variable**

This example shows how to use Model Explorer to get a list of blocks that use a specific workspace variable.

1. Open the model `f14`.
2. Open Model Explorer.
3. In the **Model Hierarchy** pane, select the **Base Workspace** node.
4. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
5. In the **Select a system** dialog box, select `f14`.
6. Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.
With **Search in referenced models** selected, you can find the target variable everywhere it is used in a model reference hierarchy. However, finding the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7 Click **OK** in response to the message to update the model diagram.

Because you just opened the model, you must update the model diagram at least once before finding a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple searches with **Find Where Used**.

8 Model Explorer displays the search results:

```
```

The property columns whose values include Mq represent the block parameters that use the Mq variable. If those property columns are not already in the view, then the Model Explorer adds them to the end of the search results display.

You can also find blocks that use a specific variable by using one of these approaches:

- In the search bar, select the **for Variable Usage** search type option.
- In the **Search Results** pane, right-click a variable and select the **Find Where Used** menu item.
- In the Model Data Editor, right-click a workspace variable and select the **Find Where Used** menu item.
Finding Unused Workspace Variables

You can use the Model Explorer to get a list of variables that are defined in a workspace but not used by a model or block. One way to get that list of variables is to right-click a workspace name in the Model Hierarchy pane and select the Find Unused Variables menu item. For example:

1. Open the f14 model.
2. Open the Model Explorer.
3. In the search toolbar, set the Update diagram field to yes.
4. In the Model Hierarchy pane, right-click the Base Workspace node and select the Find Unused Variables menu item.

5. The Model Explorer displays output similar to this:
The Simulink.findVars function provides additional options for returning information about unused workspace variables that is not available from the Model Explorer or Simulink Editor.

**Editing Workspace Variables**

In the Model Explorer, you can use the Variable Editor to edit variables from the MATLAB base workspace or model workspace. The Variable Editor is available for editing large arrays and structures.

To open the Variable Editor:

1. In the **Contents** pane, select the variable.
2. In the Dialog pane (the right pane), click the button \( \div \) near the value of the variable.
3. In the menu, select **Open Variable Editor**.

Alternatively, to open the Variable Editor from the **Contents** pane instead of the Dialog pane, begin editing the value of the variable by clicking the appropriate cell. The button appears in the cell.
Representation of Arrays with Three or More Dimensions

When the value of a variable or Simulink.Parameter object is an array with three or more dimensions, the Value column displays the array as an expression that contains a call to the reshape function.

To edit the values in the array, modify the first argument of the reshape call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

Rename Variables

This example shows how to use Model Explorer to rename a variable everywhere it is used by blocks in Simulink models.

1. Open the model sldemo_absbrake. The model loads data to the MATLAB base workspace.
2. Open Model Explorer.
3. In the Model Hierarchy pane, select the base workspace.
4. In the Contents pane, right-click the base workspace variable m and select Rename All.
5. In the Select a system dialog box, click the name of the model sldemo_absbrake to select it as the context for renaming the variable m.
6. Clear the Search in referenced models check box and click OK. The model sldemo_absbrake references the model sldemo_wheelspeed_absbrake, but only sldemo_absbrake uses the variable m.

With Search in referenced models selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The Update diagram to include recent changes check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7. Click OK in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected Update diagram to include
recent changes in the Select a system dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the Rename All dialog box, type a new name for the variable in the New name box and click OK.

You can use the hyperlinks in the Corresponding blocks section of the Rename All dialog box to view the target blocks.

**Note** You can rename only variables that the function Simulink.findVars supports.

For help with renaming files, use a project. See “Automatic Updates When Renaming, Deleting, or Removing Files” on page 18-12.

**Compare Duplicate Workspace Variables**

You can compare duplicate variables that are stored in the same workspace or in different workspaces. For example, you can compare a variable stored in the base workspace with its duplicate, which is stored in the model workspace.

1 Open a model and the Model Explorer.

2 In the search toolbar, search for the variable that is duplicated. Select the rows with the duplicate entries. Then, right-click and select Compare Selected.
3 Review the differences in the **Comparison Viewer**.
Export Workspace Variables

You can export (save) a set of variables listed in the Model Explorer, exporting either individual variables or all the variables in the base or model workspace.

One possible workflow is to export the set of variables returned with the Find Referenced Variables option or the Simulink.findVars function. For details, see “Finding Variables That Are Used by a Model or Block” on page 66-149.

**Note** All the variables that you export must be from the same workspace.

To export all the variables in a workspace in the Model Explorer to a MATLAB code file or MAT-file:

1. Select the variables that you want to export.
To select all the variables in a workspace, right-click the workspace node (for example, Base Workspace) and select the Export menu item. For example:

To select individual variables, in the Contents pane, select the variables that you want to export. Right-click one of the highlighted variables and select the Export Selected menu item.

If the Contents pane has data grouped by a property, selecting the top line in a group does not select all the variables in that group. For details about grouped data, see “Group by a Property” on page 13-22.

2 Specify whether to save the variables in a MATLAB code file or a MAT-file.

The MATLAB code file format is easier to read, is editable, and supports version control. The MAT-file format is binary, which has performance advantages.

If you specify a MATLAB code file format, the Model Explorer may create an associated MAT-file, reflecting the name of the MATLAB code file, but with an extension of .mat instead of .m.

3 Specify a name and location for the file.
If the file already exists, Model Explorer displays a dialog box asking you to choose one of these options:

- **Overwrite entire file**
  - Replaces all variables in the target file with the selected variables, which are stored in alphabetical order.

- **Update variables that exist in file and append new variables to file**
  - Updates existing variables in place and appends new variables.

- **Only update variables that exist in file**
  - Updates existing variables, but does not add any new variables, which eliminates potentially extraneous variables.

To permanently store workspace variables for a model, instead of using the base workspace, create a data dictionary. See “What Is a Data Dictionary?” on page 70-2.

## Importing Workspace Variables

You can import (load) a set of variables from a file into the base workspace or into a model workspace using the Model Explorer. When you import variables into a workspace, the Model Explorer overwrites existing variables and adds any new variables.

To import variables into a workspace:

1. In the **Model Hierarchy** pane, right-click the workspace into which you want to import variables.
2. Select the **Import** menu item.
3. In the Import from File dialog box, select a MATLAB code file or MAT-file for the variables that you want to import.

**Note** If you import a MATLAB code file, then Simulink also imports the associated MAT-file.

Model Workspace Differences from MATLAB Workspace

Each model is provided with its own workspace for storing variable values.

The model workspace is similar to the base MATLAB workspace except that:

- Variables in a model workspace are visible only in the scope of the model.
  
  If both the MATLAB workspace and a model workspace define a variable of the same name, and the variable does not appear in any intervening masked subsystem or model workspaces, the Simulink software uses the value of the variable in the model workspace. A model's workspace effectively provides it with its own name space, allowing you to create variables for the model without risk of conflict with other models.

- When the model is loaded, the workspace is initialized from a data source.

  The data source can be a Model file, a MAT-file, a MATLAB file, or MATLAB code stored in the model file. For more information, see “Data source” on page 66-166.

- You can interactively reload and save MAT-file, MATLAB file, and MATLAB code data sources.

- To store a signal object in a model workspace, set the storage class of the object to Auto. Signal objects include Simulink.Signal and subclasses that you create.

  If you specify a storage class other than Auto, you must store signal objects in the base workspace or a data dictionary to ensure the objects are unique within the global Simulink context and accessible to all models.

- When you store MATLAB variables and parameter objects (such as Simulink.Parameter) in a model workspace, some tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 38-49. In addition, if you store an AUTOSAR.Parameter object in a model workspace, the code generator ignores the storage class that you specify for the object.
**Note** When resolving references to variables used in a referenced model, the variables of the referenced model are resolved as if the parent model did not exist. For example, suppose a referenced model references a variable that is defined in both the parent model's workspace and in the MATLAB workspace but not in the referenced model's workspace. In this case, the MATLAB workspace is used.

**Troubleshooting Memory Issues**

When you use a workspace variable as a block parameter, Simulink creates a copy of the variable during the compilation phase of the simulation and stores the variable in memory. This can cause your system to run out of memory during simulation, or in the process of generating code. Your system might run out of memory if you have:

- Large models with many parameters
- Models with parameters that have a large number of elements

This issue does not affect the amount of memory that is used to represent parameters in generated code.

**Manipulate Model Workspace Programmatically**

An object of the `Simulink.ModelWorkspace` class describes a model workspace. Simulink creates an instance of this class for each model that you open during a Simulink session. The methods associated with this class can be used to accomplish a variety of tasks related to the model workspace, including:

- Listing the variables in the model workspace
- Assigning values to variables
- Evaluating expressions
- Clearing the model workspace
- Reloading the model workspace from the data source
- Saving the model workspace to a specified MAT-file or MATLAB file
- Saving the workspace to the MAT-file or MATLAB file that the workspace designates as its data source

Specify Source for Data in Model Workspace

When you use a model workspace to contain the variables that a model uses, you can choose to store the variables in one of these sources:

- The model file, which can store static variable definitions.
- A separate MAT-file or MATLAB file. You can reload the variables from the external file into the model workspace at any time.
- Your own custom MATLAB code that creates variables. You can save the code as part of the model file, and reload the code at any time.

To specify a data source for a model workspace, in the Model Explorer, use the Model Workspace dialog box. To display the dialog box for a model workspace:

1. Open the Model Explorer. On the **Modeling** tab, click **Model Data Editor**.
2. In the **Model Hierarchy** pane, right-click the model workspace.
Select the **Properties** menu item, which opens the Model Workspace dialog box.

To use MATLAB commands to change data in a model workspace, see “Use MATLAB Commands to Change Workspace Data” on page 66-172.

**Data source**

The **Data source** field in the Model Workspace dialog box includes the following data source options for a workspace:

- **Model File**

  Specifies that the data source is the model itself.
• MAT-File

Specifications that the data source is a MAT file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 66-167).

• MATLAB File

Specifications that the data source is a MATLAB file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 66-167).

• MATLAB Code

Specifications that the data source is MATLAB code stored in the model file. Selecting this option causes additional controls to appear (see “MATLAB Code Source Controls” on page 66-168).

MAT-File and MATLAB File Source Controls

Selecting MAT-File or MATLAB File as the Data source for a workspace causes the Model Workspace dialog box to display additional controls.

![Model Workspace](image)

**File name**

Specifies the file name or path name of the MAT-file or MATLAB file that is the data source for the selected workspace. If you specify a file name, the name must reside on the MATLAB path.

**Reinitialize From Source**

Clears the workspace and reloads the data from the MAT-file or MATLAB file specified by the File name field.
Save To Source

Saves the workspace in the MAT-file or MATLAB file specified by the File name field.

MATLAB Code Source Controls

Selecting MATLAB Code as the Data source for a workspace causes the Model Workspace dialog box to display additional controls.

MATLAB Code

Specifies MATLAB code that initializes the selected workspace. To change the initialization code, edit this field, then select the Reinitialize from source button on the dialog box to clear the workspace and execute the modified code.

Reinitialize from Source

Clears the workspace and executes the contents of the MATLAB Code field.
Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to Model Mask” on page 40-65.

Change Model Workspace Data

When you use a model workspace to contain the variables that a model uses, you choose a source to store the variables, such as the model file or an external MAT-file. To modify the variables at the source, you use a different procedure depending on the type of source that you selected.

Change Workspace Data Whose Source Is the Model File

If the data source of a model workspace is the model file, you can use Model Explorer or MATLAB commands to modify the stored variables (see “Use MATLAB Commands to Change Workspace Data” on page 66-172).

For example, to create a variable in a model workspace:

1. Open the Model Explorer. On the **Modeling** tab, click **Model Data Editor** or press **Ctrl+H**.
2. In the Model Explorer **Model Hierarchy** pane, expand the node for your model, and select the model workspace.

3. Select **Add > MATLAB Variable**.

You can similarly use the **Add** menu or toolbar to add a Simulink.Parameter object to a model workspace.
To change the value of a model workspace variable:

1. Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, select the model workspace.
3. In the **Contents** pane, select the variable.
4. In the **Contents** pane or in **Dialog** pane, edit the value displayed.

To delete a model workspace variable:

1. Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, select the model workspace.
3. In **Contents** pane, select the variable.
4. Select **Edit > Delete**.

**Change Workspace Data Whose Source Is a MAT-File or MATLAB File**

You can use Model Explorer or MATLAB commands to modify workspace data whose source is a MAT-file or MATLAB file.

To make the changes permanent, in the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

1. Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, right-click the workspace.
3. Select the **Properties** menu item.
4. In the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

To discard changes to the workspace, in the Model Workspace dialog box, use the **Reinitialize From Source** button.

**Changing Workspace Data Whose Source Is MATLAB Code**

The safest way to change data whose source is MATLAB code is to edit and reload the source. Edit the MATLAB code and then in the Model Workspace dialog box, use **Reinitialize From Source** button to clear the workspace and re-execute the code.
To save and reload alternative versions of the workspace that result from editing the MATLAB code source or the workspace variables themselves, see “Export Workspace Variables” on page 66-158 and “Importing Workspace Variables” on page 66-160.

**Use MATLAB Commands to Change Workspace Data**

To use MATLAB commands to change data in a model workspace, first get the workspace for the currently selected model:

```matlab
hws = get_param(bdroot, 'modelworkspace');
```

This command returns a handle to a `Simulink.ModelWorkspace` object whose properties specify the source of the data used to initialize the model workspace. Edit the properties to change the data source.

Use the workspace methods to:

- List, set, and clear variables
- Evaluate expressions in the workspace
- Save and reload the workspace

For example, the following MATLAB code creates variables specifying model parameters in the model workspace, saves the parameters, modifies one of them, and then reloads the workspace to restore it to its previous state.

```matlab
hws = get_param(bdroot, 'modelworkspace');
hws.DataSource = 'MAT-File';
hws.FileName = 'params';
hws.assignin('pitch', -10);
hws.assignin('roll', 30);
hws.assignin('yaw', -2);
hws.saveToSource;
hws.assignin('roll', 35);
hws.reload;
```

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the model workspace. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 38-52.
Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to Model Mask” on page 40-65.

Symbols

When you create a Simulink model, you can use symbols to provide values and definitions for many types of entities in the model. Model entities that you can define with symbols include block parameters, configuration set parameters, data types, signals, signal properties, and bus architecture.

A symbol that provides a value or definition must be a legal MATLAB identifier. Such an identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`. You can use the function `isvarname` to determine whether a symbol is a legal MATLAB identifier.

A symbol provides a value or definition in a Simulink model by corresponding to some item that:

- Exists in an accessible workspace
- Has a name that matches the symbol
- Provides the required information

Symbol Resolution Process

The process of finding an item that corresponds to a symbol is called symbol resolution or resolving the symbol. The matching item can provide the needed information directly, or it can itself be a symbol. A symbol must resolve to some other item that provides the information.
When the Simulink software compiles a model, it tries to resolve every symbol in the model, except symbols in MATLAB code that runs in a callback or as part of mask initialization. Depending on the particular case, the item to which a symbol resolves can be a variable, object, or function.

Simulink attempts to resolve a symbol by searching through the accessible workspaces in hierarchical order for a MATLAB variable or Simulink object whose name is the same as the symbol.

The search path is identical for every symbol. The search begins with the block that uses the symbol, or is the source of a signal that is named by the symbol, and proceeds upward. Except when simulation occurs via the `sim` command, the search order is:

1. Any mask workspaces, in order from the block upwards (see “Masking Fundamentals” on page 40-3).
2. The model workspace of the model that contains the block (see “Model Workspaces” on page 66-162).
3. The MATLAB base workspace (see “Create and Edit Variables” (MATLAB)) or, if the model is linked to a data dictionary, the dictionary (see “What Is a Data Dictionary?” on page 70-2). If the data dictionary has the **Enable access to base workspace** property selected, the search treats the dictionary and the base workspace as a single namespace.

If Simulink finds a matching item in the course of this search, the search terminates successfully at that point, and the symbol resolves to the matching item. The result is the same as if the value of that item had appeared literally instead of the symbol that resolved to the item. An object defined at a lower level shadows any object defined at a higher level.

If no matching item exists on the search path, Simulink attempts to evaluate the symbol as a function. If the function is defined and returns an appropriate value, the symbol resolves to whatever the function returned. Otherwise, the symbol remains unresolved, and an error occurs. Evaluation as a function occurs as the final step whenever a hierarchical search terminates without having found a matching workspace variable.

If the model that contains the symbol is a referenced model, and the search reaches the model workspace but does not succeed there, the search jumps directly to the base workspace or data dictionary without trying to resolve the symbol in the workspace of any parent model. Thus a given symbol resolves to the same item, irrespective of whether the model that contains the symbol is a referenced model. For information about model referencing, see “Model References”.
**Numeric Values with Symbols**

You can specify any block parameter that requires a numeric value by providing a literal value, a symbol, or an expression, which can contain symbols and literal values. Each symbol is resolved separately, as if none of the others existed. Different symbols in an expression can thus resolve to items on different workspaces, and to different types of item.

When a single symbol appears and resolves successfully, its value provides the value of the parameter. When an expression appears, and all symbols resolve successfully, the value of the expression provides the value of the parameter. If any symbol cannot be resolved, or resolves to a value of inappropriate type, an error occurs.

For example, suppose that the Gain parameter of a Gain block is given as \( \cos(a \times (b + 2)) \). The symbol \( \cos \) will resolve to the MATLAB cosine function, and \( a \) and \( b \) must resolve to numeric values, which can be obtained from the same or different types of items in the same or different workspaces. If the symbols resolve to numeric values, the value returned by the cosine function becomes the value of the Gain parameter.

**Other Values with Symbols**

Most symbols and expressions that use them provide numeric values, but the same techniques that provide numeric values can provide any type of value that is appropriate for its context.

Another common use of symbols is to name objects that provide definitions of some kind. For example, a signal name can resolve to a signal object (Simulink.Signal) that defines the properties of the signal, and a Bus Creator block Data type parameter can name a bus object (Simulink.Bus) that defines the properties of the bus. You can use symbols for many purposes, including:

- Define data types
- Specify input data sources
- Specify logged data destinations

For hierarchical symbol resolution, all of these different uses of symbols, whether singly or in expressions, are the same. Each symbol is resolved, if possible, independently of any others, and the result becomes available where the symbol appeared. The only difference between one symbol and another is the specific item to which the symbol resolves and the
use made of that item. The only requirement is that every symbol must resolve to something that can legally appear at the location of the symbol.

**Limit Signal Resolution**

Hierarchical symbol resolution traverses the complete search path by default. You can truncate the search path by using the **Permit Hierarchical Resolution** option of any subsystem. This option controls what happens if the search reaches that subsystem without resolving to a workspace variable. The **Permit Hierarchical Resolution** values are:

- **All**
  Continue searching up the workspace hierarchy trying to resolve the symbol. This is the default value.
- **None**
  Do not continue searching up the hierarchy.
- **ExplicitOnly**
  Continue searching up the hierarchy only if the symbol specifies a block parameter value, data store memory (where no block exists), or a signal or state that explicitly requires resolution. Do not continue searching for an implicit resolution. See “Explicit and Implicit Symbol Resolution” on page 66-177 for more information.

If the search does not find a match in the workspace, and terminates because the value is **ExplicitOnly** or **None**, Simulink evaluates the symbol as a function. The search succeeds or fails depending on the result of the evaluation, as previously described.

**Explicit and Implicit Symbol Resolution**

Models and some types of model entities have associated parameters that can affect symbol resolution. For example, suppose that a model includes a signal named Amplitude, and that a Simulink.Signal object named Amplitude exists in an accessible workspace. If the Amplitude signal’s **Signal name must resolve to Simulink signal object** option is checked, the signal will resolve to the object. See “Signal Properties Controls” for more information.

If the option is not checked, the signal may or may not resolve to the object, depending on the value of **Configuration Parameters > Data Validity > Signal resolution**. This
parameter can suppress resolution to the object even though the object exists, or it can specify that resolution occurs on the basis of the name match alone. For more information, see “Model Configuration Parameters: Data Validity Diagnostics” > “Signal resolution”.

Resolution that occurs because an option such as Signal name must resolve to Simulink signal object requires it is called explicit symbol resolution. Resolution that occurs on the basis of name match alone, without an explicit specification, is called implicit symbol resolution.

**Tip** Implicit symbol resolution can be useful for fast prototyping. However, when you are done prototyping, consider using explicit symbol resolution, because implicit resolution slows performance, complicates model validation, and can have nondeterministic effects.

Configure Data Properties by Using the Model Data Editor

Models contain data items such as signals, block parameters (for example, the Gain parameter of a Gain block), and data stores. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter. You can then configure properties and parameters, such as data types and dimensions, without having to locate the items in the block diagram.

While creating and debugging a model, you can configure multiple data items at once by selecting the corresponding signals and blocks in the block diagram. Work with the selected items in the Model Data Editor instead of opening individual dialog boxes. Use this technique to more quickly view and compare properties of multiple signals that are close to each other in the diagram, for example, in a subsystem.

Use the Model Data Editor to configure:

- Instrumentation for signals and data stores, which means you want to view and collect the simulation values. For example, you can log signals to compare data in the Simulation Data Inspector.
- Design attributes such as data type, minimum and maximum value, and physical units. For example, you use these attributes to:
  - Specify the values of numeric block parameters.
  - Control the interaction (interface) between components through Inport and Outport blocks and data stores (see “Configure Data Interface for Component” on page 23-24).
  - Specify the dimensions of nonscalar signals in a model.
- Storage classes, which control the representation of the data in the code (for example, C) that you generate from the model.

To open the Model Data Editor in a model, on the Modeling tab, click Model Data Editor or press Ctrl+Shift+E.

**Note** The Model Data Editor does not show information about data items in referenced models (which you reference with Model blocks). To work with data items in a referenced model, open the Model Data Editor in that model.
Configure Distant Data Items

The example model sldemo_fuelsys_dd represents the fueling system of a vehicle engine. The referenced model sldemo_fuelsys_dd_controller controls the rate of fuel flow to the engine. In this example, use the Model Data Editor to log signals in different subsystems and referenced models so you can inspect their data using the Simulation Data Inspector.

Explore Example Models

1. Open sldemo_fuelsys_dd and the referenced model sldemo_fuelsys_dd_controller.
2. Navigate to the airflow_calc subsystem.
   
   The Pumping Constant block contains a lookup table that describes the performance of a fuel pump. You can stream the output of this block to the Simulation Data Inspector.
3. Navigate to the root of the model and into the fuel_calc subsystem.
4. Navigate into the feedforward_fuel_rate subsystem.
   
   The Outport block named ff_fuel_rate passes feedforward information to the fuel rate control algorithm.
5. Navigate back to the fuel_calc subsystem and into the switchable_compensation subsystem.
   
   The Inport block named ff_fuel_rate carries the feedforward information. You can stream the output of this Inport block.

Log Signals for Data Inspection

1. Navigate to the root of the sldemo_fuelsys_dd_controller model.
2. In the Model Data Editor, inspect the Signals tab.
3. Set the Change view drop-down to Instrumentation.
4. Activate the Change scope button to display the contents of the subsystems.
   
   The Model Data Editor identifies all the signals in the model. The Path column appears.
In the **Filter Contents** box, type `ff_fuel_rate`.

The Model Data Editor updates the list of signals to include only those named `ff_fuel_rate`. You can click the link in the **Path** column to view where the signal resides within the model.

Select the **Log Data** check box for the signal whose path is `sldemo_fuelsys_dd_controller/fuel_calc/switchable_compensation`.

This instructs Simulink to send the data for the logged signals to the Simulation Data Inspector.

Filter the signals again using the text **Pumping Constant**.

The table contains one row that corresponds to the output of the Pumping Constant block.

Select the **Log Data** check box for the **Pumping Constant** signal.

Simulate the system model, `sldemo_fuelsys_dd`. During the simulation, double-click a Manual Switch block, such as **Engine Speed Selector**, to disturb the fuel control system.

When the simulation finishes, the **Simulation Data Inspector** button is highlighted. This indicates that there is data to inspect and compare. Click the **Simulation Data Inspector** button.

In the left pane, expand the **Run** node that corresponds to the simulation run and select the check boxes for the signals whose data you want to inspect and compare.

The Simulation Data Inspector presents the values for the selected signals on the same graph.

---

**Select Multiple Data Items from Block Diagram**

In the example model `sldemo_househeat`, use the Model Data Editor to log the signals in the **Heater** subsystem for inspection using the Simulation Data Inspector.

1. In the example model `sldemo_househeat`, open the **Heater** subsystem.
2. Open the Model Data Editor and select the **Signals** tab.

The Model Data Editor identifies all the signals in the subsystem.
3 In the Model Data Editor, set the **Change view** drop-down list to **Instrumentation**.

4 Using the Simulink Editor, select all the signals in the subsystem. Optionally, do not select the output of the Constant block because the signal value does not change during the simulation.

   In response, the Model Data Editor highlights the rows that correspond to the signals you selected.

5 In the Model Data Editor, for any of the signals, click the check box in the **Log Data** column.

   The Model Data Editor selects the check box for all of the selected signals.

6 Simulate the model.

7 Open the Simulation Data Inspector and, in the leftmost pane, expand the **Run** node that corresponds to the simulation run. Select the check boxes for the signals whose values you want to inspect and compare.

### Interact with a Model That Uses Workspace Variables

When you use workspace variables (such as numeric MATLAB variables and `Simulink.AliasType` objects) to share settings between data items, you can interact with those variables through the Model Data Editor. You do not need to work outside the Editor to configure the data items. In the Editor, click the **Show/refresh additional information** button, which finds variables that the model uses by updating the block diagram.

This example shows how to work with objects that a model uses to set block parameter values. You modify the value of a `Simulink.Parameter` object that the model `sldemo_fuelsys_dd_controller` uses.

1 Open the model.

   `sldemo_fuelsys_dd_controller`

2 Open the Model Data Editor **Parameters** tab.

3 In the Model Data Editor, click the **Show/refresh additional information** button.

   The data table now contains rows that correspond to variables and objects that the model uses.
4 In the model, navigate into the airflow_calc subsystem.

5 In the Model Data Editor, next to the **Filter contents** box, select the **Filter using selection** button.

With this button selected, when you select a block or signal in the block diagram, the data table shows only the data items and workspace variables that are relevant to that block or signal.

6 In the model, click the lookup table block labeled **Pumping Constant**.

The Model Data Editor shows that the block uses three workspace variables. The block acquires some breakpoint values from the `Simulink.Parameter` object `SpeedVect`.

Now, you can use the columns in the Model Data Editor to configure the properties of `SpeedVect`.

You can further interact with a variable to:

• Configure other properties that the columns do not represent:

  1 In the model, open the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**.

  2 In the Model Data Editor, select the row that corresponds to the target variable or object. If the Property Inspector does not respond, select a different row and then select the target row again.

  3 Use the Property Inspector to configure the target properties.

• Move the variable between workspaces and data dictionaries and configure the variable alongside other variables. Use the Model Explorer. To open the Model Explorer, in the Model Data Editor data table, double-click the icon in the leftmost column. For more information about using the Model Explorer, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 66-149.

• Rename a variable everywhere it is used by blocks in Simulink models. In the Model Data Editor, right-click the variable and select **Rename All**. You can rename only variables that the function `Simulink.findVars` supports.

• Find blocks that use a specific variable. In the Model Data Editor, right-click the variable and select **Find Where Used**.
Find and Organize Data by Filtering, Sorting, and Grouping

In the example model sldemo_fuelsys_dd_controller, workspace variables and parameter objects set the values of block parameters. The variables and objects reside in a data dictionary. Use the Model Data Editor to display these dictionary entries together in a group.

1. In the example model, open the Model Data Editor and select the **Parameters** tab.
2. Activate the **Change scope** button to display the contents of the subsystems.
3. Click the **Show/refresh additional information** button to display rows that correspond to the dictionary entries.
4. Right-click the **Source** column header and select **Group by This Column**.

The Model Data Editor groups the list by block or workspace (including a group for the dictionary entries).

5. Find the group labeled **Source: Dictionary**. Now, you can use the Model Data Editor to inspect and modify the attributes of the variables and objects in the dictionary.

The Model Data Editor allows you to filter a list of data items by using one or a combination of these methods:

- To filter the data table through a text search, use the **Filter contents** box.
- To filter based on the blocks or signals that you select in the model, next to the **Filter contents** box, select the **Filter using selection** button. Then, as you click blocks and signals in the model, the Model Data Editor shows you only the rows that are relevant to that block or signal. If you lasso multiple blocks or signals, the Model Data Editor shows only the rows that are relevant to those model elements.
- To filter on column-specific criteria, point to a column header and click the filter icon /sweetalert2-icon. As you type in the text box, the editor applies a substring filter to the column contents. After the filter is applied, the column displays a smaller filter icon next to the column header. To edit a filter, remove a filter, or remove all column filters, click this icon.
Inspect Individual Data Item

To focus on an individual data item, use one of these techniques:

- In the Model Data Editor, next to the Filter contents box, select the Filter using selection button. Then, in the model, click the block or signal that corresponds to the data item.
  
  Use this technique to configure the item by using the columns in the data table.

- In the model, open the Property Inspector. On the Modeling tab, under Design, click Property Inspector. Then, in the data table, click the target row. The Property Inspector shows the properties of the data item. If the Property Inspector does not respond when you click the target row, click a different row and then click the target row again.

  Use this technique to inspect all of the properties that the Model Data Editor can access at once (in other words, the union of the columns available in the Design, Instrumentation, and Code views).

- In the model, open the Property Inspector. Then, in the data table, for the target row, double-click the cell in the leftmost column (the icon). In the model, select the highlighted block or signal.

  Use this technique to inspect all properties, including those that the Model Data Editor cannot access.
Navigate from Model Data Editor to Block Diagram

To navigate from a data item in the Model Data Editor to the block in the diagram that owns the data item, double-click the icon in the left-most column. The Simulink Editor then focuses on the relevant block. Use this technique to navigate to blocks when you select Change scope to view the contents of subsystems below the current system.

Columns in the Data Table

Use this table to find more information about the purpose of the columns in the Model Data Editor.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Purpose and More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Shows the name of the block that defines the data item. For signals, also shows the number of the block port that generates the signal. For workspace variables, shows the name of the workspace or data dictionary that contains the variable.</td>
</tr>
<tr>
<td>Signal Name or Name</td>
<td>Sets the name of the signal, state, or data store. For information about naming signals, see “Signal Names and Labels” on page 71-4. For parameters, displays the programmatic name of each parameter. For workspace variables, sets the name of the variable.</td>
</tr>
<tr>
<td>Data Type</td>
<td>“Control Signal Data Types” on page 66-8 and “Control Block Parameter Data Types” on page 38-59</td>
</tr>

</tr>
<tr>
<td>Struct Name</td>
<td></td>
</tr>
<tr>
<td>Shared</td>
<td>Corresponds to the <strong>Share across model instances</strong> parameter of the Data Store Memory block. See Data Store Memory.</td>
</tr>
</tbody>
</table>
## Column Name | Purpose and More Information
---|---
Initial Value | Sets the initial value of the state or data store. See “Initializing Signal Values” on page 71-16.
Value | “Set Block Parameter Values” on page 38-2
Argument | Configures a variable in a model workspace as a model argument. See “Parameterize Instances of a Reusable Referenced Model” on page 8-89.
Path | Shows the location of the block in the model and provides a link to the block in the Simulink Editor. Visible when you click the Change Scope button.

### Two Entries Per Cell in the Data Table

When a cell contains two entries (for instance, in the Data Type column), the entry on the right side of the cell indicates compiled information. The compiled information shows you the value that the data item uses for simulation.

For example, the default data type setting for most signals in a model is Inherit: Inherit via internal rule. With this setting, after you update the block diagram, Simulink chooses a specific data type, such as single, for the signal to use for simulation. In the Model Data Editor, the cell in the Data Type column shows Inherit: Inherit via internal rule on the left side and single on the right side.

### Model Data Editor Limitations

- You cannot access these attributes by using the Model Data Editor:
  - Any settings for tunable mask parameters other than the parameter value. Some built-in blocks are masked and have tunable mask parameters.
  - Any settings for nontunable mask parameters. Some built-in blocks are masked and have nontunable mask parameters.
  - Any settings for parameters of Simscape blocks.
  - Any settings for data items in referenced models. Instead, open the Model Data Editor in the referenced models.
- Any settings for variables that are not defined in the base workspace, a model workspace, or a data dictionary. For example, you cannot access the attributes of variables created by mask initialization code.

- On the Parameters tab, the data type, minimum value, and maximum value of a Constant block. Use the Signals tab instead.

For some settings that you cannot access with the Model Data Editor, you can use the Property Inspector instead (see “Parameters”). Open the Inspector and select the target data item in the model, not in the Model Data Editor. For mask parameters, use the mask dialog box or the Mask Editor as described in “Masking Fundamentals” on page 40-3.

- The Model Data Editor does not show Stateflow data. However, the Model Data Editor shows the data for Simulink Functions that you define inside Stateflow charts.

To manage Stateflow data, events, and messages in a chart, see “Manage Data, Events, and Messages in the Symbols Pane” (Stateflow).

- When using the Model Data Editor, if you specify a storage class for a signal and do not provide a signal name, the software generates a signal name. The generated name is derived from the block that generates the signal. If a block has non-ASCII values as part of its name or any invalid C variable name, only the ASCII values in the block names generate a name for the signal. If the two ASCII block names are not unique, this issue leads to a conflict in signal names during code generation.

- On the Parameters tab, these variables are not available:
  - Variables used by non-tunable block parameters. For example, the minimum and maximum parameters on a Gain block or the Sample time on a Constant block.
  - Variant control variables
  - Variables used for symbolic dimensions

Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

Note Property types defined in level-1 data classes that are not subclasses of Simulink.Parameter, Simulink.Signal, or Simulink.CustomStorageClassAttributes are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes PropertyType and AllowedValues.

1 This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

    Simulink.data.upgradeClasses('C:\MyDataClasses')

Here, C:\MyDataClasses is the destination folder for your level-2 data classes.

Note Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

    Simulink.data.upgradeClasses uses the packagedefn.mat file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, Simulink.data.upgradeClasses adds the folder to top of the MATLAB path and saves the path.

Note If Simulink.data.upgradeClasses cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using savepath.

2 You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.
3. Resave MAT-files and models that contain level-1 data objects.
4. Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

**Note** You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```matlab
set_param(gcb, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```matlab
get_param(gcb, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```matlab
set_param(gcb, 'UserDataPersistent', 'on');
```

**Note** If persistent `UserData` for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

<tr>
<td>Variable-size signals</td>
<td>The software does not support variable-size signals. A variable-size signal is a signal whose size (number of elements in a dimension), in addition to its values, can change during model execution. For more information, see “Variable-Size Signal Basics” on page 73-2.</td>
</tr>
<tr>
<td>Multiword fixed-point data types</td>
<td>The software does not support multiword fixed-point data types larger than 128 bits.</td>
</tr>
</tbody>
</table>
| Nonzero start times              | Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time:  
  • If you do not select the Reference input model in generated harness parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis.  
  • If you select the Reference input model in generated harness parameter, a Model block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the Start time parameter to 0.  
  • Simulink Design Verifier assumes zero start time for analysis and generates signal data that begins at zero. Zero start time might impact the reporting of the objective status. For example, in the test generation analysis, the software might report some objectives as Undecided with Testcases. For more information, see “Simulation Basics” on page 26-2. |

- “Support Limitations for Stateflow Software Features” on page 66-210
Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

### Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

### Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

### Continuous Library

**ml Namespace Operator, ml Function, ml Expressions**

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. See “Access MATLAB Functions and Workspace Data in C Charts” (Stateflow).

**C or C++ Operators**

The software does not support the `sizeof` operator, which the Stateflow software allows.

**C Math Functions**

The software supports calls to the following C math functions:

- `abs`
- `ceil`
- `fabs`
• floor
• fmod
• labs
• ldexp
• pow (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see “Call C Library Functions in C Charts” (Stateflow).

>Note For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

>Note For information about exported functions, see “Export Stateflow Functions for Reuse” (Stateflow).

Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.
Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

Note For information about avoiding recursion in Stateflow charts, see “Avoid Unwanted Recursion in a Chart” (Stateflow).

Stateflow software also allows you to create cyclic behavior, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

Note For information about cyclic behavior in Stateflow charts, see “Cyclic Behavior” (Stateflow).

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a Clear event to state B, which calls state B2, which broadcasts a Set event back to state A, causing the cyclic behavior.
If you change the `send` function calls to use directed event broadcasts so that the Set and Clear events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.

**Note** For information about the benefits of directed event broadcasts, see “Broadcast Local Events to Synchronize Parallel States” (Stateflow).
Custom C/C++ Code

If your model consists of custom C/C++ code, Simulink Design Verifier supports analysis based on these settings:

- If you enable import custom code and custom code analysis options, the software supports custom C/C++ code for analysis. For more information, see “Import custom code” and “Enable custom code analysis”.
- If you enable import custom code option and the custom code analysis option is set to Off, the model is compatible for analysis, but calls to the custom code are stubbed during analysis.
- If the import custom code option is set to Off, the custom code is not supported and the model is incompatible for analysis.

Machine-Parented Data

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see “Best Practices for Using Data in Charts” (Stateflow).

Textual Functions with Literal String Arguments

The software does not support literal string arguments to textual functions in a Stateflow chart.
Custom State Attributes in Discrete FIR Filter block

This example shows how to customize the state attributes of the Discrete FIR Filter block using the Model Data Editor. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter. For more information on using the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

Consider a simple model that contains the Discrete FIR Filter block.
Using the Model Data Editor, you can configure the state of the Discrete FIR Filter to appear in the generated code as a separate global variable. This is done by declaring the storage class of the state as `ExportedGlobal`. For details on how the generated code stores internal states, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder). For more details on storage classes and how to apply them to the states, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).
Open Model Data Editor

Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.

Under the **States** tab, enter the **Name** as `myState` and select the **Storage Class** as `ExportedGlobal`. You can alternatively select the **Resolve** check box, which requires the state name to resolve to a Simulink signal object.
Build the Model and Inspect the Generated Code

This example configures the model to generate code only. Open the Configuration

Parameters by clicking the configuration button in the Simulink editor. In the Code Generation pane, select Generate code only. Click Apply.

In the Report pane, select Create code generation report and Open report automatically. Click Apply. These settings create a report and automatically open the report in a web browser.
To initiate the build, click the build model button in the Simulink editor or press Ctrl+B. The build process writes the code generation report files to the html subfolder of the build folder. Next, the build process automatically opens a MATLAB web browser window and displays the code generation report. Using this report, you can view and analyze the generated code. For more information on the generated report, see “Reports for Code Generation” (Simulink Coder).
In the `custom_state_attributes.h` file, you can see that the filter state is declared as an external variable since the storage class is `ExportedGlobal`. 
If you change the storage class and rebuild the model, you can see the generated code reflect the change. With the ability to customize the state attributes, you can streamline and customize how the state appears in the generated code.

Enumerations and Modeling

- “Simulink Enumerations” on page 67-2
- “Use Enumerated Data in Simulink Models” on page 67-8
Simulink Enumerations

Enumerated data is data that is restricted to a finite set of values. An enumerated data type is a MATLAB class that defines a set of enumerated values. Each enumerated value consists of an enumerated name and an underlying integer which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in “Enumerations” (MATLAB).

To define an enumeration for use in Simulink models, choose one of these techniques:

• Use the function Simulink.defineIntEnumType. The enumeration exists for the duration of your MATLAB session.
• Create a permanent enumeration class by subclassing one of these built-in classes:
  • Many of the built-in integer data types such as int8 and uint16
  • Simulink.IntEnumType
• Use the function Simulink.importExternalCTypes to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

Use this technique to help you:

• Replace existing C code with a Simulink model.
• Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool).
• Generate C code (Simulink Coder) that you can compile with existing C code into a single application.

For more information, see “Define Simulink Enumerations” on page 67-8.

The following examples show how to use enumerations in Simulink and Stateflow.

<table>
<thead>
<tr>
<th>Example</th>
<th>Shows How To Use...</th>

<td>Enumerated data types in a Simulink model that contains a Stateflow chart</td>
</tr>
</tbody>
</table>
For information on using enumerations in Stateflow, see “Enumerated Data” (Stateflow).

**Simulink Constructs that Support Enumerations**

- “Overview” on page 67-3
- “Block Support” on page 67-3
- “Class Support” on page 67-5
- “Logging Enumerated Data” on page 67-5
- “Importing Enumerated Data” on page 67-5

**Overview**

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See “Enumerated Values in Computation” on page 67-24 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See “Simulink Enumeration Limitations” on page 67-5 for information about certain constructs that could support enumerated types but do not.

**Block Support**

The following Simulink blocks support enumerated types:

- Constant (but Enumerated Constant is preferable)
- Data Type Conversion
- Data Type Conversion Inherited
• Data Type Duplicate
• Display
• MATLAB Function
• Enumerated Constant
• Floating Scope
• From File
• From Workspace
• Inport
• Interval Test
• Interval Test Dynamic
• Multiport Switch
• Outport
• Probe (input only)
• Relational Operator
• Relay (output only)
• Repeating Sequence Stair
• Scope
• Signal Specification
• Switch
• Switch Case
• To File
• To Workspace

All members of the following categories of Simulink blocks support enumerated types:

• Bus-capable blocks (see “Bus-Capable Blocks” on page 72-39)
• Pass-through blocks:
  • With state, like the Data Store Memory and Unit Delay blocks.
  • Without state, like the Mux block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with
enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

Class Support

The following Simulink classes support enumerated types:

- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.AliasType`
- `Simulink.BusElement`

Logging Enumerated Data

Top-level model output ports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The From File block does not support enumerated data. Use the From Workspace block instead, combined with some technique for transferring data between a file and a workspace. See “Save Run-Time Data from Simulation” for more information.

Importing Enumerated Data

Top-level model input ports and From Workspace blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or `TimeSeries` object. No interpolation occurs for enumerated values between the specified simulation times. From File blocks produce only data of type `double`, so they do not support enumerated types. See “Load Signal Data for Simulation” for more information.

Simulink Enumeration Limitations

- “Enumerations and Scopes” on page 67-5
- “Enumerated Types for Switch Blocks” on page 67-6
- “Nonsupport of Enumerations” on page 67-6

Enumerations and Scopes

When a Scope block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the Scope block for the first time before any simulation has occurred, or between simulations,
the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the Scope block is opened.

When a Floating Scope block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the Floating Scope block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

**Enumerated Types for Switch Blocks**

The control input of a Switch block can be of any data type supported by Simulink. However, the \( u_2 \neq 0 \) mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select \( u_2 \geq \text{Threshold} \) or \( u_2 > \text{Threshold} \) and specify a threshold value of the same enumerated type as the control input.
- Use a Relational Operator block to do the comparison and then feed the Boolean result of this comparison into the control port of the Switch block.

**Nonsupport of Enumerations**

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The If Action block might support enumerations, but currently does not do so.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

• “Manipulate Enumerations in Data Dictionary” on page 70-18
Use Enumerated Data in Simulink Models

Enumerated data is data that is restricted to a finite set of values. An enumerated data type is a MATLAB class that defines a set of enumerated values. Each enumerated value consists of an enumerated name and an underlying integer which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see “Simulink Enumerations” on page 67-2.

For information about generating code with enumerations, see “Use Enumerated Data in Generated Code” (Simulink Coder).

Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

• Define an enumeration class using a classdef block in a MATLAB file.
• Use the function Simulink.defineIntEnumType. You do not need a script file to define the type. For more information, see the function reference page.
• Use the function Simulink.importExternalCTypes to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

Workflow to Define a Simulink Enumeration Class

1 Create a class definition on page 67-9.
Optionally, customize the enumeration on page 67-10.

Optionally, save the enumeration in a MATLAB file on page 67-12.

Optionally, permanently store the enumeration definition in a Simulink data dictionary. See “Permanently Store Enumerated Type Definition” on page 67-15.

**Create Simulink Enumeration Class**

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an enumeration block that specifies enumeration values with underlying integer values.

Consider the following example:

```matlab
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The enumeration section specifies three enumerated values.

<table>
<thead>
<tr>
<th>Enumerated Value</th>
<th>Enumerated Name</th>
<th>Underlying Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red(0)</td>
<td>Red</td>
<td>0</td>
</tr>
<tr>
<td>Yellow(1)</td>
<td>Yellow</td>
<td>1</td>
</tr>
<tr>
<td>Blue(2)</td>
<td>Blue</td>
<td>2</td>
</tr>
</tbody>
</table>

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.
• Underlying integer values in the enumeration section need not be unique within the class and across types.
• Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.
• For simulation, an underlying integer can be any int32 value. Use the MATLAB functions \texttt{intmin} and \texttt{intmax} to get the limits.
• For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See “Configure a System Target File” (Simulink Coder) for more information.

For more information on superclasses, see “Convert to Superclass Value” (MATLAB). For information on how enumeration classes are handled when there is more than one name for an underlying value, see “How to Alias Enumeration Names” (MATLAB).

\section*{Customize Simulink Enumeration}

\subsection*{About Simulink Enumeration Customizations}

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

<table>
<thead>
<tr>
<th>Static Method</th>
<th>Purpose</th>
<th>Default Value Without Implementing Method</th>
<th>Custom Return Value</th>
<th>Usage Context</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDefaultValue</td>
<td>Specifies the default enumeration member for the class.</td>
<td>First member specified in the enumeration definition</td>
<td>A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” on page 67-21)</td>
<td>Simulation and code generation</td>
</tr>
<tr>
<td>getDescription</td>
<td>Specifies a description of the enumeration class.</td>
<td>' '</td>
<td>A character vector containing the description of the type</td>
<td>Code generation</td>
</tr>
<tr>
<td>Static Method</td>
<td>Purpose</td>
<td>Default Value Without Implementing Method</td>
<td>Custom Return Value</td>
<td>Usage Context</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>-------------------------------------------</td>
<td>----------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>getHeaderFile</td>
<td>Specifies the name of a header file. The method getDataScope determines the significance of the file.</td>
<td>' '</td>
<td>A character vector containing the name of the header file that defines the enumerated type</td>
<td>Code generation</td>
</tr>
<tr>
<td>getDataScope</td>
<td>Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method getHeaderFile to specify the generated or included header file that defines the type.</td>
<td>'Auto'</td>
<td>One of: 'Auto', 'Exported', or 'Imported'</td>
<td>Code generation</td>
</tr>
<tr>
<td>addClassNameToEnumNames</td>
<td>Specifies whether to prefix the class name in generated code.</td>
<td>false</td>
<td>true or false</td>
<td>Code generation</td>
</tr>
</tbody>
</table>

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” (Simulink Coder).

**Specify a Default Enumerated Value**

Simulink and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” (Simulink Coder).

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own getDefaultValue method to the methods section. The following code shows a shell for the getDefaultValue method:
function retVal = getDefaultValue()
% GETDEFAULTVALUE Specifies the default enumeration member.
% Return a valid member of this enumeration class to specify the default.
% If you do not define this method, Simulink uses the first member.
    retVal = ThisClass.EnumName;
end

To customize this method, provide a value for ThisClass.EnumName that specifies the desired default.

- ThisClass must be the name of the class within which the method exists.
- EnumName must be the name of an enumerated value defined in that class.

For example:

classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end

This example defines the default as BasicColors.Blue. If this method does not appear, the default value would be BasicColors.Red, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of ThisClass inside the definition of that same class is necessary because getDefaultValue returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 67-21 for more information.

**Save Enumeration in a MATLAB File**

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration BasicColors must reside in a file named BasicColors.m. Otherwise, MATLAB will not find the definition.
• You must define each class definition in a separate file.
• Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see “What Is the MATLAB Search Path?” (MATLAB), `addpath`, and `savepath`.

• You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

Change and Reload Enumeration Classes

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

<table>
<thead>
<tr>
<th>If In Base Workspace...</th>
<th>If In Cache...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do one of the following:</td>
<td>• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect.</td>
</tr>
<tr>
<td>• Locate and delete specific obsolete instances.</td>
<td>• Clear functions and close models that are caching instances of the class.</td>
</tr>
<tr>
<td>• Delete everything from the workspace by using the <code>clear</code> command.</td>
<td></td>
</tr>
</tbody>
</table>

Similarly, if you defined an enumeration class by using `Simulink.defineIntEnumType`, you can redefine that class, using the same function, even if instances exist. However, you cannot change `StorageType` for the class while instances exist.

For more information about applying enumeration changes, see “Automatic Updates for.Modified Classes” (MATLAB).
Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB that you want to import for use within the Simulink environment, you can do so programmatically with calls to one of these functions:

- `Simulink.defineIntEnumType` — Defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:
  - Character vector that describes the enumeration class.
  - Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```matlab
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static = true)
        function retVal = getDescription()
            retVal = 'Basic colors...';
        end
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
        function retVal = getHeaderFile()
            retVal = 'mybasiccolors.h';
        end
        function retVal = addClassNameToEnumNames()
            retVal = true;
        end
    end
end
```

The following function call defines the same class for use in MATLAB:
Simulink.defineIntEnumType('BasicColors', ...
   {'Red', 'Yellow', 'Blue'}, [0;1;2],...
   'Description', 'Basic colors', ...
   'DefaultValue', 'Blue', ...
   'HeaderFile', 'mybasiccolors.h', ...
   'DataScope', 'Imported', ...
   'AddClassNameToEnumNames', true);

- Simulink.importExternalCTypes — Creates Simulink representations of enumerated data types (enum) that your existing C code defines.

If a MATLAB Function block in your model uses the enumerated type, configure the model configuration parameters to include (#include) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 44-166.

**Permanently Store Enumerated Type Definition**

Whether you define an enumeration by using a class file or by using the function Simulink.defineIntEnumType, you can permanently store the enumeration definition in a Simulink data dictionary. Models that are linked to the dictionary can use the enumeration. For more information, see “Enumerations in Data Dictionary” on page 70-15.

**Simulate with Enumerations**

Consider the following enumeration class definition — BasicColors with enumerated values Red, Yellow, and Blue, with Blue as the default value:

classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in
“Enumerated Data” (Stateflow). The following Simulink model uses the enumeration defined above:

The output of the model looks like this:
The Data Type Conversion block OrigToInt specifies an **Output data type** of int32 and **Integer rounding mode**: Floor, so the block converts the Sine Wave block output, which appears in the top graph of the Scope display, to a cycle of integers: 1, 2, 1, 0, 1, 2, 1. The Data Type Conversion block IntToColor uses these values to select colors from the enumerated type BasicColors by referencing their underlying integers.

The result is a cycle of colors: Yellow, Blue, Yellow, Red, Yellow, Blue, Yellow, as shown in the middle graph. The Enumerated Constant block EnumConst outputs Yellow, which appears in the second graph as a straight line. The Relational Operator block compares the constant Yellow to each value in the cycle of colors. It outputs 1 (true).
when Yellow is less than the current color, and 0 (false) otherwise, as shown in the third graph.

The sort order used by the comparison is the numeric order of the underlying integers of the compared values, not the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See “Specify Enumerations as Data Types” on page 67-18 and “Enumerated Values in Computation” on page 67-24 for more information.

**Specify Enumerations as Data Types**

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix ? or Enum: when specifying the enumeration as a data type. You must use the prefix ? in the MATLAB Command Window. However, you can use either prefix in a Simulink model. Enum: has the same effect as the ? prefix, but Enum: is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type Enum: followed by the name of an enumeration, or select Enum: <class name> from a menu (for example, for the Output data type block parameter), and replace <class name>.

To use the Data Type Assistant, set the Mode to Enumerated, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block IntToColor, which outputs a signal of type BasicColors, has the following output signal specification:

![Parameters](image)

You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of [], an error occurs when you update the model. See “Enumerated Values in Computation” on page 67-24 for more information.
Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the `Case conditions` parameter of the Switch Case block

Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

Enumeration Value Display

Wherever possible, Simulink displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

<table>
<thead>
<tr>
<th>Block...</th>
<th>Affect on Value Display...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.</td>
</tr>
</tbody>
</table>
**Enumerated Values with Non-Unique Integers**

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 67-18. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:
Although the Enumerated Constant block outputs True, both On and True have the same underlying integer, and On is defined first in the class definition enumeration section. Therefore, the Display block shows On. Similarly, a Scope axis would show only On, never True, no matter which of the two values is input to the Scope block.

**Instantiate Enumerations**

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

**Instantiating Enumerations in MATLAB**

To instantiate an enumeration in MATLAB, enter `ClassName.EnumName` in the MATLAB Command Window. The instance is created in the base workspace. For example, if `BasicColors` is defined as in “Create Simulink Enumeration Class” on page 67-9, you can type:

```
bcy = BasicColors.Yellow
```

```
bcy =

    Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of `BasicColors` in alphabetical order:
Double-click an element or method to insert it at the position where you pressed <tab>. See “Code Suggestions and Completions” (MATLAB) for more information.

**Casting Enumerations in MATLAB**

In MATLAB, you can cast directly from an integer to an enumerated value:

```matlab
bcb = BasicColors(2)
```

```matlab
bcb =
Blue
```

You can also cast from an enumerated value to its underlying integer:

```matlab
>> bci = int32(bcb)
```

```matlab
bci =
2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

**Instantiating Enumerations in Simulink (or Stateflow)**

To instantiate an enumeration in a Simulink model, you can enter `ClassName.EnumName` as a value in a dialog box. For example, consider the following model:

The Enumerated Constant block EnumConst, which outputs the enumerated value Yellow, defines that value as follows:
You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a Constant block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` prefix, as explained in “Specify Enumerations as Data Types” on page 67-18.

You cannot specify the integer value of an enumeration member for the **Value** parameter. See “Enumerated Values in Computation” on page 67-24 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is 1.
The same syntax and considerations apply in Stateflow. See “Enumerated Data” (Stateflow) for more information.

**Enumerated Values in Computation**

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of the enumerated signal values) and input the resulting integer signal to a Gain block. See “Casting Enumerated Signals” on page 67-24 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

**Casting Enumerated Signals**

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.
You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in “Simulate with Enumerations” on page 67-15 needed two Data Conversion blocks to convert a sine wave to enumerated values.

The first block casts double to int32, and the second block casts int32 to BasicColors. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

**Casting Enumerated Block Parameters**

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of 2 and an **Output data type** of Enum: BasicColors:

An error occurs because the specifications implicitly cast a double value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of BasicColors.Blue and an **Output data type** of int32.
An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid int32.

Export Simulation Data

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as “data logging” or “saving simulation data.”

You can have data logged in several formats:

- `Simulink.SimulationData.Dataset`
- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

**Note** The `ModelDataLogs` class is supported for backward compatibility. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses `Dataset` format. In R2016a or later, when you open a model from an earlier release that had used `ModelDataLogs` format, the model will log data in `Dataset` format.
Consider converting data logged in other formats to **Dataset** format to simplify post-processing. For more information, see “Dataset Conversion for Logged Data” on page 68-22.

You can also use exported data as the input for simulating a model.

**Approaches for Exporting Signal Data**

Exporting simulation data often involves exporting signal data. You can use various approaches for exporting signal data.

<table>

**Enable Simulation Data Export**

To export the states and root-level output ports of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Settings > Data Import/Export** pane (for details, see “Model Configuration Parameters: Data Import/Export”)
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
  - Signal logging
  - Time
  - Output
  - State or final state
  - Data store

Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.

- The characteristics of the logged data, including:
  - “Data Format for Logged Simulation Data” on page 68-16
  - “Limit Data Logged” on page 68-76
  - “Samples to Export for Variable-Step Solvers” on page 68-66
View Logged Data Using Simulation Data Inspector

To inspect exported simulation data interactively, consider using the Simulation Data Inspector.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See “View Data with the Simulation Data Inspector” on page 30-2.

Memory Performance

Optimization for Logged Data

When exporting simulation data in a simulation mode other than rapid accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first timestamp, the length of the interval (time step), and the total number of timestamps.
- When multiple signals use identical timestamp sequences, the signals share a single stored timestamp sequence. Sharing a single stored timestamp can reduce memory use for logged data by as much as a factor of two. The difference in memory performance can be a critical performance factor, particularly when logging bus signals that have thousands of bus elements.

Logging to Persistent Storage

You can encounter memory issues when you log many signals in a long simulation that has many time steps. Logging to persistent storage can address this kind of memory issue.

To log to persistent storage, in the Configuration Parameters > Data Import/Export pane, select Log Dataset data to file option. Specify the kinds of logging (for example, signal logging and states logging).

- For logging output and states data, set the Format parameter to Dataset.
- If you select the Final states parameter, clear the Save final operating point parameter.

Using a Simulink.SimulationData.DatasetRef object to access signal logging and states logging data loads data into the model workspace incrementally. Accessing data for other kinds of logging loads all the data at once.
For details, see “Log Data to Persistent Storage” on page 68-47.

</tr>
</tbody>
</table>

A Simulink model performs algorithms on input signal data and produces output signals. The model defines what input data to use at the start of simulation and what output to capture at the end of simulation. As you create and simulate your model, you:

1. “Identify Model Signal Data Requirements” on page 68-9
2. “Load Input Signal Data” on page 68-13
3. “Log Output Signal Data” on page 68-14

As you create, debug, and test a model, you can use different sets of input signal data for simulation. You can use logged simulation data as input to another simulation.

Identify Model Signal Data Requirements

To use system-generated signal data, use source blocks such as a Sine Wave block. Source blocks do not require the use of a variable or external data source. If you cannot configure source blocks to meet your modeling requirements, then supply the signal data.

As you determine your signal data requirements, identify the:

- Blocks (including subsystems and Model blocks) that you need to provide data for — Design interfaces for blocks and for model components, including data types of signals.
- Range characteristics of signals, such as sample time, dimensions, and data type.
- Storage location for data for each input signal — Determine where to store signal data: in workspace variables, a MAT-file, or an external data file such as an Microsoft Excel spreadsheet.

Create a list of equation variables and constant coefficients, and then determine the coefficient values from published sources or by performing experiments on the system.
For information about storage locations for signal data, see “Signal Data Storage for Loading” on page 68-10.

**Signal Data Storage for Loading**

- “MATLAB Workspace for Signal Data” on page 68-10
- “Source and Signal Editor Blocks for Signal Data” on page 68-11
- “MAT-Files for Signal Data” on page 68-12
- “Spreadsheets for Signal Data” on page 68-12

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

**MATLAB Workspace for Signal Data**

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

**Create Signal Data in the MATLAB Workspace**

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.
- Use the `csvread` function to read data from a CSV spreadsheet into the MATLAB workspace.
• Use a model callback to load signal data.
• Use one of these Simulink logging techniques:
  • Signal logging
  • To Workspace block
  • Scope block
  • The Configuration Parameters > Data Import/Export pane, the Output, States, or Final states parameters.
• Data store
• The `sim` command configured to log simulation data

**Load Signal Data from the MATLAB Workspace**

To load signal data from a workspace, use one of these techniques:

• Add a From Workspace block.
• Use a root-level input port.

  • Specify workspace variables in the Configuration Parameters > Data Import/Export > Input parameter.
  • Use the Root Inport Mapper tool to specify the data for the Input parameter.

**Source and Signal Editor Blocks for Signal Data**

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define scenarios to use as inputs to a model, you can use the Signal Editor block. The Signal Editor block stores the scenario definitions.

Consider using a source block to:

• Avoid having to create the data manually.
• Reduce memory consumption — source blocks do not store signal data.
• Graphically represent in the model the kind of signal data.

Consider using a Signal Editor block to:
• Create and import scenarios for use in testing.

You can use scenarios with Simulink and with these products:

• Simulink Test
• Simulink Coverage
• Simulink Design Verifier
• Switch between scenarios quickly.

MAT-Files for Signal Data

Consider storing signal data in a MAT-file to:

• Load a large amount of signal data efficiently.
• Reuse the same signal data in different models.
• Reduce memory requirements for the model.
• Use different sets of signal data with the same model, with minimal model updates.

Store Signal Data in a MAT-File

To create a MAT-file to store signal data to import, you can use:

• A To File block
• The Signal Editor user interface
• MATLAB to create signal data that you store in a MAT-file
• Simulink.saveVars function to save to a MAT-file the simulation signal data that Simulink stores as workspace variables

Load Signal Data from a MAT-File

To load signal data from a MAT-file into a model, you can use a From File block.

Spreadsheets for Signal Data

Consider using an Excel or CSV spreadsheet to:

• Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.
• Load a large amount of signal data efficiently.
• Reduce memory requirements for the model.
• Use different sets of signal data with the same model, with minimal model updates.
• Share the signal data with other people who do not have Simulink installed.

**Store Signal Data in a Spreadsheet**

Use one of these approaches:

• Create the signal data directly in the spreadsheet. For spreadsheet requirements, see “Storage Formats” on page 68-276.
• Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

**Load Signal Data from a Spreadsheet**

Use the From Spreadsheet.

The From Spreadsheet block loads Microsoft Excel on all platforms. This block loads CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet block incrementally loads the data directly from the spreadsheet, to minimize memory consumption.

**Load Input Signal Data**

You can use various sources for input signal data for simulating a model. You can:

• Use existing data from a file, such as a spreadsheet.
• Write a MATLAB script to define variables for the signal data. For example, you can create `Dataset` format data that you can use with all the signal loading techniques.
• Use data logged from a previous simulation.

You can use several different approaches to load data into a model, including:

• Root-level input ports — Import signal data from a workspace, using the **Input** configuration parameter to import it to a root-level input port of an Inport, Enable, or Trigger block. You can specify the input data directly in the **Input** parameter. To import multiple signals to root-level input ports, consider using the Root Inport Mapping tool on page 68-133. That tool updates the **Input** parameter based on the signal data that you import and map to root-level input ports.
• Source blocks — Add a source block, such as Sine Wave block, to generate signals to input to another block.
• From File block — Read data from a MAT-file, outputting the data as a signal.
• From Spreadsheet block — Read data from Microsoft Excel spreadsheets or CSV spreadsheets, outputting the data as one or more signals.

To determine the approach to meet the input signal data requirements of your model, see “Comparison of Signal Loading Techniques” on page 68-124.

**Log Output Signal Data**

You can save signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Saving simulation data is also known as logging or exporting simulation data.

To determine which approach to use for logging signal data, see “Export Simulation Data” on page 68-3.

Saving simulation data in Dataset format simplifies postprocessing by providing a common format for the results of various logging techniques. Using Dataset format stores the data as MATLAB timeseries objects, which you can process with MATLAB. Simulink provides tools for converting data logged in other formats to Dataset format.

For more information about logging output signal data, see “Save Run-Time Data from Simulation”.

Data Format for Logged Simulation Data

In this section...

“Data Format for Block-Based Logged Data” on page 68-16
“Data Format for Model-Based Logged Data” on page 68-16
“Signal Logging Format” on page 68-16
“Logged Data Store Format” on page 68-17
“Time, State, and Output Data Format” on page 68-17

Data Format for Block-Based Logged Data

You can use the Scope, To File, or To Workspace blocks to export simulation data. Each of these blocks has a data format parameter.

Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Signal Logging Format” on page 68-16
- “Logged Data Store Format” on page 68-17
- “Time, State, and Output Data Format” on page 68-17

Signal Logging Format

For data that you log in Dataset format (as Simulink.SimulationData.Dataset objects), you can specify whether you want the data for individual signals in the dataset to use MATLAB timeseries or timetable elements. To control how Dataset elements are saved, set the Dataset signal format configuration parameter. The default is timeseries. For details, see “Dataset signal format”.

The Dataset signal format parameter applies to signal logging data, as well as output and states logging data when you set the Format configuration parameter to Dataset.
Logged Data Store Format

When you log data store data, Simulink uses a Simulink.SimulationData.Dataset object.

For details, see “Accessing Data Store Logging Data” on page 69-42.

Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- “Dataset” on page 68-17 (default)
- “Array” on page 68-18
- “Structure with Time” on page 68-18
- “Structure” on page 68-21

If you select the Configuration Parameters > Data Import/Export > Output check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see “Export Signal Data Using Signal Logging” on page 68-70.
  1 In the Simulink Editor, select one or more signals.
  2 Click the Simulation Data Inspector button arrow and click Log Selected Signals to Workspace.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the Log fixed-point data as a fi object parameter.

For information about the format for logged final state data, see “State Information” on page 68-286.

Dataset

Dataset format:

- Uses MATLAB timeseries objects to store logged data. MATLAB timeseries objects allow you to work with logged data in MATLAB without a Simulink license.
• Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
• Supports inclusion of units information in logged data for output data
• Does not support logging nonvirtual bus data for code generation or in rapid accelerator mode.

Array

If you select this **Array** option, Simulink saves the states and outputs of a model in a state and output array, respectively.

The state matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

**Note** Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

• Data is all scalars or all vectors (or all matrices for states)
• Data is all real or all complex
• Data all has the same data type
• Data includes bus signals

If your model outputs and states do not meet these conditions, use the **Structure** or **Structure with time** output formats (see “Structure with Time” on page 68-18).

**Structure with Time**

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters > Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.
The structure used to save outputs has two top-level fields:

- **time**
  Contains a vector of the simulation times.

- **signals**
  Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- **values**
  Contains the outputs for the corresponding output port.
  - If outputs are scalars or vectors — **values** field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
  - If the outputs are matrix (2-D) values — **values** field is a 3-D array of dimensions M-by-N-by-T. M-by-N is the dimensions of the output signal and T is the number of output samples.
  - If T = 1 — MATLAB drops the last dimension. Therefore, the **values** field is an M-by-N matrix.

- **dimensions**
  Specifies the dimensions of the output signal.

- **label**
  Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is DSTATE or CSTATE, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of DSTATE).

- **blockName**
  Specifies the name of the corresponding output port or block with states.

- **inReferencedModel**
  If the **signals** field records the final state of a block that resides in the referenced model, contains a value of 1. Otherwise, the value is false (0).

The following example shows the structure-with-time format for a nonreferenced model.
xout.signals(1)
ans =
    values: [296206x1 double]
dimensions: 1
    label: 'CSTATE'
    blockName: 'vdp/x1'
inReferencedModel: 0

The structure used to save states has a similar organization. The states structure has two top-level fields:

- **time**
  The **time** field contains a vector of the simulation times.

- **signals**
  The **signals** field contains an array of substructures, each of which corresponds to one of the states of the model.

Each **signals** structure has four fields: **values**, **dimensions**, **label**, and **blockName**. The **values** field contains time samples of a state of the block specified by the **blockName** field. The **label** field for built-in blocks indicates the type of state: either **CSTATE** (continuous state) or **DSTATE** (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the **values** field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the **values** array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The **values** field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

**Note** Simulink can read back simulation data saved to the MATLAB workspace in the **Structure with time output format**. See “Examples of Specifying Signal and Time Data” on page 68-160 for more information.
Structure

This format is the same as for Structure with time output format, except that Simulink does not store simulation times in the time field of the saved structure.

Dataset Conversion for Logged Data

In this section...

“Why Convert to Dataset Format?” on page 68-22
“Results of Conversion” on page 68-23
“Dataset Conversion Limitations” on page 68-25

Why Convert to Dataset Format?

You can use the Simulink.SimulationData.Dataset constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to Dataset format:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- ModelDataLogs

Converting data from other Simulink logging formats to Dataset format simplifies writing scripts to post-process data logged. For example, a model with multiple To Workspace blocks can use different data formats. Converting the logged data to Dataset format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to Dataset format also makes it easier to take advantage of features that require Dataset format. You can easily convert data logged in earlier releases that used a format other than Dataset to work well with Dataset data in a more recent release.

The Dataset format:

- Uses MATLAB timeseries objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the logged data, you can use MATLAB time-series methods such as filter, detrend, and resample.
• Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting Dataset object uses the variable name as its name. You can use a name-value pair to specify a Dataset name.

You can use the Simulink.SimulationData.Dataset.concat method to combine Dataset objects into one concatenated Dataset object.

Results of Conversion

Dataset objects hold data as elements. To display the elements of a Dataset variable, enter the variable name at the MATLAB command prompt. The elements of Dataset objects are different types, depending on the data they store. For example, signal logging stores data as Simulink.SimulationData.Signal elements and state logging in Dataset format stores data as Simulink.SimulationData.State elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

<table>
<thead>
<tr>
<th>Format</th>
<th>Conversion Result Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MATLAB time series</td>
<td>If you log nonbus data, during conversion, the software first adds the data as a Simulink.SimulationData.Signal object. It then adds that object as an element of the newly created Dataset. If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a Simulink.SimulationData.Signal object. It then adds that object as an element of the data set. Time-series objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.</td>
</tr>
<tr>
<td>Format</td>
<td>Conversion Result Notes</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Structure and structure with time | Structure and structure with time formats do not always contain as much information as if you log in Dataset format. However, before converting structure and structure with time formats, the data structure must have time and signals fields.  
Conversion populates a Simulink.SimulationData.Signal object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called blockName, converting adds it to the block path. Otherwise, the block path is empty.  
When scope data is logged in structure format, the logged structure has a PlotStyle field. The software uses this field to set the interpolation in the Dataset object. |
| Array                        | Arrays contain little information. For example, there is no block path information.  
Conversion adds the array to a Simulink.SimulationData.Signal object and adds it as an element of the Dataset object. The conversion leaves unavailable information such as block path and timestamp fields as either empty or with default values. |
| ModelDataLogs               | Converts data from ModelDataLogs format to Dataset format.  
**Note** The ModelDataLogs format is no longer used for signal logging. |
**Dataset Conversion Limitations**

- Converting logged data to Dataset format results in a Dataset object that contains all the information that the original logged data included. However, if there is no corresponding information for the other Dataset properties, the conversion uses default values for that information.

- To log variable-size signals, use the To Workspace block. If you convert data logged with To Workspace to be Dataset format, you lose the information about the variable-size signals.

- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:
  - The first column containing the data for the first signal in the bus
  - The second column containing data for the second bus signal, and so on

  When you convert that data to Dataset, the Dataset preserves that organization. But if you log the bus signal in Dataset format without conversion, the conversion captures the bus data as a structure of time-series objects.

- If the logged data does not include a time vector, when you convert that data to Dataset, the conversion inserts a time vector. There is one time step for each data value. However, the simulation time steps and the Dataset time steps can vary.

- Dataset format ignores the specification of frame signals. Conversion of structure or structure with time data to Dataset reshapes the data for logged frame signals.

“Convert Structure Without Time to Dataset” on page 68-28
“Programmatically Access Logged Dataset Format Data” on page 68-31

Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to Dataset format. `myvdp_timeseries` is the vdp model with two To Workspace blocks configured for `simout` and `simout1` logging data in MATLAB timeseries format. Consider using a procedure like this one if you have models that use To Workspace blocks to log data to MATLAB timeseries format.
Use the `Simulink.SimulationData.Dataset` constructor to convert the MATLAB timeseries data to Dataset format and then concatenate the two data sets.

1. Starting with the `vdp` model, add two To Workspace blocks to the model as shown.
2. Set the `Save format` parameter of both blocks. Set `Timeseries`.
3. Save the model as `myvdp_timeseries`.
4. Simulate the model.

The simulation logs data using the To Workspace blocks.

5. Access the signal logging format, `logsout`.

```matlab
logsout =
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData

Characteristics:
  Name: 'logsout'
  Total Elements: 2

Elements:
  1: 'x1'
  2: 'x2'

- Use `get` or `getElement` to access elements by index or name.
- Use `addElement` or `setElement` to add or modify elements.

Methods, Superclasses
```

6. Convert the MATLAB time-series data from both To Workspace blocks to Dataset.

```matlab
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);

ds is the variable name of the first To Workspace block data. `ds1` is the variable name of the second To Workspace block data.
```

7. Concatenate both datasets into `dsfinal`. Observe that the format of `dsfinal` matches that of `logsout`.

```matlab
dsfinal = ds.concat(ds1)
```
dsfinal =
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData

Characteristics:
    Name: 'simout'
    Total Elements: 2

Elements:
    1: 'x1'
    2: 'x2'

-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.

Methods, Superclasses

**Convert Structure Without Time to Dataset**

This example shows how to convert structure without time data to Dataset format. `myvdp_structure` is the vdp model with two To Workspace blocks configured for simout and simout1 logging data in structure format, as shown.
If you have models that use To Workspace blocks to log data to structure format, consider using a procedure like this one to convert them to Dataset format.

1. Starting with the vdp model, add two To Workspace blocks to the model as shown.
2 In the **Save format** parameter of both blocks, select **Structure**.

3 Enable signal logging for the two signals going to the two To Workspace blocks to log in **Ds** format.

4 Save the model as **myvdp_structure**.

5 Simulate the model.

The simulation logs data using the To Workspace blocks.

6 Convert the structure data from both To Workspace blocks to **Dataset**.

```matlab
ds = Simulink.SimulationData.Dataset(simout);
dsl = Simulink.SimulationData.Dataset(simout1);
```

*simout* is the variable name of the first To Workspace block data. *simout1* is the variable name of the second To Workspace block data.

With the conversion of structure without time or an array, time starts at t=0 and increments by 1.
7  Get the values of the first element in $ds$.

ds.get(1).Values.Time

ans =

   19.6802
   20.0000

9  Observe the discrepancy in timestamps between

   • Data logged in structure without time that you convert to Dataset format
   • Data logged in Dataset format

Programmatically Access Logged Dataset Format Data

When you use the default Dataset signal logging format, Simulink saves the logging data in a Simulink.SimulationData.Dataset object. For information about extracting signal data from that object, see the Simulink.SimulationData.Dataset reference page.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB `timeseries` objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Simulink.SimulationData.Dataset.get</code></td>
<td>Get element or collection of elements from the dataset, based on index, name, or block path. You can also use the <code>getElement</code> method, which shares syntax and behavior as the <code>get</code> method.</td>
</tr>
<tr>
<td><code>Simulink.SimulationData.Dataset.numElements</code></td>
<td>Get number of elements in the dataset.</td>
</tr>
</tbody>
</table>

For example of accessing signal logging data that uses the `Dataset` format, see `Simulink.SimulationData.Dataset`.

**Access Array of Buses Signal Logging Data**

Signal logging data for an array of buses uses `Dataset` signal logging format.

The general approach to access data for a specific signal in an array of buses is:

1. Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logsout` variable).
2. To get the values, index within the array of buses.
3. Index again to get data for a specific bus.

For example, to obtain the signal logging data for the Constant6 block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the Terminator block:

```plaintext```
logsout.getElement('topBus').Values.a(2,2).firstConst.data
```

Here are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_mdlref_bus`.
Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).

To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

```plaintext
logsout.getElement('AoBSig').Values(2).chirpSig.Data
ans=
    0 0.9585
```

Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (s2) that feeds into bus s1.
This example shows navigation to the Constant3 block, which is a signal in bus2.

```
logsout.getElement('s1').Values.s2(2).firstConst.Data
ans=
```

```
3
3
3
3
3
3
3
```

**Nested Arrays of Buses**

The `ex_log_nested_aob` model has an array of buses (a) that is made up of three arrays of buses: b, c, and d. The Matrix Concatenate block combines the nested arrays of buses into array of buses a.
This example shows navigation to the Constant6 block.

`logsout.getElement('topBus').Values.a(2,2).firstConst.Data`
Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, signal logging data includes a Simulink.SimulationData.Signal object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use one of these approaches:

- To find the data for the specific signal, visually inspect the displayed output of Simulink.SimulationData.Signal objects.
- Use the Simulink.SimulationData.Dataset.getElement method, specifying the block path for the source block of the signal.
- To iterate through the signals with a duplicate signal name, create a script using the Simulink.SimulationData.Dataset.getElement method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in normal mode.

1. In the model, right-click the signal.
2. In the context menu, select Properties.
3. In the Signal Properties dialog box, set Logging name to Custom and specify a different name than the signal name.
4. Simulate the model and use the Simulink.SimulationData.Dataset.getElement method with a name argument.
Tip Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see “Override Signal Logging Settings with Signal Logging Selector” on page 68-94.

Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses Dataset format, use a sprintf command within a getElement call. For example:

```plaintext
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

- “Dataset Conversion for Logged Data” on page 68-22
Log Signal Data That Uses Units

To have logged data include the units specified for signals, use the Dataset or Timeseries logging format, which stores logging information in MATLAB timeseries objects.

Signal logging uses Dataset format. Output logging (Configuration Parameters > Data Import/Export > Output) uses Dataset as the default format. The default save format for the To File and To Workspace blocks is Timeseries.

If you use Dataset or Timeseries format for signal logging or for To File block or To Workspace block logging, the logged data includes units information.

To capture units information for output logging:

1. Set the Format configuration parameter to Dataset.
2. In the Block Parameters dialog box for Outport blocks for which you want to capture units information, set the Unit parameter to match the units of the input signal.

For example, in this model the In1 block has its Unit parameter set to newton and In2 block uses m (meters). Open the model. After you simulate the model, you can see the units for the logged data.

```
logsout.get('a').Values.signal1.DataInfo
```

```
tsdata.datametadata
Package: tsdata

Common Properties:
    Units: newton (Simulink.SimulationData.Unit)
    Interpolation: linear (tsdata.interpolation)
```
• You can view the units in the data logged in the To Workspace block.

```matlab
simout1.signal2.DataInfo.Units
```

```matlab
ans =

   Units with properties:
       Name: 'm'
```

This example model shows how to view the data logged in a Time Scope block. Open the model.

To use the Time Scope block to log data, in the scope select **Configuration Properties > Logging > Log data to workspace** and specify a variable (`ScopeData` in this example). The `In3` block uses `m` (meters). Simulate the model and then at the MATLAB command line, enter:

```matlab
ScopeData.get(1).Values.DataInfo.Units
```

```matlab
ans =

   Units with properties:
       Name: 'm'
```

“Limit Data Points” on page 68-42
“Logging Intervals” on page 68-42

You can use several options to reduce the amount of data logged during a simulation. Limiting the amount of exported simulation data reduces memory usage and speeds up simulation. However, if you limit the amount of simulation data, the logged data can skip some time steps that are critical for testing and analyzing the model.

You can use multiple techniques for the same simulation.

<table>
<thead>
<tr>
<th>Technique</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify a decimation factor</td>
<td>Skip samples when exporting data.</td>
</tr>
<tr>
<td>Limit data points</td>
<td>Limit the number of samples saved to be only the most recent samples</td>
</tr>
<tr>
<td>Specify an interval for logging</td>
<td>Specify ranges of time steps for logging</td>
</tr>
</tbody>
</table>

Alternatively, for logging large amounts of data that can cause memory issues, consider logging to persistent storage. This approach preserves all the logging data, minimizing MATLAB workspace memory usage. For details, see “Log Data to Persistent Storage” on page 68-47.

Decimation

To skip samples when exporting data, apply a decimation factor. For example, a decimation factor of 2 saves every other sample. By default, decimation is set to 1, which does not skip any samples.

The approach you use to specify a decimation factor depends on the kind of logging data.
Data | How to Specify
---|---
Signal logging | Right-click the signal. In the Signal Properties dialog box, select the Decimation parameter.
Data store logging | From the Block Parameters dialog box for that block, open the Logging tab. Apply a decimation factor using the Decimation parameter.
State and output | Enter a value in the field to the right of the Decimation label.

**Limit Data Points**

To limit the number of samples saved to be only the most recent samples, set the Limit Data Points parameter.

The approach you use depends on the kind of logging data.

<table>
<thead>
<tr>
<th>Data</th>
<th>How to Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signal logging</td>
<td>Right-click the signal. In the Signal Properties dialog box, select the Limit Data Points to Last parameter.</td>
</tr>
<tr>
<td>Data store logging</td>
<td>From the Block Parameters dialog box for that block, open the Logging tab. Select the Limit Data Points to Last parameter.</td>
</tr>
<tr>
<td>Time, state, and output logging</td>
<td>Select the Limit data points configuration parameter and for the Maximum number of data points configuration parameter, specify the limit.</td>
</tr>
</tbody>
</table>

**Logging Intervals**

To specify an interval for logging, use the Configuration Parameters > Data Import/Export > Logging intervals parameter. Limiting logging to a specified interval allows you to examine specific logged data without changing the model or adding complexity to a model.
The logging intervals apply to data logged for:

- Time
- States
- Output
- Signal logging
- The To Workspace block
- The To File block

The logging intervals do not apply to final state logged data, scopes, or streaming data to the Simulation Data Inspector.

The intervals specified with **Logging intervals** establish the set of times to which the **Decimation** and **Limit data points to last** parameters apply. For example, suppose that you set the logging interval \([2, 4; 7, 9]\) with a fixed-step solver with a fixed-step size of 1. The logged times are 2, 3, 4, 7, 8, and 9.

Work with Big Data for Simulations

Simulation of models with many time steps and signals can involve big data that is too large to fit into the RAM of your computer. Such situations include:

- Logging simulation data (signal logging, output port logging, and state logging)
- Loading input signal data for simulating a model
- Running multiple or parallel simulations

To work with big data for simulations, store the data to persistent storage in a MAT-file. Using big data techniques for simulations requires additional steps beyond what you do when the data is small enough to fit in workspace memory. As you develop a model, consider logging and loading simulation data without using persistent storage unless you discover that your model has big data requirements that overload memory.

Big Data Workflow

This example is a high-level workflow for handling big data that one simulation produces and that another simulation uses as input. For more detailed information about the major workflow tasks, see:

- “Log Data to Persistent Storage” on page 68-47
- “Load Big Data for Simulations” on page 68-53
- “Analyze Big Data from a Simulation” on page 68-63

Tip This example uses a SimulationDatastore object for streaming data into a model. Alternatively, you can stream a DatasetRef object directly into a model.

1. Configure two models to log several signals.
2. Simulate the models, logging the data to persistent storage for each model.

   ```matlab
   sim(mdl1,'LoggingToFile','on','LoggingFileName','data1.mat');
   sim(mdl2,'LoggingToFile','on','LoggingFileName','data2.mat');
   ```

Logging that involves big data requires saving the data to persistent storage as a v7.3 MAT-file. Only the data logged in Dataset format is saved to the file. Data logged in other formats, such as Structure with time, is saved in memory, in the base workspace.
The data that you log to persistent storage is streamed during the simulation in small chunks, to minimize memory requirements. The data is stored in a file that contains Dataset objects for each set of logged data (for example, logsout and xout).

3 Create DatasetRef objects (dsr1 and dsr2) for specific sets of logged signals. Then create SimulationDatastore objects (dst1 and dst2) for values of elements of the DatasetRef objects. This example code creates a SimulationDatastore for the 12th element of logsout for the first simulation. For the second simulation, the example code creates a signal with values being a SimulationDatastore object for the seventh element of logsout. You can use curly braces for indexing.

```matlab
dsr1 = Simulink.SimulationData.DatasetRef('data1.mat','logsout');
dsr2 = Simulink.SimulationData.DatasetRef('data2.mat','logsout');
dst1 = dsr1{12};
dst2 = dsr2{7};
```

4 Use SimulationDatastore objects as an external input for another simulation. To load the SimulationDatastore data, include it in a Dataset object. The datastore input is incrementally loaded from the MAT-file. The third input is a timeseries object, which is loaded into memory as a whole, not incrementally.

```matlab
input = Simulink.SimulationData.Dataset;
input{1} = dst1;
input{2} = dst2;
ts = timeseries(rand(5,1),1,'Name','RandomSignals');
input{3} = ts;
sim(mdl3,'ExternalInput','input');
```

5 Use MATLAB big data analysis to work with the SimulationDatastore objects. Create a timetable object by reading the values of a SimulationDatastore object. The read function reads a portion of the data. The readall function reads all the data.

```matlab
tt = dst1.Values.read;
```

6 Set the MATLAB session as the global execution environment (mapreducer) for working with the tall timetable. Create a tall timetable from a SimulationDatastore object and read a timetable object with in-memory data.

```matlab
mapreducer(0);
ttt = tall(dst1.Values);
```

Tip For another example showing how to work with big simulation data, see Working with Big Data.

Log Data to Persistent Storage

When to Log to Persistent Storage

In some cases, logging simulation data can create large amounts of data that are too large for your computer to hold in working memory while also running efficiently. Such situations can include simulations that log many signals, simulations that run for a long time with many time steps, and parallel simulations. When your simulation configuration creates a large amount of data, you can log that data to persistent storage, rather than logging it to working memory.

You can store logged simulation data to persistent storage in a MAT-file. You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter (Log Dataset data to file) without changing the model layout.

If you use Dataset format for logging, you can log each of these kinds of data to persistent storage:

- Signal logging — Uses Dataset format only.
- States — Defaults to Dataset format. You can use other formats.
- Final states — Requires that you clear the Save final operating point parameter.
- Output — Defaults to Dataset format.
- Data stores — Uses Dataset format only.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For most models, logging to the workspace is simpler because it avoids loading and saving logging files. Compared to accessing data logged to memory, accessing data logged to persistent storage requires some additional steps. For short
simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

**Limitations for Logging to Persistent Storage**

- Only data logged in Dataset format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export + Save final operating point**.
- The Simulation Stepper and fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model. Create objects that reference the data in the file and then load the referencing object.

**Alternative Approaches for Reducing Logging Memory Usage**

When you need to simulate a model that creates a large amount of data and you do not want to log the simulation data to persistent storage, consider using one of these alternatives.

- Limit the amount of simulation data stored in the workspace.

You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Limit Amount of Exported Data” on page 68-41.

<table>
<thead>
<tr>
<th>Technique</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify a decimation factor</td>
<td>Skip samples when exporting data.</td>
</tr>
<tr>
<td>Limit data points</td>
<td>Limit the number of samples saved to be only the most recent samples.</td>
</tr>
<tr>
<td>Specify intervals for logging</td>
<td>Specify ranges of time steps for logging.</td>
</tr>
</tbody>
</table>

If you limit the amount of simulation data stored in the workspace, the logged data may not contain some time steps that are critical for testing and analyzing the model.

- Use a To File block for each signal that you want to log.

Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:
• Is a per-signal approach that can clutter a model with multiple To File blocks attached to individual signals.
• Creates a separate MAT-file for each To File block, instead of the single file created when you log to persistent storage.

**Log to Persistent Storage**

1. Specify the kinds of logging to perform (for example, signal logging and output logging) and the variable names for the logging data.
2. In the model diagram, mark selected signals for signal logging.
3. Use Dataset format for logging the data. Data that is logged in any other format is stored in the workspace.
   • Signal logging and data store logging use Dataset format only. The default format for output, states, and final states logging is Dataset.
   • For final states logging, clear the **Save final operating point** configuration parameter.
4. Enable logging to persistent storage and specify an output MAT-file name.
   • Select the **Log Dataset data to file** configuration parameter.
   • Specify the MAT-file to use. Do not use a file name from one locale in a different locale.
5. To save the logged Dataset data using timeseries or timetable elements, set the **Dataset signal format** configuration parameter. The default format is timeseries. The timetable format is helpful for MATLAB combining logged data from multiple simulations. For details about the timetable format, see “Dataset signal format”.
6. Simulate the model.

**Enable Logging to Persistent Storage Programmatically**

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to 'on', as applicable:
To log output, states, and final states data to persistent storage, set the `SaveFormat` parameter to 'Dataset'.

To log final states data to persistent storage, set the `SaveOperatingPoint` to 'off'.

**How Simulation Data Is Stored**

Logging to persistent storage saves logged simulation data in the specified MAT-file. The data is stored as a `Simulink.SimulationData.Dataset` object for each type of logging that uses Dataset format. The Dataset elements are stored as either timeseries or timetable objects, depending on how you set the `Dataset signal format` parameter. For details about the timetable format, see “Dataset signal format”.

The Dataset object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logsout`, the Dataset object in the MAT-file is `logsout`.

**Save Logged Data from Successive Simulations**

The approach you use for saving data logged from successive simulations depends on whether you are performing parallel simulations.

**Without Using Parallel Simulations**

Each time you simulate a model without using parallel simulation, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve data in the file, it retrieves the most recent version of the data. To preserve data from an earlier simulation, use one of these approaches:

- Between simulations, use the **Configuration Parameters > Data Import/Export** pane to specify a different name for the MAT-file for logging.
Between simulations, save a copy of the MAT-file. Use a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.

Programmatically specify a new file name for each simulation run.

If you run multiple simulations that overlap in time, use a unique MAT-file for each model that you log to persistent storage.

If you change the file name used for logging to persistent storage, then to access the logged data, use one of these approaches:

- Create a `Simulink.SimulationData.DatasetRef` object.
- To match the new file name, change the `Location` property of the `DatasetRef` objects.

For details about using `DatasetRef` objects to access logged data, see “Load Big Data for Simulations” on page 68-53.

**With Parallel Simulations**

For parallel simulations, for which you specify an array of input objects, if you log to file, Simulink:

- Creates a MAT-file for each simulation
- Creates `Simulink.SimulationData.DatasetRef` objects to access output data in the MAT-file and includes those objects in the `SimulationOutput` object data
- Enables the `CaptureErrors` argument for simulation

For more information about parallel simulations, see “Run Multiple Simulations” on page 28-2.

• “Load Big Data for Simulations” on page 68-53
• “Analyze Big Data from a Simulation” on page 68-63
• “Run Multiple Simulations” on page 28-2
Simulating models with many time steps and signals can use and create data that is too large to fit into working memory on your computer. When your simulation input data does not fit into memory, you can choose one of several strategies to use that data as simulation input with root-level Inport blocks. These strategies work for loading data stored in Dataset format in a Version 7.3 MAT-file, including data logged from another simulation.

1 When individual input signals are too large to fit into memory, you can use a `matlab.io.datastore.SimulationDatastore` object to access the signal data. The data from the `SimulationDatastore` object loads into the simulation incrementally in chunks that fit into memory.

2 When your simulation inputs are specified by a `Simulink.SimulationData.Dataset` object in a file that is too large to load into memory, you can stream the entire contents of the `Dataset` object into your model using a `Simulink.SimulationData.DatasetRef` object.

3 When the signals fit into memory and are stored in a file that is too large to load into memory, you can load individual signals from the file into memory using a `Simulink.SimulationData.DatasetRef` object.

All big data loading strategies are for the special case when your data does not fit into memory and can require extra steps. These examples use data that fits fully into memory to illustrate the steps required for big data loading. When your simulation inputs fit into memory, consider using other loading techniques.

### Stream Individual Signals Using SimulationDatastore Objects

When individual signals in your input data are too large to fit into memory, you can create `matlab.io.datastore.SimulationDatastore` objects for those signals and stream them into your model. To create a `SimulationDatastore` object for a signal you want to stream into your model, first create a `Simulink.SimulationData.DatasetRef` object.
to reference the Dataset object that contains your signal of interest. For example, create a DatasetRef for logged data from a simulation of the slexAircraftExample model.

\[
\text{logsout\_DSR} = \text{Simulink.SimulationData.DatasetRef('aircraftData.mat','logsout');}
\]

You can create a SimulationDatastore object for your desired signal by indexing into the DatasetRef object with curly braces or using the \text{getAsDatastore} method for the DatasetRef object. In both cases, the SimulationDatastore object exists in the Values property of the returned Simulink.SimulationData.Signal object.

When you know the index of the signal within the Dataset object, you can index into the DatasetRef object with curly braces to create a SimulationDatastore for your signal.

\[
\text{alphaRad\_ds} = \text{logsout\_DSR}\{4\}
\]

\[
\text{alphaRad\_ds} = \\
\text{Simulink.SimulationData.Signal} \\
\text{Package: Simulink.SimulationData}
\]

\[
\text{Properties:} \\
\text{Name: 'alpha, rad'} \\
\text{PropagatedName: ''} \\
\text{BlockPath: [1x1 Simulink.SimulationData.BlockPath]} \\
\text{PortType: 'outport'} \\
\text{PortIndex: 4} \\
\text{Values: [1x1 matlab.io.datastore.SimulationDatastore]}
\]

Methods, Superclasses

To create a SimulationDatastore object for a signal using the signal index, name, or block path, use the \text{getAsDatastore} method. For example, create a SimulationDatastore object for the Stick signal.

\[
\text{stick\_ds} = \text{logsout\_DSR.getAsDatastore('Stick')}
\]

\[
\text{stick\_ds} = \\
\text{Simulink.SimulationData.Signal} \\
\text{Package: Simulink.SimulationData}
\]

\[
\text{Properties:} \\
\text{Name: 'Stick'} \\
\text{PropagatedName: ''}
\]
Because the Values properties of the stick_ds and alphaRad_ds Simulink.SimulationData.Signal objects are SimulationDatastores, the signal data streams into your model. You can include a SimulationDatastore backed Signal object as an element in a Dataset object or as an item in the Input parameter comma-separated list.

**Stream an Entire Dataset Using a DatasetRef Object**

When your simulation inputs are specified in a Dataset in a file that is too large to load into memory, you can create a Simulink.SimulationData.DatasetRef object to stream your simulation inputs into your model. When you specify a DatasetRef object for the Input parameter on the Data Import/Export pane, all the signals in the Dataset object used to create the DatasetRef stream into your model. Use one of the other big data loading techniques to load or stream individual signals from a Dataset object.

When the file where your simulation input Dataset is stored contains other Datasets and data, you can use the Simulink.SimulationData.DatasetRef.getDatasetVariableNames function to view a list of the Dataset objects contained in the file. Previewing the variable names in the Dataset object is particularly useful when the file contents do not fit into memory.

datasetNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('aircraftData.mat')
datasetNames = 1x3 cell array
    {'logsout'}    {'xout'}    {'yout'}

Create a DatasetRef object for logsout.

logsout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat','logsout');

You can load logsout_DSR using the Input parameter the same way you would load a Simulink.SimulationData.Dataset object. Each signal in the Dataset object used to create the DatasetRef streams into the model in chunks that fit into memory.
Load Individual Signals from a DatasetRef Object

When your simulation input signals individually fit into memory and are stored in a Dataset object in a file that does not fit into memory, use a Simulink.SimulationData.DatasetRef object to load each signal of interest into memory. Then, you can load the signals as simulation inputs for your model.

First, create the DatasetRef object to reference the Dataset object in the file that contains the signals you want to load. For example, create a DatasetRef object for data logged to file from a simulation of the slexAircraftExample model.

```
logsout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat','logsout');
```

You can use the get or getElement methods to load individual signals into memory with the DatasetRef object. Both methods load the specified element into memory, using the same syntax. You can specify the signal you want to load into memory using its index within the Dataset object or its name. If you don't know the name of the signal you want to load, use the getElementNames method to see the names of the elements in the Dataset object referenced by the DatasetRef object.

```
elNames = logsout_DSR.getElementNames
```

```
elNames = 15x1 cell array
   {0x0 char    }
   {0x0 char    }
   {0x0 char    }
   {'alpha, rad'}
   {'q, rad/sec'}
   {0x0 char    }
   {'qGust'     }
   {'wGust'     }
   {0x0 char    }
   {0x0 char    }
   {0x0 char    }
   {0x0 char    }
   {'Stick'     }
   {0x0 char    }
   {0x0 char    }
   {0x0 char    }
```

Load the qGust signal into memory using its name.

```
qGust = logsout_DSR.getElement('qGust')
```
qGust =
    Simulink.SimulationData.Signal
    Package: Simulink.SimulationData

    Properties:
        Name: 'qGust'
        PropagatedName: ''
        BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        PortType: 'outport'
        PortIndex: 2
        Values: [1x1 timeseries]

Methods, Superclasses

You can add the qGust signal to a Dataset object of simulation input signals to load to the root-level Inport blocks in your model, or you can specify qGust as an item in the Input parameter comma-separated list.

Stream Data from a MAT-File as Input for a Parallel Simulation

This example shows how to use Simulink.SimulationData.DatasetRef objects and the `parsim` function to stream input data from a version 7.3 MAT-file for parallel simulations. Consider following the steps outlined in this example when the inputs for your simulation are too large to load into memory. For example, you can use data logged to persistent storage from one set of parallel simulations as input for another.

This example uses `parsim` to run multiple simulations of a model, with each simulation using unique input data. The model is based on the `sldemo_suspn_3dof` model, modified to use Inport blocks as the source for inputs instead of the Signal Editor block. The model simulates the response of a suspension system to different road conditions. The MAT-file used in this example contains multiple `Simulink.SimulationData.Dataset` objects representing various road conditions. The example uses DatasetRef objects to stream the contents of an entire referenced `Dataset` object as simulation input.

You can also stream data for individual signals into parallel simulations run with `parsim` using `matlab.io.datastore.SimulationDatastore` objects. For details on creating `SimulationDatastore` objects, see “Stream Individual Signals Using `SimulationDatastore` Objects” on page 68-53.

Load Model and Access Input Data

Load the `ex_sldemo_suspn_3dof_parsim_stream` model. The model receives input data through two Inport blocks, and each `Dataset` object used as simulation input contains two elements: one for each Inport.

```matlab
mdl = 'ex_sldemo_suspn_3dof_parsim_stream';
open_system(mdl)
```

You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to evaluate the contents of the MAT-file containing the input data without loading the data into memory. The function returns a cell array that contains elements for the name of each `Simulink.SimulationData.Dataset` variable the file contains. Use the function to access the variable names and determine the number of test cases in the file.

```matlab
varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('suspn_3dof_test_cases.mat');
numTestCases = numel(varNames);
```
You can stream the test case data into the model using
`Simulink.SimulationData.DatasetRef` objects. The `DatasetRef` object references a
variable in the file used to create it and loads the variable data incrementally. Create a
`DatasetRef` object for each `Simulink.SimulationData.Dataset` object in the test
cases file.

```matlab
for idx1 = 1:numTestCases
    inputData(idx1) = Simulink.SimulationData.DatasetRef('suspn_3dof_test_cases.mat',
        varNames{idx1});
end
```

**Configure and Run Parallel Simulations**

To use the set of test case inputs as input for a set of parallel simulations, create an array
of `Simulink.SimulationInput` objects that you can pass to the `parsim` function. Use
the `setExternalInput` function to specify a
`Simulink.SimulationData.DatasetRef` object corresponding to a test case as data
to stream as simulation input.

```matlab
in(1:numTestCases) = Simulink.SimulationInput(mdl);
for idx2 = 1:numTestCases
    in(idx2) = setExternalInput(in(idx2),inputData(idx2));
end
```

Use the `parsim` function to run a simulation for each test case. When you have the
Parallel Computing Toolbox™, the `parsim` function runs simulations in parallel. Without
the Parallel Computing Toolbox, the `parsim` function runs the simulations in serial.

The `parsim` function creates a worker pool based on the Parallel Computing Toolbox
configuration. By default, `parsim` uses a local pool. If you use remote workers, you can
use the `AttachedFiles` name-value pair to send the MAT-file containing the test case
input data to each worker. When you specify the `AttachedFiles` name-value pair,
`parsim` sends a copy of the file to each worker, which can take some time for large files.
For streaming input data from a large file, local workers may be faster because the
workers have access to the file without creating and sending copies. When you use
remote workers, consider storing the MAT-file in a location that all remote workers can
access and creating `DatasetRef` objects that reference that copy of the file.

```matlab
out = parsim(in);
```

[27-Aug-2019 11:47:23] Checking for availability of parallel pool...
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
[27-Aug-2019 11:49:57] Starting Simulink on parallel workers...

[27-Aug-2019 11:50:28] Loading model on parallel workers...
[27-Aug-2019 11:50:43] Running simulations...
[27-Aug-2019 11:51:31] Cleaning up parallel workers...

**View Simulation Results**

You can access the simulation results programmatically when the simulations finish. Create a plot showing the vertical displacement for the vehicle for all the road profile test cases.

```matlab
if isempty(out(1).ErrorMessage)
    legend_labels = cell(1,numTestCases);
    for i = 1:numTestCases
        if isempty(out(i).ErrorMessage)
            simOut = out(i);
            ts = simOut.logsout.get('vertical_disp').Values;
            ts.plot;
            legend_labels{i} = ['Run ' num2str(i)];
        end
        hold all
    end
end
title('Response of a 3-DoF Suspension Model')
```
You can also view `parsim` simulation results using the Simulation Manager. To view results in the Simulation Manager, use the `ShowSimulationManager` name-value pair for `parsim`. With the Simulation Manager, you can monitor the progress of the runs, view simulation data, and show the `parsim` results in the Simulation Data Inspector.

**Close Parallel Workers**

When you have finished running parallel simulations, you can close the worker pool.
delete(gcp('nocreate'));

**Related Topics**

“Load Big Data for Simulations” on page 68-53

“Log Data to Persistent Storage” on page 68-47

“Run Parallel Simulations Using parsim” on page 28-5
To access data logged to persistent storage (a MAT-file) for analysis in MATLAB, use references to the data in the MAT-file. You can work directly with data logged in a format other than Dataset format, because that data is stored in the MATLAB workspace.

**Create DatasetRef Objects to Access Logged Datasets**

When you log to a MAT-file, Simulink stores in the specified MAT-file a Simulink.SimulationData.Simulink.Dataset object whose elements are Dataset objects. There is one Dataset object for each set of logged simulation data (for example, Dataset objects for logsout and xout, for signal logging and state logging).

To access simulation Dataset format data for a set of logged simulation data, create Simulink.SimulationData.DatasetRef objects. You can access individual elements of the dataset using a DatasetRef object. For details, see “Load Individual Signals from a DatasetRef Object” on page 68-56.

**Use SimulationDatastore Objects to Access Signal Data**

To access leaf signals in a logged Dataset, create a matlab.io.datastore.SimulationDatastore object for the signal, based on the DatasetRef object for the Dataset that contains the signal. For details, see “Stream Individual Signals Using SimulationDatastore Objects” on page 68-53.

You can operate on data referenced by a SimulationDatastore object. For example, you can get the data in a chunk to be read into memory from the MAT-file. For an example, see matlab.io.datastore.SimulationDatastore.
Create Timetables for MATLAB Analysis

When you read a SimulationDatastore object, using the read or readall method the output is in MATLAB timetable format. For details about the timetable format, see “Dataset signal format”.

You can use a SimulationDatastore object to create a timetable for the signal values and read a timetable object with in-memory data. For example, for SimulationDatastore object dst1:

```matlab
tt = dst1.Values.read;
ttt = tall(dst1.Values);
```

Create Tall Timetables

You can create a tall timetable:

```matlab
mapreducer(0);
ttt = tall(dst1.Values);
```

Access Persistent Storage Metadata

If you use persistent storage for several simulations, you can have multiple MAT-files. When you run multiple simulations using batch processing, you get multiple MAT-files if you specify a different persistent storage MAT-file for each simulation. For parallel simulations, Simulink produces a separate MAT-file for each simulation run. To help you identify and understand the context of the simulation data included in a MAT-file, Simulink stores metadata about logging to persistent storage.

A Simulink.SimulationMetadata object includes in its ModelInfo structure a LoggingInfo structure with two fields:

- **LoggingToFile** — Indicates whether logging to persistent storage is enabled ('on' or 'off')
- **LoggingFileName** — Specifies the resolved file name for the persistent storage MAT-file (if LoggingToFile is 'on').

The MAT-file used for persistent storage contains a SimulationMetadata variable that stores the same simulation metadata as the Simulink.SimulationMetadata object. The SimulationMetadata is a system-generated name, not a variable name that you specify.
To access the persistent logging storage metadata, use one of these alternatives:

- View simulation metadata by using the `SimulationOutput` object `SimulationMetadata` property.
- Use tab completion to access `SimulationMetadata` object properties such as `ModelInfo` and to access field names.
- Display simulation metadata in the Variable Editor. Click the `SimulationOutput` object and use one of these approaches:
  - Select the **Explore Simulation Metadata** check box (which displays the data in a tree structure).
  - Double-click the `SimulationMetadata` row.

**Access Error Information**

You can view error message and information about the stack and causes for simulation data by using the `SimulationOutput` object `ErrorMessage` property. For parallel simulations, if you are logging to file, Simulink enables the `CaptureErrors` argument for simulation.

</tr>
<tr>
<td>“Produce Specified Output Only” on page 68-68</td>
</tr>
</tbody>
</table>

Output Options

Use the Output options list under Configuration Parameters > Data Import/Export > Additional parameters to control how much output the simulation generates when your model uses a variable-step solver.

- Refine output (default)
- Produce additional output
- Produce specified output only

Refine Output

The Refine output option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing Refine output and specifying a refine factor of 2 generates output at these times:

0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes the
simulation step size so that time steps coincide with the times that you specify for
additional output.

The refine factor applies to variable-step solvers and is most useful when you are using
ode45. The ode45 solver can take large steps. However, when you graph simulation
output, the output from this solver sometimes is not sufficiently smooth. In such cases,
run the simulation again with a larger refine factor. A value of such as 4 for ode45 can
provide much smoother results.

**Note**  This option helps the solver locate zero crossings, although it does not ensure that
Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-13).

### Produce Additional Output

Use the **Produce additional output** option to specify directly those additional times
at which the solver generates output. When you select this option, the **Data Import/
Export** pane displays an **Output times** configuration parameter. In this parameter, enter
a MATLAB expression that evaluates to an additional time or a vector of additional times.
The solver produces hit times at the output times that you specify, in addition to the times
it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

\[0, 2.5, 5, 8.5, 10\]

Choosing the **Produce additional output** option and specifying \([0:10]\) generates
output at these times:

\[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\]

and perhaps at additional times, depending on the step size chosen by the variable-step
solver.

**Tips**

- This option helps the solver locate zero crossings, although it does not ensure that
  Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-13).
- Set the **Output times** configuration parameter to a value other than the default empty
  matrix ([ ]).

---

Samples to Export for Variable-Step Solvers

68-67
• For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

**Produce Specified Output Only**

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

\[ 0, 2.5, 5, 8.5, 10 \]

Choosing the *Produce specified output only* option and specifying \([1:9]\) generates output at these times:

\[ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \]

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

**Tips**

• This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-13).

• Set the *Output times* configuration parameter to a value other than the default empty matrix (\([\ ]\)).

• In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.

• When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:
  • The times that you specify
  • All the time steps in between the values that you specify
  • The simulation start and stop times

• For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Export Signal Data Using Signal Logging

In this section...

“Signal Logging” on page 68-70
“Signal Logging Workflow” on page 68-70
“Signal Logging in Rapid Accelerator Mode” on page 68-71
“Signal Logging Limitations” on page 68-71

Signal Logging

To capture signal data from a simulation, usually you can use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 68-73 and “Enable Signal Logging for a Model” on page 68-87.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 68-3.

Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

1. Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 68-73.
2. Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 68-87.
3. Simulate the model.

Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging and then override signal logging settings to select different subsets of signals for logging. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 68-92.
Use this approach to log signals in models that use model referencing. For an example, see “Viewing Signals in Model Reference Instances”.

**Additional Signal Logging Options**

With the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See “Specify Signal-Level Logging Name” on page 68-75.
- Control how much data the simulation generates for a signal. See “Limit Data Logged” on page 68-76.
- Review the signal logging configuration for a model. See “View the Signal Logging Configuration” on page 68-80.
- Specify the samples for export for models with variable-step solvers. See “Samples to Export for Variable-Step Solvers” on page 68-66.
- Configure the model to display signal logging data in the **Simulation Data Inspector**.

**Signal Logging in Rapid Accelerator Mode**

Signal logging in rapid accelerator mode does not log the following kinds of signals. When you update or simulate a model that contains these signals, Simulink displays a warning that those signals are not logged.

- Signals inside Stateflow charts
- Signals that use a custom data type

If you set the **Configuration Parameters > Solver > Periodic sample time constraint** parameter to **Ensure sample time independent**, you cannot use signal logging in rapid accelerator mode.

**Signal Logging Limitations**

- Rapid accelerator mode supports signal logging, with the requirements and limitations described in “Signal Logging in Rapid Accelerator Mode” on page 68-71.
- Top-model and Model block software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulation modes support signal logging. For a description of limitations, see “Top-
Model SIL/PIL Limitations” (Embedded Coder) and “Model Block SIL/PIL Limitations” (Embedded Coder).

- Array of buses signals support signal logging, with the requirements described in “Import Array of Buses Data” on page 68-171.
- You cannot log bus signals directly in For Each subsystems.
- You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:
  - The For Each subsystem is in a model simulating in rapid accelerator mode.
  - The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.
- You cannot log signals that feed Function-Call subsystems or Action subsystems.
- You cannot log an input signal to a Merge block. You can log a Merge block output signal.
- For Integrator and Discrete-Time Integrator blocks that have the Show state port parameter enabled, you cannot log the state port signal.
- If you configure a bus signal or bus element for signal logging that is an input to a subsystem, you cannot automatically refactor the subsystem interface to use In Bus Element and Out Bus Element blocks. For details about that refactoring, see “Convert Models to Use Bus Element Ports” on page 72-25.
- You cannot log local data in Stateflow Truth Table blocks.

Configure a Signal for Logging

In this section...

“Mark a Signal for Logging” on page 68-73
“Specify Signal-Level Logging Name” on page 68-75
“Limit Data Logged” on page 68-76
“Set Sample Time for a Logged Signal” on page 68-77

Mark a Signal for Logging

Enable logging by marking a signal, using one of the following techniques:

• “Enable Logging Using Simulink Toolstrip” on page 68-73
• “Enable Logging Using Signal Properties” on page 68-73
• “Enable Logging Using the Model Data Editor” on page 68-74
• “Programmatic Interface” on page 68-74

The Simulink Editor menu options are generally the simplest way to mark signals for logging.

A signal for which you enable logging is a logged signal. By default, Simulink displays a logged signal indicator for each logged signal.

Enable Logging Using Simulink Toolstrip

1 In the Simulink Editor, select one or more signals.
2 On the Simulation tab, click Log Signals.

Enable Logging Using Signal Properties

1 In the Simulink Editor, right-click the signal.
2 From the context menu, select Properties.
3 In the Signal Properties dialog box, in the Logging and accessibility tab, select Log signal data.
4 Click OK.
Alternatively, you can select the **Log Selected Signals** from the context menu that appears when you right-click the selected signal.

**Enable Logging Using the Model Data Editor**

The Model Data Editor displays a flat list of signals in your model. You can sort, group, and filter the list. Use this technique to enable logging for:

- Many signals at once.
- Signals that are not close to each other in the block diagram.
- Signals that are difficult to locate in a large model or subsystem hierarchy.

To select signals to log using the Model Data Editor:

1. Open the Model Data Editor. On the **Modeling** tab, click the **Model Data Editor** button.
2. Select the **Signals** tab in the Model Data Editor.
3. Select **Instrumentation** in the drop-down.
4. Check the boxes in the **Log Data** column for signals you would like to log.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

**Programmatic Interface**

To enable signal logging programmatically for selected blocks, use the output **DataLogging** property. Set this property using the `set_param` command. For example:

1. At the MATLAB Command Window, open a model. Type
   ```matlab
vdp
   ```
2. Get the port handles of the signal that you want to log. For example, for the Mu block output port signal.
   ```matlab
   ph = get_param('vdp/Mu','PortHandles')
   ```
3. Enable signal logging for the desired output port signal.
   ```matlab
   set_param(ph.Outport(1), 'DataLogging', 'on')
   ```

   The logged signal indicator appears.
Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 68-96.

Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use one of the following approaches:

- “Signal-Level Logging Name in the Editor” on page 68-75
- “Signal-Level Logging Name in Model Explorer” on page 68-76
- “Signal-Specific Logging Name Specified Programmatically” on page 68-76

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink uses a blank name.

**Note** The signal-level logging name is distinct from the model-level signal logging name. The model-level signal logging name is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `logsout`. For details about the model-level signal logging name, see “Specify a Name for Signal Logging Data” on page 68-90.

Signal-Level Logging Name in the Editor

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. Specify the logging name:
   a. In the Signal Properties dialog box, select the **Logging and accessibility** tab.
   b. From the **Logging name** list, select **Custom**.
c Enter the logging name in the adjacent text field.

**Signal-Level Logging Name in Model Explorer**

1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.

2 If the **Contents** pane does not display the **LoggingName** property, add the **LoggingName** property to the current view. For details about column views, see “Customize Model Explorer Views” on page 13-36.

3 Enter a logging name for one or more signals using the **LoggingName** column.

**Signal-Specific Logging Name Specified Programmatically**

Enable signal logging programmatically for selected blocks with the output port **DataLogging** property. Set this property using the `set_param` command.

1 At the MATLAB Command Window, open a model. For example, type:

   vdp

2 Get the port handles of the signal that you want to log. For example, for the Mu block output port signal:

   `ph = get_param('vdp/Mu','PortHandles');`

3 Enable signal logging for the desired output port signal:

   `set_param(ph.Outport(1),'DataLogging','on');`

   The logged signal indicator appears.

4 Issue commands that use the **DataLoggingNameMode** and **DataLoggingName** parameters. For example:

   `set_param(ph.Outport(1), 'DataLoggingNameMode', 'Custom');`
   `set_param(ph.Outport(1), 'DataLoggingName', 'x2_log');`

**Limit Data Logged**

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples
You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

**Use Signal Properties to Limit Logged Data**

1. In the Simulink Editor, right-click the signal.
2. From the context menu, select **Signal Properties**.
3. In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:
   - Limit data points to last
   - Decimation

**Use Model Explorer to Limit Data Logged**

1. In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.
2. If the **Contents** pane does not display the **DataLoggingDecimation** property or the **DataLoggingLimitDataPoints** property, add one or both of those properties to the current view. For details about column views, see “Customize Model Explorer Views” on page 13-36.
3. To specify a decimation factor, edit the **Decimation** and **DecimateData** properties. To limit the number of samples logged, edit the **LimitDataPoints** property.

**Set Sample Time for a Logged Signal**

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals
- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

**Usage Notes**

Do not specify a sample time for:
Frame-based signals
Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block and a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose that a model includes a continuous signal and the sample time is inherited (-1). The logged output for that signal shows that the interpolation method is linear.
logsout.get(1).Values.DataInfo

tsdata.datametadata
  Package: tsdata

  Common Properties:
    Units: ''
    Interpolation: linear (tsdata.interpolation)

If you change the sample time to be continuous (0), the logged output for that signal shows that the interpolation method is zoh (zero-order hold).

**View Signal Logging Configuration Using the Simulink Editor**

By default, the Simulink Editor displays an indicator on each signal marked for logging. For example, this model logs the output signal of the Sine Wave block.

![Signal Properties: COUNTERBUS](image)

To view the signal properties, right-click the signal and select **Properties**.
If you programmatically override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Configure a Signal for Logging” on page 68-73.

A logged signal can also be a test point. See “Test Points” on page 71-63 for information about test points.

To hide logging indicators, on the Debug tab, click to clear Information Overlays > Log & Testpoint.

**View Logging Configuration Using the Signal Logging Selector**

In the Simulation tab, click Model Settings. Then, click Configure Signals to Log.

The Contents pane shows the signals marked for logging in the node selected in the Model Hierarchy pane. When no signals are marked for logging in a node, the Contents pane is empty. Use the arrow to the left of a hierarchical node to expand or collapse the contents of the node in the Model Hierarchy pane.

When a model includes referenced models, the check box in the Model Hierarchy pane indicates the override configuration for the model corresponding to the node.

<table>
<thead>

</tr>
</tbody>
</table>

### View Configuration of Subsystems and Linked Libraries

The following table describes default `Model Hierarchy` pane display of subsystems, masked subsystems, and linked library nodes.

<table>
<thead>
<tr>
<th>Node</th>
<th>Display Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subsystem</td>
<td>Displays subsystems all that include logged signals</td>
</tr>
<tr>
<td>Masked subsystem</td>
<td>Does not display masked subsystems</td>
</tr>
<tr>
<td>Linked library</td>
<td>Displays all subsystems that include logged signals</td>
</tr>
</tbody>
</table>

You can control how the `Model Hierarchy` pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the `Model Hierarchy` pane or use the `View` menu, using the same approach as you use in the Model Explorer. For details, see “Display Linked Library Subsystems and Masked Subsystems” on page 13-12 and “Manage Existing Masks” on page 40-18.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the ![icon](<image>) icon or `View > Show All Subsystems`. This subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.

- To display masked subsystems with logged signals, use the ![icon](<image>) icon or `View > Show Masked Subsystems`

- To display linked libraries, use the ![icon](<image>) icon or `View > Show Library Links`
Filtering Signal Logging Selector Contents

To find a specific signal or property value for a signal, use the Filter Contents edit box. Use the same approach as you use in the Model Explorer; for details, see “Filtering Contents” on page 13-31.

Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select Highlight block in model.

View Signal Logging Configuration Using the Model Explorer

1. To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.

2. In the Contents pane, set Column View to the Signals view.

[Image of Model Explorer]

For further information, see “Model Explorer: Model Hierarchy Pane” on page 13-9 and “Model Explorer: Contents Pane” on page 13-16.

Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```matlab
mdlsignals = find_system(gcs,'FindAll','on','LookUnder Masks','all',...
'FollowLinks','on','type','line','SegmentType','trunk');
```
ph = get_param(mdlsignals,'SrcPortHandle')
for i=1: length(ph)
    get_param(ph{i},'datalogging')
end

Enable Signal Logging for a Model

In this section...

| “Enable and Disable Logging at the Model Level” on page 68-87 |
| “Specify Format for Dataset Signal Elements” on page 68-88 |
| “Specify a Name for Signal Logging Data” on page 68-90 |

Enable and Disable Logging at the Model Level

To log a signal, mark it for logging. For details, see “Configure a Signal for Logging” on page 68-73.

Enable or disable logging globally for all signals that you mark for logging in a model. By default, signal logging is enabled. Simulink logs signals only if the Configuration Parameters > Data Import/Export > Signal logging parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

When signals are marked for logging, the signal data is logged to the workspace and also sent directly to the Simulation Data Inspector, by default. You can disable logging signals to the workspace through the Configuration Parameters dialog box or programmatically.

- In the Configuration Parameters dialog box, clear the Configuration Parameters > Data Import/Export > Signal logging parameter check box.
- From the command line, use the SignalLogging parameter.

  set_param(bdroot,'SignalLogging','off')

Data for signals marked for logging is always sent to the Simulation Data Inspector.

Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 68-92.
Specify Format for Dataset Signal Elements

Logged signal data is saved in Dataset format (as Simulink.SimulationData.Dataset objects). To specify whether you want the data for individual signals in the dataset to use MATLAB timeseries or timetable elements, set the Dataset signal format configuration parameter. The default is timeseries. For details, see “Dataset signal format”.

Migrate Scripts That Use Legacy ModelDataLogs API

For scripts that simulate a model created in a release earlier than R2016a that uses ModelDataLogs format for logging, update the code to log in Dataset format.

If you have already logged signal data in the ModelDataLogs format, you can use the Simulink.ModelDataLogs.convertToDataset function to update the ModelDataLogs signal logging data to use Dataset format. For example, to update the older_model_dataset from ModelDataLogs format to Dataset format:

```
new_dataset = logsout.convertToDataset('older_model_data')
```

Converting a model from using ModelDataLogs format to using Dataset format can require that you modify your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues to address after converting to Dataset format. The table provides solutions for each issue.

<table>
<thead>
<tr>
<th>Possible Issue After Conversion to Dataset Format</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code in existing callbacks, functions, scripts, or tests that used the ModelDataLogs programmatic interface to access data can result in an error.</td>
<td>Check for code that uses ModelDataLogs format access methods. Update that code to use Dataset format access methods. For example, suppose that existing code includes the following line:</td>
</tr>
<tr>
<td></td>
<td>logsout.('Subsystem Name').X.data</td>
</tr>
<tr>
<td></td>
<td>Replace that code with a Dataset access method:</td>
</tr>
<tr>
<td></td>
<td>logsout.getElement('x').Values.data</td>
</tr>
</tbody>
</table>
## Possible Issue After Conversion to Dataset Format

<table>
<thead>
<tr>
<th>Possible Issue After Conversion to Dataset Format</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mux block signal names are lost.</td>
<td>The Dataset format treats Mux block signals as a vector. To identify signals by signal names, replace Mux blocks with Bus Creator blocks.</td>
</tr>
<tr>
<td>Signal Viewer cannot be used for signal logging.</td>
<td>Simulink does not log signal logging data in the Signal Viewer. Use the signal logging output variable to view the logged data.</td>
</tr>
<tr>
<td>The unpack method generates an error.</td>
<td>The unpack method, which is supported for Simulink.ModelDataLogs and Simulink.SubsysDataLogs objects, is not supported for Simulink.SimulationData.Dataset objects. For example, if the data in mlog has three fields: x, y, and z, then: For ModelDataLogs format data, the mlog.unpack method creates three variables in the base workspace. For Dataset format data, access methods by names. For example: x = logsout.getElement('x').Values</td>
</tr>
</tbody>
</table>
Possible Issue After Conversion to Dataset Format | Solution
---|---
The ModelDataLogs and Dataset formats have different naming rules for unnamed signals. | If necessary, add signal names. In ModelDataLogs format, for an unnamed signal coming from a block, Simulink assigns a name in this form: 
SL_BlockName+<portIndex>
For example, SL_Gain1.
In Dataset format, elements do not need a name, so Simulink leaves the signal name empty.
For both ModelDataLogs and Dataset formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.
Test points in referenced models are not logged. | Consider enabling signal logging for test points in a referenced model.

Specify a Name for Signal Logging Data

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is logsout. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name car_logsout to identify the data as being the signal logging data for the car model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the Configuration Parameters > Data Import/Export > Signal logging parameter, enter the signal logging name.
- Use the SignalLoggingName parameter, specifying a signal logging name. For example:

```plaintext```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```plaintext```

Override Signal Logging Settings

Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

To reduce memory overhead and to facilitate the analysis of simulation logging results, override signal logging properties. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

• Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
• Exclude a few signals from the signal logging output.
• Override specific signal logging properties, such as decimation, for a signal.
• Collect only what you need when running multiple test vectors.

Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

• “Override Signal Logging Settings with Signal Logging Selector” on page 68-94
• “Override Signal Logging Settings from MATLAB” on page 68-99

You can use a combination of the two interfaces. The Signal Logging Selector creates Simulink.SimulationData.ModelLoggingInfo objects when saving the override...
settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the Simulink.SimulationData.ModelLoggingInfo class has a LoggingMode property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

**Scope of Signal Logging Setting Overrides**

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to Log all signals as specified in model, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to Override signals. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

**Note** Simulink rebuilds a model in the following situation:

1. The model contains one or more signals marked for signal logging.
2. You simulate the model in rapid accelerator mode.
3. You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
4. You simulate the model in rapid accelerator mode again.
Override Signal Logging Settings with Signal Logging Selector

1. Open the Signal Logging Selector, using one of the following approaches:
   - In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
   - For a model that includes a Model block, you can also use the following approach:
     a. In the Simulink Editor, right-click a Model block.
     b. In the context menu, select **Log Referenced Signals**.

   **Tip** To enable the **Configure Signals to Log** button, select the **Signal logging** configuration parameter.

2. Set **Logging Mode** to **Override signals**.
Note The Override signals setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the Model Hierarchy pane.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.

4 Override signal logging settings. Use one of the following approaches, depending on whether your model uses model referencing:

- “Models Without Model Referencing: Overriding Signal Logging Settings” on page 68-95
- “Models with Model Referencing: Overriding Signal Logging Settings” on page 68-96

Tip To open the Configuration Parameters > Data Import/Export pane from the Signal Logging Selector, use the button.

Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

1 Open the Signal Logging Selector. In the Configuration Parameters > Data Import/Export pane, click the Configure Signals to Log button.

   - If necessary, select Signal logging to enable the Configure Signals to Log button.
2 Set **Logging Mode** to **Override signals**.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.

4 In the **Contents** pane table, select the signal whose logging settings you want to override.

5 Override logging settings:
   - To disable logging for a signal, clear the **DataLogging** check box for that signal.
   - To override other signal logging settings (for example, decimation), ensure that the **DataLogging** check box is selected. Then, edit values in the appropriate columns.

### Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using one or more of these procedures:

- “Enable Logging for All Logged Signals” on page 68-96
- “Disable Logging for All Signals in Node” on page 68-97
- “Override Signal Logging for a Subset of Signals” on page 68-98
- “Override Other Signal Logging Properties” on page 68-98

#### Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is:

- Solid ( ), if logging is disabled for some of signals.
- Empty ( ), if logging is disabled for all the signals.

To enable logging of all logged signals for a node:

1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
2 Set **Logging Mode** to **Override signals**.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.

4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark (✓).

   • For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
   
   • For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

**Disable Logging for All Signals in Node**

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is:

   • Solid (☐), if logging is enabled for some signals.
   
   • Checked (✓), if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.

2 Set **Logging Mode** to **Override signals**.

3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.

4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty (☐).

   • For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
   
   • For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected referenced model.
Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

1. Open the Signal Logging Selector. In the Configuration Parameters > Data Import/Export pane, click the Configure Signals to Log button.
2. Set Logging Mode to Override signals.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.
4. In the Model Hierarchy pane, ensure that the check box for the top-level model or Model block is either solid ( ), if logging is disabled for some of the signals, or empty ( ), if logging is disabled for all the signals. Click the check box to cycle through different states.
5. In the Contents pane table, for the signals that you want to log, select the check box in the DataLogging column.

To enable logging for multiple signals, hold the Shift or Ctrl key and select a range of signals or individual signals. Select the check box in the DataLogging column of one of the highlighted signals.

Override Other Signal Logging Properties

In addition to overriding the setting for the DataLogging property for a signal, you can override other signal logging properties, such as decimation.

1. Open the Signal Logging Selector. In the Configuration Parameters > Data Import/Export pane, click the Configure Signals to Log button.
2. Set Logging Mode to Override signals.
3. View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 68-83.
4. In the Model Hierarchy pane, ensure that the check box for the top-level model or Model block is solid ( ) if logging is disabled for some signals, or empty ( ), if logging is disabled for all signals. Click the check box to cycle through different states.
In the Contents pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the DataLogging column.

To enable logging for multiple signals, hold the Shift or Ctrl key and select a range of signals or individual signals. Select the check box in the DataLogging column of one of the highlighted signals.

In the Contents pane table, modify the settings for properties, such as DecimateData and Decimation.

Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The DataLoggingOverride model parameter — Use to view or set signal logging override values for a model
- The following classes:
  - Simulink.SimulationData.ModelLoggingInfo — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
  - Simulink.SimulationData.SignalLoggingInfo — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:

![Image showing the Signal Logging Selector]

- Simulink.SimulationData.LoggingInfo — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the DataLoggingOverride parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use set_param with the DataLoggingOverride model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.
Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a Simulink.SimulationData.ModelLoggingInfo object. For example, use the following commands to create the model logging override object for the ex_bus_logging model and automatically add each logged signal in the model to that object:

```matlab
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
  'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
  'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
  'ex_bus_logging')
```

The LoggingMode property is set to OverrideSignals, which configures the model logging override object to log only the signals specified in the Signals property.

To apply the model override object settings, use:

```matlab
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the Simulink.SimulationData.ModelLoggingInfo object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants
As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

**Specify Which Models to Log**

To specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings, use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model. See the `Simulink.SimulationData.ModelLoggingInfo` documentation.

This example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```matlab
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ... 'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ... 'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
    ('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'

mi =

ModelLoggingInfo with properties:

    Model: 'ex_bus_logging'
    LoggingMode: 'LogAllAsSpecifiedInModel'
    LogAsSpecifiedByModels: {}
    Signals: []

To apply the model override object settings, use:

```matlab
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```matlab
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ... 'examples', 'ex_bus_logging')));
```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex.mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
('ex_bus_logging');
mi.LoggingMode = 'OverrideSignals';
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging',true);

To apply the model override object settings, use:
set_param(ex_bus_logging,'DataLoggingOverride', mi);

Simulink saves the settings when you save the model.

**Log a Subset of Signals**

For a simple model with a limited number of logged signals, you could create an empty Simulink.SimulationData.ModelDataLogInfo object. Then create Simulink.SimulationData.SignalLoggingInfo objects for each of the signals that you want to log, and assign those objects to the model logging information object.

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex.mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mdl = 'ex_bus_logging';
blk = 'ex_bus_logging/IncrementBusCreator';
blkPort = 1;

load_system(mdl);

ov = Simulink.SimulationData.ModelLoggingInfo(mdl);
so = Simulink.SimulationData.SignalLoggingInfo(blk,blkPort);

ov.Signals(1) = so;

% apply this object so the model
set_param(mdl,'DataLoggingOverride',ov);

% Simulate
sim(mdl);

% observe that only the signal
topOut
To apply the model override object settings, use:

```matlab
set_param(mdl, 'DataLoggingOverride', ov);
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by:

```matlab
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdlref_counter_bus')));
```

```matlab
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
    'ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA'...
    'ex_mdlref_counter_bus/Bus Creator'}, 1)
```

```matlab
pos =

4
```

```matlab
for idx=1:length(mi.Signals)
    mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);
end
```

To apply the model override object settings, use:

```matlab
set_param(ex_bus_logging,'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

**Override Other Signal Logging Properties**

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ... 'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ... 'examples', 'ex_mdlref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
    ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
    'ex_mdlref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;

To apply the model override object settings, use:

set_param(ex_bus_logging,'DataLoggingOverride', mi);

Simulink saves the settings when you save the model.

View and Access Signal Logging Data

In this section...

“Signal Logging Object” on page 68-105
“Access Data Programmatically” on page 68-106
“Handling Spaces and Newlines in Logged Names” on page 68-107
“Access Logged Signal Data in ModelDataLogs Format” on page 68-109

You can view the signal logging data during simulation, using the Simulation Data Inspector, or for paused or stopped simulations, using other visualization interfaces. See “Decide How to Visualize Simulation Data” on page 31-2.

Alternatively, you can access signal logging data programmatically, using MATLAB commands, as described in this topic.

**Tip** If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 68-80 and “Override Signal Logging Settings” on page 68-92.

### Signal Logging Object

Simulink saves signal logging data in a Simulink.SimulationData.Dataset object, which is a MATLAB workspace variable. The default name of the signal logging variable is logsout. You can change the variable name. For details, see “Specify a Name for Signal Logging Data” on page 68-90.

You can specify whether you want the data for individual signals in a dataset to use MATLAB timeseries or timetable elements. Set the Dataset signal format configuration parameter (for details, see “Dataset signal format”).

Releases earlier than R2016a also supported a ModelDataLogs format. For details, see “Migrate Scripts That Use Legacy ModelDataLogs API” on page 68-88.
Access Data Programmatically

You can use the Simulink.SimulationData.Dataset API to access signal logging data programmatically. To access Dataset object elements, use indexing with curly braces. For example, you can access the first element of the topOut signal logging Dataset object using index 1. This example is based on the use of the default setting of timeseries for the dataset elements. For details about timeseries and timetable format data, see “Dataset signal format”.

```matlab
open_system(docpath(fullfile(docroot,'toolbox','simulink','examples','ex_bus_logging')));
open_system(docpath(fullfile(docroot,'toolbox','simulink','examples','ex_mdlref_counter_bus')));
sim('ex_bus_logging')
topOut
```

Simulink.SimulationData.Dataset 'topOut' with 4 elements

<table>
<thead>
<tr>
<th>Name</th>
<th>BlockPath</th>
</tr>
</thead>
</table>
| 1  
[1x1 Signal]  | COUNTERBUS ex_bus_logging/COUNTERBUSCreator |
| 2  
[1x1 Signal]  | OUTPUTBUS ex_bus_logging/CounterA   |
| 3  
[1x1 Signal]  | INCREMENTBUS ex_bus_logging/IncrementBusCreator |
| 4  
[1x1 Signal]  | inner_bus ...erA|ex_mdlref_counter_bus/Bus Creator |

- Use braces { } to access, modify, or add elements using index.

```matlab
element1 = topOut{1}
element1 =
```

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
- Name: 'COUNTERBUS'
- PropagatedName: ''
- BlockPath: [1x1 Simulink.SimulationData.BlockPath]
- PortType: 'output'
- PortIndex: 1
- Values: [1x1 struct]

Methods, Superclasses

```matlab
element1.Values
```
ans =

    data: [1x1 timeseries]
   limits: [1x1 struct]

To search for specific elements in a Dataset object, use the find method. To return the names of the Dataset object elements, use the getNames method.

**Tip** To call a function on each specified MATLAB timeseries object, you can use the Simulink.SimulationData.forEachTimeseries function. For example, you can use this function to make it easy to resample every element of a structure of timeseries objects obtained by logging a bus signal.

### Handling Spaces and Newlines in Logged Names

Signal names in data logs can have spaces or newlines in their names when:

- The signal is named and the name includes a space or newline character.
- The signal is unnamed and originates in a block whose name includes a space or newline character.
- The signal exists in a subsystem or referenced model (or any parent block) whose name includes a space or newline character.

The following three examples show signals whose names contain:

- A space
- A signal whose name contains a newline
- An unnamed signal that originates in a block whose name contains a newline
The following example shows how to handle spaces or new lines in logged names when a model uses the default of `logsout` for the signal logging data.

```matlab
lLogsout

Simulink.SimulationData.Dataset 'logsout' with 3 elements

<table>
<thead>
<tr>
<th>Name</th>
<th>BlockPath</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>[1x1 Signal] ''</td>
</tr>
<tr>
<td>2</td>
<td>[1x1 Signal] x y</td>
</tr>
<tr>
<td>3</td>
<td>[1x1 Signal] x y</td>
</tr>
</tbody>
</table>

- Use braces {} to access, modify, or add elements using index.

To access a signal with a space or newline, use the index. For example, to access the `x  y` signal:

```matlab
>> logsout.getElement{2}

ans =

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
  Name: 'x  y'
```
Access Logged Signal Data in ModelDataLogs Format

Before R2016a, you could log signals in ModelDataLogs format. Starting in R2016a, you cannot log data in the ModelDataLogs format. Signal logging uses the Dataset format.

However, you can use data that was logged in a previous release using ModelDataLogs format.

For more information, see Simulink.ModelDataLogs.

Related Examples

- “Save Run-Time Data from Simulation”
- “Export Signal Data Using Signal Logging” on page 68-70
- “Migrate Scripts That Use Legacy ModelDataLogs API” on page 68-88
- “Log Signals in For Each Subsystems” on page 68-110
Log Signals in For Each Subsystems

The approach you use to log data for a signal in a For Each subsystem depends on whether the signal is a:

- **Nonbus signal** — Log directly in a For Each subsystem
- **A bus or array of buses signal** — Use one of these approaches:
  - Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. This approach works well for many models.
  - Attach the signal to an Outport block and log the signal outside of the For Each subsystem. Use this approach when you want to log a whole bus signal, and that bus signal includes many bus element signals.

**Note** You cannot log bus signals directly in a For Each subsystem.

You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:

- The For Each subsystem is in a model simulating in rapid accelerator mode.
- The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.

The data for each logged signal in a For Each subsystem is saved in a separate Dataset element as a Simulink.SimulationData.Signal object. The format of the logged signal data depends on how you set the **Dataset signal format** configuration parameter:

- If the setting is timeseries, then each signal object contains an array of MATLAB timeseries objects. The array keeps the data from different For Each iteration separate.
- If the setting is timetable, then each signal object contains a cell array of MATLAB timetable objects. The dimensions of this array match the number of For Each
iterations. For example, if the For Each subsystem has three iterations, then the
logged data has a 3x1 array of timeseries or timetable objects. For nested For
Each subsystems, each layer of nesting adds another dimension to the logged data.

**Log Signal in Nested For Each Subsystem**

This example logs a signal in a nested For Each subsystem.

Open the `ex_loginsideforeach_nested` model.

```matlab
open_system(docpath(fullfile(docroot,'toolbox','simulink',
                               'examples','ex_loginsideforeach_nested.slx')))
```

In the Simulink Editor, open the **For Each Subsystem1** block, and inside that
subsystem, open the **For Each Subsystem2** block.

Simulate the model and examine the signal logging data for the first iteration of the top
subsystem and the third iteration of the bottom subsystem. The 2x3 timeseries results
from two iterations at the first For Each level and three iterations at the second (nested) level

```matlab
sim('ex_loginsideforeach_nested');
logsout.get('nestedDelay')
```
ans =

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
struct with fields:

    Name: 'nestedDelay'
  PropagatedName: ''
        BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        PortType: 'outport'
        PortIndex: 1
        Values: [2x3 timeseries]

Return the values of the `nestedDelay` object.

cellsout.get('nestedDelay').Values(1,3)
timeseries

Common Properties:
    Name: 'nestedDelay'
    Time: [5x1 double]
    TimeInfo: [1x1 tsdata.timemetadata]
    Data: [1x1x5 double]
    DataInfo: [1x1 tsdata.datametadata]

**Log Bus Signals in For Each Subsystem**

This example logs a two bus signal in a For Each subsystem. For one bus signal, you use a Bus Selector block and then log each selected signal. For the other bus signal, you use Outport blocks and log outside of the For Each subsystem.

Open the `ex_for_each_log_bus` model.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink','examples','ex_for_each_log_bus.slx')))
```
In the Simulink Editor, open the **For Each Subsystem** block.

To log the signals in the **limits** bus signal, the signal is branched to a **Bus Selector** block, and each of the bus element signals is marked for signal logging.

To log the whole **COUNTERBUS** signal, the bus signal is connected to an **Outport** block. The output signal from the For Each subsystem is marked for signal logging. To have the bus signal cross the subsystem boundary, the **Bus Creator** block that creates the **COUNTERBUS** signal has the **Output data type** parameter set to **Bus: COUNTERBUS** and **Output as nonvirtual bus** check box selected.

Simulate the model and examine the signal logging output. Focus on one of the bus element signals logged inside the For Each subsystem and on the bus signal logged outside of the For Each subsystem.

```
sim('ex_for_each_log_bus');
logsout
```

**Simulink.SimulationData.Dataset 'logsout' with 3 elements**

<table>
<thead>
<tr>
<th>Name</th>
<th>BlockPath</th>
</tr>
</thead>
<tbody>
<tr>
<td>OutsideForEach</td>
<td>ex_for_each_log_bus/For Each Subsystem</td>
</tr>
<tr>
<td>&lt;lower_saturation_limit&gt;</td>
<td>...g_bus/For Each Subsystem/Bus Selector</td>
</tr>
<tr>
<td>&lt;upper_saturation_limit&gt;</td>
<td>...g_bus/For Each Subsystem/Bus Selector</td>
</tr>
</tbody>
</table>

- Use braces `{ }` to access, modify, or add elements using index.
Return the values of the `lower_saturation_limit` object.

```matlab
logsout{2}.Values
```

3×1 timeseries array with properties:

- **Events**
- **Name**
- **UserData**
- **Data**
- **DataInfo**
- **Time**
- **TimeInfo**
- **Quality**
- **QualityInfo**
- **IsTimeFirst**
- **TreatNaNasMissing**
- **Length**

Return the values of the `OutsideForEach` object.

```matlab
logsout{1}.Values
```

ans =

3×1 struct array with fields:

- **data**
- **limits**

If the `Dataset` signal format is `timetable`, then the output is a cell array of `timetable` objects. For example:

```matlab
out = sim('ex_for_each_log_bus', 'DatasetSignalFormat', 'timetable');
out.logsout{2}.Values
```

ans =

3x1 cell array

{11x1 timetable}
{11x1 timetable}

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 68-125.

Source Blocks

You can add a source block, such as a Sine Wave block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the Sine Wave Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.
The output data types of source blocks vary. For example, a Sine Wave block outputs a vector of real doubles.

For an example of using a source block, see “Build and Edit a Model in the Simulink Editor” on page 1-24.

**Recommended Uses**

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements
- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

**Limitations**

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

**Root-Level Input Ports**

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- Enable
- Inport
- Trigger block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter or a `sim` command argument. For an example, see “Load Data to Model a Continuous Plant” on page 68-142.

To import many signals to root-level input ports, consider using the Root Inport Mapper tool. This tool updates the **Input** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see “Map Data Using Root Inport Mapper Tool” on page 68-133.
Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the Configuration Parameters > Data Import/Export > Additional parameters > Output options parameter to Produce additional output.

Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use Dataset format.
- The Root Inport Mapper tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 68-188.
From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For an example, see “From File Block Loading Timeseries Data”.

Recommended Uses

Consider using a From File block for loading:

• Large amounts of data. For a Version 7.3 MAT-file, the From File block loads data incrementally from the MAT-file during simulation.

Tip To convert a Version 7.0 file to Version 7.3 (for example, my_data_file.mat that contains the variable var), at the MATLAB command line, enter:

```matlab
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

• Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.

• Data stored in a MAT-file that is separate from the model file.

Limitations

• For Version 7.0 or earlier MAT-file, the From File block reads only array-format data.
• Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently. See “MAT-File Variable” on page 68-278.
• The From File block supports reading nonvirtual bus signals in MATLAB timeseries format.
• For array data, the From File block reads only double signal data.
• Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation”.

From Spreadsheet Block

The From Spreadsheet block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.

Recommended Uses

Use the From Spreadsheet block for loading:

• Large Microsoft Excel or CSV spreadsheets. The From Spreadsheet block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
• Spreadsheets that you expect to modify. The From Spreadsheet block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.
Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in “Supported Microsoft Excel File Formats” on page 68-191.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

From Workspace Block

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the Data parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see “Use From Workspace Block for Test Case” on page 68-149.

Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals
• Data that you saved using a To Workspace block in MATLAB timeseries format, without manual changes to the data
• Data saved in a previous simulation by a To Workspace block in either Timeseries or Structure with Time format for use in a later simulation

Limitations
• The data expressions that you specify must evaluate to one of these types of data:
  • A MATLAB timeseries object
  • A structure of MATLAB timeseries objects
  • An array or structure containing an array of simulation times and corresponding signal values

Signal Editor Block
Using a Signal Editor block, you can create interchangeable scenarios to use in a model.

For examples of how to use a Signal Editor block, see:
• “Load Data for an Input Test Case” on page 68-147
• “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode”

Recommended Uses
Use the Signal Editor block to create and load scenarios to use in testing.

These products integrate the Signal Editor block into their workflows:
• Simulink Test
• Simulink Coverage
• Simulink Design Verifier

Limitations
• Function-calls
• Array of buses
• Buses while using rapid accelerator mode
• timetable objects
• Ground signals

The Signal Editor block supports dynamic strings. It does not support strings with maximum length. In addition, strings in the Signal Editor block cannot output:

• Non-scalar MATLAB strings.
• String data that contains missing values.
• String data that contains non-ASCII characters.

Comparison of Signal Loading Techniques

In this section...

| “Techniques” on page 68-124 |
| “Impact of Loading Techniques on Block Diagrams” on page 68-124 |
| “Comparison of Techniques” on page 68-125 |

Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source on page 68-116 block, such as the Sine Wave block, to generate signal data as input to another block
- Root-level input port on page 68-117 (Inport, Enable, or Trigger block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapper tool. “Root-level input ports” refers to both approaches and “Root Inport Mapper tool” refers specifically to using that tool.
- From File on page 68-119 block
- From Spreadsheet on page 68-120 block
- From Workspace on page 68-121 block
- Signal Editor block

Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapper tool allows you to visualize the signal data that is loaded.

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the Configuration Parameters >
**Data Import/Export** > **Input** parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapper tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

**Test Harness Models**

You can use a test harness model with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Editor block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapper tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness models can be simpler to create than setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 68-245

**Comparison of Techniques**

Each technique addresses many of these modeling considerations:

- “Purpose of Importing Signal Data” on page 68-126
- Model Development Phase on page 68-126
- “Signal Data” on page 68-127
- “Data Format or Type” on page 68-128
- “Bus Support” on page 68-128
- “Time Points” on page 68-129
- “Location for Data Storage” on page 68-129
- “Signal Data Inspection” on page 68-130
- “Handling of Loaded Data” on page 68-130
- “Simulation Mode” on page 68-131
**Purpose of Importing Signal Data**

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

<table>
<thead>
<tr>
<th>Modeling Goal</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform local, temporary testing by importing a small set of signal data</td>
<td>All From File, From Spreadsheet, and From Workspace blocks work well for this goal. Root-level input ports for reusable systems.</td>
</tr>
<tr>
<td>Test a model that you want to use as a referenced model</td>
<td>Root-level input ports.</td>
</tr>
<tr>
<td>Verify a model by using multiple test cases</td>
<td>Root Inport Mapper tool, using exported signal data. Signal Editor block.</td>

<tr>
<td>Test a discrete algorithm</td>
<td>All Root-level input ports work well for this goal.</td>
</tr>
</tbody>
</table>

**Model Development Phase**

<table>
<thead>
<tr>
<th>Modeling Requirement</th>
<th>Suggested Signal Loading Technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial prototyping</td>
<td>Signal values that source blocks generate meet your requirements, use Source blocks on page 68-116. From File, From Spreadsheet, and From Workspace blocks.</td>
</tr>
</tbody>
</table>
### Modeling Requirement

<table>
<thead>
<tr>
<th>Modeling Requirement</th>
<th>Suggested Signal Loading Technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>System testing, sharing, and code generation</td>
<td>Root-level input port on page 68-117.</td>
</tr>
<tr>
<td></td>
<td>You can use the Root Inport Mapper tool to create and map signal data to load</td>
</tr>
<tr>
<td></td>
<td>Signal Editor block</td>
</tr>
</tbody>
</table>

For many models, loading signal data to a root Inport block is an effective approach. The Root Inport Mapping tool on page 68-133 provides a convenient way to load data for several signals to root inports.

### Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

<table>
<thead>
<tr>
<th>Signal Data</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Large data set</td>
<td>From File and From Spreadsheet blocks work well for large data sets, because they incrementally load the data. You can log big simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.</td>
</tr>
<tr>
<td>Data exported by using a To File block</td>
<td>From File block.</td>
</tr>
<tr>
<td>Data exported by using a To Workspace block</td>
<td>From Workspace block.</td>
</tr>
<tr>
<td>Excel or CSV spreadsheet</td>
<td>From Spreadsheet block, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.</td>
</tr>
<tr>
<td>Variable-size signals</td>
<td>From Workspace block.</td>
</tr>
</tbody>
</table>
**Data Format or Type**

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or Dataset). A few signal loading techniques have some limitations for specific formats.

**Note** Some of the Root Inport Mapper tool map modes do not support all the data types that you can use with the tool. For details, see “Choose a Base Workspace and MAT-File Format” on page 68-188.

<table>
<thead>
<tr>
<th>Data Format or Type</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>All.</td>
</tr>
<tr>
<td></td>
<td>For array data in a Version 7.0 MAT-file, the From File block loads only double signal</td>
</tr>
<tr>
<td></td>
<td>values. Use Version 7.3 MAT-files for other types of signal data.</td>
</tr>
<tr>
<td>Structure with time</td>
<td>All.</td>
</tr>
<tr>
<td>Structure without time</td>
<td>All.</td>
</tr>
<tr>
<td>MATLAB timeseries</td>
<td>All.</td>

</tr>
<tr>
<td>Fixed-point</td>
<td>From File block has a word length limit of 32 or fewer bits.</td>
</tr>
<tr>
<td>Function-call</td>
<td>Root-level input ports (select the <strong>Output function call</strong> parameter).</td>
</tr>
</tbody>
</table>

**Bus Support**

You can use any of the signal loading techniques to load bus data. However, for some kinds of bus data, you need to use a specific technique.
### Type of Bus or Bus Element

<table>
<thead>
<tr>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual and nonvirtual buses</td>
</tr>
<tr>
<td>Partial bus specification</td>
</tr>
<tr>
<td>Array of buses signals</td>
</tr>
</tbody>
</table>

### Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

<table>
<thead>
<tr>
<th>Time Points for Signal Data</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single time point</td>
<td>All.</td>
</tr>
<tr>
<td>Continuous</td>
<td>All.</td>
</tr>
<tr>
<td>Discrete</td>
<td>All.</td>
</tr>
<tr>
<td>Repeated sequence without time</td>
<td>Structure data by using root-level input ports and From Workspace block.</td>
</tr>
</tbody>
</table>

### Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

<table>
<thead>
<tr>
<th>Location</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the base or model workspace</td>
<td>From Workspace block.</td>
</tr>
<tr>
<td></td>
<td>Root-level input ports or a Trigger, Enable, or Function-Call Subsystem block.</td>
</tr>
</tbody>
</table>
**Location**

<table>
<thead>
<tr>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>In a MAT-file separate from the model file</td>
</tr>
<tr>
<td>From File and Signal Editor blocks. You can log big simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>In an Excel or CSV spreadsheet</td>
</tr>
<tr>
<td>From Spreadsheet block.</td>
</tr>
<tr>
<td><strong>Tip</strong> For Excel and CSV spreadsheet requirements, see “Storage Formats” on page 68-276. Loading CSV data is supported only for Microsoft Windows platforms.</td>
</tr>
</tbody>
</table>

**Signal Data Inspection**

The Root Inport Mapper tool, From File block, and Signal Editor block each provide an interface for plotting and inspecting the signal data to load.

**Handling of Loaded Data**

How Simulink processes the signal data as it loads it into a model impacts the signal logging technique that you choose.

<table>
<thead>
<tr>
<th>Data Loading Handling</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Incremental data loading</td>
<td>From File and From Spreadsheet blocks.</td>
</tr>
<tr>
<td>Interpolation</td>
<td>All.</td>
</tr>
<tr>
<td>Extrapolation</td>
<td>From File, From Spreadsheet, and Signal Editor blocks. For information about From Workspace extrapolation, see “Form output after final data value by”.</td>
</tr>
<tr>
<td>Zero-crossing detection</td>
<td>All except root-level input ports.</td>
</tr>
<tr>
<td>Fast restart</td>
<td>All techniques.</td>
</tr>
</tbody>
</table>
Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

<table>
<thead>
<tr>
<th>Simulation Modes</th>
<th>Supported Techniques</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal and accelerator</td>
<td>All</td>
</tr>
<tr>
<td>Rapid accelerator</td>
<td>All, with these limitations:</td>
</tr>
<tr>
<td></td>
<td>• Root-level input ports only support array and structure data formats.</td>
</tr>
<tr>
<td></td>
<td>• The From Workspace block does not support timeseries format.</td>
</tr>
<tr>
<td></td>
<td>• The Signal Editor block does not support buses in this mode.</td>
</tr>
<tr>
<td>ERT/GRT</td>
<td>All</td>
</tr>
<tr>
<td></td>
<td>From Workspace and From File blocks are not tunable.</td>
</tr>

Map Data Using Root Inport Mapper Tool

Use the Root Inport Mapper tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping imports signal data meets most modeling requirements and maintains model flexibility (for supported signal data, see “Create Signal Data for Root Inport Mapping” on page 68-187).

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapper tool to update the Input parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapper tool:

1. Create signal data in the MATLAB workspace.
2. For a Simulink model, import the data from the workspace. You can visualize the data you import.
3. Map the data to root-level inports.
4. Simulate the model.
5. Save the Root Inport Mapper scenario.
The Model

This model has three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data. Open the model.

This example shows how you can use the Root Inport Mapper tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

Create Signal Data

You can define the signal data as MATLAB timeseries objects.

1. Define the time values for the signal data.

   ```
   sampleTime = 0.01;
   endTime = 10;
   numberOfSamples = endTime * 1/sampleTime +1;
   timeVector = (0:numberOfSamples) * sampleTime;
   ```

2. Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

   ```
   signal_1 = timeseries(sin(timeVector)*10,timeVector);
   signal_2 = timeseries(rand(size(timeVector)),timeVector);
   ```

3. Create the signals for the bus.

   ```
   busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
   busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
   ```

4. Create the bus object for the output data type of the Bus_1 Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.
busInfo = Simulink.Bus.createObject(busSignal);

**Import and Visualize Workspace Signal Data**

Import the signal data that you created from the workspace into the Root Inport Mapper tool. Then you can use the tool to visualize the imported data.

1. Open the Root Inport Mapper tool. Open the Block Parameters dialog box for one of the Inport blocks in the model and click **Connect Input**.
2. In the Root Inport Mapper tool, select the **From Workspace** button.

3. In the Import dialog box, specify a **MAT-file** to save signals to.
4. To clear the data variables, click the **Name** check box. Then click the check boxes for the `busSignal`, `signal_1`, and `signal_2` signals.

Although in this example you select all the signals, you can select a subset of signals.
5 You can visualize signals. In the Root Inport Mapper dialog box toolbar, click **Signals > Edit MAT-File**.

6 In the Select Linked MAT-file window, select the MAT-file to which you saved the signals and click **OK**.

The **Signal Editor** user interface appears. You can select signals to plot. For example, to see a plot of `signal_1`, in the Navigation pane, expand the scenario data set (in this example, the top node, `untitled`) and then expand the `signal_1` entry. Select the check box for `signal_1(1,1,:)` to plot the data.

![Signal Editor Interface](image)

7 Close the **Signal Editor** user interface by clicking the **Close** button.

### Map the Data to Inports

After you import the data, you map which data to use for specific Inport blocks.

1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select the **Signal Name** option button.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.
You can specify options for the mapping. In the toolbar, select **Options**. Select **Update Model**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.

Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Map to Model**. The dialog box shows the mapped data.

### Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapper tool, click **Save > Save As** and save the scenario as an `.mldatx` file.

### Simulate the Model

1. In the Navigation pane, select the scenario data set.
2. In the toolbar, click **Mark for Simulation**.

   The model is now set up to simulate using the workspace signal data that you mapped to root-level Inport blocks.
3. Simulate the model.

   This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the Configuration Parameters > Data Import/Export pane, the Output, States, or Final states parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see “Load Data to Model a Continuous Plant” on page 68-142.

**Load Logged Data**

Here is a workflow for using signal logging data for standalone simulation of a referenced model. You can use a similar approach for other data logged in Dataset format.
Use the default signal logging output variable, logsout, or specify a variable using the Configuration Parameters > Data Import/Export > Signal logging edit box.

Simulate the parent model.

The signal logging output is a Simulink.SimulationData.Dataset object.

Use the Simulink.SimulationData.Dataset.getElement method to access the logged data. The logging data for individual signals is stored in Simulink.SimulationData.Signal objects.

For the referenced model that you want to simulate standalone, use the Simulink.SimulationData.Signal.getElement method to specify signal elements for the Configuration Parameters > Data Import/Export > Input parameter.

For example:

Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see the open the sldemo_mdlref_bus model. After you open the model, double-click the blue block labeled Interface Specification and see the sections called:

- Logging Model Reference Signals
- Loading Data

Also, the “Load Data to Model a Continuous Plant” on page 68-142 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 68-171.

Configure Logging to Meet Loading Requirements

Different logging techniques support different data formats. Most logging techniques support the Dataset format, which provides a consistent data format for logged signal data. You can use the Simulink.SimulationData.Dataset constructor to convert other data formats to Dataset format.
To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

Load Data to Model a Continuous Plant

A continuous plant model uses signal data that is smooth and uninterrupted in time. There is signal data for each time value. A continuous plant model uses a continuous solver (any solver other than an explicit discrete solver). The solver can be fixed-step or variable. The model includes blocks from the Continuous library in Simulink, such as an Integrator block.

To load data to represent a continuous plant, consider using either a root-level input port or a From Workspace block. Using a From Workspace block can be useful when loading data to a port buried deep within a model.

For the signal data:

• Specify a time vector and signal values extracted from a continuous plant. For example, extract from data that you acquire experimentally or from the results of a previous simulation.
• Use any of the data formats listed in “Specify Input Data” on page 68-151. Here are recommended formats for the following imported data sources:
  • Another simulation — Dataset
  • An equation — MATLAB time expression
  • Experimental data — MATLAB timeseries, structure with time, a structure without time, or a data array

For structure data, see “Specify Time Data” on page 68-159.

Use Simulation Data to Model a Continuous Plant

This example illustrates how to use logged data from the simulation of one model in the simulation of a second model. For more information, see “Load Data Logged In Another Simulation” on page 68-139.

When using data from a simulation that uses a variable-step solver for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

1. Open the ex_data_import_continuous model.
This model uses the ode15s solver and produces continuous signals.

2 To use the output of this model as input to the simulation of another model, log the signal that you want to use. In the Simulink Editor, select that signal, and click Log Signals.

**Note** To enable signal logging, select the Configuration Parameters > Data Import/Export > Signal logging parameter. This model has Signal logging enabled.

3 Simulate the model.

Simulating the model saves the logged signal to the workspace in the Simulink.SimulationData.Dataset object, logsout.

Use the Simulink.SimulationData.Dataset.getElement method to access the logged data. The logged data for an individual signal is stored in a Simulink.SimulationData.Signal object. The Dataset object created by this model contains one logged signal: StepResponse.

4 Open the second model, ex_data_import_continuous_second.

You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to load the logged data as input for the simulation. The Inport block has the Interpolate data option selected.

5 In the second model, select the Configuration Parameters > Data Import/Export > Input parameter.

Use the Simulink.SimulationData.Signal.getElement method to specify the StepResponse signal element:
Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (u). In the Data Import/Export pane, set the **Output options** parameter to **Produce additional output** and the **Output times** parameter to:

```matlab
time = logsimout.getElement('StepResponse').Values.Time
```

Simulate the second model.

**Note** Simulink does not feed minor time step data through root input ports. For details about minor time steps, see “Types of Sample Time” on page 7-15.

**More About**

- “Overview of Signal Loading Techniques” on page 68-116
Load Data to Test a Discrete Algorithm

Discrete signals are signals that you define using evenly spaced time values. One signal value is read at each time step, using the sample time of the source block.

Use a structure that has an empty time vector, which results in the model using the sample time of the source block. Using this approach avoids possible mismatches between the vector and the Simulink time steps. The double-precision rounding used by computers and the values expected by Simulink can differ.

Suppose that you want to import signal data for this simple model.

1 In the Block Parameters dialog box for the Inport block:
   • Set the sample time.
   • Clear the Interpolate data parameter.

2 For the data that you want to import, specify a structure variable that does not include a time vector. For example, for the variable called import_var:

   ```
   import_var.time = [];
   import_var.signals.values = [0; 1; 5; 8; 10];
   import_var.signals.dimension = 1;
   ```

   The input for the first time step is read from the first element of an input port value array. The value is 0. The value for the second time step is read from the second element of the value array (1), and so on.

   For details about how to specify the signal value and dimension data, see “Loading Data Structures to Root-Level Inputs” on page 68-157.

3 Select the Configuration Parameters > Data Import/Export > Input parameter and specify import_var for the data to import.

If you are using a From Workspace block to import data, use a similar approach. In addition, set the Form output after final data value by parameter to a value other than Extrapolation.

Load Data for an Input Test Case

Guidelines for Importing a Test Case

Typically when importing a test case data, you want to minimize the number of time points. The test data focuses on discontinuities in the signal data.

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Editor block, all of which support zero-crossing detection.

You can load data of these types:

- A `Simulink.SimulationData.Dataset`
- Array
- `Simulink.SimulationData.Signal`
- Structure
- A structure array containing data for all input ports (not supported by Signal Editor block)
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values
- Time expression (not supported by Signal Editor block)
Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps. For details about specifying a time vector, see “Specify Time Data” on page 68-159.

Use any of the input data formats described in “Forms of Input Data” on page 68-153, except for MATLAB time expressions.

**Example of Test Case Data**

The following is an example of test case data:

![Graph](image)

The following two examples use this test case data.
Use From Workspace Block for Test Case

1. Open the model `ex_data_import_test_case_from_workspace`.

2. Enable zero-crossing detection. In the From Workspace block dialog box, select **Enable zero-crossing detection**. Zero-crossing detection allows you to capture discontinuities accurately.

3. Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector, which generates a zero crossing and forces the variable-step solver to take a time step at this exact time. For details, see “Load Data Using the From Workspace Block” on page 68-279.

   Define the `var` structure representing the test case:
   ```
   var.time = [0 1 1 5 5 8 8 10];
   var.signals.values = [0 0 2 2 2 3 3 3]';
   var.signals.dimensions = 1;
   ```

4. To import the test case structure, in the From Workspace block dialog box, in the **Data** parameter, specify `var`.

5. Simulate the model. The Scope block reflects the test case data.

Use Signal Editor Block for Test Case

Instead of using a From Workspace block, you can use a Signal Editor block to either:

- Create a signal interactively
- Import a signal from a MAT-file

1. Create a model with Signal Editor, Gain, and Scope blocks.
2 Create a structure and save it in a MAT-file:

```matlab
scenario = Simulink.SimulationData.Dataset;
time = [0 1 1 5 5 8 8 10];
data = [0 0 2 2 2 3 3 3]';
scenario{1} = timeseries(data,time);
scenario{1}.Name = 'var';
save var.mat scenario
```

3 Open the Signal Editor dialog box by double-clicking the Signal Editor block.
4 In the File name parameter, enter var.mat.
5 In the Active scenario parameter, select scenario. Click OK.

The Scope block display reflects the test case data from the MAT-file.

Load Data to Root-Level Input Ports

In this section...

“Specify Input Data” on page 68-151
“Forms of Input Data” on page 68-153
“Time Values for the Input Parameter” on page 68-154
“Data Loading” on page 68-154
“Loading Dataset Data to Root-Level Inputs” on page 68-154
“Loading MATLAB Timeseries Data to Root-Level Inputs” on page 68-156
“Loading MATLAB Timetable Data to Root-Level Inputs” on page 68-157
“Loading Data Structures to Root-Level Inputs” on page 68-157
“Loading Data Arrays to Root-Level Inputs” on page 68-162
“Loading MATLAB Time Expressions to Root Inports” on page 68-164

You can load data from a workspace to a root-level inport modeled using one of these blocks:

- Inport block
- Enable block
- Trigger block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the Configuration Parameters > Data Import/Export > Input parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Root Inport Signal Data” on page 68-184.

You can also import data from a workspace using a From Workspace block. For details, see the From Workspace documentation and “Load Data for an Input Test Case” on page 68-147.

Specify Input Data

You can specify input data manually, using the Input configuration parameter. To load many signals to root-level input ports, consider using the Root Inport Mapping tool, which
automatically specifies in the **Input** parameter the data you map using the tool. For details, see “Map Data Using Root Inport Mapper Tool” on page 68-133.

1 Select the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

**Note** The use of the **Input** configuration parameter is independent of the setting for the **Format** configuration parameter for saving logged data.

2 Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see “Forms of Input Data” on page 68-153.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at run-time for each simulation time step using the input \( u = UT(t) \) for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using one of the input data forms described in “Forms of Input Data” on page 68-153.

**Comma-Separated List**

If you specify **Dataset** data, specify only one **Dataset** object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression must evaluate to an appropriate object that corresponds to a specific root-level input port in the model. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponds to the first root-level input port, the second to the second root-level input port, and so on. The dimensions for each data sample must match the dimensions of the data specified in the input block parameter.

For an Enable or Trigger block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports \( \text{in1} \) and \( \text{in3} \), and to use ground values for port \( \text{in2} \), enter the following in the **Input** parameter:

\[ \text{in1, [], in3} \]
Forms of Input Data

You can provide input data with the following formats:

- **Simulink.SimulationData.Dataset** — Collection of logged data in MATLAB timeseries format. For more information, see “Loading Dataset Data to Root-Level Inputs” on page 68-154.
- **MATLAB timeseries** — For more information, see:
  - “Loading MATLAB Timeseries Data to Root-Level Inputs” on page 68-156
  - “Load Bus Data to Root-Level Input Ports” on page 68-166
- **Simulink.SimulationData.DatasetRef** — For more information, see “Load Big Data for Simulations” on page 68-53
- **MATLAB timetable** — For more information, see “Loading MATLAB Timetable Data to Root-Level Inputs” on page 68-157.
- **Array** — See “Loading Data Arrays to Root-Level Inputs” on page 68-162.
- **Simulink.SimulationData.Signal** — For more information, see “Load Data Logged In Another Simulation” on page 68-139.
- **matlab.io.datastore.SimulationDatastore** — For more information, see “Work with Big Data for Simulations” on page 68-44.
- **Structure** — To simplify the specification of external input data, you can load data for a subset of root-level input port blocks. This approach avoids having to create data structures for the ports for which you want to use ground values. For information about ground values, see “Initialize Signals and Discrete States” on page 71-54. For more information about loading structure data, see “Loading Data Structures to Root-Level Inputs” on page 68-157.
- **Structure array containing data for all input ports.**
- **Empty matrix** — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- **Time expression** — For more information, see “Loading MATLAB Time Expressions to Root Imports” on page 68-164.

**Note** When you specify timetable data to load, the timetable must contain data for only one signal.
For information about importing bus data, see “Load Bus Data to Root-Level Input Ports” on page 68-166.

**Time Values for the Input Parameter**

Time values that you specify in the **Input** parameter do not control the times the solver uses. Solvers have their own logic for propagating time and might require input data at an arbitrary time value. The **Interpolate** parameter setting for the root-level input block (for example, the root-level Inport block) specifies how to handle output at time steps for which no corresponding workspace data exists.

The time values specified in the **Input** parameter cannot be sparse or include `NAN` or `Inf` values.

**Data Loading**

If you select the **Interpolate data** option for the corresponding Inport, Enable, or Trigger block, Simulink linearly interpolates or extrapolates input values as necessary.

Simulink resolves symbols used in the external input specification as described in “Symbol Resolution” on page 66-174. The `sim` command provides some data import capabilities that are available only for programmatic simulation.

If you use a `Simulink.SimulationData.Dataset` object that includes a `matlab.io.datastore.SimulationDatastore` object as an element, then the data stored in persistent storage is streamed in from a file. For more information, see “Load Big Data for Simulations” on page 68-53.

**Loading Dataset Data to Root-Level Inputs**

You can use a Dataset object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one Dataset object and do not include it in a comma-separated list. The number of elements in the Dataset must match the number of root-level input ports.

**Dataset Elements**

A Dataset object can include elements with different data types.
For individual non-bus signal data, you can specify these types of data for Dataset elements:

- `timeseries`
- `timetable`
- `matlab.io.datastore.SimulationDatastore`
- `double` vectors or structure of `double` data
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See “Loading Data Arrays to Root-Level Inputs” on page 68-162.
  - An `nx1` array for a root input port that drives a function-call subsystem.

For bus signals, use a structure with a data element for each leaf signal, using one of these formats:

- A MATLAB `timeseries` object
- A MATLAB `timetable` object
- A `matlab.io.datastore.SimulationDatastore` object
- An empty matrix
- Another structure, with data elements for each signal that are consistent with these requirements for a structure for bus data

**Note** When you specify `timetable` data to load, the `timetable` can contain data for only one signal.

**Create a Dataset Object for Inport Blocks**

To generate a `Simulink.SimulationData.Dataset` object from the root-level Inport blocks in a model, you can use the `createInportDataset` function. Signals in the generated dataset have the properties of the Inport blocks and the corresponding ground values at model start and stop times. You can create `timeseries` and `timetable` objects.
for the time and values for signals for loading. The other signals use ground values. Each timetable object must contain data for only one signal.

You can load into a root-level input port data specified by a MATLAB timeseries object that resides in a workspace.

**Note** This documentation about importing MATLAB timeseries data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

### Loading MATLAB Timeseries Data to Root-Level Inputs

**Time Dimension**

When you create a MATLAB timeseries object to import data to Simulink, the time dimension (number of time samples) depends on the dimension and the type of signal data.

<table>
<thead>
<tr>
<th>Signal Data Dimension or Type</th>

<td><code>ts = timeseries([1 2], t, 'InterpretSingleRowDataAs3D', true);</code></td>
</tr>
</tbody>
</table>
Enum Data

If you specify an enum in timetable data, clear the Interpolate data parameter for the corresponding Inport block.

Loading MATLAB Timetable Data to Root-Level Inputs

In general, you can load MATLAB timetable data the same way you load MATLAB timeseries data. Each timetable must contain data for only one signal.

Loading Data Structures to Root-Level Inputs

Data Structures

You can load to a root-level input port data from the workspace in the form of a structure, whose name you specify in the Configuration Parameters > Data Import/Export > Input parameter. For information about defining MATLAB structures, see “Create Structure Array” (MATLAB).

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the Input parameter, see “Structures for All Ports or for Each Port” on page 68-158.

The structure always includes a signals substructure, which contains a values field and a dimensions field. Depending on the modeling task that you want to perform, the structure can also include a time field. The form of a structure that you use depends on the type of signals for which you are importing data:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector. Specify a signals field, which contains an array of substructures, each of which corresponds to a model input port.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve (continuous) or a curve that has discontinuities (jumps) over its range (discrete). Specify a signals field, which contains an array of substructures, each of which corresponds to a model input port. You can specify a time field, which contains a time vector. See “Specify Time Data” on page 68-159.

For examples of importing data for discrete and continuous signals, see:
Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one signals field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, in1, in2,..., inN. The value in1 is the data for first input port in the model, in2 for the second input port, and so on.

To specify one structure for all ports:

- The values field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the time field.

  If the inputs for a port are scalar or vector values, the values field must be an M-by-N array. If you specify a time vector, M must be the number of time points specified by the time field and N is the length of each vector value.

  If the inputs for a port are matrices (2-D arrays), the values field must be an M-by-N-by-T array. M and N are the dimensions of each matrix input and T is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding dimensions field of the workspace structure must equal [4 5] and the values array must have the dimensions 4-by-5-by-51.

- The dimensions field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the dimensions field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the dimensions field must be a two-element vector whose:
  - First element specifies the number of rows in the matrix
  - Second element specifies the number of columns
**Note**  Set the **Port dimensions** parameter of the Inport or the Trigger block to be the same value as the **dimensions** field of the corresponding input structure. If the values differ, you get an error message when you try to simulate the model.

**Specify Time Data**

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

<table>
<thead>
<tr>
<th>Signal Data</th>
<th>Time Data Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inport or Trigger block with a discrete sample time</td>
<td>Do not specify a time vector. Simulink loads one signal value at each time step.</td>
</tr>
<tr>
<td>Signal Data</td>
<td>Time Data Recommendation</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Evenly spaced discrete signals</td>
<td>Use an expression in this form:</td>
</tr>
<tr>
<td></td>
<td><code>timeVector = timeStep * [startTime:numSteps-1]</code>'</td>
</tr>
<tr>
<td></td>
<td>The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you want minus 1. For example, to specify 50 time values at 0.2 time steps:</td>
</tr>
<tr>
<td></td>
<td><code>T1 = 0.2 * [0:49]'</code></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Do <em>not</em> use an expression in this form:</td>
</tr>
<tr>
<td></td>
<td><code>timeVector = [startTime:timeStep:endTime]</code>'</td>
</tr>
<tr>
<td></td>
<td>For example, do not use:</td>
</tr>
<tr>
<td></td>
<td><code>T2 = [0:0.2:10]'</code></td>
</tr>
<tr>
<td></td>
<td>This time vector form is not equivalent to the form that multiplies by time steps (T1), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the T2 form can lead to mismatches between the provided time vector and the times steps taken by Simulink, resulting in unexpected simulation results.</td>
</tr>
<tr>
<td>Unevenly spaced values</td>
<td>Use any valid MATLAB array expression; for example, [1:5 5:10] or (1 6 10 15).</td>
</tr>
<tr>
<td></td>
<td>The From Workspace, From File, and Signal Editor blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.</td>
</tr>
</tbody>
</table>

**Examples of Specifying Signal and Time Data**

In the first example, consider the following model that has a single input port:
1  Create an input structure for loading 11 time samples of a two-element signal vector of type int8 into the model:

\[
N = 10 \\
Ts = 0.1 \\
a.time = Ts*[0:N]'; \\
c1 = int8([0:1:10]'); \\
c2 = int8([0:10:100]'); \\
a.signals(1).values = [c1 c2]; \\
a.signals(1).dimensions = 2;
\]

2  In the Configuration Parameters > Data Import/Export > Input parameter edit box, specify the variable a.

3  In the Inport block dialog box, in the Signal Attributes tab, set Port dimensions to 2 and Data type to int8.

As another example, consider a model that has two inputs.

Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, a, as follows, in the MATLAB workspace:

\[
a.time = 0.1*[0:1]'; \\
a.signals(1).values = \text{sin}(a.time); \\
a.signals(1).dimensions = 1; \\
a.signals(2).values = \text{cos}(a.time); \\
a.signals(2).dimensions = 1;
\]
Enter the structure name (a) in the Configuration Parameters > Data Import/Export > Input parameter edit box.

**Note** In this model you do not need to specify the dimension and data type, because the default values are 1 and double.

### Loading Data Arrays to Root-Level Inputs

You can load to a root-level input port data from the workspace in the form of a data array, which you specify in the Configuration Parameters > Data Import/Export > Input parameter.

This import format consists of a real (noncomplex) matrix of data type double. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal that drives the trigger port must be the last data item.

The total number of columns of the input matrix must equal $n + 1$, where $n$ is the total number of signals entering the model input ports.

### Specify the Input Expression

The default input expression for a model is `[t, u]` and the default input format is Array. If you define `t` and `u` in the MATLAB workspace, simply select the Configuration Parameters > Data Import/Export > Input parameter to input data from the model workspace.

Suppose that you have a model with two Inport blocks:

- The **In1** block accepts two signals (the block has the Port dimensions parameter set to 2).
- The **In2** block accepts one signal (the block uses the default value for the Port dimensions parameter).

You define `t` and `u` in the MATLAB workspace:
numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t),cos(t),4*cos(t)];

When the simulation runs, the signal data sin(t) and cos(t) are assigned to In1 and the signal data 4*cos(t) is assigned to In2. Signal data is input for 100 time points.

**Note** The array input format allows you to load only real (noncomplex) scalar or vector data of type double. Use the structure format to input complex data, matrix (2-D) data, and data types other than double.

**Arrays for Input Ports Driving Function-Call Subsystems**

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a Dataset object. The array must be an nx1 array. For the root-level Inport block, select the **Output function call** parameter.

For example, this Dataset object has an array element x:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x,'theElementName');
```

This model uses the ds data set in the **Configuration Parameters > Data Import/Export > Input** parameter.
When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem show that the Function-Call Subsystem was triggered only for the times specified in an array stored in ds:

```matlab
>> logsout{1}.Values.Time
ans =
1
3
7
8
```

**Loading MATLAB Time Expressions to Root Inports**

**Specify the Input Expression**

You can use a MATLAB time expression to load data from a workspace into a root-level input port. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. Suppose that a model has one vector Inport that accepts two signals. Also, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. Here are valid input time expressions for such a model:
'3*sin(t), cos(2*t)'

'4*timefcn(w*t)+7'

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable t when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression sin is interpreted as sin(t).

Load Bus Data to Root-Level Input Ports

In this section...

"Imported Bus Data Requirements" on page 68-166
"Import Bus Data to a Top-Level Inport" on page 68-168
"Get Information About Bus Objects" on page 68-170
"Create Structures of Timeseries Objects from Buses" on page 68-171
"Import Array of Buses Data" on page 68-171

You can import bus data to top-level input ports by manually specifying the data in the Input configuration parameter or by using the Root Inport Mapper tool. For information about importing bus data using the Root Inport Mapper tool, see “Import Bus Data” on page 68-197.

Imported Bus Data Requirements

You can import bus (virtual, nonvirtual, or array of buses) data to a top-level input port defined by a bus object (see Simulink.Bus). In the top-level Inport block, set Data type to Bus and specify the name of a bus object. To specify data values for bus signals, use a structure of:

- MATLAB timeseries objects
- MATLAB timetable objects
- A combination of timeseries and timetable objects

Bus elements for which you do not include a field in the structure use ground values. You can use an empty matrix to specify to use ground values.

**Note** When you specify timetable data to load, the timetable must contain data for only one signal.

The structure of timeseries or timetable (or both) objects must match the bus elements in terms of:

- Hierarchy
• Name of the structure field, which must match the bus element name. (The name property of the timeseries object does not need to match the bus element name.)
• Data type
• Dimensions
• Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can include the structure as an element of a Dataset object. You can use a structure in a comma-separated list. You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports in1 and in3, and to use ground values for port in2, enter the following in the Input parameter:

in1, [], in3

**Note** If you use a structure of MATLAB timeseries objects for a root Inport block in a model with multiple root Inport blocks, all root Inport blocks must use MATLAB timeseries or timetable objects. Convert any root Inport block data that uses Simulink.TsArray or Simulink.Timeseries objects to MATLAB timeseries objects.

**Initialize Bus Signals**

You can initialize bus signals, including using partial specification of initialization data. For details, see “Specify Initial Conditions for Bus Signals” on page 72-79.

For details about importing array of bus data to a root Inport block, see “Import Array of Buses Data” on page 68-171.

**Limitations for Importing Bus Data to Top-Level Inputs**

The signal data that you can use the Root Inport Mapper tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use Dataset format.
Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the In1 block is inherited (nonbus data) and the data type of the In2 block is defined by the bus object `BusObject`. The model has a callback that loads `BusObject` and its sub-bus `BusObject1`.

![Diagram of model showing two Inport blocks connected to Scope blocks.](image)

The `BusObject` bus object has two elements:

- `c`
- `s1`, which is a nested bus that has two elements:
  - `a`
  - `b`

1. Open the .
2. Create a MATLAB timeseries object for In1, for which you want to import nonbus data.

For example:

```matlab
t1 = (1:10)';
d1 = sin(t1);
in1 = timeseries(d1,t1);
```

3. Create an input structure, which can consist of MATLAB timeseries objects or MATLAB timetable objects, or a combination of those types of objects. Create one timeseries or timetable object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the `b` bus element, so it does not need a timeseries or timetable object for that element.
t2 = (1:5)';
d2 = cos(t2);
in2.c = timeseries(d1,t1);
in2.s1.a = timetable(seconds(t2),d2);

The MATLAB timeseries objects that you create must match the corresponding bus elements, as described in “Imported Bus Data Requirements” on page 68-166.

4 Create a Dataset object and add in1 and in2 to the data set.

```matlab
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1,'in1_signal');
ds = ds.addElement(in2,'in2_signal');
```

5 In the Configuration Parameters > Data Import/Export > Input parameter edit box, enter the Dataset object ds.

6 Simulate the model. The Scope block connected to In2 shows the imported bus data.
Get Information About Bus Objects

To determine the number of MATLAB timeseries objects and data type, complexity, and dimensions needed for creating a structure of timeseries objects from a bus, use these methods:

- `Simulink.Bus.getNumLeafBusElements`
- `Simulink.Bus.getLeafBusElements`

For example, for the bus object `BusObject`:

```matlab
num_el = BusObject.getNumLeafBusElements
num_el =
    3
el_list = BusObject.getLeafBusElements
```
el_list =

3x1 BusElement array with properties:

Min
Max
DimensionsMode
SampleTime
Description
Units
Name
DataType
Complexity
Dimensions

el_list(1).Dimensions

ans =

1

Create Structures of Timeseries Objects from Buses

If you have timeseries objects defined, you can use them to create a structure of timeseries objects based on a bus object. Use the Simulink.SimulationData.createStructOfTimeseries function. For example, if you have defined timeseries objects ts1, ts2, and ts3, and you have a bus object MyBusObject, you can use this command to create a structure of timeseries objects:

input = Simulink.SimulationData.createStructOfTimeseries(...
   'MyBusObject',{ts1,ts2,ts3});

The number of timeseries objects in the cell array must match the number of leaf elements in the bus object. The data type, dimensions, and complexity of each timeseries object must match those attributes of the corresponding bus object leaf node.

Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB timeseries objects.
**Note** You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

### Full Specification of Data

You can use logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to specify fully the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

### Partial Specification of Data

To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For nested bus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object `MyBus`. You can open the model (`ex_partial_loading_aob_model`) and the MATLAB code that defines the data to import (`ex_partial_loading_aob_data.m`).

When you simulate `ex_partial_loading_aob_model`, you see:
The input Inport block uses the MyBus bus object as its data type.
The *MyBus* array of buses includes *MyBus*(1) and *MyBus*(2). The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes *MyBus*(1) and *MyBus*(2). The color highlighting shows the nodes of the array of buses for which data is being imported.
Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file ex_partial_loading_aob_data.m.
%% Create timeseries data for leaf signals
N = 10; Ts = 1;
Time = ((0:N)*Ts)';
[m, n] = size(Time);

ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);

%% Create individual timeseries objects to represent Z, B, D1 and D2
ZT = timeseries(ZData, Time, 'Name', 'Z');
BT = timeseries(BData, Time, 'Name', 'B');
D1T = timeseries(D1Data, Time, 'Name', 'D1');
D2T = timeseries(D2Data, Time, 'Name', 'D2');

%% Construct MyBusValue(1)

% Y(2).D
Y(2) = struct('D', D1T);

% Set X.B to empty to allow the second element to support specification for
% this field
X = struct('B', []);

% MyBusValue(1)
MyBusValue(1) = struct('Z', ZT, 'Y', Y, 'X', X);
clear X Y;

%% Construct MyBusValue(2)

% Specify timeseries for MyBusValue(2).X.B
MyBusValue(2).X.B = BT;

% Specify timeseries for MyBusValue(2).Y(2).D
MyBusValue(2).Y(2).D = D2T;
In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.
- The structure specifies data for `Y(2)`. You can skip the first and last nested buses of `Y` (that is, `Y(1)` and `Y(3)`).

This example specifies data for `Y(2)`; you can skip the first and last nested buses of `Y` (that is, `Y(1)` and `Y(3)`).

After you define the `MyBusValue` variable for the import data, set the Configuration Parameters > Data Import/Export > Input parameter to `MyBusValue`.

Load Input Data for a Bus Using In Bus Element Blocks

This example shows how to use In Bus Element blocks to load input data for a bus. Using In Bus Element blocks allows flexibility in the design and implementation of external interfaces for buses. You can use an In Bus Element block to load data for an element of a bus and to load data for an entire bus. You can also use multiple In Bus Element blocks to select the same bus element.

Open and Inspect the Model

Open the `ex_load_inbuselement` model.

```matlab
open_system('ex_load_inbuselement.slx')
```

One or more In Bus Element blocks can define a port in a model. The `ex_load_inbuselement` model has one port, `InBus`, defined by three In Bus Element blocks. The label for each In Bus Element block indicates the bus element the block selects. The `InBus` port corresponds to a bus containing a nested bus, `a`, with signals `x` and `y`, and an individual signal, `b`. 
Use the **Input** parameter on the **Data Import/Export** pane to specify workspace data to load as simulation input for the port in the model. The **Input** parameter for the `ex_load_inbuselement` model loads the variable `struct1`, which maps to the port according to the **Port Number** defined in the In Bus Element block dialog box.

### Create Input Data

Ports that load bus data accept structures composed of individual `timeseries`, `timetable`, and `matlab.io.datastore.SimulationDatastore` objects. The hierarchy of the structure must match the hierarchy of the bus. Ports that use In Bus Element blocks to select bus elements allow partial specification and overspecification of data.

This example creates the structure using three `timeseries` signals that correspond to a sine wave, a line, and a constant.

```matlab
time = linspace(0,10,11);
sineData = sin(time);
constData = 3*ones(11,1);
lineData = linspace(0,10,11);
tsSine = timeseries(sineData,time);
tsConst = timeseries(constData,time);
tsLine = timeseries(lineData,time);
```

Construct the structure, `struct1`, to provide the input data for the port in the model. The structure field names must match the bus element names.

```matlab
struct1.a.x = tsConst;
struct1.a.y = tsLine;
struct1.b = tsSine;
```

### Fully Specify Input Data

The data created in the previous section fully specifies data for the signals selected by the In Bus Element blocks in the model. Simulate the model and observe the signals on the Dashboard Scope blocks.
Partially Specify Input Data

When you use In Bus Element blocks to select bus elements, you can partially specify data using a structure that does not include one or more selected elements. Elements without data defined in the structure use ground signal values for simulation.

For example, edit the label for the In Bus Element block that selects element InBus.a.y so that the In Bus Element block selects InBus.a.z. The structure that maps to the InBus port does not contain a field for z in the nested structure, a. When you simulate the model, without modifying the structure, the Dashboard Scope shows ground for InBus.a.z.
Change the In Bus Element port block that selects `InBus.a.z` back to select `InBus.a.y`.

**Overspecify Input Data**

When you use In Bus Element blocks to select bus elements, you can overspecify data for the port. Overspecified input data contains signals that are not selected by any of the In Bus Element blocks in the model.

For example, change the label for the In Bus Element block that selects `InBus.a.y` to select `InBus.b`. Now, none of the In Bus Element blocks selects `InBus.a.y`, while the structure still contains the data for that element.

Simulate the model and observe the signals on the Dashboard Scope blocks.
Load Input Data for a Bus Using In Bus Element Blocks
Map Root Inport Signal Data

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Open the Root Inport Mapper Tool” on page 68-184</td>
</tr>
<tr>
<td>“Command-Line Interface” on page 68-185</td>
</tr>
<tr>
<td>“Import and Mapping Workflow” on page 68-185</td>
</tr>
<tr>
<td>“Choose a Map Mode” on page 68-185</td>
</tr>
</tbody>
</table>

To import, visualize, and map signal and bus data to root-level input ports, use the Root Inport Mapper tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level input ports include:

- Inport blocks
- Enable blocks
- Trigger blocks

Root-level input ports import data from the MATLAB workspace based on the value of the `Configuration Parameters > Data Import/Export > Input` parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data you import and map to root-level inports.
- Visually inspect signal data without loading all the data into MATLAB memory.

**Tip** To determine whether another data import technique meets your specific modeling requirements (such as the amount of data or the storage location) better, see “Comparison of Signal Loading Techniques” on page 68-124.

**Open the Root Inport Mapper Tool**

Use either of these approaches to open the Root Inport Mapper tool:
• In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.

• In the block parameters dialog box for the Inport block, select **Connect Input**.

**Command-Line Interface**

You can use the `getRootInportMap` to create a custom object to map signals to root-level input ports and `getSlRootInportMap` to create a custom mapping mode. For more information, see “Create and Use Custom Map Modes” on page 68-258.

**Import and Mapping Workflow**

1. Identify and possibly create signal data to import and map on page 68-187.
2. Import on page 68-194 and inspect signal data on page 68-199.
3. Map the imported signal data on page 68-184. For example, you can map the signal data by block path or signal name.
4. Simulate the model using the mapped data. After associating a scenario with the model, you can generate scripts for simulation with scenarios on page 68-257 to perform batch simulations.
5. Optionally, save the current Root Inport Mapper scenario on page 68-261 for future reference or to share with other people.

**Tip** To extend the Root Inport Mapper tool map modes, you can create a custom mapping file function to map data to root-level inports.

**Choose a Map Mode**

To specify how you want the Root Inport Mapper tool to map the signal data to a model, select from these map modes in the **MAP TO MODEL** section of the toolbar:

• **Block name** — Connect signal data to ports based the name of a root-level input port block.

• **Block path** — Connect signal data to ports based the path of a root-level input port block.

• **Signal name** — Connect signal data to ports based on the name of the signal on a port.
• Port order — Connect sequential port numbers to the imported data.
• Custom — Connect signal data to ports based on the definitions in a custom mapping file.

Each supported input format supports one or more mapping modes. To import MATLAB timeseries data, for example, you use any mapping mode. To import data array signal data, use the port order mapping mode.

More About
• “Create Signal Data for Root Inport Mapping” on page 68-187
Create Signal Data for Root Inport Mapping

The first step for using the Root Inport Mapper tool is to know the source of signal data to import and map. You can use existing data (for example, in a Microsoft Excel spreadsheet), create data in a MAT-file, or use the Signal Editor interface to create signal data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 68-185.

Choose a Source for Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 68-188.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapper tool.

For more information, see “Choose a Base Workspace and MAT-File Format” on page 68-188 and “Supported Microsoft Excel File Formats” on page 68-191.

Tip To load input data for a simulation from a Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.
You can also use the Signal Editor interface to create and edit signal data. For more information, see “Create and Edit Signal Data” on page 68-200.

**Choose a Naming Convention for Signals and Buses**

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (scenario) is interchangeable. For example, you can have two MAT-files with the same set of variables named with the naming convention but different data values. Then, you can switch the scenarios of input data into and out of a model easily.

**Choose a Base Workspace and MAT-File Format**

The Root Inport Mapper tool supports the MATLAB data types or formats described in the table for imported signal data. For each data type, you can use the mapping modes indicated in the table.

</table>
Note If your MAT-file or base workspace contains data in a format that the Root Inport Mapper tool does not support, the tool ignores that data.

Note Although the Root Inport Mapper tool accepts these formats, it can only link in a Simulink.SimulationData.Dataset object. To convert the data in your MAT-file to a Simulink.SimulationData.Dataset object, in the Root Inport Mapper From dialog box, select the Convert signals into a scenario dataset and save to MAT-file check box. Alternatively, use the convertToSlDataset function to convert your data.

Note When you specify a timetable as an element in the Dataset or a bus, the timetable must contain data for only one signal.

Dataset Signal Data

If data sets have nonunique element names, use the Port Order map mode.

MATLAB Timeseries Signal Data

If you have MATLAB timeseries data that includes enumeration data, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

Array Signal Data

The Root Inport Mapper tool tries to map the data array to a single input port. In this case, you can choose any of the map modes.

Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level Enable or Trigger block.

1 In the MATLAB workspace, create or load a bus object on page 72-55 for the bus data you want to import and map.
If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.

Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:

- Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.
- Create the bus in the base workspace and then save it to a MAT-file.

Set up the model to load the bus object.

- For root-level Inport blocks that you map signals to, set the **Data type** field to `Bus`. Specify the name of the variable for the bus object to be used for signal mapping.
- Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see “Alternative Workflows to Load Mapping Data” on page 68-251.

Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`) and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSlDataset` function to convert MAT-file contents to `Simulink.SimulationData.Dataset` objects.

In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```matlab
signal1 = Simulink.SimulationData.Signal;
signal1.Name = 'signal1';
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');
signal1.PortType = 'inport';
signal1.PortIndex = 1;

signal2 = Simulink.SimulationData.Signal;
signal2.Name = 'signal2';
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');
signal2.PortType = 'inport';
signal2.PortIndex = 2;
```
signal3 = Simulink.SimulationData.Signal;
signal3.Name = 'signal3';
signal3.PortType = 'inport';
signal3.PortIndex = 3;

2 In the MATLAB workspace, select signal1, signal2, and signal3. Right-click the selection, and in the context menu, click Save as. Save the file as mySigData.mat.

3 Open the MAT-file.

    open mySigData.mat

    ans =

        signal1: [1x1 Simulink.SimulationData.Signal]
    signal2: [1x1 Simulink.SimulationData.Signal]
    signal3: [1x1 Simulink.SimulationData.Signal]

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapper tool maps the signal data from the MAT-file to corresponding ports.

### Supported Microsoft Excel File Formats

You can use the Root Inport Mapper tool to import data from Excel spreadsheets. You can also use the Root Inport Mapper tool to import signal data in CSV files on a Windows system with Microsoft Office installed. The Root Inport Mapper tool does not support Excel spreadsheet charts.

- Use sheet names that follow MATLAB variable name rules. If you import from a sheet whose name does not follow these rules, the Root Inport Mapper tool uses a modified sheet name. This modified sheet name follows the MATLAB variable name rules. For example, if you have a sheet name Group Name, the Root Inport Mapper uses the modified name GroupName.
- Use the first row of a sheet to specify signal names. Either specify a signal name for every signal or do not specify any signal names. If you do not specify any signal names, the tool assigns signal names using the format Signal#.
- For time values, use the first column of the remaining rows. The time values must increase for each row.
- Put signal values in the remaining columns.
• During import, the Root Inport Mapper tool converts formatted numbers from Excel spreadsheets to doubles.
• The Root Inport Mapper tool does not support block path mapping mode for spreadsheets.

This example of a Microsoft Excel spreadsheet is set up for root-inport mapping.

• The sheet name is `sigData`, which is a valid MATLAB variable name.
• The first row contains the signal names `signal1`, `signal2`, and `signal3`.
• The first column has six time values that increase for each row.
• In each row with a time value, columns to the right of the first column contain signal data values for each signal.

Import Signal Data for Root Inport Mapping

In this section...

“Import Signal Data” on page 68-194
“Import Bus Data” on page 68-197
“Import Signal Data from Other Sources” on page 68-197
“Import Data from Signal Editor” on page 68-197
“Import Test Vectors from Simulink Design Verifier Environment” on page 68-197

Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 68-187. For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 68-185.

For data import purposes, the Root Inport Mapper From MAT-File and From Workspace dialog boxes provide a Convert signals into a scenario dataset and save to MAT-file check box, selected by default. To convert the data in your MAT-file to a Simulink.SimulationData.Dataset object, select this check box. Alternatively, use the convertToSlDataset function to convert your data.

Note The Root Inport Mapper tool uses the term link to refer to the act of importing Simulink data. The sources from which you can link your data are in the LINK section of the tool.

To import signal data for root-inport mapping:

1 Open the Root Inport Mapper tool. In the Configuration Parameters > Data Import/Export pane, click Connect Input.
2 In the LINK section, select the data source.
   • To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select From Spreadsheet or From MAT-File and browse to the MAT-file or spreadsheet file. To return to the LINK section, click OK.
Note To import bus data for root import mapping, see “Import Bus Data” on page 68-197.

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From dialog box displays the contents of the spreadsheet, file, or base workspace.
Select the data that you want to import, and then click OK.

The Root Import Mapper tool displays the imported data.

Alternatively, you can create signal data to map using the Signals > New MAT-File option. For more information, see “Create and Edit Signal Data” on page 68-200.
Import Bus Data

Use bus objects for bus data that you want to import and map to root inports or bus element ports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB struct. You can also create the bus in the base workspace and save it to a MAT-file. For more information, “Bus Signal Data for Root Inport Mapping” on page 68-189.

To import the bus data, in the LINK section of the Root Inport Mapper toolstrip, click From MAT-File. Select the MAT-file that contains the bus data and click OK.

Import Signal Data from Other Sources

Use the Root Inport Mapper tool to import signals from other sources.

• To import signals from models that contain Signal Editor blocks, see “Import Data from Signal Editor” on page 68-197.

• You can import Excel spreadsheet data. The Root Inport Mapper tool imports a worksheet as a Simulink.SimulationData.Dataset object that contains timeseries elements.

• To import test vectors from Simulink Design Verifier, see “Import Test Vectors from Simulink Design Verifier Environment” on page 68-197.

Import Data from Signal Editor

You can import and map data from the Signal Editor block in a MAT-file. For more information, see “Load Data with Interchangeable Scenarios Using Signal Editor Block” on page 68-265.

Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before importing, use the Simulink Design Verifier sldvsimdata function to convert a Simulink Design Verifier test structure to a Simulink.SimulationData.Dataset
object. This file contains a test vector structure \texttt{sldvData}. Save the output to a \texttt{MAT-file} and then import that file into the Root Inport Mapper tool.

View and Inspect Signal Data

After you import signal or bus data, you can view and inspect signal data using tools such as:

- Signal Editor on page 68-200
- Simulation Data Inspector on page 30-2
- The `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` plot method, where the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 68-185.

“Save and Send Changes to the Root Inport Mapper Tool” on page 68-237

Use the Signal Editor to create and edit input signals that you can organize for multiple simulations. You can then save the signal data to a MAT-file for simulation or to map to root-level ports. You can access the Signal Editor in the following ways:

- `signalEditor` function — Signal Editor starts from the command line.
- From the Root Inport Mapper on page 68-184 — To create a MAT-file for your new signal data, select *Signals > New MAT-File*. To link in an existing signal data file from an existing scenario and edit the signals in that file, use the *Signals > Edit MAT-File*.
- From the Signal Editor block

Signal Editor works only with MAT-files.
You can manipulate signals in these ways:

- Create and edit multiple signals in multiple data sets.
- Use signal notations to create more complicated signals using MATLAB expressions.
- Use existing scenarios to get existing data sets for which you can edit and create signals.
- Create and edit multidimensional signals.

While editing signal data:

- Use tabular editing or MATLAB to modify signal data.
- Modify signal properties such as name, interpolation, and unit properties.
- Drag and drop signals to change signal hierarchies for buses and data sets.
- Use signal notations and variables to replace signal data.

Alternatively, you can import data from external sources and edit them in Signal Editor. For more information, see “Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment” on page 68-202.

**Differences Between the Root Inport Mapper Signal Editor and Other Signal Editors**

Generally, the Signal Editor user interface is the same regardless of how you access it. Here are the differences in the Root Inport Mapper Signal Editor:

- **FILE section** Save and Sync and SAVE commands save and synchronize to the Root Inport Mapper.
- **Insert section** Scenario command always has the option, Scenario from Model.

If you start the function with a model name, the signalEditor function Signal Editor user interface shows the option Scenario from Model in the Insert section.

**Table Editing Data Support**

The Signal Editor user interface supports all signal data types that Simulink supports and that are editable.
Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment

You can use **Signals > Edit MAT-File** to link in MAT-file data from these sources for editing.

- Signal Builder blocks, see “Link in Data from Signal Builder” on page 68-202

**Link in Data from Signal Builder**

You can link in and edit data exported from the Signal Builder block in a MAT-file or MATLAB. Use one of these methods to export the data:

- Signal Builder block **File > Export Data > To MAT-file** option, then link in the MAT-file.
- **signalbuilder get** function with data sets, then perform either of these steps:
  - Import the data sets in the workspace and save to a MAT-file
  - Save the data sets in the workspace to a MAT-file and import the MAT-file

For more information on exporting from a Signal Builder block, see “Exporting Signal Group Data” on page 71-117.

**Link in Test Vectors from Simulink Design Verifier Environment**

You can link in and edit Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before linking in, use the Simulink Design Verifier **sldvsimdata** function to convert a Simulink Design Verifier test structure to a set of **Simulink.SimulationData.Dataset** objects. This file contains a test vector structure **sldvData**. Save the output to a MAT-file and then import that file into Signal Editor.

**Use Scenarios to Group and Organize Inputs**

Signal Editor uses scenarios to group and organize sets of inputs to be saved to a MAT-file for a single simulation. To create signal data using existing data sets from existing scenarios, or create an empty scenario into which to add signals, use the Signal Editor **Scenario** menu.
<table>
<thead>
<tr>
<th>Action</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>To create a scenario from the root inports of a model</td>
<td>Select <strong>Scenario &gt; Scenario from Model</strong>. (Available only when accessing Signal Editor from the Root Inport Mapper.)</td>
</tr>
<tr>
<td></td>
<td>You can also use the <code>signaleditor</code> function with a model argument.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> When using this option, the resulting scenario contains signals with the data types and dimensions of the inport ports.</td>
</tr>
<tr>
<td>To create an empty scenario and create signals from scratch</td>
<td>Select <strong>Scenario &gt; Blank Scenario</strong>.</td>
</tr>
<tr>
<td>To import scenarios from MATLAB workspace</td>
<td>Select <strong>Scenario &gt; From Workspace</strong>.</td>
</tr>
</tbody>
</table>

After you have your scenario:

- To begin inserting signals, use the other options in the **Insert** section. For more information, see “Create Signals and Signal Data” on page 68-205.
- To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 68-220.
Insert Signals

To insert signals into scenarios, select the scenario, then click a signal type from the Insert section.

- **Signal**
  
  Use the **Signal** split button to specify how you want to define the signal data:
  
  - **Blank Signal** — Add signal data directly into a table (see “Work with Basic Signal Data” on page 68-206).
  
  - **Author Signal** — Author signal data using signal notations and variables (“Create Signals with MATLAB Expressions and Variables” on page 68-210).

- **Bus**
- **Ground**
- **Function Call**

If you need a function-call signal for a root input with explicit periodic sample time, insert a ground signal instead. Simulink then executes the function-call automatically.

The new signals appear in the **Scenarios and Signals** section.
You can also insert multiple signals of the same type. For more information, see “Create Signals with the Same Properties” on page 68-224.

To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 68-220.

To edit the properties of a signal:

- For tabular editing, see “Work with Basic Signal Data” on page 68-206.
- To replace the signal data or edit the signal notation using MATLAB expressions, see “Replace Signal Data with MATLAB Expressions” on page 68-226.

Create Signals and Signal Data

Create signal data either from existing model data (scenarios) or start with an empty scenario. To a scenario, add signals and data by:

- Adding signal data directly into a table (“Work with Basic Signal Data” on page 68-206).
- Authoring signal data using signal notations and variables (“Create Signals with MATLAB Expressions and Variables” on page 68-210).

After inserting the signal, view and plot the data by clicking the Plot/Edit check box.

If the data does not plot as expected, use the Fit to window button in the Zoom & Pan section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

Explore the plots using the Measure and Zoom & Pan sections on the toolbar.

- In the Measure section, use the Data Cursors button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the Zoom & Pan section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.
<table>
<thead>
<tr>
<th>Type of Zoom or Pan</th>
<th>Button to Click</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zoom in along the T and Y axes.</td>
<td>📈</td>
</tr>
<tr>
<td>Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.</td>
<td>📈</td>
</tr>
<tr>
<td>Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.</td>
<td>📈</td>
</tr>
<tr>
<td>Zoom out from the graph.</td>
<td>📈</td>
</tr>
<tr>
<td>Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.</td>
<td>📈</td>
</tr>
<tr>
<td>Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.</td>
<td>📈</td>
</tr>
</tbody>
</table>

**Work with Basic Signal Data**

To add and edit basic signal data, select a signal and click the associated **Plot/Edit** check box. A plot of the signal displays. Under the signal plot is a tabular editor.
To insert or delete a data row for a signal, use ◼️ or ◼️, respectively.

To change the data type for signal data, select the type from the drop-down.

**Note** You cannot change data types to or from a fixed-point data type.
• To change the time or data for each signal, edit the associated column of the data row, then click **Apply** to update the plot of the signal.
Note If the data is fixed-point data, hovering over the data in the table displays a summary of the data

- Ideal Value — Requested value.
- Fixed-Point Value — Value resulting from casting the ideal value as a fixed-point value.
- Absolute Error — Absolute error of value.
- Relative Error — Difference between cast value and the original value.
- Additional error information, such as whether the error is an overflow or underflow.

- To change the size of the plot or tabular area, move the separator up and down.
To create multidimensional signals, use one of these methods. For more information, see “Add and Edit Multidimensional Signals” on page 68-227.

- In the Default Properties for Insertion dialog box, enter a dimension greater than 1 in the Dimensions parameter.
- In the Author and Insert dialog box, enter a MATLAB expression that creates multidimensional signals in the Data parameter.

Instead of using the tabular editor to define signal data, you can use MATLAB expressions.

**Create Signals with MATLAB Expressions and Variables**

To add signals using MATLAB expressions and variables, select the Signal Editor Signal > Author Signal option.
• **Time** — Enter the range of time for the data.
• **Data** — Enter the MATLAB expression for the signal.
• **Data type** — Select or enter the signal data type.
  
  - `double`
  - `single`
  - `int8`
  - `uint8`
  - `int16`
  - `uint16`
  - `int32`
  - `uint32`
  - `boolean`
  - `fixdt(1,16)`
• fixdt(1,16,0)
• fixdt(1,16,2^0,0)
• string
• Enum: <class name>

If you enter your time and data and then select a fixed-point data type, the Signal Editor displays a fixed-point proposed data type for your data.

• To help you select a fixed-point data type, click the **Show Histogram** button. Clicking this button displays a plot of the signal data using the selected fixed-point data type. The graph displays:

<table>
<thead>
<tr>
<th>Column</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Values</td>
<td>The negative, positive, and zero signal values.</td>
</tr>
<tr>
<td>Potential Overflows</td>
<td>Bins the signal values that may overflow.</td>
</tr>
<tr>
<td>In-Range</td>
<td>Bins the signal values that are within acceptable range.</td>
</tr>
<tr>
<td>Potential Underflows</td>
<td>Bins the signal values that may underflow.</td>
</tr>
</tbody>
</table>

To see the difference that a data type may have on the histogram, select:

• User Specified
• Binary Scaling
• Slope & Bias Scaling

For more information, see “Histogram Plot of Signal” (Fixed-Point Designer).

• To apply the proposed fixed-point data type to your data, click the **Use proposed data type** button.

When you click **Insert Signal**, the interface evaluates the signal, updates the signal information in the dialog box, and adds the signal to the **Scenarios and Signals** section. In addition, the number of samples, signal data type, and signal dimension also appear.
To see example Time and Data entries, click the Show Examples button. To experiment with the signals from these example signal notations, click the Apply Example button for the associated example. You can also modify the examples before inserting.

For example, to create a sine wave, click the Apply Example button next to that example and click the Insert Signal button. Observe that dialog box displays the number of samples, signal data type, and signal dimensions.
To view the signal, cancel the Author and Insert dialog box, navigate to the **Scenarios and Signals** section, and click the **Plot/Edit** button for the new signal. If a signal has real and imaginary parts, both parts display in one plot.
Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

<table>
<thead>
<tr>
<th>Type of Zoom or Pan</th>

<td>![Pan button]</td>
</tr>
</tbody>
</table>

**Tip** To produce signals with linearly spaced values for time, use the `linspace` function, for example:

- **Time** — `linspace(0,10,101)`
- **Data** — `[0:0.1:10]`
Create Freehand Signal Data Using Mouse or Multi-Touch Gestures

Freehand signal data is data that you add graphically. Signal Editor allows you to add freehand signal data using a mouse or touchscreen (if available and supported). While using a touchscreen, use common multi-touch gestures such as tap, pan, pinch, and double-tap (select all).

To add freehand signal data, select the Signal Editor **Signal > Draw Signal** option. A **Draw** tab opens.
You can draw your own signal lines or points, use MATLAB expression to enter data, move signal lines or points across the canvas, take an image of the lines of the canvas, and add the data to the Signal Editor.

To create signal data, in the **Tools** section:

- Insert a single data point by clicking **Insert Point** (Ctrl+P) and then clicking in the graph area. If you add additional points, the tool connects the points. This action is touchscreen supported with the tap gesture.
- Insert a signal line by clicking **Insert Line** (Ctrl+L) and then clicking in the graph area. To extend the line, click on the endpoints of the line and draw the extension. This action is touchscreen supported with the pan and pinch gestures.

**Tip** When you insert signals or signal lines, the canvas adds a shaded area bound by the leftmost and rightmost endpoints. While in **Insert Line** mode, you cannot add
more points within this shaded area. You add additional line points outside the shaded area.

- Draw a signal freehand by clicking **Draw** (Ctrl+D) and drawing in the canvas. This action is touchscreen supported with the pan and pinch gestures.

- Draw a signal using MATLAB expressions by clicking **Expression** (\( f(x) \), Ctrl+E). Enter time and data values that create signal points that are scalars or vectors whose number of points match the time points.

To select or move signal data, in the **Signal** section:

- Select a point or line by clicking **Select** (\( \text{Select} \), Ctrl+T) and then selecting the point or area to be selected. This action is touchscreen supported with the pan and pinch gestures; to select all points, double-tap the touchscreen.

- Move a point or line by clicking **Move** (\( \text{Move} \), Ctrl+M). This action is touchscreen supported with the pan gesture.

To edit or remove the signal data, in the **Edit** section:

- Change the data of a point by clicking **Edit Point** (\( \text{Edit Point} \)). In the Edit Point dialog box, enter the new **Time** and **Data** values. These values must be scalar.

To work with the canvas, use the tools in the **Align**, **Show**, and **Zoom** sections.

- Snap the canvas graph to various grids using the tools in the **Align** section. Snapping to grid helps you better control data accuracy while drawing signals. For example, consider snapping to the \( x \)-grid to uniformly sample signal values or snapping to the \( y \)-grid to control the amplitude of a ramp signal.

- Toggle the display of data points, grid lines, and data markers in the canvas, explore the commands in the **Align** and **Show** sections. To zoom in and out of the canvas, see **Zoom & Pan**. These actions are touchscreen supported with the pan and pinch gestures. For more information, see “Create Signals and Signal Data” on page 68-205.

To work with signal properties, use the parameters in the **Signal Properties** section. For example, to see the changed values of your signal as you change data types in the **Data type** parameter, select the **Show result of cast to data type**. The original line is blue,
the changed values are represented by the black line. This graphic illustrates a signal line with negative double values recast as uint8.

To capture an image of the signal data, in the **Capture** section, click **Screenshot**. In the Save a screenshot dialog box, specify a name and graphic type for the file.

When you are done drawing the signal, in the **Insert** section:

1. To add the signal to the Signal Editor, click **Insert signal**.
2. To return to the main Signal Editor window and check that the signal has been added, click **Close draw tab**.
3. To observe the drawn signal data In Signal Editor, click the signal name in the hierarchy.

For an example of how to add a freehand ramp signal, see “Draw a Ramp Using Snap to Grid for Accuracy” on page 68-235.

**Change Signal Names and Hierarchy Orders**

In the **Scenarios and Signals** section, you can change signal names and hierarchy order, create duplicates of signals, and delete signals. Simulink ignores leading and trailing spaces in signal names.
• To change a signal name, double-click the name and change it.

• To change the unit or interpolation of a signal, click the plus sign and click the **Unit** or **Interpolation** check boxes.

The pane updates with **Unit** and **Interpolation** columns.
• In the **Unit** column, enter an appropriate unit expression. For a suggested list of unit expressions, see allowed units.

• In the **Interpolation** column, from the drop-down list, select **linear** or **zero order hold**.

  **Note**  Interpolation affects only the plotting of signals in the Signal Editor user interface.

• To change the order of a signal in the hierarchy, drag and drop it. For example, you can drag and drop signals into a bus.
Alternatively, use the **Move Up** and **Move Down** buttons in the **Adjust** section.

- To copy a signal and paste it under the original, right-click it and select **Duplicate Signal**.
Alternatively, use the **Duplicate** button in the **Adjust** section. You can also adjust the default properties of the signal you duplicate. For more information, see “Create Signals with the Same Properties” on page 68-224.

- To copy a signal and paste it elsewhere in hierarchy, select **Copy** and then **Paste**.

**Create Signals with the Same Properties**

To create signals of the same predefined type, use the **Duplicate** button in the **Adjust** section. To change the predefined signal type, click the **Defaults** icon, ![Defaults Icon]. A Default Properties for Insertion dialog box displays.
- **Data type** — From the drop-down list, select the signal data type.
- **Enumeration** — When you select the Enum data type, this parameter displays. Enter the class name of your enumeration.

If you define an enumeration class that contains the same integer value multiple times, for example:

```matlab
classdef(Enumeration) hEnumColors_duplicateValues < Simulink.IntEnumType
enumeration
    Red(118)
    Yellow(-14)
    Blue(90)
    Green(87)
    White(-14)
```
The Signal Editor treats the first enumeration value (Red (118)) as the canonical value and equates all subsequent instances of the same underlying integer 118 to the enumerated name Red. In other words, Pink equals Red.

- **Interpolation** — From the drop-down list, select linear or zero order hold.
- **Unit** — Enter an appropriate unit expression. For a suggested list of unit expressions, see Allowed Units.
- **Dimensions** — Enter the number of dimensions for the signal.
- **Signal type** — From the drop-down list, select real or complex.
- **Bus object** — From the drop-down list, select the bus object for which to define the dimensions. If you leave the Bus object parameter at the default <object name>, Signal Editor adds empty buses.
- **Dimensions** — Enter the number of dimensions for the bus object.

### Replace Signal Data with MATLAB Expressions

You can replace signal data using MATLAB expressions at any time, regardless of how you created the original signal data. To replace signal data, select that signal in the Scenarios and Signals section, and then click the replace button (.scalar). Use the Author and Replace Signal Data dialog box as if you were inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 68-210.

**Note** You cannot change data types to or from a fixed-point data type.

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.
**Tip** To produce signals with linearly spaced values for time, use the `linspace` function. For example, using:

- **Time** — `linspace(0,10,11)`
- **Data** — `[0:10]`

---

### Add and Edit Multidimensional Signals

To add multidimensional signals, use either of these options:

- Change the **Dimensions** property in the Default Properties for Insertion dialog box, and then use **Insert > Blank Signal** to insert a new signal.
• Enter multidimensional signal data in the Author and Insert dialog box Data parameter, such as [(1:10)’ (1:10)’].

When you click the Plot/Edit check box for the signal, the tabular area displays the signal with columns for each dimension. You can edit the data individually in the tabular area, or click the replace button to replace the signal with a MATLAB expression. Use the Author and Replace Signal Data dialog box as though you are inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 68-210.

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.

For example, to create signal data with two columns and time from 1 to 10:

1. In the Signal Editor, select Signal > Author Signal.
2. Enter signal data with two columns and time from 1 to 10:
   - **Time** — [1:10]
   - **Data** — [(1:10)’ (1:10)’]
3 Click **Insert Signal**.

The hierarchy updates with the new signal data.

4 Expand the new signal and click the **Plot/Edit** check boxes for the new signal data. Observe the associated plots and the tabular data for the signal.
Tip If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

You can edit the data directly in the table.
Or you can replace data completely with a new expression by clicking the **Replace** button and entering a new time range and data in the Author and Replace Signal Data dialog box.
Add Signals to Scenarios

This example describes how to create a scenario to be linked to from the Root Inport Mapper tool. You can then start the Signal Editor to manipulate and add signals to this scenario.

1. In the MATLAB Command Window, create some data by typing:

   ```matlab
ts = timeseries([0;20],[0;10]);
```

2. In Simulink Editor, create a model that contains three Inport blocks, three Gain blocks, a Mux block, and a Scope block. Connect these blocks as shown:

   ![Diagram of Simulink model](image)

3. Set the gain for the Gain blocks to 5, 10, and 15, respectively.

4. Click one of the Inport blocks, then click the Connect Input button.

   The Root Inport Mapper tool displays.

5. In Root Inport Mapper Link section, select From Workspace.

6. In the From Workspace window, enter a name to store the MAT-file, then click OK.

7. In the Scenario section of the Signal Editor, click Signals > Edit MAT-File.

8. In the Edit Signal File window, select the new MAT-file and click OK.

   The Signal Editor displays.

9. Add a signal, Signal, to the scenario. Right-click the scenario and select Insert > Blank Signal.

   This action adds Signal with these default properties.
Alternatively, insert signals by clicking a signal type from the Insert section or using the Signal split button to author a signal using signal notations.

10 Change the default properties of signals you want to add. In the Insert section, select Defaults. In the Default Properties for Insertion dialog box, change the data type to boolean, then right-click the scenario and select Insert > Blank Signal.

This action adds Signal1 with the data type boolean.

11 To check that the data type is boolean, click the plot check box for Signal1.
Work with Data in Signals

This example describes how to add and delete data to the signals in the linked scenario. To create a model and data to work with, see “Add Signals to Scenarios” on page 68-232.

1. In the Signal Editor, in the Scenarios and Signals section, click the plot check box for the signal ts.
2 Add some data to the signal \( t_s \).

   a Click the add row icon and add some signals. To add a signal row between other signals, click the signal before and click the add row icon.

   b When done, click **Apply**. Clicking **Apply** updates the plot.

3 Remove the time 20 line from the signal. Select 20 and click .

4 Alternatively, if you want to replace all the signal data for \( t_s \) with a signal defined with signal notations, click the replace button and use the Author and Replace Signal Data dialog box to define new data.

**Draw a Ramp Using Snap to Grid for Accuracy**

This example describes how to create a ramp signal by selecting some points in the canvas.

1 In Signal Editor, select **Signal > Draw Signal**.

2 To line up the signal data values along horizontal and vertical lines, select **Snap X to Grid** and **Snap Y to Grid**.

3 In the canvas, add three points:
• Two points horizontal to each other
• One point set to the right at an angle to the other signals

4 In the Signal Properties section, in **Name**, change the signal name to **Ramp** and press **Enter**.

5 To add the signal to the Signal Editor, in the **Insert** section, click ✅.

6 To return to the main Signal Editor window and check that the signal has been added, click ✗.

7 To observe the drawn signal data In Signal Editor, click the **Plot/Edit** check box for the **Ramp** signal name in the hierarchy.
Save and Send Changes to the Root Inport Mapper Tool

When you are done adding and modifying signals and scenarios, use the **Save and Sync** button to save the changes to a MAT-file. The Signal Editor also sends the data to the Root Inport Mapper Tool:

- If the Root Inport Mapper tool has the scenario loaded, the Root Inport Mapper tool updates with the new data.
- If the Root Inport Mapper tool has the scenarios mapped and your changes affect the mapping, the Root Inport Mapper tool unmaps the scenario.

Map Signal Data to Root Inports

In this section...

“Select Map Mode” on page 68-239
“Set Options for Mapping” on page 68-240
“Select Data to Map” on page 68-241
“Map Data” on page 68-242
“Understand Mapping Results” on page 68-242
“Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 68-245
“Alternative Workflows to Load Mapping Data” on page 68-251

After you import data, map signal data to root inports by selecting map modes and options and selecting data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 68-185.

Select Map Mode

To map signal data to root-level ports, use one of these map modes in the MAP TO MODEL section of the Root Inport Mapper toolstrip. The mapping mode you select from the toolstrip, such as Block Name or Port Order, is maintained between MATLAB sessions and models. You do not have to select the map mode each time you want to map signal data to root inports.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Map Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-inport block, the data is mapped to the corresponding port.</td>
<td>Block Name</td>
</tr>
</tbody>
</table>

68-239
### Set Options for Mapping

If you want to set up mapping options, in the MAP TO MODEL section on the Root Inport Mapper toolstrip, click **Options**. The option you select from the toolstrip, such as **Update Model** or **Allow Partial**, is maintained between MATLAB sessions and models. You do not have to select the option each time you want to map signal data to root inports.

To map the signals, see “Map Data” on page 68-242.
<table>
<thead>
<tr>
<th>Goal</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update the model and review the data types of root-level inports and imported data.</td>
<td><strong>Update Model.</strong> Compare the signal data and import parameters to the root-level port and display the results. If you do not select this option, the tool maps the imported data to the root-level inport but does not update the model.</td>
</tr>
<tr>
<td>Use strong data typing when mapping data from spreadsheets.</td>
<td><strong>Use Strong Data Typing with Spreadsheets.</strong> Clear this check box to allow the Root Inport Mapper tool to automatically convert spreadsheet input signals to the data types of the corresponding root inports. The Root Inport Mapper tool can cast the spreadsheet data to only these data types: double, single, int8, uint8, int16, uint16, int32, uint32. If you select this check box or if the root inport is not one of these data types, you may receive a data type mismatch error.</td>
</tr>
<tr>
<td>Import bus data that is only partially defined.</td>
<td><strong>Allow partial.</strong> Confirm that any partially specified bus data you import maps properly to root-level inports.</td>
</tr>
<tr>
<td>Identify unassigned root inports and detect incomplete input data sets.</td>
<td><strong>Notify of Missing Signals.</strong> Show inputs with missing signals.</td>
</tr>
</tbody>
</table>

### Select Data to Map

To specify a subset of scenarios to map, click the down arrow on the **Map to Model** button. You can choose different mapping modes for different scenarios.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map all the scenario datasets (default).</td>
<td><strong>Map All</strong></td>
</tr>
<tr>
<td>Map the datasets of the scenarios currently selected in the SCENARIO DATASET section.</td>
<td><strong>Map Selected</strong></td>
</tr>
<tr>
<td>Map the disconnected datasets.</td>
<td><strong>Map Unconnected</strong></td>
</tr>
<tr>
<td>Map datasets that previously failed a mapping.</td>
<td><strong>Map Failed</strong></td>
</tr>
<tr>
<td>Map datasets that previously caused warnings.</td>
<td><strong>Map Warned</strong></td>
</tr>
</tbody>
</table>
Map Data

After you import signals or buses, you can map data.

1. On the Root Import Mapper toolbar, click Map to Model.

   The results of a signal mapping appear in the SCENARIO DATASET tab.

2. In the FILE section, click a data set to see the mapping results.

   - The SIMULATION READINESS section lists the input data and the status of the mapping.

     **Note** See “Understand Mapping Results” on page 68-242.

     - The mapping definition for the input data is applied to the model.

   After you save and close the model, when you load input data of the same scenario to the workspace, the model uses the mapping defined for that scenario.

   For an example of mapping signal data to root-level inputs, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 68-245.

   After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Mapping Data” on page 68-251.

Understand Mapping Results

When you complete the import and map process, the SIMULATION READINESS section displays the results in the status area. The results depend on whether you select the Update Model option when you set up the mapping.
<table>
<thead>
<tr>
<th>Status</th>
<th>Update Model</th>
<th>Continue Without Update Model</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓</td>
<td>The properties of the mapped data and the inport are appropriate for simulation.</td>
<td>The data type, dimension, and signal type properties of the data and inport are compatible.</td>
</tr>
</tbody>
</table>
| !      | Not applicable | Comparison of data and root-level port data type, dimension, and signal type properties cannot determine whether there is a match. If you do not update the model before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the inport data types. Confirm that you set these block parameters correctly:  
Inport block parameter **Data type** is not set to **Inherit:auto**.
Inport block parameter **Dimension** is not set to -1.
Inport block parameter **Signal type** cannot be **auto**. |
| ✗      | The properties of the mapped data and the inport are not appropriate for simulation. | One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level inport. |

To enable the model to simulate, if Root Inport Mapper does not find inport signals to map, it maps these inports to ground and displays the mapped signal as empty ([ ])..

This figure shows mapping successes, failures, and ground assignments. If there are issues, the status column displays suggested resolutions. Read through and diagnose the issues.
Sometimes the **SIMULATION READINESS** section shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Update Model** check box from the **Options** menu, select it and click **Map to Model** again.

In the Root Inport Mapper tool, clicking **Mark for Simulation** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box. It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**.

If your model uses configuration references to reference configuration sets, you cannot mark the model for simulation. To use this data to simulate the model with the Root Inport Mapper tool, use the Model Explorer to activate a configuration set first.

This graphic illustrates the application of the changes to the model configuration for the model in “Map Data” on page 68-242.
To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the Simulation Readiness section. The selected Inport block is outlined with blue.

**Note** When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

**Converting Harness-Driven Models to Use Harness-Free External Inputs**

This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files for the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

**Save Harness Data to MAT-Files**

Before converting the model to be harness-free, collect the test cases in the harness.

For this example, you will modify the model `sldemo_autotrans` from the Modeling an Automatic Transmission Controller example.

Open the example model. In the MATLAB Command Window, type `sldemo_autotrans`. 
Exporting Signal Builder Block Groups

Export data that defines Signal Builder block signal groups to a MAT-file from the Signal Builder window. To export Signal Builder signal data, formatted as Simulink.SimulationData.Dataset, to a MAT-file, open the Signal Builder window and select **File > Export Data > To MAT-File**. In the dialog, enter a name for the MAT-file to contain the data and the number of the group you want to export. For this example, the file name is `slexAutotransRootInportPassingManeuver.mat` and the group number is 1 for the Passing Maneuver group.

**Remove the Signal Builder Block**

Remove the Signal Builder block named ManeuversGUI and replace it with two inports.

1. Delete the Signal Builder block named ManeuversGUI.
2. From the **Simulink/Commonly Used Blocks** library, drag two inport blocks into the model.
3. Connect the input ports to the lines previously connected to the Signal Builder block.
4. Rename the input ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.
Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.

### Set Up Harness-Free Inputs

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

In the Modeling tab, select Model Settings. In the Data Import/Export pane, click the **Connect Input** button.
Map Signals to Root Inport

The Root Inport Mapper tool opens.

The example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **From MAT-File** button on the Root Inport Mapper toolbar. When the link dialog appears, click the Browse button. In the browser, select the MAT-file that you saved earlier.

---

Select a Mapping Mode

When you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:
• **Port Order** - Maps in the order it appears in the file to the corresponding port number.

• **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.

• **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.

• **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.

• **Custom** - Maps using a MATLAB function.

Earlier in this example, you saved input data to variables of the same name as the harness signals Throttle and Brake, and added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries try to match input data variable names to the names of the input ports. To select this option:

1. Click the **Block Name** radio button.
2. Click the **Options** button and select **Update Model**. This verifies the mapping.
3. Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine compatibility issues. The status of this compatibility is reflected by the table colors green, orange, or red. Warnings and errors are flagged with diagnostic messages. If the **Options > Update Model** option is not selected, Root Inport Mapper determines the compatibility status by evaluating these block parameters and assigned signals:

• **Data Type** - Double, single, enum, ....

• **Complexity** - Real or complex

• **Dimensions** - Signal dimensions vs port dimensions
Finalize the Inputs to the Model

Review the results of the mapping compatibility. Click the Scenario Dataset 'PassingManeuver' in the scenario dataset list. To prepare for simulation, click **Mark for Simulation**. This action applies the mapping variables to the Configuration Parameter **Data Import/Export > External Input** text box. If this text box has content, it is overwritten.

Simulating the Model

With the changes applied you can now simulate the model and view the results. Run the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.
Alternative Workflows to Load Mapping Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

**Command Line or Script**

To load data and simulate the model from the MATLAB command line, use commands similar to:

```matlab
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:
- Creates signal groups with variable names $In1$, $In2$, and $In3$, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

**Note** The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

```matlab
% Create signal groups
fileName = 'testCase';
for k =1 :3
    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    % create a dataset
    ds = Simulink.SimulationData.Dataset();
    ds = ds.addElement( var1, 'var1');
    ds = ds.addElement( var2, 'var2');
    ds = ds.addElement( var3, 'var3');

    % Save the data
    save([fileName '_' num2str(k) '.mat'],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
    % Load the MAT-file.
    load([fileName '_' num2str(k) '.mat']);

    % Simulate the model
    simOut{k} = sim('model_name');
end
```

**Use the PreLoadFcn Model Callback**

When you are satisfied with the data and mapping, you can configure your model to load a MAT-file containing the signal group into the MATLAB workspace. Call the `load` function in the PreLoadFcn callback for the model.

1. After saving the MAT-file, on the **Modeling** tab, click the **Model Settings** drop-down and select **Model Properties**.
2. In the Model Properties window, select the **Callbacks** tab and then the PreLoadFcn node.
3 Enter a command to load the MAT-file containing the signal data. For example:
   load d_signal_data.mat;
4 Click OK and save the model.

Preview Signal Data

Preview input signal or bus data with the **Signal Preview** window. You can access this window from:

- From File block
- Simulink.SimulationData.DatasetRef and Simulink.SimulationData.Dataset plot methods

1. Preview input signal or bus data with the **Signal Preview** window.

   - For From File block, browse to a MAT-file that contains the data you want to preview, then plot the data by clicking 📈.
   - For Simulink.SimulationData.Dataset or Simulink.SimulationData.DatasetRef elements, use the plot method on the dataset.

If you view and inspect signal using the Simulink.SimulationData.Dataset or Simulink.SimulationData.DatasetRef plot method, the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.
2 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

<table>
<thead>
<tr>
<th>Type of Zoom or Pan</th>

Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see “Root Inport Mapping Scenarios” on page 68-261).

1. Associate your scenario with the model.
2. In the SCRIPT section, click Generate MATLAB Script and supply a script name when prompted.
3. To run the script, click Run Script.
4. To evaluate the results of the simulation, see the base workspace.

The resulting script uses the Simulink.SimulationInput object and parsim function.

Simulink.SimulationInput | parsim

More About
• “Root Inport Mapping Scenarios” on page 68-261
Create and Use Custom Map Modes

You can create custom map modes to supplement the map modes that the Root Inport Mapper tool provides (see “Choose a Map Mode” on page 68-185).

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 68-185.

Create Custom Mapping File Function

If you do not want to use the map modes in the Root Inport Mapper tool, create a custom mapping file function. For example, consider creating a custom mapping file function if:

• Your signal data contains a common prefix that is not in your model.
• You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

For examples, see these files in the folder `matlabroot/help/toolbox/simulink/examples` (open).

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BlockNameIgnorePrefixMap.m</td>
<td>Custom mapping file function that ignores the prefix of a signal name when importing signals</td>
</tr>
<tr>
<td>BlockNameIgnorePrefixData.mat</td>
<td>MAT-file of signal data to be imported</td>
</tr>
<tr>
<td>ex_BlockNameIgnorePrefixExample</td>
<td>Model file into which you can import and map data</td>
</tr>
</tbody>
</table>

In addition, see the example Using Mapping Modes with Custom-Mapped External Inputs.

To create a custom mapping file function:

1. Create a MATLAB function with these input parameters:
   - Model name
   - Signal names specified as a cell array of character vectors
• Signals specified as a cell array of signal data
2 In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
3 Save and close the MATLAB function file.
4 Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

1 Open the model that you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
2 Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.
3 In the **Load from workspace** section, click **Connect Input**.
4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
5 In the **MAP TO MODEL** section of the toolstrip, click **Custom**.
6 In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for the Attaching Input Data to External Inputs via Custom Input Mappings example.

**Tip** The Root Inport Mapper tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.

7 Click **Options** and select the **Compile** check box.
8 Click **Map**.

The model is compiled and the Root Inport Mapper tool gets updated.

To understand the mapping results, see “Understand Mapping Results” on page 68-242.

9 Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation. For more information, see “Alternative Workflows to Load Mapping Data” on page 68-251.
Custom Mapping Modes Similar to Simulink Modes

If your custom mapping mode is similar to a Simulink mapping mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see Using Mapping Modes with Custom-Mapped External Inputs.

Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the Configuration Parameters > Data Import/Export > Input parameter

Root Inport Mapping Scenarios

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Open Scenarios” on page 68-261</td>
</tr>
<tr>
<td>“Save Scenarios” on page 68-262</td>
</tr>
<tr>
<td>“Open Existing Scenarios” on page 68-262</td>
</tr>
<tr>
<td>“Work with Multiple Scenarios” on page 68-263</td>
</tr>
</tbody>
</table>

Use the Root Inport Mapper tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapper tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel). Place the signal files in the last known location (where you used the Root Inport Mapper tool most recently) or the MATLAB path.

**Open Scenarios**

To open an existing scenario, click **Open**. If you are working in another scenario, the Root Inport Mapper tool displays a message.
To... | Click...
---|---
Open a new scenario. Remove the existing scenario without saving it. | No
Cancel opening a scenario. | Cancel
To save the existing scenario, click Yes. Then click the Open button again to open an existing scenario. | Yes

### Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar is has an asterisk (*), you can save a scenario.

1. On the Root Inport Mapper toolbar, select **Save > Save As**.
2. In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.
   - To save the signals and the scenario file, click **Yes**.
     
     If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

1. On the Root Inport Mapper tool toolbar, click **Save**.
2. Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.
   
   If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overwrite the existing <code>.mldatx</code> file.</td>
<td>Yes</td>
</tr>
<tr>
<td>Exit the dialog box. The tool does not save the scenario.</td>
<td>No</td>
</tr>
</tbody>
</table>

### Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:
• Double-click the previously saved scenario file (*.mldatx). The Root Inport Mapper tool opens and loads the model. Alternatively, right-click the file and select **Open**.

• When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.

• If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.

• Open the Root Inport Mapper tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Click</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save the existing scenario and associated data before loading the new scenario.</td>
<td>Yes</td>
</tr>
<tr>
<td>Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario.</td>
<td>No</td>
</tr>
</tbody>
</table>

**Work with Multiple Scenarios**

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapper tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the Simulink.SimulationData.Dataset format:

1. To convert the signals to a Simulink.SimulationData.Dataset format, use the `convertToSlDataset` function.

2. Link to the new data set. You do not need to reopen the scenario.

Load Data with Interchangeable Scenarios

To easily exchange scenarios within models, use the Signal Editor block. This block displays, creates, edits, and switches scenarios, where scenarios contain information about groups of signals, such as:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the associated model
- Map mode
- Mapping options
- Mapped state

Use scenarios to exchange groups of signals in your model, such as when running multiple simulations or working with test harnesses.

**Tip** The Signal Editor displays, creates, and edits interchangeable scenarios and is better integrated with other Simulink capabilities such as units, signals in MAT-files, and signal edit and creation. Consider using the Signal Editor block in models where you use the Signal Builder block. The Signal Builder block is not recommended to work with signal groups. For more information on benefits of the Signal Editor block, see “Replace Signal Builder Block with Signal Editor Block” on page 68-269.

Load Data with Interchangeable Scenarios Using Signal Editor Block

The Signal Editor block gets groups of signals (scenarios) from MAT-files.
The block has three sections.

- **Scenario** — Set up a scenario by specifying the MAT-file containing the list of scenarios and selecting the active (current) scenario.

- **Signal properties** — Use the Signal Editor user interface to examine, create, and edit scenarios and associated signals. The Signal Editor user interface organizes the signals according to the scenarios that contain them.

- **Parameters** — Select the active signal to be output and set up characteristics, such as unit, sample time, linear interpolation, and so forth, for the active signal. To change the active signal, use the drop-down list.
**Explore the Signal Editor Block**

This example shows how to use the Signal Editor block with the “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode” example, which runs multiple simulations of a Monte Carlo study in parallel using Parallel Computing Toolbox. Parallel execution leverages the multiple cores of your host machine to run many simulations more quickly. If you do not have Parallel Computing Toolbox, this example runs the simulations in serial. The model simulates vehicle dynamics based on the interaction between road and suspension for different road profiles. This example stores its road profile scenarios in the `matlab\toolbox\ssldemo_suspn_3dof_sigData.mat` file.

1. In the `sldemo_suspn_3dof` model, open the Signal Editor (named Road Profiles) block.

   The Signal Editor block **File Name** parameter contains the MAT-file `sldemo_suspn_3dof_sigData.mat`.

   Observe that:

   - **Active scenario** automatically sets to the first scenario, Road1. This setting means that the remainder of the block parameters apply to the signals in that scenario. To change the active scenario, select a new scenario from the list of scenarios.

   - **Active signal** automatically sets to the first signal Left tire in the active scenario, Road1. This setting means that the remainder of the settings in the **Parameter** section apply to the active signal. To change the active signal, select a new signal from the list of signals.

2. Explore and edit the scenarios in the MAT-file. Click ![Edit](image).

   The Signal Editor user interface displays a list of scenarios contained in the MAT-file. Explore and change the scenarios and associated signals. If you make changes, you can save them back to the MAT-file by clicking **Save**.
The output from the block is the active signal data. To simulate the model sequentially using each scenario and signal, use the `parsim` function. This function simulates dynamic systems multiple times in parallel or serial. For an example on how to use `parsim`, see “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode“.
Replace Signal Builder Block with Signal Editor Block

The Signal Editor provides similar functionality to the Signal Builder block, but with greater flexibility. Replace the Signal Builder with the Signal Editor block. The benefits of Signal Editor block include:

- Signal data storage in a MAT-file outside the model
- Signal editing and creation
- Support for Simulink signal attributes, such as dimension and complexity
- Support for standard Simulink data types, including bus and fixed-point
- Unique signal-level data types for outputs
- Multiple rates for outputs
- Support for Simulink units
- Zero crossing on page 3-13 detection and data interpolation unique to each signal

To port signal data and properties from the Signal Builder block to Signal Editor block, use the `signalBuilderToSignalEditor` function. For the current model, this function stores to a MAT-file the signal data and properties from an existing Signal Builder block, adds a Signal Editor block to the current model, and modifies the Signal Editor block to reference the new MAT-file.

For an example see “Replace Signal Builder Block with Signal Editor Block”.

Considerations

Converting from the Signal Builder block to the Signal Editor block is relatively straightforward using the `signalBuilderToSignalEditor` function. However, take into account these considerations:

- Internal storage format and preprocessing of data differ between the Signal Builder and Signal Editor blocks. When using the variable step solver, different simulation time steps and mismatched output occur in the two blocks. To minimize the difference between the outputs of both blocks, you can:
  - Reduce the value of **Max step size** of the variable step solver.
  - Insert more data points in the input signal of the Signal Editor block to better represent its shape.
- Use the fixed-step solver or set the sample time for both blocks to the same discrete sample time (greater than 0). For more information on discrete sample times, see “Discrete Sample Time” on page 7-15.
- The Signal Builder block supports only doubles. To change the data type or otherwise change the signals after conversion, click the button in the Signal Editor block to access the Signal Editor user interface.

**Get Number of Scenarios and Signals**

To programmatically get the total number of scenarios and signals in the Signal Editor block, use the `get_param NumberOfScenarios` and `NumberOfSignals` properties. The values of these properties are character vectors. To convert these values to doubles, use the `str2double` function.

`NumberOfScenarios` and `NumberOfSignals` are read-only properties available only through `get_param`. The block dialog box does not provide these values.

Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block can include units information for Dataset or Timeseries logging formats.

Logging top-level model Outport block data from a previous simulation contains units information if:

- These Data Import/Export configuration parameter settings:
  - Output is enabled.
  - Format is Dataset.
  - For the Outport blocks that you log, in the Block Parameters dialog box, you set the Unit parameter.

Otherwise, to include units in signal data that you load, for the Units property of the MATLAB timeseries objects that you want to load, specify a Simulink.SimulationData.Unit object.

Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Outport block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

Load Data Using the From File Block

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Data Loading” on page 68-273</td>
</tr>
<tr>
<td>“Sample Time” on page 68-274</td>

<td>“Detect Zero Crossings” on page 68-275</td>
</tr>
<tr>
<td>“Create Data for a From File Block” on page 68-275</td>
</tr>
</tbody>
</table>

To load signal data into a model using a From File block:

1. Create a MAT-file with the signal data that you want to load. See “Create Data for a From File Block” on page 68-275.

2. Add a From File block to a model. Connect the From File block to the block that the From File provides input to.

3. Double-click the From File block and specify:
   - The path to the file that you want to load data from
   - The data format for the From File block output
   - How the data is loaded, including sample time, how data for missing data points is handled, and whether to use zero-crossing detection

Data Loading

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory at the start of simulation. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For each simulation time hit for which the MAT-file contains no matching timestamp, Simulink uses interpolation or extrapolation to obtain the needed data. You specify the interpolation and extrapolation methods.

During simulation, the From File block cannot load data from a MAT-file that a To File block is exporting data to.
Sample Time

The From File block Sample time parameter specifies the sample time to load data from a MAT-file. The timestamps in the file must be monotonically nondecreasing. For details, see the From File block documentation.

Simulation Time Hits Without Corresponding Time Data

If a simulation time hit does not have a corresponding MAT-file timestamp, then the From File block output depends on:

- Whether the simulation time hit occurs before the first timestamp, within the range of timestamps, or after the last timestamp
- The interpolation or extrapolation methods that you select
- The data type of the MAT-file data

For details about interpolation and extrapolation options, see the documentation for these From File block parameters:

- Data extrapolation before first data point
- Data interpolation within time range
- Data extrapolation after last data point

Duplicate Timestamps

Sometimes the MAT-file includes duplicate timestamps (two or more data values that have the same timestamp). In such cases, the From File block action depends on when the simulation time hit occurs, relative to the duplicate timestamps in the MAT-file.

Suppose that the MAT-file contains the following data, with three data values having a timestamp value of 2:

| time stamps: | 0 1 2 2 2 3 4 |
| data values: | 2 3 6 4 9 1 5 |

The following table describes the From File block output.
### Simulation Time, Relative to Duplicate Timestamp Values in MAT-File

<table>
<thead>
<tr>
<th>Before the duplicate timestamps</th>
<th>Uses the first of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 6.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>At or after the duplicate timestamps</td>
<td>Uses the last of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 9.)</td>
</tr>
</tbody>
</table>

### Detect Zero Crossings

Zero-crossing detection locates a discontinuity in timestamps, without resorting to excessively small time steps. By default, the From File block does not enable zero-crossing detection.

For the From File block, zero-crossing detection occurs only at timestamps in the file. Simulink examines only the timestamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

For more information, see the From File block documentation of the **Enable zero-crossing detection** parameter.

### Create Data for a From File Block

- “NaN Values Not Supported” on page 68-275
- “Data Saved by a To File Block” on page 68-276
- “Supported MAT-File Versions” on page 68-276
- “Storage Formats” on page 68-276
- “Timestamps” on page 68-277
- “Bus Data” on page 68-278
- “MAT-File Variable” on page 68-278

### NaN Values Not Supported

Do not include NaN values in a MAT-file that you load into a From File block.
**Data Saved by a To File Block**

The From File block loads data that was written by a To File block without any modifications to the data or any other special provisions.

**Supported MAT-File Versions**

The supported MAT-file versions are:

- Version 7.0 or earlier
- Version 7.3

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory when the simulation begins. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For more information about MAT-files, see “MAT-File Versions” (MATLAB).

**Convert Version 7.0 and Earlier Version MAT-Files**

If you have a Version 7.0 or earlier version MAT-file that you want to use with the From File block, consider converting the file to Version 7.3. Use a Version 7.3 MAT-file if you want the From File block to load data incrementally during simulation or you want to use MATLAB timeseries data. For example, to convert a Version 7.0 file named `my_data_file.mat` that contains the variable `var`, at the MATLAB command prompt, enter:

```matlab
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

**Storage Formats**

When the From File block loads data from a MAT-file, that data must be stored in array format or as a MATLAB timeseries object.

**Array Data**

You can use the array format only for vector, double, noncomplex signal data.

For a Version 7.0 MAT-file, the From File block loads array data, but not MATLAB timeseries data.

The array format for stored data is a matrix containing two or more rows. The matrix in the MAT-file must have the following form:
The first element of each column contains a timestamp. The remainder of each column contains data for the corresponding output values. Each element must be a double. Elements cannot include a NaN, Inf, or -Inf.

**MATLAB Timeseries Data**

To use bus data with a From File block, use the MATLAB timeseries format.

MATLAB timeseries format data can have:

- Any dimensionality and complexity
- Any built-in data type, including Boolean
- A fixed-point data type with a word length of up to 32 bits
- An enumerated data type

For data stored using the array format, the width of the From File output depends on the number of rows in the matrix. For a matrix containing \( m \) rows, the block outputs a vector of length \( m - 1 \).

The MATLAB timeseries format supports the following simulation and code generation modes:

- Normal
- Accelerator
- Rapid accelerator
- Model reference accelerator

See the From File block documentation for an example of creating a MAT-file with MATLAB timeseries data load with a From Workspace block.

**Timestamps**

The timestamps in the file must be monotonically nondecreasing.
**Bus Data**

The From File block supports loading nonvirtual bus signals.

The data must be in a MATLAB structure that matches the bus hierarchy. Each leaf of the structure must be a MATLAB `timeseries` object.

The structure can underspecify the bus signal, but must not overspecify the bus signal. The structure cannot have any elements that do not have corresponding signals in the bus.

The structure does not require a `timeseries` object for every element in the bus hierarchy. However, the structure must have a `timeseries` object for at least one of the signals in the bus. For signals that do not specify data, the From File block outputs the ground values.

**MAT-File Variable**

If a MAT-file contains only one variable, then the From File block uses that variable. If the MAT-file contains more than one variable:

- For Version 7.3 MAT-files, the From File block uses the variable that is first alphabetically.
- For Version 7.0 or earlier MAT-files, the From File block uses the first variable. However, for these versions, the ordering algorithm for variables is complicated. Use a MAT-file that contains only the variable with the data that you want the From File block to load.

**Related Examples**

- “Comparison of Signal Loading Techniques” on page 68-124
Load Data Using the From Workspace Block

In this section...

“Specify the Workspace Data” on page 68-280
“Use Data from a To File Block” on page 68-283
“Load Dataset Data” on page 68-283
“Specifying Variable-Size Signals” on page 68-283
“Store Data for Model Linked to Data Dictionary” on page 68-283
“Sample Time” on page 68-284
“Interpolate Missing Data Values” on page 68-284
“Specify Output After Final Data” on page 68-284
“Detect Zero Crossings” on page 68-284

To load signal data with a From Workspace block:

1 Create a workspace variable with the signal data that you want to load.
2 Add a From Workspace block to a model. Connect the From Workspace block to the block that the From Workspace block provides input to.
3 Double-click the From Workspace block and configure:
   - The workspace data to load
   - The data format for the From Workspace block output
   - How the data is loaded, including sample time, how data for missing data points are handled, and whether to use zero-crossing detection

Suppose that the workspace contains a column vector of times named T and a column vector of corresponding signal values named U. Entering the expression \([T \ U]\) for Data parameter yields the required input array. If the required array or structure exists in the workspace, enter the name of the structure or matrix in the Data parameter.

An alternative to using a From Workspace block for loading workspace data is to load data to a root-level input port. For more information, see “Root-Level Input Ports” on page 68-117.
Specify the Workspace Data

Double-click the From Workspace block, and in the Data parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB timeseries object

  Real signals of type double can be in any format that the From Workspace block supports. For complex signals and real signals of a data type other than double, use any format except Array.

- A structure of MATLAB timeseries objects

  For bus data, use a structure of MATLAB timeseries objects. Match the bus hierarchy and specify a timeseries object for each leaf signal in the bus. Set up the data the same way as you do for loading bus signals to a root-level input port. For details, see “Load Bus Data to Root-Level Input Ports” on page 68-166.

- A structure, with or without time

  For details, see “Specify Structure Data for the From Workspace Block” on page 68-280.

- A two-dimensional matrix

  You can use a matrix to specify only one-dimensional signals. The first element of each matrix row is a timestamp. The rest of each row is a scalar or vector of signal values.

Specify Structure Data for the From Workspace Block

You can use a structure for one-dimensional or multidimensional signals, with or without time values. For the structure, use this format:

- A signals.values field, which contains a column vector of signal values.
- An optional signals.dimensions array, which contains the dimensions of the signal.
- An optional time vector of doubles, which is a column vector of timestamps.

  The nth time element is the timestamp of the nth signals.values element.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For examples, see:

- “Load Data to Test a Discrete Algorithm” on page 68-145
- “Use From Workspace Block for Test Case” on page 68-149

For both discrete and continuous signals, specify a signals field, which contains an array of substructures, each of which corresponds to a model input port.

Each signals substructure must contain two fields: values and dimensions.

- The values field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the time field.

  If the inputs for a port are scalar or vector values, the values field must be an M-by-N array. If you specify a time vector, M must be the number of time points specified by the time field and N is the length of each vector value.

  If the inputs for a port are matrices (2-D arrays), the values field must be an M-by-N-by-T array. M and N are the dimensions of each matrix input and T is the number of time points. Suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of your model input ports. Then, the corresponding dimensions field of the workspace structure must equal [4 5] and the values array must have the dimensions 4-by-5-by-51.

- The dimensions field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the dimensions field must be a scalar value that specifies the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the dimensions field must be a two-element vector whose first element specifies the number of rows in the matrix and whose second element specifies the number of columns.

For continuous signals, you can specify a time field, which contains a time vector. How you specify the time values depends on the kind of signal data that you want.

For information about defining MATLAB structures, see “Create Structure Array” (MATLAB).
<table>
<thead>
<tr>
<th><strong>Signal Data</strong></th>
<th><strong>Time Data Recommendation</strong></th>
</tr>
</thead>
</table>
| Evenly spaced discrete signals | Use an expression in this form:  
\[
\text{timeVector} = \text{timeStep} \times [\text{startTime}:\text{numSteps}-1]' 
\]
The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you want minus 1. For example, to specify 50 time values at 0.2 time steps:  
\[
T1 = 0.2 \times [0:49]' 
\]

**Note**  Do *not* use an expression in this form:  
\[
\text{timeVector} = [\text{startTime}:\text{timeStep}:\text{endTime}]' 
\]
For example, do not use:  
\[
T2 = [0:0.2:10]' 
\]
This time vector form is not equivalent to the form that multiplies by time steps (\(T1\)), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the \(T2\) form can lead to unexpected simulation results.

| Unevenly spaced values | Use any valid MATLAB array expression; for example,  
\([1:5 \ 5:10]\) or \((1 \ 6 \ 10 \ 15)\).  
The From Workspace, From File, and Signal Editor blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry. |

If you load a structure that does not specify a time vector:

1. Set **Sample time (-1 for inherited)** to a value other than 0 (continuous).
2. Clear **Interpolate data**.
3. Set **Form output after final data value by** to a value other than **Extrapolation**.
Use Data from a To File Block

You can use the From Workspace block to load data exported by a To Workspace block in a previous simulation for use in a later simulation. Save the To Workspace block data in either Timeseries or Structure with Time format. Loading data that was exported to a file by a To File block using MATLAB timeseries does not require that you change the data.

If you set the To File block Save format parameter to Array, transpose the exported array data. The data saved by the To File block contains columns with consecutive timestamps, followed by the corresponding data. The transposed data contains rows with consecutive timestamps, followed by the corresponding data. To provide the required format, use MATLAB load and transpose commands with the MAT-file. To avoid transposing the data again, resave the transposed data.

Load Dataset Data

To use workspace data that is in the Simulink.SimulationData.Dataset format, extract a MATLAB timeseries object from the data set. For example, if you use signal logging with the Dataset format and use the default output variable logsout, for a single logged signal enter:

logsout.get(1).values

Specifying Variable-Size Signals

You can use a To Workspace block (with the Structure or Structure With Time format) or a root Outport block to log variable-size signals. Then use the To Workspace variable with the From Workspace block.

Alternatively, create a MATLAB structure that contains variable-size signal data. For each values field in the structure, include a valueDimensions field that specifies the runtime dimensions for the signal. For details, see Simulink Models Using Variable-Size Signals on page 73-7.

Store Data for Model Linked to Data Dictionary

When you use a From Workspace block in a model that is linked to a data dictionary, you must choose the location to store the data that the block refers to. Set the value of the
**Data** parameter based on the workspace or dictionary that contains the target data to load. For more information, see “Load Data Using the From Workspace Block” on page 68-279.

**Sample Time**

The From Workspace block **Sample time** parameter specifies the sample time to load data from a workspace. The timestamps in the workspace data must be monotonically nondecreasing. For details, see “Specify Sample Time” on page 7-3.

**Interpolate Missing Data Values**

To use linear Lagrangian interpolation to compute data values for time hits that occur between the time hits for which the workspace supplies the data, select **Interpolate data**.

For variable-size signals, clear **Interpolate data**.

**Specify Output After Final Data**

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

In the From Workspace block documentation, see the **Form output after final data value by** parameter.

**Detect Zero Crossings**

By default, the From Workspace block does not enable zero-crossing detection. Zero-crossing detection locates discontinuities, without resorting to excessively small time steps.

The **Enable zero-crossing detection** parameter applies only if the sample time is continuous (0).

68-284
If you select the **Enable zero-crossing detection** parameter, and if an input array contains multiple entries for the same time hit, Simulink detects a zero crossing at that time hit.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

State Information

In this section...

“Simulation State Information” on page 68-286
“Types of State Information” on page 68-286
“Format for State Information Saved Without Operating Point” on page 68-289
“State Information for Referenced Models” on page 68-290

Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information for calculating the output signal value for the current simulation step.

Some examples of uses of saved state information include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

Types of State Information

You can save these kinds of state information.

<table>

</tbody>
</table>

For both ModelOperatingPoint and final state logging, Simulink saves state information at one of these points:

- At the final time step
- At the execution time at which the simulation paused or stopped

For additional information about ModelOperatingPoint, see “Limitations of Saving and Restoring Operating Point” on page 26-56.

**Format for State Information Saved Without Operating Point**

If you do not use the ModelOperatingPoint for saving state information, then use Configuration Parameters > Data Import/Export > Format to specify the data format for the saved state information.

You can set Format to:
The Array option for the Configuration Parameters > Data Import/Export > Format option supports compatibility with models developed in earlier releases, when Simulink supported only the array format for saving state information.

The array format reflects the order of signals. The order of saved state information can change between simulations when you change any of the following:

- The model (even without changing the signal)
- The simulation mode
- The code generation mode

The Structure and Structure with time formats are easier to read and consistent across simulations. Also, these two formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.
- Dataset format:
  - Uses MATLAB timeseries objects to store logged data. MATLAB timeseries objects allow you to work with logged data in MATLAB without a Simulink license.
  - Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
  - Does not support logging nonvirtual bus data for code generation or rapid accelerator mode.

**State Information for Referenced Models**

When Simulink saves states in the structure or structure-with-time format, it adds an inReferencedModel subfield to the signals field of the structure. The value of this
additional subfield is true (1) if the signals field records the final state of a block that resides in the referenced model. For example:

```matlab
xout.signals(1)
```

```matlab
ans =
```
```
values: [101x1 double]
dimensions: 1
label: 'DSTATE'
blockName: [1x66 char]
inReferencedModel: 1
```

If the signals field records a referenced model state, its blockName subfield contains a compound path of a top model path and a referenced model path. The top model path is the path from the model root to the Model block that references the referenced model. The referenced model path is the path from the referenced model root to the block whose state the signals field records. The compound path uses a | character to separate the top and referenced model paths. For example:

```matlab
>> xout.signals(1).blockName
```

```matlab
ans =
```
```
sldemo_mdlref_basic/CounterA|sldemo_mdlref_counter/Previous Output
```

Save State Information

**In this section...**

| “Save State Information for Each Simulation Step” on page 68-292 |
| “Save Partial Final State Information” on page 68-292 |
| “Examine State Information Saved Without the Operating Point” on page 68-293 |
| “Save Final State Information with Operating Point” on page 68-295 |

---

### Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

1. Select the **Configuration Parameters > Data Import/Export > States** check box.
2. In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default xout variable.
3. Also in the **Data Import/Export** pane, set the **Format** parameter to **Dataset**, **Structure**, or **Structure with time**, unless you use array format for compatibility with a legacy model.

   Dataset format does not support:
   - Logging states information inside a function-call subsystem
   - Rapid accelerator simulation mode
   - Code generation
4. Click **Apply**.
5. Simulate the model.

### Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

1. Select the **Configuration Parameters > Data Import/Export > Final states** check box.
2. In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default xFinal variable.
Clear the **Save final operating point** parameter.

Set the **Format** parameter to **Dataset**, **Structure**, or **Structure with time**.

Click **Apply**.

Simulate the model.

---

**Examine State Information Saved Without the Operating Point**

If you enable the **Configuration Parameters > Data Import/Export > Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for **States** information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

**Final State Information in Dataset Format**

For example, suppose that you saved final state information in **Dataset** format, and use the default `xFinal` variable for the saved state information.

`xFinal`

```matlab
xFinal =

Simulink.SimulationData.Dataset 'xFinal' with 2 elements

<table>
<thead>
<tr>
<th>Name</th>
<th>BlockPath</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 [1x1 State]</td>
<td>CSTATE   vdp/x1</td>
</tr>
<tr>
<td>2 [1x1 State]</td>
<td>DSTATE   vdp/x2</td>
</tr>
</tbody>
</table>
```

- Use braces `{ }` to access, modify, or add elements using index.

Examine the first element of the state data set.

`xFinal{1}`

```matlab
ans =

Simulink.SimulationData.State
Package: Simulink.SimulationData
```
Properties:
  Name: 'CSTATE'
  BlockPath: [1x1 Simulink.SimulationData.BlockPath]
  Label: CSTATE
  Values: [1x1 timeseries]

**Final State Information in Structure with Time Format**

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
```

```
xFinal =
```

```
    time: 20
    signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
```

```
an =
```

```
    values: 2.0108
    dimensions: 1
    label: 'CSTATE'
    blockName: 'vdp/x1'
    stateName: ''
    inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the `x1` block is 2.018.

**Note** If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.
Save Final State Information with Operating Point

To save complete state information, save the ModelOperatingPoint object for a simulation.

1. Select the Configuration Parameters > Data Import/Export > Final states check box.
2. Also in the Data Import/Export pane, select the Save final operating point parameter.
3. In the edit box next to the Save final operating point parameter, enter a variable name for the ModelOperatingPoint object and click Apply.
4. Simulate the model.

For more information about using the operating point, see “Save and Restore Simulation Operating Point” on page 26-48.

Load State Information

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Import Initial States” on page 68-296</td>
</tr>
<tr>
<td>“Initialize a State” on page 68-296</td>
</tr>
<tr>
<td>“Initialize States in Referenced Models” on page 68-298</td>
</tr>
</tbody>
</table>

**Import Initial States**

To initialize a simulation, you can use:

- Final state information (with or without ModelOperatingPoint object) from a previous simulation
- State information that you create in MATLAB

Use Configuration Parameters > Data Import/Export parameters to import initial states.

1. Enable the Initial state parameter.
2. In the Initial state edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify Dataset, structure, or structure with time data.

**Initialize a State**

You can initialize a specific state. This example creates an initial state structure for the x2 state of the vdp model. The x1 state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the x1 state.

1. Open the model.
   ```matlab
   open_system('vdp');
   ```
2. Set the SaveFormat model argument to 'Structure'.
   ```matlab
   set_param('vdp','SaveFormat','Structure');
   ```
Obtain an initial state structure.

```matlab
states = Simulink.BlockDiagram.getInitialState('vdp');
```

Set the initial value of the signals structure element associated with \( x_2 \) to 2.

```matlab
states.signals(2).values = 2;
```

Remove the signals structure element associated with \( x_1 \).

```matlab
states.signals(1) = [];
```

Use the `states` variable for the `vdp` model. Select the initial state configuration parameter.

```matlab
set_param('vdp','LoadInitialState','on','InitialState','states');
```

Simulate the model and examine the initial values of \( x_2 \) and \( x_1 \).

```matlab
sim('vdp');
states

states =

struct with fields:

    time: 0
    signals: [1×1 struct]

states.signals

ans =

struct with fields:

    values: 2
    dimensions: 1
    label: 'CSTATE'
    blockName: 'vdp/x2'
    stateName: ''
    inReferencedModel: 0
    sampleTime: [0 0]
```

When you simulate the model, both states have the initial value of 2. The initial value of the \( x_2 \) state is assigned in the `states` structure, while the initial value of the \( x_1 \) state is assigned in its Integrator block.
Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use operating point.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

Working with Data Stores

- “Data Store Basics” on page 69-2
- “Model Global Data by Creating Data Stores” on page 69-13
- “Log Data Stores” on page 69-40
Data Store Basics

A data store is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

To share data between the instances of a reusable algorithm (for example, a subsystem in a custom library or a reusable referenced model), you can use a data store. For more information about data sharing for a reusable referenced model, see “Share Data Among Referenced Model Instances” on page 8-45.

Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only input and output ports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

Goto and From Blocks as a Signal Routing Alternative

In some cases, you may be able to use a simpler technique, Goto blocks and From blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed
anywhere. See the Goto and From block reference pages for more information about Goto/From links.

Local and Global Data Stores

You can define two types of data stores:

- A local data store is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (Simulink.Signal).

- A global data store is accessible from throughout the model hierarchy, including from referenced models. Define a global data store only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 69-13.

For information about using referenced models, see “Model References”.

Data Store Diagnostics

- “About Data Store Diagnostics” on page 69-3
- “Detecting Access Order Errors” on page 69-4
- “Detecting Multitasking Access Errors” on page 69-6
- “Detecting Duplicate Name Errors” on page 69-8
- “Data Store Diagnostics in the Model Advisor” on page 69-11

About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.
Detecting Access Order Errors

- “Data Store Diagnostics and Models Referenced in Accelerator Mode” on page 69-5
- “Data Store Diagnostics and the MATLAB Function Block” on page 69-6

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

- Detect read before write
- Detect write after read
- Detect write after write

These diagnostics appear in the Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block pane, where each can have one of the following values:

- Disable all — Disables this diagnostic for all data stores accessed by the model.
- Enable all as warnings — Displays the diagnostic as a warning in the MATLAB Command Window.
- Enable all as errors — Halts the simulation and displays the diagnostic in an error dialog box.
- Use local settings — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box Diagnostics tab. You can set each diagnostic to none, warning, or error. The value specified by an individual block takes effect only if the corresponding configuration parameter is Use local settings. See “Model Configuration Parameters: Data Validity Diagnostics” and the Data Store Memory documentation for more information.

The most conservative technique is to set all data store diagnostics to Enable all as errors in Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:
An error occurred during simulation because the data store A is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter Detect read before write to Use local settings, then setting that parameter to none in the Diagnostics pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to error in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

**Data Store Diagnostics and Models Referenced in Accelerator Mode**

For models referenced in Accelerator mode, Simulink ignores the following Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block parameters if you set them to a value other than Disable all.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

1. In the Simulink Editor, in the **Modeling** tab, click **Model Advisor**.
2. Select **By Task**.
3. Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

### Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as `A=foo(A)` might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

### Detecting Multitasking Access Errors

Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

1. A task is writing to a data store.
2. A second task interrupts the first task.
3. The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Multitask data store** to **warning** (the default) or **error**. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask data store** to **error**.
Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.
With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

The Multitask Data Store diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store’s reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

**Detecting Duplicate Name Errors**

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Duplicate data store names to warning or error. By default, the value of the diagnostic is none, suppressing duplicate name detection. The next figure shows a problem detected by setting Duplicate data store names to error:
The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

**Data Store Diagnostics in the Model Advisor**

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

“Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues”

“Check data store block sample times for modeling errors”

“Check if read/write diagnostics are enabled for data store blocks”

**Specify Initial Value for Data Store**

In general, to specify an initial value for a data store, you can use the same techniques that you use for other blocks. See “Initialize Signals and Discrete States” on page 71-54.

With most blocks, you can take advantage of scalar expansion to minimize the effort of specifying an initial value for a nonscalar signal. When you specify a scalar initial value, each element in the signal uses that scalar.

However, when you set the **Dimensions** parameter to `-1` in a Data Store Memory block (the default), you cannot use scalar expansion. Instead, you must specify an initial value that has the same dimensions as the stored signal. To take advantage of scalar expansion of the initial value, set the **Dimensions** parameter to a specific value such as `[1 2]` or `[1 myDim]` (for symbolic dimensions).

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see “Data Store Basics” on page 69-2.

**Data Store Examples**

**Overview**

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 69-25 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 69-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

**Note** In addition to the following examples, see the sldemo_mdlref_dsm model, which shows how to use global data stores to share data among referenced models.
**Local Data Store Example**

The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.

![Diagram](image)

This model uses a data store to permit subsystem A to signal that its output is invalid. If subsystem A’s output is invalid, the model uses the output of subsystem B.

**Global Data Store Example**

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.
In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace.

Create and Apply Data Stores

**Note** To use buses and arrays of buses with data stores, perform *both* the following procedure and “Setting Up a Model to Use Data Stores with Buses and Arrays of Buses” on page 69-32.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

1. Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see “Data Stores and Software Verification” on page 69-2.

2. Create data stores using the techniques described in “Data Stores with Data Store Memory Blocks” on page 69-17 or “Data Stores with Signal Objects” on page 69-20. For greater reliability, consider assigning rather than inheriting data store attributes, as described in “Specifying Data Store Memory Block Attributes” on page 69-17.
Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in “Access Data Stores with Simulink Blocks” on page 69-22.

Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in “Order Data Store Access” on page 69-25.

Apply the techniques described in “Data Store Diagnostics” on page 69-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.

If you intend to generate code for your model, see “Data Stores in Generated Code” (Simulink Coder).

To create a data store, you create a Data Store Memory block or a Simulink.Signal object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A Data Store Memory block implements a local data store. See “Data Stores with Data Store Memory Blocks” on page 69-17.
- A Simulink.Signal object can act as a local or global data store. See “Data Stores with Signal Objects” on page 69-20.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with Simulink.Signal objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with Simulink.Signal objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.
Data Stores with Data Store Memory Blocks

- “Creating the Data Store” on page 69-17
- “Specifying Data Store Memory Block Attributes” on page 69-17

Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters to define the data store's properties. The Data store name property specifies the name of the data store that the Data Store Write and Data Store Read blocks access. See Data Store Memory documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the Data store name must resolve to Simulink signal object option and using a signal object as the data store name. See “Specifying Attributes Using a Signal Object” on page 69-18 for details.

Specifying Data Store Memory Block Attributes

A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a Simulink.Signal object to specify the attributes explicitly.
Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box or the Model Data Editor Data Stores tab (in the Modeling tab, click Model Data Editor) to specify the data type and complexity of a data store. In the next figure, the block dialog box sets the Data type to uint16 and the Signal type to real.

![Block Parameters: Data Store Memory](image)

Specifying Attributes Using a Signal Object

You can use a Simulink.Signal object to specify data store attributes for a Data Store Memory block.

Tip: To establish an implicit data store, as described in “Data Stores with Signal Objects” on page 69-20, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.
The next figure shows a Data Store Memory block that specifies resolution to a Simulink.Signal object, named A. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.

Alternatively, on the Model Data Editor **Data Stores** tab (on the **Modeling** tab, click **Model Data Editor**), while editing the data store name, click the nearby action button and select **Create and Resolve**. In the Create New Data dialog box, set **Value** to Simulink.Signal.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the Simulink.Signal object A has the following inherited properties: **DataType**, **Complexity**, and **SampleTime**.

\[ A = \]
Simulink.Signal (handle)
  CoderInfo: [1x1 Simulink.CoderInfo]
  Description: ''
  DataType: 'auto'
     Min: []
     Max: []
     Unit: ''
  Dimensions: 1
  DimensionsMode: 'auto'
  Complexity: 'auto'
  SampleTime: -1
  InitialValue: 0

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 69-21.

**Use Model Data Editor to Configure Data Store Memory Blocks in a List**

Use the Data Stores tab in the Model Data Editor to configure the parameters of a Data Store Memory block. Use this technique to configure the data store without locating it in the model and to configure the data store together with other interface elements such as Inport and Outport blocks. The Model Data Editor also shows you information for Data Store Read and Data Store Write blocks in the same list.

To open the Model Data Editor, in the Modeling tab, click Model Data Editor. For information about using the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

**Data Stores with Signal Objects**

- “Creating the Data Store” on page 69-20
- “Local and Global Data Stores” on page 69-21
- “Signal Object Attributes for Data Stores” on page 69-21

**Creating the Data Store**

To use a Simulink.Signal object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the Data store name of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.
**Local and Global Data Stores**

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace or a data dictionary, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

**Signal Object Attributes for Data Stores**

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The property values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```matlab
Error = Simulink.Signal;  
Error.Description = 'Use to signal that subsystem output is invalid';  
Error.DataType = 'boolean';  
Error.Complexity = 'real';  
Error.Dimensions = 1;  
Error.SampleTime = 0.1;
```

**Attributes for Local Data Stores**

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- `DataType`
- `Complexity`
- `SampleTime`

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes
Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

**Attributes for Global Data Stores**

The following table describes the parameter requirements for global data stores.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Global Data Store Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataType</td>
<td>Must be set explicitly</td>
</tr>
<tr>
<td>Complexity</td>
<td>Must be set explicitly</td>
</tr>
<tr>
<td>Dimensions</td>
<td>Can be set or inherited</td>
</tr>
<tr>
<td>SampleTime</td>
<td>Can be set or inherited</td>
</tr>
</tbody>
</table>

**Modify Attributes of Data Store Defined by Signal Object**

You can use the Model Data Editor (in the **Modeling** tab, click **Model Data Editor**) to modify and inspect the attributes of data stores, Data Store Read, and Data Store Write blocks. On the **Data Stores** tab, to show the attributes of data stores that you define by using signal objects (such as Simulink.Signal), click the **Show/refresh additional information** button. Then, if a Data Store Read or Data Store Write block shown in the data table refers to a data store defined by a signal object, the table includes a row that corresponds to the object.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

**Access Data Stores with Simulink Blocks**

- “Writing to a Data Store” on page 69-22
- “Reading from a Data Store” on page 69-23
- “Accessing a Global Data Store” on page 69-24

**Writing to a Data Store**

To set the value of a data store at each time step:

1. Create an instance of a Data Store Write block at the level of your model that computes the value.
2. Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.
3 Connect the output of the block that computes the value to the input of the Data Store Write block.

**Reading from a Data Store**

To get the value of a data store at each time step:

1. Create an instance of a Data Store Read block at the level of your model that needs the value.
2. Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.
3. Connect the output of the Data Store Read block to the input of the block that needs the data store value.
Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word global above the data store name.
Order Data Store Access

- “About Data Store Access Order” on page 69-25
- “Ordering Access Using Function Call Subsystems” on page 69-25
- “Ordering Access Using Block Priorities” on page 69-29

About Data Store Access Order

To obtain correct results from data stores, you must control the order of execution of the data store’s reads and writes. If a data store’s read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

This section describes several strategies for explicitly controlling the order of execution of a data store’s reads and writes. See “Data Store Diagnostics” on page 69-3 for techniques you can use to detect and correct potential data store errors without running simulations.

Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:
Model Global Data by Creating Data Stores
The subsystem Before contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem After, which contains the Data Store Read.

**Ordering Access Using Block Priorities**

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.
The Model block beforeDSM has a lower priority than afterDSM, so it is guaranteed to execute first. Since beforeDSM is atomic, all of its operations, including the Data Store Write, will execute prior to afterDSM and all of its operations, including the Data Store Read.

**Data Stores with Buses and Arrays of Buses**

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals
- Frame-based signals
Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a Simulink.Signal object. Before performing the procedure, you must understand how to use data stores in a model, as described in “Create and Apply Data Stores” on page 69-15.

To use buses and arrays of buses with data stores:

1. Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see “Create and Specify Bus Objects” on page 72-58.

2. Add a data store (using a Data Store Memory block or a Simulink.Signal object) for storing the bus data.

3. Specify the bus object as the data type of the data store. For details, see “Specify a Bus Object Data Type” on page 66-48.

4. In the Model Configuration Parameters > Diagnostics > Connectivity pane, set the Mux blocks used to create bus diagnostic to error.

5. If you use a MATLAB structure for the initial value of the data store, then set Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection to Simplified. For details, see “Specify Initial Conditions for Bus Signals” on page 72-79 and “Underspecified initialization detection”.

6. (Optional) Select individual bus elements to write to or read from a data store. For details, see “Accessing Specific Bus and Matrix Elements” on page 69-32.

Accessing Specific Bus and Matrix Elements

Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the Element Assignment pane of the Data Store Write block and the Element Selection pane of the Data Store Read block. Selecting specific bus or matrix elements offers the following benefits:

- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
• Faster simulation of models with large buses and arrays of buses.

Writing Specific Elements to a Data Store

Note The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the DataStoreElements parameter to specify elements. For details, see “Specification using the command line” on page 69-37.

To assign specific bus or matrix elements to write to a data store:

1. Select the Data Store Write block and in the parameters dialog box, select the Element Assignment pane. For example, suppose you are using a bus with a data store named DSM:

   ![](image)

2. Expand all the elements in the Signals in the bus list.
3 Specify the elements that you want to write to the data store. For example:

- In the **Signals in the bus** list, click B. Then click **Select>>** to select the element B.
- To write all the elements of A2 (in the A nested bus), select A2[5x1]. Then click **Select>>**.
- To write the second element of A2 in the C2 nested bus, select the A2[5x1] element. In the **Specify element(s) to assign** text box, edit the text to say DSM.C.C2.A2(2,1).
4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.

- To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
- To remove an assigned element, click **Remove**.

5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

**Reading Specific Elements from a Data Store**

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 69-33. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:
• An **Element Selection** pane instead of an **Element Assignment** pane
• A **Selected element(s)** list instead of an **Assigned element(s)** list

**Specifying Elements to Assign or Select**

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see “Creating, Concatenating, and Expanding Matrices” (MATLAB).

**Note** To select matrix elements, you cannot use dynamic indexing with the **Element Assignment** and **Element Selection** panes of Data Store Read and Bus Assignment block pairs or Data Store Write and Bus Selector block pairs. You can, however, use a MATLAB Function block for dynamic indexing.

**Valid element specifications**

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 69-33.
**Valid Syntax**  

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSM.A.A2(:, :)</td>
<td>Selects all elements in every dimension</td>
</tr>
<tr>
<td>DSM.A.A2([1, 3, 5], 1)</td>
<td>Selects the first, third, and fifth elements</td>
</tr>
<tr>
<td>DSM.A.A2(2:5, 1)</td>
<td>Selects the second through the fifth element</td>
</tr>
</tbody>
</table>

**Invalid element specifications**

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 69-33.

<table>
<thead>
<tr>
<th>Invalid Syntax</th>
<th>Reason the Syntax Is Invalid</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSM.A.A2(:)</td>
<td>You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.</td>
</tr>
<tr>
<td>DSM.A.A2(2:end, 1)</td>
<td>You cannot use the end operator.</td>
</tr>
<tr>
<td>DSM.A.A2(idx, 1)</td>
<td>You cannot use variables to specify indices. Consider using a MATLAB Function block.</td>
</tr>
<tr>
<td>DSM.A.A2(-1, 1)</td>
<td>The dimension –1 is not within the valid dimension bounds.</td>
</tr>
</tbody>
</table>

**Specification using the command line**

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (#) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```matlab
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

**Rename Data Stores**

- “Rename Data Store Defined by Block” on page 69-38
• “Rename Data Store Defined by Signal Object” on page 69-38

**Rename Data Store Defined by Block**

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

1. In a Data Store Memory block dialog box, type a new name in the Data store name box, and click Rename All.
2. In the Rename All dialog box, confirm the new data store name in the New name field, and click OK

**Note** You cannot use Rename All to rename a data store if you create a Simulink.Signal object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding Simulink.Signal object using Model Explorer. For an example, see “Rename Data Store Defined by Signal Object” on page 69-38.

**Rename Data Store Defined by Signal Object**

This example shows how to rename a data store defined by a Simulink.Signal object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

1. Open the model sldemo_mdlref_dsm. The model creates a Simulink.Signal object ErrorCond in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
2. Open Model Explorer.
3. In the Model Hierarchy pane, select the base workspace.
4. In the Contents pane, right-click the data store ErrorCond and select Rename All.
5. In the Select a system dialog box, click the name of the model sldemo_mdlref_dsm to select it as the context for renaming the data store ErrorCond.
6. Select Search in referenced models since ErrorCond is a global data store that is used in a referenced model. Click OK.
The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

### Customized Data Store Access Functions in Generated Code

Embedded Coder provides a storage class that you can use to specify customized data store access functions in generated code. See “Apply Built-In and Customized Storage Classes to Data Elements” (Embedded Coder) and “Access Data Through Functions with Storage Class GetSet” (Embedded Coder).

<tr>
<td>“Logging Data Stores Created with a Simulink.Signal Object” on page 69-42</td>
</tr>
<tr>
<td>“Accessing Data Store Logging Data” on page 69-42</td>
</tr>
</tbody>
</table>

Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging – view the order of all data store writes
- Confirming a model modification – use the logged data to establish a baseline for comparing results to identify the impact of a model modification

For an example of logging a global data store, see “Using Data Stores Across Multiple Models”.

Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.
Data Store Logging Limitations

Limitations for using data store logging in a model are:

• To log data for a data store memory:
  • Simulate the top-level model in Normal mode.
  • For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  • Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
• You cannot log data stores that use custom data types, including buses.

Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

1 In the model, open the Model Data Editor. In the Modeling tab, click Model Data Editor.
2 On the Data Stores tab, set the Change view drop-down list to Instrumentation.
3 In the data table, for the target data store, select the check box in the Log Data column.

If the target data store does not appear in the table, click the Change scope button to display data stores that are defined in subsystems below your current system.

4 Optionally, to configure additional logging characteristics such as the maximum number of data points to log, open the Property Inspector (in the Modeling tab, under Design, click Property Inspector). Use the Property Inspector to open the block dialog box and inspect the Logging tab.

5 Enable data store logging with the Model Configuration Parameters > Data Import/Export > Data stores parameter.
6 Simulate the model.

Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.
Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a Simulink.Signal object. See “Data Stores with Signal Objects” on page 69-20 for details.

To log a data store that you create with a Simulink.Signal object:

1. Create a Simulink.Signal object in a workspace that is visible to every component that needs to access the data store, as described in “Data Stores with Signal Objects” on page 69-20.

2. Use the name of the Simulink.Signal object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.

3. From the MATLAB command line, set **DataLogging** (which is a property of the LoggingInfo property of Simulink.Signal) to 1.

   For example, if you use a Simulink.Signal object called **DataStoreSignalObject** to create a data store, use the following command:

   ```matlab
   DataStoreSignalObject.LoggingInfo.DataLogging = 1
   ```

4. Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the LoggingInfo property of the Simulink.Signal object: **Decimation**, **LimitDataPoints**, and **MaxPoints**.

5. Enable data store logging with the Model Configuration Parameters > Data Import/Export > Data stores parameter.

6. Simulate the model.

Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:
### Class

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simulink.SimulationData.BlockPath</td>
<td>Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy</td>
</tr>
<tr>
<td>Simulink.SimulationData.Dataset</td>
<td>Stores logged data elements and provides searching capabilities; use to group Simulink.SimulationData.Element objects in a single object</td>
</tr>
<tr>
<td>Simulink.SimulationData.DataStoreMemory</td>
<td>Stores logging information from a data store during simulation</td>
</tr>
</tbody>
</table>

You can also convert data logged in formats other than Dataset. For more information, see “Dataset Conversion for Logged Data” on page 68-22.

### Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The `sldemo_mdlref_dsm` model illustrates approaches for viewing data store logging data.

### Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```matlab
dsmout.getElement('RefSignalVal')
```

```matlab
ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData
Properties:
    Name: 'RefSignalVal'
    Blockpath: [1x1 Simulink.SimulationData.BlockPath]
    Scope: 'local'
    DSMWriterBlockPaths: [1x2 Simulink.SimulationData.BlockPath]
    DSMWriters: [101x1 uint32]
    Values: [101x1 timeseries]
```
To access an element by index, use the

What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation that enter and exit Inport and Outport blocks.

Dictionary Capabilities

<table>

**Sections of a Dictionary**

A Simulink data dictionary consists of four sections:

- **Design Data**: Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

  This section can store only certain classes and data types. See “Valid Design Data Classes” on page 70-11 for more information.

- **Configurations**: Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

  When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “About Configuration References” on page 14-29.
This section can also store variant configuration objects, which belong to the Simulink.VariantConfigurationData class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

**Note** If you load a configuration set from the data dictionary that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

- **Embedded Coder Dictionary**: Contains code generation definitions for use with Embedded Coder. To inspect and modify code definitions stored in a data dictionary, use the Embedded Coder Dictionary not the Model Explorer.
- **Other Data**: Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 70-12 for more information.

### Dictionary Usage for Models Created with Different Versions of Simulink

Simulink provides version handling for data dictionaries. When these events occur, Simulink synchronizes data in a dictionary for use with a model regardless of the Simulink version used to create the model:

- You link a model to a data dictionary that was saved in a previous version of Simulink—for example, you link a model that you develop in R2018b with a dictionary saved in R2018a.
- You open a model that is linked to a data dictionary and was saved in a previous version of Simulink—for example, you developed a model that uses a data dictionary in R2018a and you open that model in R2018b to continue development.

You can view the Simulink version in which a data dictionary is saved in the **Details** pane of the MATLAB editor. You also have the option to export (save) a data dictionary for use with models created using a different version of Simulink. To use a data dictionary you saved in a newer Simulink version in an older Simulink version, you need to export it first.

To export a data dictionary:
1. In the **Current Folder** pane of the MATLAB Command Window, navigate to the location of the data dictionary.

2. Double-click the name of the dictionary.

3. In the Model Explorer, right-click the name of the data dictionary. If you have made changes to the dictionary, in the context menu, select **Save Changes**.

4. Right-click the name of the data dictionary. In the context menu, select **Export to Previous Version**.

5. In the Export Data Dictionary to Previous Version dialog box, specify the previous version of Simulink in which you want to save the model. Specify the folder into which you want Simulink to place the new version of the dictionary. The folder that you specify cannot contain dictionaries that are part of the existing dictionary hierarchy. Then, click **OK**.

6. Verify that the new version of the data dictionary exists in the folder that you specified.

**Manage and Edit Entries in a Dictionary**

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Create, Edit, and Manage Workspace Variables” on page 66-143 and “View and Revert Changes to Dictionary Data” on page 70-28.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 70-48.
Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 70-35 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 70-38.

Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

Migrate Single Model to Use Dictionary

This example shows how to link a single standalone model to a single data dictionary.

**Note** Simulink does not import simulation data such as Timeseries objects into the data dictionary.

1. Open the f14 model, which loads design data into the base workspace.
2. Save a copy of the model to your current folder. Open the copy.
3. In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
4. In the **Model Properties** dialog box, click **New** to create a data dictionary.

![Model Properties dialog box](image)

5. Name the data dictionary, save it, and click **Apply**.
6. Click **Migrate data**.
7. Click **Migrate** in response to the message about copying referenced variables.
8  (Optional) Clear **Enable access to base workspace**.
9  Click **OK**.
10  To open the dictionary, in the Simulink Editor, click the model data badge in the bottom left corner, then click the **Data Dictionary** link. To inspect the contents of the dictionary, in the Model Explorer **Model Hierarchy** pane, select a node under the dictionary node.

**Migrate Model Reference Hierarchy to Use Dictionary**

This example shows how to link a parent model and all its referenced models to a single data dictionary.

1. Open the example model `sldemo_mdlref_datamngt`, which references the model `sldemo_mdlref_counter_datamngt`.
2. Save copies of the models to your current folder.
3. Open the top model, `sldemo_mdlref_datamngt`.
4. In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
5. In the **Model Properties** dialog box, click **New** to create a data dictionary.
6. Name the data dictionary, save it, and click **Apply**.
7. Click **Change all models** in response to the message about linking referenced models that do not already use a dictionary.
8. Click **Migrate data**.
Click Migrate in response to the message about copying referenced variables.

(Optional) Clear Enable access to base workspace.

Click OK.

Considerations before Migrating to Data Dictionary

After you link a model to a data dictionary, you can choose to migrate data from the base workspace into the dictionary. If you choose to migrate data, take these considerations into account.

Check for Data-Loading Callbacks

You can use model callbacks such as the PreLoadFcn callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file myData.mat.

```matlab
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Simulink Manifest Tools to find data-loading callbacks. See “Analyze Model Dependencies” on page 19-23.

Check Scripts

A new model has access to the base workspace by default, but does not lose access when it is linked to a data dictionary. Scripts must be written with the assumption that the model can have access to the base workspace, the data dictionary, or both.

If you make explicit references to the base workspace by using the handle base in your scripts, consider changing these references.

Consider this example. Here, the script searches the base workspace for variable sensor and sets the parameter enable depending on the value of sensor.noiseEnable.

```matlab
if evalin('base','sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```
When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```matlab
if Simulink.data.evalinGlobal(myExampleModel,...
    'sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

The `Simulink.data.evalinGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

**Check Tunable Parameters for Code Generation**

- If your model is linked to a data dictionary, and the model does not have access to the base workspace (see “Continue to Use Shared Data in the Base Workspace” on page 70-13), Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.

- If you use the Simulink interface to migrate a model to use a data dictionary, and you choose to migrate base workspace data, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.

- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.

- If you set the `DataDictionary` property of a model from the command line, you can convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

**Data Used by Model References**

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.
The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries.

Duplicate data definitions can exist in a model reference hierarchy under these conditions:

- Each model in the hierarchy can see only one definition.
- Definitions must be the same across models in the hierarchy.

For more information, see “Determine Where to Store Variables and Objects for Simulink Models” on page 66-134.

**Valid Design Data Classes**

You can import, store, or create MATLAB variables that use Simulink supported data types, such as boolean and int32, and structures in the **Design Data** section of a Simulink data dictionary. You can also use objects of these classes and objects of most classes that subclass these classes:

- Simulink.AliasType
- Simulink.Bus
- Simulink.NumericType
- Simulink.Parameter
- Simulink.LookupTable
- Simulink.Breakpoint
- Simulink.Signal
- Simulink.Variant
- Simulink.data.dictionary.EnumTypeDefinition
- embedded.fi
- embedded.fimath
- numlti

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary:

- Simulink.ConfigSet
• Simulink.VariantConfigurationData

Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the Other Data section of a Simulink data dictionary, except for the following:

• Arrays of objects created from built-in or custom classes
• Custom classes that have a property with any of these names:
  • LastModified
  • LastModifiedBy
  • DataSource
  • Status
  • Variant

Migration With From Workspace Blocks

If a model contains a From Workspace block that refers to a variable in the base workspace, you can migrate the model to a data dictionary. However, the migration process takes different actions depending on the nature of the variable that the block refers to:

• If the value of the variable is not a timeseries object, the migration process imports the variable to the Design Data section of the data dictionary. The block can still refer to the variable.
  • If the value of the variable is a timeseries object (which a data dictionary cannot store), the migration process does not import the variable. Then, when you try to update the diagram or simulate the model, the From Workspace block cannot find the variable and issues an error. In such a case, you can configure the block to refer to the base workspace variable by using the evalin function. See “Use with Data Dictionary”.

Data Dictionary Limitations

• Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
• You cannot import certain kinds of design data such as meta class objects and timeseries objects into the Design Data section of a data dictionary.
Simulink does not allow implicit signal resolution for a model linked to a data dictionary. To use a data dictionary, set the model configuration parameter **Signal resolution** to Explicit only or None.

If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

In other words, migrate a model to use a data dictionary before protecting it.

**Continue to Use Shared Data in the Base Workspace**

You can continue to store shared data in the base workspace and store model-specific data in the data dictionary by:

- Enabling access to the base workspace for the model.
- Enabling access to the base workspace from a data dictionary.

To enable access to the base workspace for a model, in the Model Properties dialog box, on the **Data** tab, select **Enable access to base workspace**. For a new model, this check box is selected by default. If the model is not linked to a data dictionary, this option must be selected.

You can also allow access to the base workspace from a data dictionary. For an existing dictionary, in the Model Explorer, select **Enable access to base workspace**.

When you allow base workspace access from a data dictionary, these limitations and ramifications apply:

- In general, you cannot interact with base workspace data through the dictionary.

  - When you inspect the contents of the dictionary in the Model Explorer, you cannot see base workspace data. To interact with base workspace data, in the **Model Hierarchy** pane, select the **Base Workspace** node.

  - With the programmatic interface of the data dictionary (see “Store Data in Dictionary Programmatically” on page 70-48), to interact with base workspace data, you can use only these functions with a **Simulink.data.dictionary.Section** object:

    - assignin
• exist
• evalin

Consider using functions such as Simulink.data.assigninGlobal instead. See “Transition to Using Data Dictionary” on page 70-52.

• Change-tracking features, such as the ability to view and revert changes to dictionary entries (see “View and Revert Changes to Dictionary Entries” on page 70-28), do not apply to base workspace data.

• When you export data from a dictionary (see “Import and Export Dictionary Data” on page 70-21), Simulink ignores base workspace data.

• Simulink treats the base workspace and the dictionary as a single namespace. However you can define two variables with the same name, one in the base workspace and one in the dictionary. In this case, the variables must be identical and the variable in the dictionary is used.

**Migrate Complicated Model Hierarchy with Shared Data**

For examples, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 70-38.

• “Analyze Model Dependencies” on page 19-23
Enumerations in Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. Enumeration classes defined in MATLAB by the data dictionary are owned by that dictionary and cannot be cleared by using `Simulink.clearIntEnumType`. When you close a data dictionary, the dictionary clears the enumeration classes that it owns. If an instance of an enumeration class exists when you close the dictionary, that enumeration class is not cleared and you become the owner of the class. As the owner of the class, you can then find or clear the class by using `Simulink.findIntEnumType` and `Simulink.clearIntEnumType`. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

**Import Design Data**

1. Open a model that uses enumerated types for design data or for blocks in the model.
2. In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
3. In the **Model Properties** dialog box, click **New** to create a data dictionary.
4. Name the data dictionary, save it, and click **Apply**.
5. Click **Migrate data**.
6. Click **Migrate** in response to the message about copying referenced variables.
7. Simulink reports the enumerated types that were not imported into the data dictionary.
Click OK.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

**Import Enumerated Types**

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary, Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

1. At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

   ```matlab
   % Find all variables and enumerated types used in model blocks
   usedTypesVars = Simulink.findVars(' EnumsReporting', 'IncludeEnumTypes', true);
   % Here, EnumsReporting is the name of the model and
   % usedTypesVars is an array of Simulink.VariableUsage objects
   
   % Find indices of enumerated types that are defined by MATLAB files or P-files
   enumTypesFile = strcmp({usedTypesVars.SourceType}, 'MATLAB file');
   
   % Find indices of enumerated types that are defined using the function
   % Simulink.defineIntEnumType
   enumTypesDynamic = strcmp({usedTypesVars.SourceType}, 'dynamic class');
   
   % In one array, represent indices of both kinds of enumerated types
   enumTypesIndex = enumTypesFile | enumTypesDynamic;
   ```
% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'

enumTypeNames =
    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'

2 Open the data dictionary, and represent it with a Simulink.data.Dictionary object.

ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')

ddConnection =

    Dictionary with properties:

        DataSources: {0x1 cell}
    HasUnsavedChanges: 0
        NumberOfEntries: 3

3 Use the importEnumTypes method to import the enumerated types that are used by blocks in the model. The method saves changes made to the target dictionary, so before you use the method, confirm that unsaved changes are acceptable.

[successfulMigrations, unsuccessfulMigrations] = ... importEnumTypes(ddConnection,enumTypeNames)

successfulMigrations =

1x6 struct array with fields:

    className
    renamedFiles

unsuccessfulMigrations =

1x2 struct array with fields:

    className
    reasons
When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

4 Open the dictionary to view the migrated enumerated types.

![Model Explorer](image)

**Manipulate Enumerations in Data Dictionary**

These examples show how to operate on existing enumerations in a data dictionary.

- “Rename Enumerated Type Definition” on page 70-19
- “Rename Enumeration Members” on page 70-19
- “Delete Enumeration Members” on page 70-19
• “Change Underlying Value of Enumeration Member” on page 70-19

**Rename Enumerated Type Definition**

1. In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
2. Find enumeration objects used by your model that are derived from the type with the old name.
3. Replace these objects with those derived from the renamed type.
4. Delete the type with the old name.

**Rename Enumeration Members**

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members, change these references to match the renamed member.

**Delete Enumeration Members**

1. Find references in your model to an enumeration member you want to delete.
2. Replace these references with an alternate member.
3. Delete the original member from the enumeration.

**Change Underlying Value of Enumeration Member**

You can change the values of enumeration members when you represent these values as MATLAB variables or by using Value field of Simulink.Parameter objects.

1. Find references in your model to an enumeration member whose value you want to change.
2. Make a note of these references.
3. Change the value of the enumeration member.
4. Manually update references to the enumeration member in your model.

Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

1 In the Simulink Editor, in the Modeling tab, click Model Explorer to open the Model Explorer.
2 Select File > Open. Then browse to an existing dictionary.
3 In the Model Hierarchy pane, right-click the Design Data section of the dictionary and select Import from File. Then browse to and select the MAT-file or MATLAB file that contains the data to import.
Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.
If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

**Import Other Data from File**

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

1. In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
2. Select **File > Open**. Then browse to an existing dictionary.
3. In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.
4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.
Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.
If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

1. In the Simulink Editor, in the Modeling tab, click Model Explorer to open the Model Explorer.
2. Open a data dictionary using File > Open Data Dictionary.
3. In the Model Hierarchy pane, expand the dictionary node and select Design Data > Export to File. Then save the design data to a MAT-file or MATLAB script.
The dictionary does not export enumerated data types (which are stored as `Simulink.data.dictionary.EnumTypeDefinition` objects). To transfer or copy an enumerated type from one dictionary to another, use the Model Explorer to cut or copy and paste the object.

**See Also**

**Related Examples**

- “View and Revert Changes to Dictionary Data” on page 70-28
- “Migrate Models to Use Simulink Data Dictionary” on page 70-7
View and Revert Changes to Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

1 Open the sldemo_fuelsys_dd_controller model.
2 Open the data dictionary linked to this model. Click the model data badge in the bottom left corner of the model, then click the Data Dictionary link.
3 In the Model Explorer Model Hierarchy pane, under the dictionary node, select the Design Data node.
4 In the Contents pane, change st_range to 0.0002 and zero_thresh to 200.

The Status column of these entries changes to Mod, indicating that they have been modified.
5 Click the heading of the Status column to sort the entries. Then, select the modified entries, which are indicated by the Mod status.
6 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.
In the **Contents** pane of the Model Explorer, right-click `zero_threshold` and select **Revert to Saved**.
Simulink reverts zero_thresh to its value at the time of the last save action.

8 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the Home tab, in the File section, click Compare.

9 Select the dictionaries to compare and merge.

10 In the comparison report, select the merge direction for each dictionary entry.
View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.
If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

```matlab
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

2 Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.

3 In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.

4 In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from 3 to 4.

5 Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

The entry reverts to the definition from the last saved version of the dictionary.

6 The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.
The table **Dictionary references in sldemo_fuelsys_dd.sldd** shows that the script removed the reference to the dictionary sldemo_fuelsys_dd_plant. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to sldemo_fuelsys_dd.

Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

Open dictionary for partitioning

1. Open the Model Explorer. In the Simulink Editor, in the Modeling tab, click Model Explorer.
2. Select File > Open.

Browse and locate your dictionary.

Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

Name the reference dictionary and save it.

Both dictionaries appear as nodes in the Model Hierarchy pane.

2. In the Model Hierarchy pane, select the dictionary that serves as the parent.
3. In the dialog box pane, in the Referenced Dictionaries section, click Add Reference. Browse to the location of the reference dictionary and add it as a reference.
Move entries into reference dictionary

1. In the Model Hierarchy pane, select the Design Data node of the parent dictionary.

2. In the Contents pane, select the entries you want to move to the reference dictionary.

3. For one of the selected entries, set DataSource to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

   To make the DataSource column visible, click Show Details in the Contents pane. In the text box, enter DataSource, and add DataSource to the list of displayed columns.

Organize display of entries

1. Click the name of the DataSource column to sort the entries by the dictionaries that define them.
2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

- “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 70-38
- “What Is a Data Dictionary?” on page 70-2
Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 70-2.

To take this component-based approach to data management, create a shared dictionary that contains common data and a separate dictionary for each component that contains the data needed by that component.

Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component in the system has a dictionary, and dictionary references allow the components to share data.

Explore Example Model Hierarchy

1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
2 Copy these files to a writable folder:
   - ProjectData_Contr.mat
   - ProjectData_ContrSub1.mat
   - ProjectData_ContrSub2.mat
   - ProjectData_ContrSubs.mat
   - ProjectData_Plant.mat
   - ProjectData_System.mat
   - ex_SystemModel
   - ex_PlantComp_Lvl1
   - ex_PlantComp_Lvl2
   - ex_ContrComp
   - ex_ContrComp_Sub1_Lvl1
3 Load the MAT-files to create design data in the base workspace.

4 Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.

5 On the **Modeling** tab, select **Compare > Dependencies > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component. The controller component contains two subcomponents, each of which consist of two models.

6 In the model, update the diagram. Each bus signal in the model uses a `Simulink.Bus` object as a data type. The objects, `SensorBus` and `CtrlBus`, are in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` use the bus objects for root-level inputs and outputs, which means the plant and controller components share the objects.

7 In the base workspace, double-click the `Simulink.NumericType` object named `FloatType`. Signals, parameters, and other data items in the controller component use this shared data type.
8 In the Model Explorer **Model Hierarchy** pane, expand the node `ex_SystemModel`. Click the Configurations node. In the **Contents** pane, the node Reference to `SimConfigSet` appears. `SimConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for simulation, all of the models in the hierarchy refer to `SimConfigSet`.

9 Right-click the node Controller (ex_ContrComp) and select **Open**.

10 In the Model Explorer **Model Hierarchy** pane, expand the new node `ex_ContrComp`. Click the Configurations node.

In the **Contents** pane, the node Reference to `CodeGenConfigSet` appears. `CodeGenConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for code generation, the models in the controller component refer to `CodeGenConfigSet`. The models in the plant component do not use `CodeGenConfigSet`.

11 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the Select a system dialog box, select `ex_SystemModel` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables `coeff`, `init`, `mu`, and `rho`.

The table shows the models that share each variable in the base workspace.

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Models Using the Variable</th>
<th>Scope of Sharing</th>
</tr>
</thead>
<tbody>
<tr>
<td>CtrlBus</td>
<td>Top-level models in the plant and controller components</td>
<td>Shared globally by entire system</td>
</tr>
<tr>
<td>SensorBus</td>
<td>Top-level models in the plant and controller components</td>
<td>Shared globally by entire system</td>
</tr>
<tr>
<td>SimConfigSet</td>
<td>All models in the hierarchy</td>
<td>Shared globally by entire system</td>
</tr>
<tr>
<td>Variable Name</td>
<td>Models Using the Variable</td>
<td>Scope of Sharing</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>rho</td>
<td>ex_PlantComp_Lvl2, ex_ContrComp_Sub1_Lvl2, and ex_ContrComp_Sub2_Lvl2</td>
<td>Shared globally by entire system</td>
</tr>
<tr>
<td>mu</td>
<td>ex_PlantComp_Lvl1 and ex_PlantComp_Lvl2</td>
<td>Shared by models in the plant component</td>
</tr>
<tr>

<td>All models in the controller component</td>
<td>Shared by controller component and subcomponents</td>
</tr>
<tr>
<td>CodeGenConfigSet</td>
<td>All models in the controller component</td>
<td>Shared by controller component and subcomponents</td>
</tr>
<tr>
<td>init</td>
<td>ex_ContrComp_Sub1_Lvl2 and ex_ContrComp_Sub2_Lvl1</td>
<td>Shared by controller subcomponents</td>
</tr>
<tr>
<td>diff</td>
<td>ex_ContrComp_Sub1_Lvl1 and ex_ContrComp_Sub1_Lvl2</td>
<td>Shared by models in the first controller subcomponent</td>
</tr>
<tr>
<td>coeff</td>
<td>ex_ContrComp_Sub2_Lvl1 and ex_ContrComp_Sub2_Lvl2</td>
<td>Shared by models in the second controller subcomponent</td>
</tr>
</tbody>
</table>

Suppose that separate teams of developers maintain the plant component and the controller components. You can use data dictionaries to store and scope the shared design data.

**Create Shared Global Dictionary**

Create a shared global data dictionary that contains the data shared globally by the entire system.

1. In the Model Explorer, select **File > New > Data Dictionary**.
2 Set the new dictionary name to GlobalShare and click Save.
3 In the Model Hierarchy pane, right-click the GlobalShare node and select Show Empty Sections.
4 In the Model Hierarchy pane, select Base Workspace. In the Contents pane, select the design data that are shared globally by the entire system: CtrlBus, SensorBus, and rho.
5 Right-click and select Copy.
6 In the Model Hierarchy pane, right-click the Design Data node under GlobalShare and select Paste.
7 Similarly, copy SimConfigSet from the Base Workspace and copy to the Configurations node under GlobalShare.

Create Dictionary for Plant Component

Create a data dictionary for data shared by models in the Plant component. Add a reference from this dictionary to the shared global dictionary.

1 In the Model Explorer, select File > New > Data Dictionary.
2 Set the new dictionary name to Plant and click Save.
3 In the Model Hierarchy pane, select the node Plant. In the Dialog pane, under Referenced Dictionaries, click Add.
4 Double-click GlobalShare.sldd.
5 In the Model Hierarchy pane, right-click the node Plant and select Save Changes.

Link Plant Component to Dictionary and Migrate Data

Link the Plant component to its component dictionary then migrate data shared by models in the Plant component from the base workspace to the dictionary.

1 Open the model ex_PlantComp_LVL1.
2 In the model, update the diagram.
3 If the Diagnostic View displays an error for multiple inconsistent definitions of SimConfigSet, select Delete others next to the GlobalShare instance. This fix keeps the definition in the GlobalShare dictionary and removes other definitions that can be seen by the model.
4 In the Modeling tab, under Design, click Link to Data Dictionary.
5 In the dialog box, click Browse.
6 Double-click Plant.sldd.
7 In the Model Properties dialog box, click Apply. Click Change all models in response to the message about linking referenced models.
8 In the Model Properties dialog box, click Migrate data.
9 In the Migrate Data dialog box, select Include data from referenced models and then click Migrate.
10 (Optional) In the Model Properties dialog box, clear Enable access to base workspace.
11 Remove the previous method for loading model data. In the Model Properties dialog box, on the Callbacks tab, clear the PreLoadFcn for the model.
12 Click OK.

Create Dictionary for Controller Component

Create a data dictionary that contains the data shared by models in the controller component. This dictionary can also reference the shared global dictionary.

1 In the Model Explorer, select File > New > Data Dictionary.
2 Set the new dictionary name to Controller and click Save.
3 In the Model Hierarchy pane, select the node Controller. In the Dialog pane, under Referenced Dictionaries, click Add.
4 Double-click GlobalShare.sldd.
5 In the Model Hierarchy pane, right-click the node Controller and select Save Changes.

Link Controller Component to Dictionary and Migrate Data

Link the Controller component to its component dictionary then migrate data shared by models in the Controller component from the base workspace to the dictionary.

1 Open the model ex_CtrComp.
2 If the Diagnostic View displays an error for multiple inconsistent definitions of SimConfigSet, select Delete others next to the GlobalShare instance. This fix keeps the definition in the GlobalShare dictionary and removes other definitions that can be seen by the model.
3 In the Modeling tab, under Design, click Link to Data Dictionary.
4 In the dialog box, click Browse.
5  Double-click Controller.sldd.
6  In the **Model Properties** dialog box, click **Apply**. Click **Change all models** in response to the message about linking referenced models.
7  In the **Model Properties** dialog box, click **Migrate data**.
8  In the Migrate Data dialog box, select **Include data from referenced models** and then click **Migrate**.
9  (Optional) In the **Model Properties** dialog box, clear **Enable access to base workspace**.
10 Remove the previous method for loading model data. In the **Model Properties** dialog box, on the **Callbacks** tab, clear the **PreLoadFcn** for the model.
11 Click **OK**.

**Link System to Global Dictionary**

Finally, link the top model to the global dictionary.

1  Open the model ex_SystemModel.
2  In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
3  In the dialog box, click **Browse**.
4  Double-click GlobalShare.sldd.
5  In the **Model Properties** dialog box, click **OK**. Click **Change this model only** in response to the message about linking referenced models.

**Inspect Data Storage**

In the Model Explorer **Model Hierarchy** pane, select the dictionary node Plant. In the **Contents** pane, to view the contents of Plant.sldd, click **Show Current System and Below**. The contents of the Design Data and Configurations sections appear.
Similarly, view the contents of Controller.sldd.

The **DataSource** column shows the variables and objects that each dictionary stores.

All of the globally shared variables, such as CtrlBus and SensorBus, reside in GlobalShare.sldd. The variable init, which both of the controller subcomponents share, resides in Controller.sldd.

If the development team assigned to the controller component must make changes to the globally shared variables, they access the GlobalShare dictionary file. Similarly, if the team must make changes to the variable init, they must access the Controller dictionary file.
Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a project.

1. Open your saved model `ex_SystemModel`. On the Simulation tab, select New > Project > New Project from this Model.
2. Specify a name for the project in the Project name box. Click Create.
3. In the project, click Dependency Analysis. Click Analyze.

The system model, `ex_SystemModel`, is linked to the dictionary `GlobalShare.sldd`. The plant component and the controller component are each linked to a separate dictionary. To access the shared data, the component dictionaries reference the dictionary `GlobalShare.sldd`. These dictionaries form a reference hierarchy.

Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, on the Modeling tab, select Find > Find Ref Variables. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select Find Where Used to display all of the models that use the variable. For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 66-149.
At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

Store Data in Dictionary Programmatically

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace (see “What Is a Data Dictionary?” on page 70-2). To interact with the data in a dictionary programmatically:

1. Create a Simulink.data.Dictionary object that represents the target dictionary.
2. Create a Simulink.data.dictionary.Section object that represents the target section, for example the Design Data section. Use the object to interact with the entries stored in the section and to add entries.
3. Optionally, create Simulink.data.dictionary.Entry objects that each represent an entry in the target section. Use these objects to interact with individual entries in the target section.

To programmatically access variables for the purpose of sweeping block parameter values, consider using Simulink.SimulationInput objects instead of modifying the variables through the programmatic interface of the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 38-52.

To programmatically interact with the Embedded Coder section of a data dictionary, see “Configure Code Definitions Programmatically” (Embedded Coder).
Add Entry to Design Data Section of Data Dictionary

1  Represent the Design Data section of the data dictionary
   myDictionary_ex_API.sldd with a Simulink.data.dictionary.Section
   object named dDataSectObj.

   myDictionaryObj = ...
   Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
   dDataSectObj = getSection(myDictionaryObj,'Design Data');

2  Add an entry to the Design Data section of myDictionary_ex_API.sldd an entry
   myNewEntry with value 237.

   addEntry(dDataSectObj,'myNewEntry',237)

Increment Value of Data Dictionary Entry

1  Represent the data dictionary entry fuelFlow with a
   Simulink.data.dictionary.Entry object named fuelFlowObj. fuelFlow is
   defined in the data dictionary myDictionary_ex_API.sldd.

   myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
   dDataSectObj = getSection(myDictionaryObj,'Design Data');
   fuelFlowObj = getEntry(dDataSectObj,'fuelFlow');

2  Store the value of the target entry in a temporary variable. Increment the value of the
   temporary variable by one.

   temp = getValue(fuelFlowObj);
   temp = temp+1;

3  Set the value of the target entry by using the temporary variable.

   setValue(fuelFlowObj,temp)

Data Dictionary Management

Use Simulink.data.Dictionary objects to interact with entire data dictionaries.
<table>

### Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use Simulink.data.dictionary.Section objects to interact with data dictionary sections.

<table>
<thead>
<tr>
<th><strong>Goal</strong></th>
<th><strong>Use</strong></th>
</tr>
</thead>

</tbody>
</table>
Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use Simulink.data.dictionary.Entry objects to manipulate data dictionary entries.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Represent data dictionary entry with Entry object</td>
<td>Simulink.data.dictionary.Section.getEntry method</td>

<td>Simulink.data.dictionary.Entry.getValue method</td>
</tr>
<tr>
<td>Delete data dictionary entry</td>
<td>Simulink.data.dictionary.Entry.deleteEntry method</td>
</tr>
<tr>
<td>Store enumerated type definition in dictionary</td>
<td>Simulink.data.dictionary.EnumTypeDefinition class</td>
</tr>
</tbody>
</table>

Transition to Using Data Dictionary

Using a data dictionary can complicate programmatic interaction with model data. If you link a model to a dictionary:
You can no longer interact with the model data by using simple commands at the command prompt. Instead, you must use the programmatic interface of the dictionary (Simulink.data.Dictionary).

When you select the dictionary property **Enable access to base workspace** (see “Continue to Use Shared Data in the Base Workspace” on page 70-13), depending on the storage location of the target data, you must use either simple commands or the programmatic interface.

To help transition from using the base workspace to using data dictionaries, consider using these functions. The functions operate on model data regardless of the storage location of the data.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change value of data dictionary entry or workspace variable in context of Simulink model</td>
<td>Simulink.data.assigninGlobal</td>
</tr>
<tr>
<td>Evaluate MATLAB expression in context of Simulink model</td>
<td>Simulink.data.evalinGlobal</td>
</tr>
<tr>
<td>Determine existence of data dictionary entry or workspace variable in context of Simulink model</td>
<td>Simulink.data.existsInGlobal</td>
</tr>
</tbody>
</table>

**Programmatically Migrate Single Model to Use Dictionary**

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```matlab
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.sldd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base workspace
Simulink.data.importInGlobal(dictionaryObj, varNames);
```
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);

**Note**  This code does not migrate the definitions of enumerated data types that were used
to define model variables. If you import model variables of enumerated data types to a
data dictionary but do not migrate the enumerated type definitions, the dictionary is less
portable and might not function properly if used by someone else. To migrate enumerated
data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page
70-15.

## Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from
an external file to a data dictionary without creating or altering variables in the base
workspace.

1. Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook.
   Use the upper-left corner of the sheet to provide names for the two breakpoints and
   for the table. Use column B and row 2 to store the two breakpoints, and use the rest
   of the sheet to store the table. For example, your lookup table might look like this:

   ![lookup_table](image)

   Save the workbook in your current folder as my2DLUT.xlsx.

2. Copy this custom function definition into a MATLAB file, and save the file in your
   current folder as importLUTToDD.m.

   ```matlab
   function importLUTToDD(workbookFile,dictionaryName)
       % IMPORTLUTTODD(workbookFile,dictionaryName) imports data for a
       % two-dimensional lookup table from a workbook directly into a data
       % dictionary. The two-dimensional lookup table in the workbook can be
       % any size but must follow a standard format.
   ```
% Read in the entire first sheet of the workbook.
[data,names,~] = xlsread(workbookFile,1,'');

% Divide the raw imported data into the breakpoints, the table, and their
% names.
% Assume breakpoint 1 is in the first column and breakpoint 2 is in the
% first row.
% Assume cells A2, B1, and B2 define the breakpoint names and table name.
bkpt1 = data(2:end,1);
bkpt2 = data(1,2:end);
table = data(2:end,2:end);
bkpt1Name = names{2,1};
bkpt2Name = names{1,2};
tableName = names{2,2};

% Prepare to import to the Design Data section of the target data
% dictionary.
myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
dDataSectObj = getSection(myDictionaryObj,'Design Data');

% Create entries in the dictionary to store the imported breakpoints and
% table. Name the entries using the breakpoint and table names imported
% from the workbook.
addEntry(dDataSectObj,bkpt1Name,bkpt1);
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)

3 At the MATLAB command prompt, create a data dictionary to store the lookup table data.
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');

4 Call the custom function to import your lookup table to the new data dictionary.
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')

5 Open the data dictionary in Model Explorer.
show(myDictionaryObj)

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.
Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

% Define the names of a parent data dictionary and two reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD,'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD,'partDD_Data_ex_API.m');

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries to the parent dictionary
addDataSource(parentDD,typesDDName);
addDataSource(parentDD,paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to a reference dictionary
paramEntries = find(designData_parentDD,'-value','-class','Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary to a reference dictionary
typeEntries = find(designData_parentDD,'-value','-class','Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
**Make Changes to Configuration Set Stored in Dictionary**

You can store a configuration set (a `Simulink.ConfigSet` object) in the Configurations section of a dictionary. To change the setting of a configuration parameter in the set programmatically:

1. Create a `Simulink.data.dictionary.Entry` object that represents the configuration set (which is an entry in the dictionary). For example, suppose the name of the dictionary is `myData.sldd` and the name of the `Simulink.ConfigSet` object is `myConfigs`.

   ```matlab
dictionaryObj = Simulink.data.dictionary.open('myData.sldd');
configsSectObj = getSection(dictionaryObj,'Configurations');
entryObj = getEntry(configsSectObj,'myConfigs');
```

2. Store a copy of the target `Simulink.ConfigSet` object in a temporary variable.

   ```matlab
temp = getValue(entryObj);
```

3. In the temporary variable, modify the target configuration parameter (in this case, set **Stop time** to 20).

   ```matlab
set_param(temp,'StopTime','20');
```

4. Use the temporary variable to overwrite the configuration set in the dictionary.

   ```matlab
setValue(entryObj,temp);
```

5. Save changes made to the dictionary.

   ```matlab
saveChanges(dictionaryObj)
```

About Signals

A signal is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

Many blocks can accept or output signals of any data or numeric type and dimensionality. Other blocks impose restrictions on the attributes of the signals that they can handle.

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations).

Note Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink
signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

**Creating Signals**

Create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine block from the Simulink Sources library into your model. For information about blocks that create signals in a model, see “Sources”.

You can use the Viewers and Generators Manager to create signals in your model without using blocks. For more information, see “Viewers and Generators Manager” on page 29-93.

**Signal Line Styles**

A Simulink model can include many different types of signals. For details, see “Signal Types” on page 71-8. Different line styles help you to differentiate the signal types.

As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. The only line style that you can customize is the nonscalar signal type. For information about this option, see “Wide Nonscalar Lines” on page 71-71.

**Signal Properties**

**Specify Signal Properties**

Use the Property Inspector, the Model Data Editor, or the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To access the signal properties in the Property Inspector, first display the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**. When you select a signal, the properties appear in the Property Inspector. To use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), inspect the **Signals** tab and select a signal. To use the Signal Properties dialog box, right-click a signal and select **Properties**. For information about the benefits of each approach, see “Setting Properties and Parameters” on page 1-53.

**Programmatically Specify Signal Properties**

To specify signal properties programmatically, use a function such as `get_param` to get a handle to the block output port that creates the signal line. Then, use `set_param` to set the programmatic parameters of the port.

For an example, see “Name a Signal Programmatically” on page 1-17.

To learn how to map signal properties to programmatic port parameters, see “Signal Properties Dialog Box Overview”.

**Signal Names and Labels**

You can name a signal. By default, the signal name appears below a signal, displayed as a signal label. You can name a signal interactively in the model or by using the Property
Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the Model Data Editor (on the **Modeling** tab, click **Model Data Editor** | **Signals** tab, or the Signal Properties dialog box. You can also name the signal at the command prompt (see “Name a Signal Programmatically” on page 1-17). For a summary of how to work with signal names and labels in the Simulink Editor, see “Signal Name and Label Actions” on page 1-93.

The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- Do not use a less than character (<) to start a signal name.
- The signal name can resolve to a Simulink.Signal object. (See Simulink.Signal.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function namelengthmax.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Export Signal Data Using Signal Logging” on page 68-70.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 68-107.
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (signal#) to all input signal names, where # is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function isvarname to determine whether a signal name is a legal MATLAB identifier.

**Signal Display Options**

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, on the **Debug** tab, use the **Information Overlays** menu to include in the model layout information about signal attributes, such as:
• Port data types
• Design ranges
• Signal dimensions
• Signal resolution

For details, see “Display Signal Attributes” on page 71-66.

You can also highlight a signal and its source or destination blocks. For details, see “Highlight Signal Sources and Destinations” on page 71-39.

**Store Design Attributes of Signals and States**

You can use block parameters and signal properties to specify signal design attributes such as data type, minimum and maximum values, physical unit, and numeric complexity. To configure states, you can use block parameters. When you use these block parameters and signal properties, you store the specifications in the model file.

Alternatively, you can specify these attributes by using the properties of a Simulink.Signal object that you store in a workspace or data dictionary. See Simulink.Signal and “Data Objects” on page 66-75.

Choose which strategy to use based on your modeling goals.

• To improve model portability, readability, and ease of maintenance, store these specifications in the model file. Use the Property Inspector, the Model Data Editor, block dialog boxes, and signal properties dialog boxes to access the parameters and properties. You do not need to save and manage external Simulink.Signal objects. Consider setting the model configuration parameter **Signal resolution** to None, which disables the use of Simulink.Signal objects by the model.

To configure design attributes and code generation settings for signals by using a list that you can sort, group, and filter, consider the Model Data Editor. With this tool, you store the specifications in the model file instead of using Simulink.Signal objects. See “Configure Data Properties by Using the Model Data Editor” on page 66-179.

• To separate these specifications from the model so that you can manage each independently, use Simulink.Signal objects. You can then configure the specifications in a flat list that you can sort, group, and filter with the Model Data Editor or the Model Explorer. To determine where to permanently store the objects, see “Determine Where to Store Variables and Objects for Simulink Models” on page 66-134.
Testing Signals

You can perform the following kinds of tests on signals:

- “Minimum and Maximum Values” on page 71-7
- “Connection Validation” on page 71-7

Minimum and Maximum Values

For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Signal Ranges” on page 71-47.

Connection Validation

Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities.

To detect signal compatibility errors before running a simulation, update the diagram.

Scenarios

The Signal Editor block displays interchangeable groups of scenarios. Use the Signal Editor to display, create, edit, and switch interchangeable scenarios.

Scenarios can help with testing a model.

Control Signals

A control signal is a signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal.
When you update or simulate a block diagram, Simulink uses a dash-dot pattern to redraw lines representing the control signals.

**Composite (Bus) Signals**

You can group multiple signals into a hierarchical composite signal, called a *bus*, route the bus from block to block, and extract constituent signals from the bus where needed. When you have many parallel signals, buses can simplify the appearance of a model and help to clarify generated code. A bus can be either virtual or nonvirtual.

For example, if you open and simulate the *busdemo* example model, the *bus1*, *bus2*, and *main_bus* signals are bus signals. These virtual bus signals use the triple line style.
For information about buses, see slexBusExample and “Virtual Bus” on page 72-3.

Virtual Signals

In this section...

“About Virtual Signals” on page 71-11
“Mux Signals” on page 71-11

About Virtual Signals

A virtual signal is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; they have no mathematical or physical significance. Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as Bus Creator, can generate either virtual or nonvirtual signals.

The nonvirtual components of a virtual signal are called regions. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Bus signals can also be virtual or nonvirtual. For details, see “Types of Composite Signals” on page 72-2.

Mux Signals

A Simulink mux is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. A Simulink mux is not a hardware multiplexer, which combines multiple data streams into a single channel. A Simulink mux does not combine signals in any functional sense: it exists only virtually, and its only purpose is to simplify the visual appearance of a model. Using a mux has no effect on simulation or generated code.

You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux just as if the values existed in a contiguous vector, and the result is a contiguous vector, not a mux. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage.
The Simulink documentation refers, sometimes interchangeably, to “muxes”, “vectors”, and “wide signals”, and all three terms appear in Simulink dialog box labels and API names. This terminology can be confusing, because most vector signals are nonvirtual and hence are not muxes. To avoid confusion, reserve the term “mux” to refer specifically to a virtual vector.

A mux is a virtual vector signal. The constituent signals of a mux retain their separate existence in every way, except visually. You can also combine scalar and vector signals into a nonvirtual vector signal, by using a Vector Concatenate block. The signal output by a Vector Concatenate block is an ordinary contiguous vector, inheriting no special properties from the fact that it was created from separate signals.

To create a composite signal whose constituent signals retain their identities and can have different data types, use a Bus Creator or Out Bus Element block, rather than a Mux block. For details, see “Types of Composite Signals” on page 72-2.

**Using Muxes**

The Signal Routing library provides two virtual blocks for implementing muxes:

**Mux**

Combine several input signals into a mux (virtual vector) signal

**Demux**

Extract and output the values in a mux (virtual vector) signal

To implement a mux signal:

1. Select a Mux and Demux block from the Signal Routing library.
2. Set the Mux block **Number of inputs** and the Demux block **Number of outputs** block parameters to the desired values.
3. Connect the Mux, Demux, and other blocks as needed to implement the desired signal.

The next figure shows three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.
To reduce visual complexity, you can hide block names. In this example, the line connecting the blocks, representing the mux signal, is wide because the model was built with the Nonscalar Signals option enabled (on the Debug tab, select Information Overlays > Nonscalar Signals). See “Display Signal Attributes” on page 71-66 for details.

Signals input to a Mux block can be any combination of scalars, vectors, and muxes. The signals in the output mux appear in the order in which they were input to the Mux block. You can use multiple Mux blocks to create a mux in several stages, but the result is flat, not hierarchical, just as if the constituent signals had been combined using a single mux block.

The values in all signals input to a Mux block must have the same data type.

If a Demux block attempts to output more values than exist in the input signal, an error occurs. A Demux block can output fewer values than exist in the input mux, and can group the values it outputs into different scalars and vectors than were input to the Mux block. However, the Demux block cannot rearrange the order of those values. For details, see Demux.

**Note** Do not use Mux and Demux blocks to create and access buses.

Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 66-3 for more information.

Signal Dimensions, Size, and Width

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as vectors and 2-D or multidimensional signals as matrices. A one-element array is frequently referred to as a scalar.

The size of a signal refers to the number of elements that a signal contains. The size of a matrix (2-D) signal is generally expressed as M-by-N, where M is the number of columns and N is the number of rows making up the signal. The size of a vector signal is referred to as the width of the signal.

For more information, see “Signal Dimensions” on page 71-30.

Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:
• Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
• Create a Constant block in your model and set its value to a complex number.
• Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the Real-Imag to Complex conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

**Initializing Signal Values**

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

<table>
<thead>
<tr>
<th>Signal Data Type</th>
<th>Default Initial Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric (other than fixed-point)</td>
<td>Zero</td>
</tr>
<tr>
<td>Fixed-point</td>
<td>Real-world ground value</td>
</tr>
<tr>
<td>Boolean</td>
<td>False</td>
</tr>
<tr>
<td>Enumerated</td>
<td>Default value</td>
</tr>
</tbody>
</table>

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

• For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
• For some blocks, such as Outport, Data Store Memory, and Memory, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 71-54.

**Viewing Signal Values**

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either the Scope block or the Signal & Scope Manager to graph time-varying signals on an
oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 29-8. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, see “Floating Scope and Scope Viewer Tasks” on page 29-82
- The Signal & Scope Manager, see “Viewers and Generators Manager” on page 29-93
- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Test Points” on page 71-63.

**Displaying Signal Values in Model Diagrams**

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 71-17
- “Display Signal Value After Simulation” on page 71-17

**Display Data Tips During Simulation**

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

1. In the Simulink Editor, on the **Debug** tab, select **Output Values**, go to the **Signal** tab, and toggle on the **Output Value Label > Toggle Value Displays** button.
2. To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 37-20.

**Display Signal Value After Simulation**

To display, below a specific signal, the signal value after simulation:

1. Right-click the signal.
2. In the context menu, select **Show Value Label of Selected Port**.
Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 68-4.

</tr>
<tr>
<td>“How Simulink Propagates Signal Labels” on page 71-21</td>
</tr>
</tbody>
</table>

#### Propagated Signal Labels

When you enable the display of signal label propagation for output signals of the blocks listed in “Blocks That Support Signal Label Propagation” on page 71-19:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, `<sig1>`).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (<> ) for the label.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (<const>) is based on the name of the upstream output signal of the Constant block (const).

![Signal Label Propagation Diagram](image)

For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 71-21.

#### Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several connection blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.
The connection blocks that support signal label propagation are:

- Enable
- From
- Function Call Split
- Goto
- Inport (subsystem only; not model input ports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger
- Two-Way Connection (a Simscape block)

The Bus Creator and Bus Selector blocks do not support signal label propagation. However, if you want to view the hierarchy for any bus signal, use the “Signal Hierarchy Viewer” on page 72-33.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The Show propagated signals parameter is available only for blocks that support signal label propagation. For details, see “Display Propagated Signal Labels” on page 71-20.

**Display Propagated Signal Labels**

You can display propagated signal labels for individual signals, or display the propagated signal labels for all signals in a model. To display the labels for all signals, in the Simulink Editor, on the Debug tab, select Information Overlays > Propagated Signal Labels.

To display a propagated signal label for an individual signal:

1. Right-click the signal for which you want to display a propagated signal label and select Properties.
2. In the Signal Properties dialog box, select Show propagated signals.
The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as 'on'. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```matlab
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs,'FindAll','on','type','line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)
    % set(signalLines(i),'signalPropagation','off');
    set(signalLines(i),'signalPropagation','on');
end
```

If a signal already has a label, then an **alternative** approach for displaying a propagated signal label is:

1. In the model diagram, click the signal label.
2. Remove the label text.
3. In the signal label text box, enter an angle bracket (`<`).
4. Click outside the signal label.

Simulink displays the propagated signal label.

### How Simulink Propagates Signal Labels

Understanding how Simulink propagates signal labels helps you to:

- Anticipate the scope of the signal label propagation, from source to final destination
- Configure your model to display signal labels for the signals that you want

For output signals from supported blocks, you can choose to have Simulink display propagated signal labels. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 71-19.

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:
- “Processing for Referenced Models” on page 71-26
- “Processing for Variants and Configurable Subsystems” on page 71-28

**General Signal Label Propagation Processing**

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

1. Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
2. Stops when it encounters a block that either:
   - Supports signal label propagation and has a signal name
   - Does not support signal label propagation
3. Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
4. Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the Out1 port).
Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

Simulink uses the signal name of the Constant block output signal, \texttt{const}. The propagated signal label for the Subsystem block output signal is \texttt{<const>}. 

If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (\texttt{<>}).
Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const-from` for the output signal of the From block, as shown below.

The propagated signal label for the Subsystem block output signal changes to `<const-from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.

In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus signal of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (a and b).
Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in “Display Propagated Signal Labels” on page 71-20, use the default setting for the Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does not reflect the name `input_1` until after you update the diagram or simulate the model.
Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when both of these conditions occur:

- The output signals for variant models have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

Signal Dimensions

In this section...

“About Signal Dimensions” on page 71-30
“Simulink Blocks that Support Multidimensional Signals” on page 71-31

About Signal Dimensions

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as **vectors** and 2-D or multidimensional signals as **matrices**. A one-element array is frequently referred to as a **scalar**. A **row vector** is a 2-D array that has one row. A **column vector** is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as `[4 3]`. See “Multidimensional Arrays” (MATLAB) for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals. To determine the signal dimensionality of a particular block, see the block documentation. See “Determine Output Signal Dimensions” on page 71-32 for information on what determines the dimensions of output signals for blocks that can output nonscalar signals.

**Note** Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See “Variable-Size Signal Basics” on page 73-2.
Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

1. In the MATLAB command line, enter `showblockdatatypetable`.

   A separate window with the Simulink Block Data Type Support table opens.

2. In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An `X` in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

About Signal Dimensions

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

To determine the dimensions that a signal ultimately uses for simulation, first update the block diagram (for example, by pressing Ctrl+D). Then, choose one of these techniques:

- Display the dimensions directly on the block diagram. Use this technique to trace signal dimensions along a path of blocks. In the model, on the Debug tab, select Information Overlays > Signal Dimensions).
- Inspect the dimensions in the Model Data Editor, which shows you information in a searchable, sortable table. In the table, the right side of each cell in the Dimensions column shows the true dimensions of the corresponding signal line in the model. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

Determining the Output Dimensions of Source Blocks

A source block is a block that has no inputs. Examples of source blocks include the Constant block and the Sine Wave block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block Interpret vector parameters as 1-D parameter is off (that is, not selected in the block parameter dialog box). If the Interpret vector parameters as 1-D parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.
As an example of how the output value parameters and **Interpret vector parameters as 1-D** parameter of a source block determine the dimensionality of its output, consider the Constant block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block output.

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

**Determining the Output Dimensions of Nonsource Blocks**

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 71-33).

**Signal and Parameter Dimension Rules**

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

**Input Signal Dimension Rule**

All nonscalar inputs to a block must have the same dimensions.
A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see “Scalar Expansion of Inputs and Parameters” on page 71-35).

**Block Parameter Dimension Rule**

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 71-35).

- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

**Vector or Matrix Input Conversion Rules**

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.

- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.

- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

**Note** You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.
Scalar Expansion of Inputs and Parameters

Scalar expansion is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to block inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

<table>

**Scalar Input and Nonscalar Parameter**

In this example, the Constant block input to the Gain block is scalar. The Gain block *Gain* parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar *Gain* parameter, as reflected in the simulation results in the Display block.

![Diagram of scalar input and nonscalar parameter](image1)

**Nonscalar Input and Scalar Parameter**

In this example, the Constant block input to the Gain block is nonscalar. The Gain block *Gain* parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.

![Diagram of nonscalar input and scalar parameter](image2)

**Scalar and Nonscalar Inputs and No Associated Parameter**

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector `[3 3 3]`. 

![Diagram of scalar and nonscalar inputs and no associated parameter](image3)
Get Compiled Port Dimensions

To get the dimensions of port signals, pause the simulation by using the **Step Forward** button. Select a block and use the `PortHandles` parameter. Then use the `GetCompiledPortDimensions` parameter. For example, if you step forward in this model and select the Constant block:

```matlab
ph = get_param(gcb,'PortHandles');
dim = get_param(ph.Outport,'CompiledPortDimensions')
dim =
    2     2     3
```

For nonbus ports, the result is an array in which the first element is the number of dimensions (in this case 2), and the next two elements (corresponding to the number of dimensions) are the values of the dimensions.

For bus signals, the results include some extra elements. Suppose that you step forward in a model with buses and you select the Bus Creator block that contains a nested bus:
ph = get_param(gcb, 'PortHandles');
dim = get_param(ph.Outport, 'CompiledPortDimensions')

dim = [-2 4 1 2 1 1 3 4 5 6 5 2 3 4 5 6]

The first element is -2, which indicates that the signal is a bus. The second element is the number of leaf nodes. The subsequent elements follow the same pattern as for nonbus signals. In this example, the third element represents the number of dimensions for the first signal in the bus (in this case 1), and the next number is the value in that dimension (2).

Highlight Signal Sources and Destinations

In this section...

“Highlight Signal Source” on page 71-39
“Highlight Signal Destination” on page 71-40
“Choose the Path of a Trace” on page 71-41
“Subsystems” on page 71-42
“Show All Possible Paths of a Trace” on page 71-43
“Display Port Values Along a Trace” on page 71-43
“Remove Highlighting” on page 71-45
“Resolve Incomplete Highlighting to Library Blocks” on page 71-45
“Limitations” on page 71-46

You can highlight a signal and its source or destination blocks, then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem and model reference boundaries, allowing you to trace a signal across multiple subsystem levels. If a signal is composite, all source or destination blocks are highlighted. See “Types of Composite Signals” on page 72-2.

To continue the trace towards the source or destination of the signal, use the left and right arrow keys of your keyboard, respectively.

Highlight Signal Source

To begin a trace to the source blocks of a signal, select the Highlight Signal to Source option from the context menu for the signal. The badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that write the value of the signal
To continue tracing towards the source of the signal, press the **Left** arrow key.

**Highlight Signal Destination**

To begin a trace to the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. Press the **Right** arrow key to move the trace towards the final destination. The badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the Inport block for the line that you select

In this example, the selected trace shows a path of the signal from the Stick Input to the Elevator Command in the Controller subsystem of the f14 model.
In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate Inport blocks.

![Diagram of signal flow](image)

**Choose the Path of a Trace**

In some situations, a signal trace can take multiple viable paths in the next segment of the trace. This can be seen when a signal is combined or split through a Mux or Demux block, or if it is branched out as an input to another block. In such cases, the options are highlighted in blue and can be cycled using the **Up** and **Down** arrow keys on the keyboard. Once you have highlighted the block to which you would like to move, proceed as normal.

![Diagram showing trace paths](image)

In the figure above, the trace to source has reached the Sum block where it can take one of three possible paths. The first option to Gain Zd is highlighted in blue.
Subsystems

When the trace reaches a subsystem, it does not automatically trace in. Instead, the trace highlights the target subsystem and you are able to see a preview of the trace within the subsystem.

In this example, the selected signal trace to destination has reached the Controller subsystem of the f14 model. You can see that the contents of the subsystem are visible and the next segment of the trace is highlighted within the preview.

When the trace comes out of a subsystem, the subsystem preview also displays the path of the trace inside it. The next example shows the path of a trace through the Aircraft Dynamics Model subsystem from the input wGust to vertical velocity w output.
**Note** You cannot jump over a subsystem or a referenced model in your trace. You need to trace the signal path through them.

## Show All Possible Paths of a Trace

To highlight all possible paths a trace can take, press Ctrl key along with the **Left** (towards source) or the **Right** (towards destination) key. You can continue to trace as before.

To clear the highlighting, simultaneously press the Ctrl key and the arrow key in the direction opposite to the trace.

## Display Port Values Along a Trace

After you trace the path of a signal, press the L key to display the values of a signal at the output port of each block.
If you highlight all the possible paths of the trace as described in “Show All Possible Paths of a Trace” on page 71-43, press the **Ctrl + L** to view the signal values at all the output ports.
Remove Highlighting

To remove all highlighting, right-click the model, and then select **Remove Highlighting**, or, on the **Signal** tab, click **Remove Trace**. You can also press **Ctrl+Shift+H** or click the icon at the top right corner of the editor.

To back up a trace, press the arrow key opposite to the original intent of the trace. For example, if you would like to back up a trace to the destination of the signal, press the left arrow key. To back up a trace to the source of a signal, press the **right arrow** key.

Resolve Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block,
respectively. To display the complete path, press Ctrl+D to update the diagram. The diagram update resolves all library references and displays the complete path to a destination block or from a source block.

**Limitations**

The signal tracing tool has the following limitations in its usage:

- The signal trace does not preserve bus information when tracing into or out of a referenced model.
- Tracing past a Goto block changes the active level to that containing the matching From block. However, this does not guarantee that the matching From block is the active block if there are other valid blocks at the same level.
- Signal tracing is unsupported by certain blocks. Unsupported blocks are blocks where:
  - You cannot trace into them to highlight their contents. Examples of such blocks include but are not limited to Stateflow charts, Simscape subsystems, and function blocks.
  - You cannot cross them and continue tracing (e.g. Simscape blocks).
- The styling of the signal does not update with modifications to the model when signal tracing is enabled.
- The operation to “Show All Possible Paths of a Trace” on page 71-43 does not traverse through referenced models in the same way as it does subsystems. Referenced models are treated as non-virtual blocks and the impact region will not highlight their contents.

Signal Ranges

In this section...

“About Signal Ranges” on page 71-47
“Blocks That Allow Signal Range Specification” on page 71-47
“Specify Ranges for Signals” on page 71-48
“Check for Signal Range Errors” on page 71-50
“Unexpected Errors or Warnings for Data with Greater Precision or Range than double” on page 71-52
“Optimize Generated Code” on page 71-53

About Signal Ranges

Many Simulink blocks allow you to specify a range of valid values for their output signals. Simulink provides a diagnostic that you can enable to detect when blocks generate signals that exceed their specified ranges during simulation. See the sections that follow for more information.

Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

• Abs
• Constant
• Data Store Memory
• Data Type Conversion
• Difference
• Discrete Derivative
• Discrete-Time Integrator
• Gain
• Inport
• Interpolation Using Prelookup
• 1-D Lookup Table
Specify Ranges for Signals

In general, use the Output minimum and Output maximum parameters of a block to specify a range of valid values for the block output signal. Exceptions include the Data Store Memory, Inport, Outport, and Signal Specification blocks, for which you use their Minimum and Maximum parameters to specify a signal range. See “Blocks That Allow Signal Range Specification” on page 71-47 for a list of applicable blocks.

To access these parameters, use the Property Inspector (on the Modeling tab, under Design, click Property Inspector), the Model Data Editor (on the Modeling tab, click Model Data Editor), or the block dialog box. To use each technique efficiently, see “Setting Properties and Parameters” on page 1-53.

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with double data type. For example, you can use:

- A literal number such as 98.884. Implicitly, the data type is double.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 38-13) whose data type is double. Use this technique to share a minimum or maximum value between multiple data items.
However, you cannot use variables to set the Min or Max properties of a Simulink.Signal object.

The scalar value that you specify applies to each element of a composite signal (for example, when the signal is nonscalar or a bus). For information about scalar expansion, see “Scalar Expansion of Inputs and Parameters” on page 71-35.

To leave the minimum or maximum of a signal unspecified, use an empty matrix [], which is the default value.

**Specify Ranges for Modeling Constructs**

If you use modeling constructs such as bus signals, data stores, and Stateflow charts, you can use different techniques to specify design range information. Use the information in the table.

<table>
<thead>
<tr>
<th><strong>Description of Target Signal</strong></th>
<th><strong>Technique and More Information</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Numerically complex signal</td>
<td>When you specify an <strong>Output minimum</strong> or <strong>Output maximum</strong> for a signal that is numerically complex, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as $(\sqrt{a^2+b^2})$.</td>
</tr>
<tr>
<td>Signal elements in a bus</td>
<td>If you assemble the bus by using a Bus Creator block, you can specify range information on the upstream blocks that feed the Bus Creator. Regardless of the technique you use to assemble the bus, you can create a Simulink.Bus object and use it as the data type of the bus signal. In this case, consider specifying range information by using the Min and Max properties of the Simulink.BusElement objects that reside in the bus object. For more information, see “Specify Bus Properties with Bus Objects” on page 72-55.</td>

**Check for Signal Range Errors**

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see “Specify Ranges for Signals” on page 71-48) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- **DataTypeMin** is the minimum value representable by the block data type.
- **MinValue** is the minimum value the block should output, specified by, e.g., **Output minimum**.
- **VALUE** is the signal value that the block outputs.
- **MaxValue** is the maximum value the block should output, specified by, e.g., **Output maximum**.
- **DataTypeMax** is the maximum value representable by the block data type.

**Note** It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.
Enable Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

1. In your model window, on the **Modeling** tab, click **Model Settings**.
   
   Simulink displays the Configuration Parameters dialog box.

2. In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics > Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to **error** or **warning**.

3. Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See “Simulation range checking” for more information.

**Simulate Models with Simulation Range Checking**

To check for signal range errors or warnings:

1. Enable the **Simulation range checking** diagnostic for your model (see “Enable Simulation Range Checking” on page 71-51).

2. In your model window, click **Run** to simulate the model.

   Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **error**, Simulink stops the simulation and generates an error (for example, in the Diagnostic Viewer).

   Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **warning**, Simulink generates a warning message in the MATLAB Command Window. Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.
Signal Range Propagation for Virtual Blocks

Some virtual blocks (see “Nonvirtual and Virtual Blocks” on page 37-2) allow you to specify ranges for their output signals, for example, the Inport and Outport blocks. When the Simulation range checking diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the tightest range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:

![Model Diagram]

In this model, the Constant block specifies its Output maximum parameter as 300, and that of the Inport block is set to 100. Suppose you enable the Simulation range checking diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block. Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink generates an error.

Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than double, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.
However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```plaintext
format long
98.8847692348509014 + eps(98.8847692348509014)
```

```
ans =
98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

### Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

“Use Signal Objects to Initialize Signals and Discrete States” on page 71-56
“Using Signal Objects to Tune Initial Values” on page 71-58
“Example: Using a Signal Object to Initialize a Subsystem Output” on page 71-58
“Initialization Behavior Summary for Signal Objects” on page 71-59

About Initialization

Note For information about initializing bus signals, see “Specify Initial Conditions for Bus Signals” on page 72-79.

Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the Start time of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., Outport, Data Store Memory, or Memory, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent.

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in “Symbol Resolution” on page 66-174.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see Simulink.Signal and the Merge block.
Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.

To access these block parameters, choose one of these techniques:

- Use the Model Data Editor (on the Modeling tab, click Model Data Editor). Use this technique to configure multiple signals and states with a searchable, sortable table. To initialize a block state or data store, you can use the appropriate tab (States or Data Stores). To initialize a signal, state, or data store, you can use the Parameters tab and find the row that corresponds to the relevant block parameter.

  For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

- Use the Property Inspector (on the Modeling tab, under Design, click Property Inspector). Use this technique to configure one signal or state at a time. Select the
block that maintains the target state or generates the target signal and find the relevant block parameter.

- Use the block parameter dialog box. Use this technique to configure one signal or state at a time or to compare the configurations of a few signals or states side by side.

For more information about techniques to access block parameters (including the parameters that control signal and state initialization), see “Setting Properties and Parameters” on page 1-53.

**Use Signal Objects to Initialize Signals and Discrete States**

You can use signal objects that have a storage class other than ‘auto’ or, when you set the default storage class of the corresponding data category to Default (the default setting) in the Code Mapping Editor, 'Model default' to initialize:

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

1. Create the signal object.

   On the Model Explorer toolbar, select **Add > Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as S1. Alternatively, use this command at the command prompt:

   ```
   S1 = Simulink.Signal;
   ```

   The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

   Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 66-84.
2 Set the signal object storage class to a value other than Auto or Model default. In the Model Explorer Contents pane, select the signal object. In the Dialog pane, set Storage class to ExportedGlobal. Alternatively, use this command at the command prompt:

\[ S1.CoderInfo.StorageClass = 'ExportedGlobal'; \]

3 Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

In the Model Explorer Dialog pane, set Initial value to 0.5. Alternatively, use this command at the command prompt:

\[ S1.InitialValue = '0.5' \]

If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty ([ ]) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

**Classic initialization mode:** In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as [ ]):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

**Simplified initialization mode:** In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks
Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see Simulink.Parameter) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a Memory block state named M1. To do this, you might create a signal object named M1, set its storage class to 'ExportedGlobal', set its initial value to K (M1.InitialValue='K'), where K is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the Memory block to [] to avoid consistency errors. You could then change the initial value of the Memory block state any time during the simulation by changing the value of K at the MATLAB command line and updating the block diagram (e.g., by typing Ctrl+D).

Example: Using a Signal Object to Initialize a Subsystem Output

The following example shows a signal object specifying the initial output of an enabled subsystem.
Signal $s$ is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem Outport block must be $[]$ or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 66-94.

**Initialization Behavior Summary for Signal Objects**

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.
### Signal or Discrete State

<table>
<thead>
<tr>
<th>Signal or Discrete State</th>
<th>Description</th>
<th>Behavior</th>
</tr>
</thead>
</table>
| S1                       | Root input port      | - Initialized to $S1.InitialValue$.  
                            - If you use the Data Import/Export pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant. |
<table>
<thead>
<tr>
<th>Signal or Discrete State</th>
<th>Description</th>
<th>Behavior</th>
</tr>
</thead>
</table>
| X1                       | Unit Delay block — Block with a discrete state that has an initial condition | • Initialized to X1.InitialValue.  
  • Simulink checks whether X1.InitialValue matches the initial condition specified for the block and displays an error if a mismatch occurs.  
  • At first write, the output equals X1.InitialValue and the state equals S1.  
  • At each time step after the first write, the output equals the state and the state is updated to equal S1.  
  • If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem Enable block parameter States when enabling is set to reset. |
| X2                       | Data Store Memory block | • Data type work (DWork) vector initialized to X2.InitialValue. For information on work vectors, see “DWork Vector Basics”.  
  • Simulink checks whether X2.InitialValue matches the initial condition specified for the block, and displays an error if a mismatch occurs.  
  • Data Store Write blocks overwrite the value. |
| S2                       | Output of an enabled subsystem | • Initialized to S2.InitialValue or the value of the Outport block. If multiple initial values are specified for the same signal, all initial values must be the same.  
  • The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value.  
  • The initial value is also used as a reset value if the subsystem Enable block parameter States when enabling or Outport block parameter Output when disabled is set to reset. |
| S3                       | Persistent signals | • Initialized to S3.InitialValue.  
  • The output value is reset by the block at each time step.  
  • Affects code generation only. For simulation, setting the initial value for S3 is irrelevant because the values are overwritten at model simulation start time. |

Test Points

What Is a Test Point?

A test point is a signal that Simulink guarantees to be observable when using a Floating Scope block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see “Signal storage reuse” (Simulink Coder)) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if Minimize algebraic loop occurrences is selected (for more information about algebraic loops, see “Algebraic Loop Concepts” on page 3-33).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Appearance of Test Points in the Generated Code” (Simulink Coder).

Marking a signal as a test point has no impact on signal logging that uses the Dataset logging format. For information about logging signals, see “Export Signal Data Using Signal Logging” on page 68-70.

Configure Signals as Test Points

Use one of the following ways to designate a signal as a test point:

- Open the Signal Properties dialog for the signal and check Test Point in the Logging and accessibility section.
- Use the Model Data Editor for batch configuration and for signals that are difficult to locate in a large model or hierarchy of subsystems. On the Signals tab, set the
Change view drop-down list to Instrumentation and use the Test Point column. For information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 66-179.

- To configure Stateflow data in a chart as test points, see “Monitor Test Points in Stateflow Charts” (Stateflow).

To configure a signal as a test point programmatically:

1. Get handles to the ports of the block.
   
   ```
   portHandles = get_param('myModel/myBlock','portHandles');
   ```
   
   `portHandles` is a structure. Each field stores a handle to a block port.

2. Extract a handle to the output port that creates the target signal line.
   
   ```
   outportHandle = portHandles.Outport;
   ```

3. Set the port parameter TestPoint to 'on'.
   
   ```
   set_param(outportHandle,'TestPoint','on')
   ```

**Displaying Test Point Indicators**

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals s2 and s3 are test points:

![Model diagram](image)

**Note** Simulink does not display an indicator on a signal that is specified as a test point by a Simulink.Signal object, because such a specification is external to the graphical model.

A signal that is a test point can also be logged. See “Export Signal Data Using Signal Logging” on page 68-70 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.
To turn display of test point indicators on or off, in the Simulink Editor, on the Debug tab, select Information Overlays > Log & Testpoint to enable or disable the option.

**See Also**

**Related Examples**
- “Signal Values” on page 71-15
- “Signal Basics” on page 71-2
A signal line in a model has attributes such as data type, dimensions, and numeric complexity. When you display these attributes on the block diagram, you can:

- Make the model easier to understand by others.
- Determine the value of the attribute that the signal ultimately uses for simulation (for example, when a signal uses an inherited data type).
- Plan your strategy to control these attributes along a data path (a series of connected blocks).

Additionally, to inspect and specify these attributes in a searchable, sortable table, you can use the Model Data Editor (see “Configure Data Properties by Using the Model Data Editor” on page 66-179).

### Ports & Signals Menu

In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu offers the following options for displaying signal properties on the block diagram:

- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 71-67)
- Design Ranges (See “Design Ranges” on page 71-69)
- Signal Dimensions (See “Signal Dimensions” on page 71-69)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 71-70)
In addition, you can display sample time information. In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu provides the choices of **Colors** and **Text**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Text** option provides black codes on the signal lines which indicate the type of sample time. If you select both **Colors** and **Text**, then both the colors and the annotations display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time rate. If **Colors** is enabled, color codes also appear in the legend. The same is true if **Text** is enabled.

### Port Data Types

Displays the data type that each signal uses for simulation and code generation. The data type appears next to the output port that emits the signal.

The notation \((c)\) indicates that the signal is numerically complex \((i)\).

If you use data type aliases (such as a `Simulink.AliasType` objects in the base workspace or a data dictionary) to set output data types in your model, by default, the diagram displays the aliases.
If you create a chain of aliases (for example, by using one Simulink.AliasType object as the base type of another Simulink.AliasType object), the diagram displays only the alias that you use to set the output data type of each signal. The diagram does not display the underlying aliases in the chain.

To display the lowest underlying base data type (such as int8, single, or s16En14) as well as the alias, in the Debug tab, open the Information Overlays drop-down. Under Ports click Base Data Types and Alias Data Types.
Alternatively, you can display the base type and not the alias by selecting **Base Type**.

When you use a fixed-point data type, the diagram displays the base type by using a standard notation that indicates the characteristics of the type (such as signedness and binary fraction length). To interpret this notation, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).

Enabling this option also enables the display of signal attributes at model load time and as you edit the model. For more information, see “Display Signal Attributes at Model Load Time” on page 13-73.

**Design Ranges**

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

Ranges are displayed in the format \([\text{min}..\text{max}]\). In the above example, the design range at the output port of the Mux block is displayed as \([-10..\text{mixed}]\), because the two signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see “Common Block Properties”.

**Signal Dimensions**

Display the dimensions of nonscalar signals next to the line that carries the signal.
The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as \([N_1 \times N_2]\) where \(N_i\) is the size of the \(i\)th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays \(N\{M\}\) where \(N\) is the number of signals carried by the bus and \(M\) is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements \(\{M\}\).

Enabling this option also enables the display of signal dimensions at model load time and as you edit the model. For more information, see “Display Signal Attributes at Model Load Time” on page 13-73.

**Signal to Object Resolution Indicator**

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

![Signal resolution icon](image)

A signal resolution icon indicates only that the **Signal name must resolve to signal object** property for a signal is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.
Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal x2 must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

To suppress the display of signal resolution icons, in the model window, on the Debug tab, select Information Overlays > Signal Resolves to Object to disable. This option is enabled default. To restore signal resolution icons, enable Signal Resolves to Object. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 66-174
- “Initialize Signals and Discrete States” on page 71-54
- Simulink.Signal

**Wide Nonscalar Lines**

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.
See “Mux Signals” on page 71-11 for more information about vector and matrix signals.

“Simulation from Signal Builder Block” on page 71-120

About Signal Groups

To display, create, and edit interchangeable groups of signal sources and quickly switch the groups into and out of a model, use the Signal Builder block. You can define any piecewise linear signal shape (waveform).

Note The Signal Builder block is not recommended to work with signal groups. Instead, use the Signal Editor block to display, create, edit, and switch interchangeable scenarios. For more information, see “Load Data with Interchangeable Scenarios” on page 68-265.

Use signal groups when testing a model, especially when using them in conjunction with the Simulink Assertion block and the Model Coverage Tool from the Simulink Coverage. For a description of the Model Coverage Tool, see “Model Coverage Collection Workflow” (Simulink Coverage).

Solver pane settings in Model Configuration Parameters can affect the Signal Builder block output. See “Simulation Phases in Dynamic Systems” on page 3-2 and “Compare Solvers” on page 3-8 for a description of how solvers affect simulation.
**Note** The Signal Builder block adds a port for each signal you create. The block **Position** parameter limits the number of ports the Signal Builder block can have, and therefore the number of signals you can create. For more information, see the **Position** parameter at “Common Block Properties”.

You can also use the `signalbuilder` function to populate a Signal Builder block.

**Supported Waveforms**

The Signal Builder block supports these waveforms.

**Using the Signal Builder Block with Fast Restart**

After you turn on fast restart:

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
  - Import signals or signal groups
  - Change signal output settings
- You can click the **Run all** button once. To reenable the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

**Editing Signal Groups**

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

**Creating and Deleting Signal Groups**

To create a signal group:

1. In Signal Builder, copy an existing signal group.
2. Modify it to suit your needs.

To copy an existing signal group:

1. In Signal Builder, select the group from the list.
2 Select **Group > Copy**.

A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

### Renaming Signal Groups

To rename a signal group:

1. In Signal Builder, select the group from the list.
2. Select **Group > Rename**.
3. Edit the existing name in the dialog box or enter a new name. Click **OK**.

### Moving Signal Groups

To reposition a group in the stack of group panes:

1. In Signal Builder, select the pane.
2. To move the group lower in the stack, select **Group > Move Down**.
3. To move the pane higher in the stack, select **Group > Move Up**.

### Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

### Creating Signals

To create a signal in the currently selected signal group:

1. In Signal Builder, from the Active Group list, select the group you want to add the signal to.
2. Select **Signal > New**.

The menu lists the waveforms you can add.

### Waveform Description Inputs Output

<table>
<thead>
<tr>
<th>Waveform</th>
<th>Description</th>
<th>Inputs</th>
<th>Output</th>
</tr>
</thead>
</table>
| Custom  | Custom piecewise linear waveform; custom values must fit within the display area | • **Time values**  
Vector of two or more time coordinates  
• **Y values**  
Vector of two or more signal amplitudes that correspond to the values in **Time values**  
The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length. | **Note** Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more). |

3. Select the waveform you want to add.  
4. Specify the inputs (in the prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.  
1. In the MATLAB Command Window, create data for two variables, \( t \) and \( y \).
t = 1:10
y = 1:10

These vectors must be the same size.

2 Create a model and add a Signal Builder block.
3 Double-click the Signal Builder block.
4 Select **Signal > New > Custom**.
5 In the Custom Waveform window, enter \( t \) in the **Time values** field and \( y \) in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.

![Signal Builder window](image)

**Defining Signal Output**

To specify the type of output to use for sending test signals:
1 In Signal Builder, select **Signal > Output**.
2 From the list, select:

   - **Ports**

     Default. Sends individual signals from the block. An output port named Signal N appears for each Signal N.

   - **Bus**

     Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

**Tip**

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
- The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the Bus Selector block to select the signals from this bus.
- If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.

**Copying and Pasting Signals**

To copy a signal from one group and paste it into another group as a new signal:

1 In Signal Builder, select the signal you want to copy.
2 Select **Edit > Copy**.
3 Select the group you want to paste the signal into.
4 Select **Edit > Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

1 Select the signal you want to copy.
2 Select **Edit > Copy**.
3 Select the signal on the axis that you want to update.
4 Select **Edit > Paste**.
Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose Delete or Cut from the Edit menu. Signal Builder deletes the signal from the current group. Because each signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

Renaming a Signal

To rename a signal:

1. In Signal Builder, select Signal > Rename.

   A dialog box appears with an edit field that displays the current name of the signal.

2. Edit or replace the current name with a new name.

3. Click OK.

You can also edit the signal name in the Name field in the lower-left corner of the Signal Builder window.

Replacing a Signal

To replace a signal:

1. In Signal Builder, select the signal, then select Signal > Replace with.

   A menu of waveforms appears. It includes a set of standard waveforms (Constant, Step, and so on) and a Custom waveform option.

2. Select one of the waveforms.

   If you select a standard waveform, Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

| Sampled Gaussian Noise| Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency. | • **Frequency (Hz)**  
Waveform frequency, in hertz  
• **Mean**  
The mean value of the random variable output  
• **Standard Deviation**  
The standard deviation squared of the random variable output  
• **Seed (empty to use current state)**  
The initial seed value for the random number generator |
| Pseudorandom Noise    | Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency. | • **Frequency (Hz)**  
Frequency with which waveform fluctuates between Upper value and Lower value, in hertz  
• **Upper value**  
Upper limit of signal  
• **Lower value**  
Lower limit of signal  
• **Seed**  
The initial seed value for the random number generator |
| Poisson Random Noise  | Poisson random noise waveform that alternates between 0 and 1 | • **Avg rate (1/sec)**  
Average rate of transition between 0 and 1  
• **Seed (empty to use current state)**  
The initial seed value for the random number generator |
<table>
<thead>
<tr>
<th>Waveform</th>
<th>Description</th>
<th>Inputs</th>
</tr>
</thead>
</table>
| Custom  | Custom piecewise linear waveform. Custom values must fit within the display area. | • **Time values**  
Vector of two or more time coordinates  
• **Y values**  
Vector of two or more signal amplitudes that correspond to the values in **Time values**  
The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length. |

**Note** Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Changing a Signal Index

To change a signal index:

1. In Signal Builder, select the signal, then select **Signal > Change Index**.

   A dialog box appears with a drop-down list field containing the existing index of the signal.

2. From the drop-down list, select another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

### Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

1. In Signal Builder, select the waveform, then select **Signal > Hide**.

2. To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list.

Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in “Importing Signal Group Sets” on page 71-88.

To create an interchangeable set of signal groups:

1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.

By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

2 Use the block signal editor to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

Note Each signal group must contain the same number of signals.

3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple
signals, the signals might have different end times. However, Signal Builder block requires the end times of signals within a group to match. If a mismatch occurs, Signal Builder block matches the end times by holding the last value of the signal with the smaller end time.

See “Simulating with Signal Groups” on page 71-119 for information on using signal groups in a model.

**Importing Signal Group Sets**

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See “Importing Signal Groups from Existing Data Sets” on page 71-88 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file 3Grp_3Sig.xls in the folder `matlabroot\help\toolbox\simulink\ug \examples\signals` (open).

Signal Builder accepts signals only of type double.

If you import a `Simulink.SimulationData.Dataset` data set, the block imports it as its own group.

**Importing Signal Groups from Existing Data Sets**

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

**Note** You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.
The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (.xls, .xlsx)
- Comma-separated value (CSV) text files (.csv)
- MAT-files (.mat)

**Tip** To import signal data from an Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

**Note** Signal Builder block uses the `xlsread` function. See the `xlsread` documentation for information on supported platforms.

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where # increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.
For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where # increments with each additional signal.
This example contains an acceptably formatted CSV file. The contents represent one signal group.

0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0

For MAT-files:

- The Signal Builder block supports data store logging that the `Simulink.SimulationData.Dataset` object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled.
- For backwards compatibility, the Signal Builder block supports logged data from the `Simulink.ModelDataLogs` object and interprets this data as a single group. The `ModelDataLogs` format will be removed in a future release.
- Signal Builder block does not support:
  - Simulink output as only a structure
  - Simulink output as only an array

**Note** Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace `Save` command to save the variables to a MAT-file. Import this file to the Signal Builder block.
Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

1. Create a model and drag a Signal Builder block into that model.
2. Double-click the block.
   
   The Signal Builder window appears with its default Signal 1.
3. In Signal Builder, select **File > Import from File**.
   
   The Import File dialog box appears.
4. In the **File to Import** field, enter a signal data file name or click **Browse**.
   
   The file browser appears.
5. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

   **Note** If you try to import an improperly formatted data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays a more detailed error message (if there is one). For example:

```
File 'signals.mat' format does not comply with Signal Builder required format.
There is no 'time' parameter defined.
............... 
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.
Select the signals you want to import. To import all the signals, click **Select All**.

From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Replace existing dataset**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the status. For example:
The confirmation also enables the OK and Apply buttons.

9 If you are satisfied with the status message, click Apply to replace the existing signal data with the contents of this file.

When selecting Replace existing dataset, the software gives you the opportunity to save the existing contents of the Signal Builder block.

10 Click a button, as follows:
<table>
<thead>
<tr>
<th>To...</th>
<th>Click...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save the contents of the Signal Builder block before replacing it with the new signal data.</td>
<td>Yes, save as</td>
</tr>
</tbody>
</table>

**Note**  This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content.

| Replace the contents of the Signal Builder block without saving them first. | No, import without saving                      |
| Stop the replacement process.                                             | Cancel                                         |

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.
12 Click **OK**.
13 Inspect the updated Signal Builder window to confirm that your signal data is intact.
14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

**Appending Selected Signals to All Existing Signal Groups**

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 71-92.
1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

   The Signal Builder window appears.
3. In the Signal Builder window, select **File > Import from File**.

   The Import File dialog box appears.
4. In the **File to Import** field, enter a signal data file name or click **Browse**.

   The file browser is displayed.
5. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

   **Note** If you try to import an improperly formatted signal data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

   ```
   File 'signals.mat' format does not comply with Signal Builder required format.
   There is no 'time' parameter defined.
   ................
   ```

   The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.
6. Select the signals you want to import. In this example, there are three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Select all the signals in `myGroup1`.

   ![Signal Groups](image)

   7. From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Append selected signals to all groups**.

   The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not
appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

8. Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```
3 signal(s) will be appended to each group.
Selected signal name(s):
Before:
Sig1
Sig2
Sig3

After:
Sig4
Sig5
Sig6

Signal name(s) in the block:
Before:
Sig1
Sig2
Sig3

After:
Sig1
Sig2
Sig3
Sig4
Sig5
Sig6

(Names may have been renamed for uniqueness.)
```

The confirmation also enables the **OK** and **Apply** buttons.

Observe the **Before** and **After** headings for the signals. These sections indicate the names of the block and imported data signals before and after the append action.

9. If you are satisfied with the status message, click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.

10. The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.
11 Click OK.

12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.

13 Close the Signal Builder window and save and close the model. For example, save the model as signalbuilder2.

**Appending Selected Signals to Sequential Existing Signal Groups**

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.
This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 71-92.

1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.
3. Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_THree`.

4. In the Signal Builder window, select **File > Import from File**.
5. In the **File to Import** field, enter a signal data file name or click **Browse**.
6. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.
**Note** If you try to import an improperly formatted signal data file, an error message pop-up window appears. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not comply with Signal Builder required format.
There is no 'time' parameter defined.
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

7. Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.

8. From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Append selected signals to different groups (in order)**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

9. Click the **Confirm Selection** button.

   If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:
The confirmation also enables the **OK** and **Apply** buttons.

10 If you are satisfied with the status message, click **Apply** to append the signals. The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.
11 Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.
To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.
Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder3`.

Appending Signal Groups to Existing Groups

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named `MyGroup1`, the software renames the imported group to `MyGroup2` upon appending. If you add another group named `MyGroup1`, the software names that latest version `MyGroup3`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 71-92.
1. In the MATLAB Command Window, type `signalbuilder1`.
2. Double-click the Signal Builder block.

The Signal Builder window appears.

3. Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Three signals exist in each group.

4. Double-click the block.

5. In the **File to Import** text field, enter a signal data file name or click **Browse**.

6. If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.
7  Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.

8  Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select myGroupB.

9  From the **Placement for Selected Data** list, select the action to take on the signal group. For example, select **Append groups**.

   The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

10 Click the **Confirm Selection** button.

   If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:
The confirmation also enables the **OK** and **Apply** buttons.

11 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB.
Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

**Appending Signals with the Same Name to Existing Signal Groups**

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

1. Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
2. Append a signal named `Sig1` to `myGroup1`.
3. Observe that the software increments `Sig1` to `Sig4` before appending it to `myGroup1`. 

12
Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

1. Assume your Signal Builder block has a signal group, myGroup1, with the signals Sig1, Sig2, and Sig3.
2. Append a signal group named myGroup2 whose signal names are SigA, SigB, and SigC.
3. Observe that the software:
   - Appends myGroup2.
   - Renames the signals in myGroup1 to be the same as those in myGroup2.

Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have the signal data from a file whose contents you want to import. See “Importing Signal Groups from Existing Data Sets” on page 71-88 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder `matlabroot\help\toolbox\simulink\examples` (open), as examples:

- **SigBldCustomFile.xls** — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

```
<table>
<thead>

```

- **createSignalBuilderSupportedFormat.m** — Custom MATLAB function that uses `xlsread` to read Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:

  - **grpNames** — Cell array that contains group name character vectors with number of rows = 1, number of columns = number of groups.
• **sigNames** — Cell array that contains signal name character vectors with number of rows = 1, columns = number of signals.

• **time** — Cell array that contains time data with number of rows = number of signals, columns = number of groups.

• **data** — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

• Number of signals in each group must be the same.

• Signal names in each group must be the same.

• Number of data points in each signal must be the same.

• Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1xN] or [Nx1], where N is the number of data points in every signal.

1 Identify the format of your custom signal data, for example:

   SigBldCustomFile.xls

2 Create a custom MATLAB function that:

   a  Uses a MATLAB I/O function, such as xlsread, to read your custom formatted signal data. For example, createSignalBuilderSupportedFormat.m.

   b  Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

3 Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

   createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')

4 Import the reformatted signal data file, OutputData.mat, into the Signal Builder block (see "Importing Signal Group Sets" on page 71-88).

### Editing Waveforms

Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.
Reshaping a Waveform

Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.

The Signal Builder displays the waveform points to indicate that the waveform is selected.

To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the Esc key.
**Working with Points**

You can work with points in a waveform:

- To select a point in a waveform, first select the waveform. Then, position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.

- To insert a point, select the waveform and **Shift**+click the section for the point.
- To deselect the point, press the **Esc** key.
- To delete a point, select the point and press the **Backspace** or **Delete** keys.
• To edit a point with the `signalbuilder` function, use the `signalbuilder set` function to replace the waveform. You cannot programmatically remove a point.

**Selecting Segments**

To select a line segment, first select the waveform that contains it. Then, left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.

To deselect the segment, press the `Esc` key.

**Moving Waveforms**

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 71-115) or by 0.1 inches if the snap grid is not enabled.

**Dragging Segments**

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.
Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

**Dragging points**

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the $y$-axis to the desired location. To drag the point along the time (horizontal) axis, press the Shift key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

**Snap Grid**

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder Axes menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the Axes menu to select the spacing that you prefer.
**Inserting and Deleting points**

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

**Editing Point Coordinates**

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

**Editing Segment Coordinates**

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point** and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

**Changing the Color of a Waveform**

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

**Changing a Waveform Line Style and Thickness**

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. Edit the thickness value and click **OK**.

**Signal Builder Time Range**

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change
both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 71-117).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 71-120 for more information).

| Note | When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model. |

### Changing a Signal Builder Time Range

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu.

In the dialog box, edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively.

### Exporting Signal Group Data

You can export data that defines Signal Builder block signals groups to a MAT-file or the MATLAB Workspace.

To export Signal Builder signal data, formatted as `Simulink.SimulationData.Dataset`, to a MAT-file, select **File > Export Data > To MAT-file**.
- **File name** — Enter a name for the MAT-file to contain the data.
- **Group indices** — Enter one or signal group numbers for which you want to export the data, specified as a scalar or vector. Numbers must correspond to an existing group in the block.

Alternatively, you can use the `signalbuilder` `get` function to return one or more data sets. For example:

```
[ds1 ds2]=signalbuilder(block,'get',[group1 group2])
```

To export signal data to the MATLAB workspace, select **File > Export Data > To Workspace**.

The Signal Builder exports the data by default to a workspace variable named `channels`. To export to a differently named variable, enter the variable name in the **Variable name** field. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure `xData` and `yData` fields contain the coordinate points defining signals in the currently selected signal group.

To access all the data in the signal groups of a Signal Builder block, use the `signalbuilder` `get` function:

```
[time, data]=signalbuilder(block,'get',signal,group)
```

For example:

```
% For time 0 to 5, create three signal groups.
block = signalbuilder([], 'create', [0 5], {{[2 2] [4 4] [7 8];[0 2] [0 4] [7 10]});
% Get the signals for all three groups.
[time, data]=signalbuilder(block,'get',[1 2],[1:3])
```

```
time =

2×3 cell array
   [1×2 double] [1×2 double] [1×2 double]
   [1×2 double] [1×2 double] [1×2 double]

data =

2×3 cell array
```
Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the Run or Run all button in the Signal Builder window (see “Running All Signal Groups” on page 71-119).

If you want to capture inputs and outputs that the Run all button generates, consider using the SystemTest™ software.

Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, and so on, all from the Signal Builder window.

Running All Signal Groups

To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the Run all button from the Signal Builder toolbar. The Run all button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Coverage on your system and are using the Model Coverage Tool, the Run all button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.
Note To stop a series of simulations started by the Run all command, enter Ctrl+C at the MATLAB command line.

**Simulation from Signal Builder Block**

To control simulations from the Signal Builder block, select File > Simulation Options.

**Signal values after final time**

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block.

- To output the last defined value of each signal in the currently active group for the remainder of the simulation, select Hold final value. For example:

![Graph](image)

- To output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation, select Extrapolate. For example:
• To output zero for the remainder of the simulation, select Set to zero. For example:

![Graph showing output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.]

**Sample time**

To output a continuous signal, enter 0 in the Sample time parameter. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.
To output a discrete signal, enter the sample time of the signal in this parameter. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a 0.5 second sample time.

Enable zero crossing

To have the Signal Builder block detect zero-crossing events, set **Enable zero crossing** On (default). The Signal Builder block sets the zero-crossing detection on the From Workspace block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-13.

Using Composite Signals
Types of Composite Signals

To reduce visual complexity in a model, you can combine signals into composite signals. The signals that a composite signal contains are called elements. Elements retain their separate identities, which let you extract them from the composite signal.

You can access composite signal elements by name or index, depending on the composite signal type.

- Index-based composite signals are flat, regardless of whether you create them in stages. They require that all input signals have the same data type.
- Name-based composite signals allow for signal hierarchy. They are generically called buses.

Note A Simulink bus is analogous to a bundle of wires held together by tie wraps. A Simulink bus is not analogous to a hardware bus, such as the bus in computer hardware architecture.

Not all blocks can accept buses and some blocks implicitly convert buses to vectors. To learn which blocks support which types of buses, see “Bus-Capable Blocks” on page 72-39. To learn how to identify implicit bus-to-vector conversions, see “Manage Bus-to-Vector Conversions”.

When you group signals into a composite signal, you can decide whether they affect simulation and code generation.

- A virtual composite signal simplifies the visual appearance of a model by combining two or more signal lines into one line. It does not group the signals in any functional sense and, therefore, does not affect simulation or code generation.
- A nonvirtual composite signal visually and functionally groups signals, affecting both simulation and code generation.

Models can use a combination of these composite signal types.

**Virtual Bus**

This model shows a virtual bus that contains signals a, b, and c.

![](image)

The Bus Creator block creates a virtual bus within a subsystem or model. The Bus Selector block extracts elements of the bus within a subsystem or model by specifying element names.

This model shows an equivalent virtual bus passing through a subsystem boundary.
Out Bus Element blocks create a virtual bus at a subsystem or model interface. In Bus Element blocks extract specified elements of a bus at a subsystem or model interface by specifying element names.

You can use virtual buses to:

- Contain bus elements that have different sample rates.
- Cross model reference boundaries, if the referenced model only uses a few of the bus elements.

Using a virtual bus is simpler and can be more efficient than using a nonvirtual bus. By accessing elements directly, virtual buses execute faster than nonvirtual buses in simulations and generated code. Only the elements of a virtual bus appear in generated code, even when the virtual bus is associated with test points.

To specify and validate the properties of a virtual bus, you can specify a Simulink.Bus object.

Some modeling features require nonvirtual buses, such as MATLAB Function blocks and Stateflow charts.

**Nonvirtual Bus**

This model shows a nonvirtual bus that contains signals a, b, and c.
The Bus Creator block creates a nonvirtual bus within a subsystem or model. The Bus Selector block extracts elements of the bus within a subsystem or model by specifying element names.

For nonvirtual buses at subsystem or model interfaces, use Outport and Inport blocks.

You can use nonvirtual buses to:

- Display and log bus signals with a Scope block.
- Construct an array of buses.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Interface with external code through an S-function.
- Package bus data as structures in the generated C code.

A Simulink.Bus object must define the bus you want to make nonvirtual. The bus object specifies only the architectural properties of a bus. For example, a bus object can specify element names, hierarchy, order, and data types. A bus object does not specify the values of the signals in a bus. For more information, see “Specify Bus Properties with Bus Objects” on page 72-55.

Since a virtual bus can specify a bus object, a bus becomes nonvirtual when you also select the Output as nonvirtual bus parameter.

All elements of a nonvirtual bus must use the same sample time, even if the associated bus object specifies inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal or of all signals in a bus.

The type of bus can make a significant difference in the efficiency, size, and readability of generated code. Generated code represents a nonvirtual bus as a structure. The structure
can be helpful for tracing the correspondence between the model and code. Generating code for nonvirtual buses can result in multiple copies of some buses. If you intend to generate code for a model that uses buses, see “Generate Efficient Code for Bus Signals” (Simulink Coder). For an example of the difference between virtual and nonvirtual buses in generated code, see “Generate Code for Buses” on page 72-16.

**Concatenated Signal**

This model shows a concatenated signal that places the input matrices side by side.

The Matrix Concatenate block creates concatenated signals. Elements can be either vectors or matrices, depending on how you configure this block. The Selector block extracts signals based on specified indices. The extracted signals can be grouped differently than the input signals.

You can use concatenated signals in mathematical operations.

To group signals with a Vector Concatenate or Matrix Concatenate block, the signals must have the same data type. When the data type is a bus object, the inputs must be nonvirtual buses.

Concatenated nonvirtual buses are also known as an array of buses. In an array of buses, all elements are nonvirtual buses that use the same bus object to specify properties. An array of buses is equivalent to an array of structures in MATLAB. You can use an array of buses to model a multichannel system. While all the channels have the same properties, each of the channels may have a different value.

In this model, a Vector Concatenate block creates an array of buses.
For more information on arrays of buses, see “Combine Buses into an Array of Buses” on page 72-89.

**Mux Signal**

This model shows a mux signal that places the three input signals side by side.
The Mux block creates multiplexed signals. The Demux block extracts all signals, which may be grouped differently than the input signals. For examples, see “Extract Vector Elements Using the Demux Block”. The Selector block extracts signals based on specified indices. The extracted signals can be grouped differently than the input signals.

You can use a multiplexed signal anywhere that you use an ordinary contiguous vector. For example, you can perform calculations on a multiplexed signal. The computation affects each constituent value in the multiplexed signal, as if the values existed in a contiguous vector. Using a multiplexed signal to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage. You can also use a Mux block to create a vector of function calls.

Input signals for a Mux block can be any combination of scalars, vectors, and multiplexed signals, but they must have the same data type. The signals in the output multiplexed signal appear in the same order as the input signals for the Mux block. You can use multiple Mux blocks to create a multiplexed signal in stages, but the result is flat as if you used a single Mux block.

Getting Started with Buses

You can combine signals into a bus signal and then access the bus as a whole or select specific signals from the bus. These examples show the fundamentals of creating and using buses in models and in generated code. For additional information, see “Virtual Bus” on page 72-3.

</table>

**Tip** For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

For more information, see “Simplify Bus Interfaces” on page 72-20.

These examples are simple, to focus on the basic steps in creating and using buses. Buses are most useful when you have many signals that make sense to combine to reduce visual...
complexity. The examples also include steps to label blocks and signals, to clarify the relationship between signals and buses and between blocks. If you choose to build the example models step-by-step, you can skip those steps if you like.

**Create and Use Virtual Buses**

This example shows how to combine signals into virtual buses. The model selects individual signals (bus elements) from a virtual bus and uses the bus elements as individual signals.

**Tip** To change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus, you can use a Bus Assignment block. For details, see “Assign Signal Values to a Bus” on page 72-44.

To see the completed model, open the `ex_bus_tutorial_virtual` model. When you simulate the model, the bus signal lines indicate that the buses are virtual.
Perform these steps to gain experience creating and using virtual buses.

1. From the Simulink Start Page, select a blank model template.
2. In the Simulink Editor, add a Chirp Signal block and a Sine Wave block.
3. Create a bus for the signals from the two blocks. Drag to select the blocks and in the action bar that appears, click **Create Bus**.

   Simulink adds a Bus Creator block and connects the input signals to that block.

4. By default, the Bus Creator block name does not appear. To add a block name, select the block and from the action bar that appears, select **Show Block Name**. Then edit the name, changing it from **Bus Creator** to **SubBus**.

5. You do not have to label the signals in a bus. However, labeling makes it easier to see the relationship between bus element signals and bus signals. Label the output signal for the Chirp Signal block. Right-click the signal and select **Properties**. In the **Signal name** property, enter **chirp**. Similarly, set the Sine Wave signal name to **sine**.

   **Note** Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (**signal#**) to all input signal names, where # is the input port index.

   Do not use a less than character (<) to start a signal name.

6. Add a Step block below the Sine Wave block.

7. To create a nested bus, add a Bus Creator block to the right of the current blocks. Connect the signal from the **SubBus** block and the signal from the Step block to the second Bus Creator block.
8. Label the output signal from the SubBus block `subBus` and the signal from the Step block `step`.

9. Show the block name for the Bus Creator block that creates the nested bus. Change the name to `NestedBus`.

10. Attach a Scope block to the `nestedBus` signal.

11. To the right of the `NestedBus` block, add a Subsystem block and connect the `NestedBus` output signal to the subsystem.

12. Connect the Subsystem block output port to a Scope block.

13. In the subsystem, disconnect the Inport and Outport blocks and insert a Bus Selector block to the right of the Inport block. Connect the Inport block to a Bus Selector block.

14. Show the Bus Selector block name. Change the name to `BusSelector`.

15. To the right of the Bus Selector block, add a Saturation block and set its **Lower limit** parameter to `-inf`.

16. Combine the `chirp` signal and the Saturation block output signal into a bus.

17. Combine the bus signal and the `step` signal into a nested bus.

18. Connect the nested bus to the Outport block.

19. To see the simulation results, simulate the model and open the Scope blocks.
Create and Use Nonvirtual Buses

This example changes the virtual buses used in the \texttt{ex\_bus\_tutorial\_virtual} model to nonvirtual buses. To see the completed model, open the \texttt{ex\_bus\_tutorial\_nonvirtual} model. Nonvirtual buses are required for certain modeling situations. Generating code for a nonvirtual bus represents the bus as a structure. For more information about when to use nonvirtual buses, see “Nonvirtual Bus” on page 72-4.

When you simulate the model, the bus signal lines indicate that the virtual are converted to nonvirtual buses.

Perform these steps to gain experience creating and using nonvirtual buses.
1. Open the `ex_bus_tutorial_virtual` model.

2. Bus signals do not specify whether they are virtual or nonvirtual; they inherit that specification from the block in which they originate. Every block that creates or requires a nonvirtual bus must have an associated bus object.

   For the SubBus block, specify to produce nonvirtual bus output. In the Block Parameters dialog box, set **Output data type** to **Bus: subBus**. This setting uses the `subBus` bus object, which provides bus properties that Simulink uses to validate the bus signal.

   Also, select the **Output as nonvirtual bus** parameter.

   **Note** When you use bus objects to create nonvirtual buses, the bus object must be in the base workspace before simulating the model. You need to define the bus object or use an already defined bus object. To simplify this example, when you open the model, a model callback loads the necessary bus objects into the base workspace. To see the callback, on the **Modeling** tab, under the **Model Settings** dropdown, click **Model Properties** and open the **Callbacks** tab.

   For information about creating bus objects, see “Specify Bus Properties with Bus Objects” on page 72-55.

3. In the NestedBus block, set **Output data type** to **Bus: topBus** and select the **Output as nonvirtual bus** parameter.

4. The `subBus` bus object expects the second input signal in the bus to be called `sine`. Although the Bus Selector block selected the `sine` signal from the bus, the default name of the output signal of the Saturation block is not `sine`. Use the **Signal Properties** dialog box to name the Saturation block output signal `sine`.

5. The `topBus` bus object expects the first input signal in the bus to be called `subSignal`. Use the **Signal Properties** dialog box to name the bus signal `subSignal`.

6. To see the simulation results, simulate the model and open the Scope blocks. The results are the same as when you simulate the `ex_bus_tutorial_virtual` model that you used as a base for this model.
Generate Code for Buses

The simulation results are the same for the model that uses virtual buses (ex_bus_tutorial_virtual) and for the model that uses nonvirtual buses (ex_bus_tutorial_nonvirtual). However, the generated code is different.

Adding a Unit Delay block and an Outport block after the Subsystem block in each of the models helps to highlight the differences in the generated code.
Generated Code for the Virtual Bus Model

Generate code from the `ex_bus_tutorial_virtual_code_gen` model.

The virtual buses do not affect the generated code. For example, in the generated file `ex_bus_tutorial_virtual_code_gen.c`, the algorithm in the model `step` function effectively implements three `Unit Delay` blocks (one for each meaningful signal, such as `chirp`, that passes through the block).

```c
/* UnitDelay: '<Root>/Unit Delay' */
rtb_chirp = ex_bus_tutorial_virtual_code_DW.UnitDelay_1_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_signal2 = ex_bus_tutorial_virtual_code_DW.UnitDelay_2_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_step = ex_bus_tutorial_virtual_code_DW.UnitDelay_3_DSTATE;
```

Generated Code for the Nonvirtual Bus Model

For the nonvirtual bus model, the **Output data type** is set to `Bus: topBus` and Scope blocks are commented out, because Scope blocks are not needed for the generated code and do not support code generation.

Generate code from the `ex_bus_tutorial_nonvirtual_code_gen` model.
The nonvirtual buses appear in the generated code as structures. Each Simulink.Bus object appears as a structure type. The type definitions appear in ex_bus_tutorial_nonvirtual_code_gen_types.h.

```c
typedef struct {
    real_T chirp;
    real_T sine;
} subBus;

typedef struct {
    subBus subSignal;
    real_T step;
} topBus;
```

The algorithm in the model step function can implement the Unit Delay block as a single line of code. The block state and output are structures of type topBus.

```c
/* UnitDelay: '<Root>/Unit Delay' */
rtb_UnitDelay = ex_bus_tutorial_nonvirtual_c_DW.UnitDelay_DSTATE;
```

Simplify Bus Interfaces

To simplify subsystem and model interfaces, you can use In Bus Element and Out Bus Element blocks as inputs and outputs. You can use these blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. For example, this model uses Inport, Bus Selector, Bus Creator, and Outport blocks.

Here is an equivalent model that uses bus element port blocks.

Bus element port blocks:
- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.
Consider using bus element ports for models with bus signals that you anticipate changing frequently during the model development process.

**Tip** To refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks, you can use Simulink Editor action bars. Conversion operations are supported only when the signal lines or blocks do not have any extra specification. For details, see “Convert Models to Use Bus Element Ports” on page 72-25.

Bus element port blocks have these restrictions:

- The Out Bus Element output bus is a virtual bus.
- Bus objects associated with signals used with bus element port blocks are ignored.
- You cannot specify the underlying Inport or Outport block specifications, such as word length.

**Bus Element Ports**

The simplified interface involves creating bus element ports. Use In Bus Element blocks to select elements from a bus signal that is fed to a subsystem. For nonbus signals (including arrays of buses) that feed a subsystem, the In Bus Element block can pass (if no signals are selected) through the value of the input signal for use within the subsystem.

Use Out Bus Element blocks to combine subsystem signals into a virtual bus to output from the subsystem.

You can use bus element port blocks with virtual buses. For nonvirtual bus signals, arrays of buses, and nonbus signals, these limitations apply:

- For array of bus signals and nonbus signals, the bus element port blocks can only pass through the whole signal, rather than selecting individual elements of the signal.
- An Out Bus Element block outputs a virtual bus signal from the subsystem.

The In Bus Element block is of block type Inport. The Out Bus Element block is of block type Outport. The bus element port blocks support inherited workflows. You can use the Block Parameters dialog box of a bus element port block to specify bus element attributes, such as data type or dimensions.
In the same subsystem, you can use a combination of bus element port blocks with Inport and Outport blocks. However, to improve the readability of the model, define a bus interface for a subsystem by using bus element port blocks throughout the subsystem.

Bus element port blocks have these restrictions:

• The Out Bus Element output bus is a virtual bus.
• Bus objects associated with signals used with bus element port blocks are ignored.
• You cannot specify the underlying Inport or Outport block specifications, such as word length.

**Note** If you save a model containing bus element port blocks to a version of Simulink earlier than R2017a, Simulink converts the model to use a subsystem that contains Bus Selector and Bus Creator blocks, as appropriate.

### Create Bus Element Ports

For a new subsystem, creating bus element ports involves adding In Bus Element blocks to select subsystem input signals and Out Bus Element blocks to create virtual bus output signals for the subsystem. For examples showing the workflow for adding bus element ports, see the In Bus Element documentation.

**Note** The In Bus Element block has two different names, depending on the Simulink library in which it appears. The functionality of both blocks is the same.

- In the Sources library and the Ports & Subsystems library — In Bus Element
- In the Signal Routing library — Bus Element In

The Out Bus Element block has two different names, depending on the Simulink library in which it appears. The functionality of both blocks is the same.

- In the Sinks library and the Ports & Subsystems library — Out Bus Element
- In the Signal Routing library — Bus Element Out

### Add In Bus Element Blocks

To add an In Bus Element block, you can:
- Drag the block from the Library Browser. This action adds a port or adds a new
  element if a port with the same name exists.
- Use quick insert. This action adds a port.
- Copy the block from an existing block. Either use copy and paste or right-click and
  drag the block. If you use the right-click approach, specify whether to use the same
  port as the original block for new block or to add a subsystem port.
- In the Block Parameters dialog box list of input signals, select a signal and click .

**Tip** Before selecting a signal, make sure that a bus input signal is connected to a
subsystem input port.

To select a signal from the input port, use one of these approaches. To select multiple
signals from an input bus signal, create multiple In Bus Element blocks, one for each
selected signal.

- Using the Block Parameters dialog box, select from the signals that are in the bus
  connected to this port. The signals listed in black are already selected and used in the
  subsystem, and signals in grey are available but are not used already. Signals in red
  are not available in the input bus signal. For example, signals a and b are already
  selected, signal c is available to select, and signal d is not available.

```
\begin{verbatim}
\bf{InBus}
  \textit{a}
  \textit{b}
  \textit{c}
  \textit{d}
\end{verbatim}
```

After you select the signals, click .

- In the Simulink Editor, edit the element part of the block icon text. If the port is
  already connected outside the subsystem, you can select from a list of available
  signals. For example, if you did a right-click copy of an In Bus Element port block and
  used the existing port, you can click on text to change the selected element.
If you delete the b (the element part of the block icon text), then you get a list of signals that you can select.

To pass through a whole signal, leave the element section of the block icon text empty.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box Set color option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements. You can change the name of the port using the Block Parameters dialog box.

**Add Out Bus Element Blocks**

To output multiple signals from a subsystem as a bus signal, create multiple Out Bus Element blocks, one for each signal that you want to include in the bus. To add an Out Bus Element block, you can:

- Drag the block from the Library Browser. This action adds a port or adds a new element if a port with the same name exists.
- Use quick insert. This action adds a port.
- Copy the block from an existing block. Either copy and paste or right-click and drag the block. If you use the right-click approach, specify whether to use the same port as the original block for the new block or to add a subsystem port.
- In the Block Parameters dialog box, click Set color option. To change the signal name, double-click the signal name in the tree view or in the block diagram and edit the icon text.
If an Out Bus Element block creates a signal A, then another Out Bus Element block for the same port cannot specify signal A (or a child of signal A) as an element.

To add a nested bus, in the Block Parameters dialog box, click \(\text{†} \). To remove blocks associated with selected elements, click \(\square\).

You can reorder bus elements by dragging and dropping a signal in the list of signals in the Block Parameters dialog box.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box Set color option. This action sets the color of blocks associated with selected elements, or of all blocks if you do not select elements.

**Convert Models to Use Bus Element Ports**

You can refactor a subsystem interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks. Conversion operations are supported only when the signal lines or blocks do not have any extra specification, including signal logging. You can:

- Convert Inport and Bus Selector blocks in a subsystem to In Bus Element blocks.
- Convert Outport and Bus Creator blocks in a subsystem to Out Bus Element blocks.
- Transform input or output interfaces of subsystems to use bus element port blocks.

For examples that show how to convert models to use bus element ports, see slexBusExample.

**Convert Subsystem Bus Selector Blocks**

You can convert a subsystem that uses Bus Selector blocks to use In Bus Element blocks instead.

1. Click the Bus Selector block that is connected to the Inport block.
2. From the action bar, select **Bus Element Ports**.
The converted subsystem uses In Bus Element blocks.

You can do a similar conversion for multiple layers of Bus Selector blocks.

1. Perform the conversion on the Bus Selector block that is connected to the Inport block.
2. Convert the second Bus Selector block.

**Note** This action is not available if the Bus Creator block output signal has a branch.
**Convert Subsystem Bus Creator Blocks**

You can convert a subsystem that uses Bus Creator blocks to use Out Bus Element blocks instead.

1. Click the Bus Creator block that is connected to the Outport block.
2. From the action bar, select **Bus Element Ports**.

The converted subsystem uses Out Bus Element blocks.

You can do a similar conversion for multiple layers of Bus Creator blocks.
1 Perform the conversion on the Bus Creator block that is connected to the Outport block.

2 Convert the second Bus Creator block.

**Transform Subsystem Input and Output Interfaces**

You can convert signals between subsystems to use In Bus Element and Out Bus Element blocks.

**Note** Conversion of existing subsystem inputs and outputs to use bus element ports creates virtual buses. If your model relies on the types of the original signals being nonvirtual buses, array of buses, or scalars, choose one of these options:

- Do not perform the conversion.
- Modify the model so that it works properly with the newly created virtual buses.

1 Perform a marquee selection of the signals that connect two subsystems.

2 From the action bar, select **Create Bus**.

The conversion creates Out Bus Element blocks in the source subsystem and In Bus Element blocks in the destination subsystem.
In the converted model, there is one bus signal between the subsystems, and the BasicSrc and BasicDst subsystems use In Bus Element and Out Bus Element blocks, respectively.
If the input of a subsystem is not directly connected to another subsystem, you can transform the input of the subsystem. If you transform the subsystem input, Simulink...
inserts a Bus Creator block to maintain connectivity and the subsystem uses In Bus Element blocks.

1. Perform a marquee selection of the input signals of the subsystem.
2. From the action bar, select **Create Bus**.

The converted model uses Bus Creator blocks for subsystem inputs and Bus Selector blocks for subsystem outputs. The converted subsystem (Subsystem3) contains In Bus Element and Out Bus Element blocks.

Display Information About Buses

Viewing information about bus signals can help you during model creation, debugging, and analysis. To view information about buses, you can use different approaches, depending on your modeling task:

- To display bus signals in a bus hierarchy interactively, use the “Signal Hierarchy Viewer” on page 72-33.
- To display the value of a specific port or port values for a block before simulation, right-click on the signal and select **Show Value Label of Selected Port**. For details, see “Port Value Display” on page 72-36.
- To display at the MATLAB command line the type and hierarchy of a bus signal use the CompiledType and SignalHierarchy parameters. For details, see “CompiledBusType and SignalHierarchy Parameters” on page 72-37.

**Signal Hierarchy Viewer**

You can use the Signal Hierarchy Viewer to display information about a signal. To display the bus hierarchy:

1. Right-click a signal line.
2. Select the **Signal Hierarchy** option. The Signal Hierarchy Viewer dialog box appears.

For example, open the busdemo model.
Right-click the main_bus signal (output signal for the Bus Creator block), and select **Signal Hierarchy**.
Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

You can also open the Signal Hierarchy Viewer in the Simulink Editor.

1. Select a signal.
2. On the Signal tab, in the Hierarchy section, click the Signal Hierarchy button.

**Note** To produce accurate results at edit time, the Signal Hierarchy Viewer requires that the model compiles successfully.

To filter the displayed signals, click the Options button on the right-hand side of the Filter by name edit box ( ![Options icon](placeholder.png)).

- To use MATLAB regular expressions for filtering signal names, select Enable regular expression. For example, to display all signals whose names end with a lowercase r (and their immediate parents), enter r$ in the Filter by name edit box. For details, see “Regular Expressions” (MATLAB).
- To use a flat list format to display the list of filtered signals, based on the search text in the Filter by name edit box, select Show filtered results as a flat list. The flat list format uses dot notation to reflect the hierarchy of bus signals. This example shows a flat list format for a filtered set of nested bus signals.
Port Value Display

To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in `ModelBus`. 
For more information about port value display, see “Display Value for a Specific Port” on page 37-24.

**CompiledBusType and SignalHierarchy Parameters**

To get information about the type and hierarchy of a bus signal in a compiled model, use these parameters with the `get_param` command:

- **CompiledBusType** — For a compiled model, returns information about whether the signal connected to a port is a bus and whether the signal is a virtual or nonvirtual bus.
- **SignalHierarchy** — If the signal is a bus, returns the name and hierarchy of the signals in the bus.

Before you use these commands, for `CompiledBusType`, update the diagram or simulate the model.

For example, open and simulate the `busdemo` model.
This code illustrates how you can use the SignalHierarchy and CompiledBusType parameters:

```matlab
mdl = 'busdemo';
open_system(mdl)
% Obtain the handle a port
ph = get_param([mdl '/Bus Creator'], 'PortHandles');
% SignalHierarchy is available at edit time
sh = get_param(ph.Outport, 'SignalHierarchy')
% Compile the model
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
% Terminate the model
busdemo([],[],[],'term');
```

Bus-Capable Blocks

Bus-capable blocks can accept bus signals as input, produce bus signals as output, or both. Some bus-capable blocks work with nonvirtual buses, but not with virtual buses. Some bus-capable blocks have additional requirements for bus signals; see the block documentation for details.

Buses that contain signals of enumerated data types do not pass through a block that requires a nonzero scalar initial value (such as a Unit Delay block). Use a structure value to initialize signals with enumerated types.

Root level bus outputs are not logged when you select the **Output** configuration parameter. Use standard signal logging instead, as described in “Export Signal Data Using Signal Logging” on page 68-70.

Do not use signal logging for bus or arrays of buses directly from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals to log or add

Nest Buses

You can nest buses to any depth. To create a nested bus, use a Bus Creator block. If one of the inputs to the Bus Creator block is a bus, then the output is a nested bus. To select a signal within a nested bus, use a Bus Selector block.

For example, in the next model, the Bus3 bus signal combines two signals, motor3 and motor4. The Bus2 signal combines the Bus3 bus signal and the motor1 and motor2 signals. The Bus1 signal combines the Bus2 bus signal and the motor5 signal.

All the signals retain their separate identities, as if no bus creation and selection occurred. You can use Bus Selector blocks to select individual signals from a nested bus.

The Simulink software automatically handles most of the complexities involved. For example, you can have Simulink repair broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. To enable these automatic repairs, in the Configuration Parameters dialog box, set the Repair bus selections diagnostic to Warn and repair. The repairs occur when you update a model. To save the repairs, save the model.
Circular Dependency in Bus Definitions

Nesting buses can produce a loop of Bus Creator, Bus Selector, and bus-capable blocks that inadvertently includes a bus as an element of itself. The resulting circular definition cannot be resolved and therefore causes an error.

The error message that appears specifies the location at which the Simulink software determined that the circular structure exists. The error is not really at any one location: the structure as a whole is in error. Nonetheless, the location cited in the error message can be useful for beginning to trace the definition cycle. However, the circular structure is not always obvious on visual inspection.

1. Begin by selecting a signal line associated with the location cited in the error message.
2. Right-click a signal and choose Highlight Signal to Source or Highlight Signal to Destination. See “Highlight Signal Sources and Destinations” on page 71-39 for more information.
3. Continue choosing signals and highlighting their sources and destinations until the cycle becomes clear.
4. Restructure the model to eliminate the circular bus definition.

Because the problem is a circular definition rather than a circular computation, the cycle cannot be broken by inserting additional blocks. You cannot fix the circular definition the way that you can break an algebraic loop by inserting a Unit Delay block. Restructure the model to eliminate the circular bus definition.

Assign Signal Values to a Bus

To assign the values of a signal to bus element, you can use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect to the Bus Assignment block ports:

- The bus signal to which you want to assign the signal values
- The signals whose values you want to assign to specified bus elements

Connect the bus signal to the first input port of the Bus Assignment block, and one or more signals to be assigned to the other ports. The Block Parameters dialog box lists the signals available for assignment in the bus. The bus can be virtual or nonvirtual. Select the elements to which you want to assign signal values. If you specify more than one signal to assign values to, the Bus Assignment block adds ports.

The signals that you assign values to can be nonbus or bus signals. The signals must match the attributes of the signals in the original bus.

Update a Bus Element

This simple example illustrates the mechanics of using the Bus Assignment block. In more complex models, using a Bus Assignment block simplifies updating a bus to reflect the processing that occurs in a separate component, such as a subsystem or referenced model. Here is the model after you simulate it.
Some key steps in constructing this model are:

1. Connect two Constant blocks to a Bus Creator block. The value of signal a is 1, and the value of signal b is 2.

2. Connect the Bus Creator output signal `const_bus` to the first port of a Bus Assignment block. The bus elements a and b are available to assign new values to them.

3. Connect the Constant block output signal c to the second port of the Bus Assignment block.

4. For the Bus Assignment block, in the Block Parameters dialog box Signals in the bus list, select the a signal and click Select>>.

   ![Block Parameters: Bus Assignment](image)

5. Use a Bus Selector to select signals a and b from the `const_bus` signal and connect those signals to Display blocks.

6. Simulate the model. The Display blocks show that the value of signal a, which was 1 when the `const_bus` bus was created, is now 3, reflecting the assignment of the c signal from the `Const3` block.

Correct Buses Used as Vectors

When a block that requires a vector input receives a bus input, the bus is implicitly treated as a vector. Configuring a model to avoid using buses as vectors:

- Improves loop handling
- Contributes to consistent edit and compile-time behavior

Correct Buses Using the Model Advisor

When correcting buses used as vectors, the Model Advisor generally provides the most efficient approach.

1. On the Modeling tab, click Model Advisor.
2. Select the top model, then click OK.
3. Select By Task > Modeling Signals and Parameters using Buses > “Check bus signals treated as vectors”.
4. Click the Run This Check button.

The Model Advisor reports any cases of buses treated as vectors.
5. Follow the Model Advisor suggestions for correcting errors reported by the check.

For additional information about using the Model Advisor, see “Check Your Model Using the Model Advisor” on page 5-2.

Add Bus to Vector Blocks

To explicitly convert a bus to a vector, add Bus to Vector blocks using one of these approaches:

- Insert the Bus to Vector block into buses treated as vectors.
- Use the Simulink.BlockDiagram.addBusToVector function, which automatically inserts Bus to Vector blocks where buses are treated as vectors.

For example, model ex_bus_to_vector treats buses as vectors by using the buses as inputs to Gain blocks.
This figure shows the same model with Bus to Vector blocks after the Bus Creator block.

The Scope block shows the simulation results.

The simulation results are the same in either case. The Bus to Vector block is virtual, and does not affect simulation results, code generation, or performance.

**Reorganize the Model**

To avoid feeding a bus into a block that requires a vector input, you can manually replace the source for a block that requires vector inputs.

For example, in model `ex_bus_to_vector`, the Gain block requires a vector signal. However, the input signal is a bus created by a Bus Creator block.
To provide the required vector signal for the Gain block, replace the Bus Creator block with a Mux block.

Reorganizing the model manually poses these challenges:

- Identifying all occurrences in a model can be difficult.
- Dealing with many occurrences in a model is time-consuming and error-prone.
- Reorganizing the model to address this issue can interfere with other aspects of the model.

**Identify Implicit Bus-to-Vector Conversions**

To identify buses treated as vectors:

- Use the Model Advisor **Check bus signals treated as vectors** check.
- Use the `Simulink.BlockDiagram.addBusToVector` function.
- Set configuration parameter **Bus signal treated as vector** to **warning** or **error**. The default setting for **Bus signal treated as vector** is **none**, which generates no warning or error message when a block implicitly converts a bus to a vector during simulation.

More About

• “Types of Composite Signals” on page 72-2
Specify Bus Signal Sample Times

The technique that you use to combine signals that use different sample times depends on the virtuality of the bus.

- Virtual buses can combine signals that have different sample times.
- Nonvirtual buses require that every element signal has the same sample time.

Sample Times for Nonvirtual Buses

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that results in a nonvirtual bus that violates this requirement generates an error. All buses and signals input to a Bus Creator block that outputs a nonvirtual bus must have the same sample time.

To include signals or a bus in a nonvirtual bus that has elements with different sample times, you can change the sample time of bus element signals by inserting Rate Transition blocks upstream of the Bus Creator block.
However, some blocks automatically convert virtual buses to nonvirtual buses. Examples of these kinds of blocks include as root-level Outport and Inport blocks, MATLAB Function, and S-Function blocks. You can use a single Rate Transition block after a Bus Creator block to transition all the signal elements to a single sample time.
For more information about automatic conversion of virtual buses to nonvirtual buses, see “Bus Conversion” on page 72-134.

**Specify Sample Times for Signal Elements**

To control the sample time of each signal element in a bus, specify the sample time in the Block Parameters dialog box of the block that generates the signal element.

To specify a sample time for a signal in a Simulink.Bus object, a best practice is to use the default SampleTime value of -1.

- “Sample Time”
Specify Bus Properties with Bus Objects

A bus can have an associated bus object, which provides properties that Simulink uses to validate the bus signal. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. Another way of thinking of a bus object is that it is similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a bus object defines the configuration and properties of the signals that the associated bus must have.

A bus object is an instance of class Simulink.Bus that can be stored in a location such as the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size.

A bus object serves as the root of an ordered hierarchy of bus elements, which are instances of class Simulink.BusElement. Each element completely specifies the properties of a signal in a bus, such as its name, data type, and dimensionality. The order of the elements contained in the bus object defines the order of the signals in the bus. A bus object can also specify properties that were not defined by constituent signals, but were left to be inherited.

Bus Object Workflow

Using bus objects in a model involves performing these tasks, in many cases iteratively.

1  “Determine Whether to Use Bus Objects” on page 72-56
2  “Determine How to Manage Bus Objects” on page 72-57
3  “Create and Specify Bus Objects” on page 72-58
4  “Save Bus Objects” on page 72-59
5  “Map Bus Objects to Models” on page 72-60
Determine Whether to Use Bus Objects

Required Uses of Bus Objects

You must use bus objects for these modeling configurations:

- Nonvirtual buses that cross model reference boundaries
- Stateflow charts with bus input or output
- S-function or Legacy Code Tool interface with external code

You can associate a bus object with multiple blocks. Some blocks require that you specify a bus object if the block has a bus input or output. When a bus object governs a signal input or output for a block, the signal must be a bus that has the properties specified by the object. Any variance causes an error.

These blocks require a bus object for bus input and output.

- Constant

- From Workspace
- Function Caller
- Inport (top-level)
- Interpolation Using Prelookup
- MATLAB Function
- MATLAB System
- Outport (top-level)
- Prelookup
- S-Function
- State Reader

Optional Uses of Bus Objects

If you use Bus Creator block parameters to specify bus signal properties, all blocks downstream from the bus inherit the same properties.
You can use Bus Creator block parameters to define virtual buses and perform limited error checking. To perform thorough error checking on a bus, associate a bus object with that bus. Using bus objects to check bus signals for errors is important when you want to create reusable and shareable model components.

To make tracing the correspondence between the model and the generated code for a bus easier, use a nonvirtual bus. The generated code for a nonvirtual bus produces a structure. Nonvirtual buses can result in multiple copies of some bus signals.

These blocks can specify a bus object for bus input and output.

- Argument Inport
- Argument Outport
- Bus Creator
- In Bus Element
- Out Bus Element
- Permute Dimensions
- Probe
- Reshape
- Signal Conversion
- Signal Specification
- Unit Delay

**Determine How to Manage Bus Objects**

You can save bus objects to these locations:

- Data dictionary
- MATLAB file
- MAT-file
- Database or other external files

If you do not save bus objects, then when you reopen a model that uses the bus objects, you need to recreate the bus objects.

Different bus object storage locations provide different advantages.

### Create and Specify Bus Objects

To create and edit bus objects interactively, use the Bus Editor. Bus objects created with this tool are initially stored in the base workspace.

To create and edit bus objects programmatically, see “Create Bus Objects Programmatically” on page 72-67. Bus objects created from classes and functions are initially stored in either the base workspace or a MATLAB file.

After you create a bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides. To associate a block with a bus, in the Block Parameters dialog box, set Data type to Bus: <object name> and replace <object name> with the bus object name.

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding signal in the model must have the same attributes.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

If you do not want to change the bus object, you can:
• Create a bus object that matches the changes to the bus and use the new bus object for the blocks that the changed bus connects to.
• Revert the bus changes so that the bus continues to match the associated bus object.

**Save Bus Objects**

To save bus objects stored in the base workspace, you can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just bus objects.

<table>
<thead>
<tr>
<th>Location</th>
<th>File Creation Method</th>
<th>File Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data dictionary</td>
<td>See “Migrate Models to Use Simulink Data Dictionary” on page 70-7.</td>

<td>Bus objects</td>
</tr>
</tbody>
</table>

You can customize bus object export by providing a custom function that writes to a location outside MATLAB. For example, exported bus objects can be saved as records in a database. See “Customize Bus Object Import and Export” on page 72-70 for details.

When you modify saved bus objects, you must resave them to keep the changes.
Map Bus Objects to Models

Before you simulate a model, all the bus objects it uses must be loaded into the base workspace. For automation and consistency across models, mapping bus objects to models is important.

- By identifying all of the bus objects that a model requires, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a bus object, you can ensure that changes to a bus object do not cause unexpected changes in any of the models that use the bus object.

To ensure the necessary bus objects load before model execution, consider:

- Projects — Automatically load or run files that define bus objects by configuring the files to run when you open a project. For details, see “Project Management”.
- Data dictionaries — Store bus objects with variables and other objects for one or more models.

To share a bus object among models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 70-35.

- Databases — Capture mapping information in an external data source, such as a database.

You can customize bus object import by providing a custom function that reads from a location outside MATLAB. See “Customize Bus Object Import and Export” on page 72-70 for details.

- Model callbacks — Automatically load or run files that define bus objects by using the load function in a model callback.

    If a model uses only a few bus objects, consider copying the bus object code directly into the callback, instead of loading a file. For an example, open model and examine the callback.

To find where a bus object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 66-151.

**Tip** Using a rigorous and standard naming convention is very helpful for mapping bus object usage. For example, consider the model and data required for an actuator control
function. Naming the model `Actuator` and the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively, makes the connection between the bus objects and the model clear.

Note that this approach can cause issues if the output from one model is fed directly to another model. In this case, the naming mismatch results in an error.

Create Nonvirtual Buses

Nonvirtual buses affect simulation and code generation. A block connected to a nonvirtual bus reads inputs and writes outputs by accessing copies of the individual signals in the bus. These copies are stored in the area of memory allocated to the bus.

You can use nonvirtual buses to:

• Display and log bus signals with a Scope block.
• Construct an array of buses.
• Have bus data cross MATLAB Function block or Stateflow chart boundaries.
• Interface with external code through an S-function.
• Package bus data as structures in generated code.

To create a nonvirtual bus, you must specify a bus object data type and that the bus is nonvirtual at a Bus Creator, In Bus Element, Out Bus Element, Inport or Outport block.

• Set Data type to Bus: <object name>, where <object name> is the bus object name.
• Select Output as nonvirtual bus or, for output port blocks, Output as nonvirtual bus in parent model.

You can use a bus object to specify the data type for a block without specifying that the bus is a nonvirtual bus. Bus objects are optional for virtual buses, but required for nonvirtual buses. For more information on bus objects, see “Specify Bus Properties with Bus Objects” on page 72-55.

Model specifies nonvirtual buses, which can be identified by their line style after model compilation.
If you clear **Output as nonvirtual bus** for a Bus Creator block and update the diagram, the output bus becomes virtual and the line style changes to three solid lines.
Use Nonvirtual Buses with MATLAB Function Blocks

If a MATLAB Function block outputs a structure, then you need to use a bus object to define a bus output. In model ex_bus_object_matlab_func, the MATLAB Function block includes MATLAB code that creates a structure.

To see the structure definition, double-click the MATLAB Function block.

```matlab
function y = fcn(u1,u2)
    y.u1 = u1;
    y.u2 = u2;
    y.mathOperations.sum = u1+u2;
    y.mathOperations.product = u1*u2;
```

Open the Bus Editor and expand the bus object definition that represents the structure.
To see how the bus object is used to define the bus output for the MATLAB Function block, in the MATLAB Editor, click **Edit Data** and then click **y**. The output **Type** is defined as the `function_bus` bus object.

• “Create Bus Objects Programmatically” on page 72-67
Create Bus Objects Programmatically

To create a bus object and its bus elements programmatically from scratch or based on a block, data, or C code.

- “Create Bus Objects from Blocks” on page 72-68 — Create a bus object and its bus element objects based on a block in a model.
- “Create Bus Objects from MATLAB Data” on page 72-68 — Create a bus object and its bus elements based on a MATLAB structure or cell array.
- “Create Bus Objects from External C Code” on page 72-69 — Create a bus object and its bus elements based on your external C code (struct). Use the Simulink.importExternalCTypes function.

As you create bus objects programmatically, you can store them in either the MATLAB workspace or in a MATLAB file. After you create a bus object, you can use MATLAB commands to save the bus objects to a MAT-file (see “Save and Load Workspace Variables” (MATLAB)). To simulate a block that uses a bus object, that bus object must be in the base workspace or in a data dictionary.

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding bus element signal must have the same data type and dimensions.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

Create Simulink.Bus and Simulink.BusElement Objects Directly

You can create a Simulink.Bus object and its Simulink.BusElement objects programmatically. The bus objects are stored in the base workspace. For each bus element object, specify the name, dimensions, and data type. The other bus element object properties are optional. For the bus object, specify the bus elements. The other bus
object properties are optional. For example, this code creates two bus element objects that are then used as the elements of the CONTROL bus object.

clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'VALVE1';
elems(1).Dimensions = 1;
elems(1).DimensionsMode = 'Fixed';
elems(1).DataType = 'double';
elems(1).SampleTime = -1;
elems(1).Complexity = 'real';

elems(2) = Simulink.BusElement;
elems(2).Name = 'VALVE2';
elems(2).Dimensions = 1;
elems(2).DimensionsMode = 'Fixed';
elems(2).DataType = 'double';
elems(2).SampleTime = -1;
elems(2).Complexity = 'real';

CONTROL = Simulink.Bus;
CONTROL.Elements = elems;

This script is similar to the file you get if you save a bus object to a MATLAB file and choose the Object format. For information about saving bus objects, see “Save Bus Objects” on page 72-59.

Create Bus Objects from Blocks

You can create a bus object and its bus elements programmatically based on a block in a model. Use the Simulink.Bus.createObject function and specify the model and blocks for which to create bus objects for. Before you use the function, the model must be compilable. For example, if you specify a Bus Creator block that is at the highest level of a nested bus hierarchy, the function creates bus objects for all of the buses in the hierarchy. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB file.

Create Bus Objects from MATLAB Data

You can create a bus object from cell arrays of bus information in MATLAB, using the Simulink.Bus.cellToObject function. Each cell subordinate cell array represents a bus object and includes the following data, reflecting Simulink.Bus object properties:
The Elements field is a cell array defining these properties for each Simulink.BusElement object:

{ElementName,Dimensions,DataType,SampleTime,Complexity,DimensionsMode,Min,Max,Units,Description}

You can create a bus object from a MATLAB structure of timeseries objects, using the Simulink.Bus.createObject function. Alternatively, you can specify a numeric MATLAB structure. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB file.

Create Bus Objects from External C Code

You can create a bus object that corresponds to a structure type (struct) that your existing C code defines. Then, in preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can use the bus object to package signal or parameter data according to the structure type. To create the object, use the Simulink.importExternalCTypes function.

Customize Bus Object Import and Export

You can use the Bus Editor to import bus objects to the base workspace and to export bus objects from the base workspace, as described in “Save Bus Objects” on page 72-59. By default, the Bus Editor can save bus objects to, and import bus objects from, a MATLAB file or MAT-file. The files must be in a location that is accessible using an ordinary Open or Save dialog box.

You can write customized MATLAB functions that provide alternative import or export (or both) functionality. For example, you can write a customized function that stores the objects as records in a database, in a format that your organization uses.

After you design and implement a custom bus object import or export function, use the Simulink Customization Manager to register the function. The registration process establishes custom import and export functions as callbacks for the Bus Editor Import to Base Workspace and Export to File commands. The callbacks replace the default capabilities of the Bus Editor. Customizing the Bus Editor import and export capabilities has no effect on other MATLAB or Simulink functions. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

To create bus objects from external C code, you do not need to make customizations. See “Create Bus Objects from External C Code” on page 72-69.

Required Background Knowledge

Customizing bus object import or export requires that you understand:

- MATLAB language and programming techniques
- Simulink bus object syntax
- The proprietary format into which you translate bus objects, and the techniques necessary to access the facility that stores the objects.
- Any platform-specific techniques for obtaining data from the user, such as the name of the location in which to store or access bus objects.

Write a Bus Object Export Function

A custom bus object export function requires at least one argument. You can use additional arguments to handle special actions by the function. The value of the first
argument is a cell array containing the names of all bus objects that the Bus Editor has selected. You can use functions, global variables, or any other MATLAB technique, to provide values for any additional arguments. The general algorithm of a customized export function is:

1. Iterate over the list of object names in the first argument.
2. Obtain the bus object corresponding to each name.
3. Translate the bus object to the proprietary syntax.
4. Save the translated bus object in the local repository.

This example shows the syntactic shell of such an export callback function is:

```matlab
function myExportCallBack(selectedBusObjects)
    disp('Custom export was called!');
    for idx = 1:length(selectedBusObjects)
        disp([selectedBusObjects{idx} ' was selected for export.']);
    end
```

Although this function does not export any bus objects, it is syntactically valid and can be registered. It accepts a cell array of bus object names, iterates over them, and prints each name. An operational export function:

- Uses each name to retrieve the corresponding bus object from the base workspace
- Converts the object to proprietary format
- Stores the converted object

The additional logic is enterprise-specific.

## Write a Bus Object Import Function

A custom bus object import function can take zero or more arguments to perform its task. You can use functions, global variables, or any other MATLAB technique to provide argument values. Also, the function can poll the user for information, such as a designation of where to obtain bus object information. The general algorithm of a custom bus object import function is:

1. Obtain bus object information from the local repository.
2. Translate each bus object definition to a `Simulink.Bus` object.
3. Save each bus object to the MATLAB base workspace.
This example shows the syntactic shell of an import callback function is:

```matlab
def function myImportCallBack
disp('Custom import was called!');
end
```

Although this function does not import any bus objects, it is syntactically valid and can be registered with the Simulink Customization Manager. An operational import function:

- Gets a designation of where to obtain the bus objects to import
- Converts each bus object to a `Simulink.Bus` object
- Stores the object in the base workspace

The additional logic is enterprise-specific.

### Register Customizations

To customize bus object import or export, provide a customization registration function that inputs and configures the Customization Manager whenever you start Simulink software or refresh Simulink customizations. The steps for using a customization registration function are:

1. Create a file named `sl_customization.m` to contain the customization registration function. Alternatively, you can use an existing customization file.
2. At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument is the Customization Manager.
3. Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized bus object import and export functions.
4. If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently used locations are `matlabroot` and the current working folder. Alternatively, you can extend the search path.

Here is a simple example of a customization registration function:

```matlab
function sl_customization(cm)
disp('My customization file was loaded.');
cm.BusEditorCustomizer.importCallbackFcn = @myImportCallBack;
cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallBack(x);
end
```
When Simulink starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. Simulink loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the example customization function displays a message (which an actual function probably would not). The function establishes that the Bus Editor uses a function named `myImportCallBack()` to import bus objects, and a function named `myExportCallBack(x)` to export bus objects.

The function corresponding to a handle that appears in a callback registration can be undefined when the registration occurs. However, it must be defined when the Bus Editor calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m`, except when it starts up or refreshes customizations. Any changes to functions in the customization file are ignored until one of those events occurs. By contrast, changes to other MATLAB files on the MATLAB path take effect immediately.

For more information, see “Registering Customizations” on page 74-25.

**Change Customizations**

You can change the handles established in the `sl_customization` function by:

- Changing the function to specify the changed handles
- Saving the function
- Refreshing customizations by executing `sl_refresh_customizations`

Simulink traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting in the `sl_customization` function the appropriate `BusEditorCustomizer` element to `[]` and then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```matlab
cm.BusEditorCustomizer.clear```

72-73
where `cm` was previously set to a customization manager object (see “Register Customizations” on page 72-72).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately, unless they are in the `sl_customization.m` file itself. If the callback functions are in the `sl_customization.m` file, they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

To select virtual bus element inputs, you can use In Bus Element blocks. To create virtual bus outputs, you can use Out Bus Element blocks.

For nonvirtual buses, you must use Inport and Outport blocks.

- To pass a bus into a referenced model by using an Inport block, see “Use Buses with Root-Level Inport Blocks” on page 72-75.
- To pass a bus out of a referenced model by using an Outport block, see “Use Buses with Root-Level Outport Blocks” on page 72-76.
- To accept a bus as an input to a nonvirtual Inport block in an atomic subsystem, see “Use Buses with Atomic Subsystem Nonvirtual Inport Blocks” on page 72-76.

Use Buses with Root-Level Inport Blocks

To pass a bus from an Inport block into a referenced model, in the Block Parameters dialog box of the Inport block:

- Set the **Data type** parameter to *Bus: <object name>*
- Replace *<object name>* with the name of the bus object name that defines the bus that the Inport block produces.

Root-level Inport blocks convert virtual buses to nonvirtual buses. All signals in a nonvirtual bus must have the same sample time. For details, see “Specify Bus Signal Sample Times” on page 72-51.

For information about importing data to root-level Inport blocks, see “Load Bus Data to Root-Level Input Ports” on page 68-166.
Use Buses with Root-Level Outport Blocks

Root-level Outport blocks convert virtual buses to nonvirtual buses. All signals in a nonvirtual bus must have the same sample time. For details, see “Specify Bus Signal Sample Times” on page 72-51.

A root level Outport block of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically converts the bus to a vector having the same number of elements as the bus, and outputs that vector.

To use a bus signal that contains mixed data types as an input to a root-level Outport block, in the Block Parameters dialog box of the Outport block:

- Set Data type to Bus: <object name>.
- Replace <object name> with the name of the bus object name that defines the bus that the Outport block produces.

In a model hierarchy, if the bus signal in a top model is virtual, the signal is converted to nonvirtual (see “Bus Conversion” on page 72-134). For information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 72-132.

Use Buses with Atomic Subsystem Nonvirtual Inport Blocks

By default, an Inport block is a virtual block and accepts a bus as input. However, an Inport block is nonvirtual if both of these conditions exist:

- The Inport block is in an atomic subsystem.
- The signal or any of its elements (if the signal is a bus) are directly connected to the output of the subsystem.

For information about the difference between virtual and nonvirtual blocks, see “Nonvirtual and Virtual Blocks” on page 37-2.

The Inport block can accept a bus when either of these conditions is true:

- All elements of the bus can be converted to a vector (all the elements must have the same data type).
- The bus is a nonvirtual bus.
If bus elements have different data types, attempting to simulate the model halts the simulation and produces an error message. You can avoid violating this condition without changing the semantics of your model by inserting a Signal Conversion block between the Inport and Outport blocks.

For example, the following model, which includes an atomic subsystem, does not simulate.

In the subsystem, the Inport block labeled `nonvirtual` is nonvirtual because it resides in an atomic subsystem and one of its bus elements (labeled `a`) directly connects to a subsystem output.

Further, the bus (`bus1`) connected to the subsystem inputs has elements of differing data types. As a result, you cannot simulate this model.
To break the direct connection to the subsystem output, after the nonvirtual Inport block, insert a Signal Conversion block. Set the Signal Conversion block Output parameter to Signal copy. Inserting the Signal Conversion block enables you to simulate the model.

- “Specify Initial Conditions for Bus Signals” on page 72-79
- “Specify Bus Properties with Bus Objects” on page 72-55
Specify Initial Conditions for Bus Signals

Bus signal initialization is a special form of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 71-54. For details about initializing arrays of buses, see “Initialize Arrays of Buses” on page 72-107.

Bus signal initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus signal. By default, the initial value for a bus element is the ground value (represented by 0). Bus initialization involves specifying nonzero initial conditions.

You can use bus signal initialization features to:

• Specify initial conditions for signals that have different data types.
• Apply a different initial condition for each signal in the bus.
• Specify initial conditions for a subset of signals in a bus without specifying initial conditions for all the signals.
• Use the same initial conditions for multiple blocks, signals, or models.

Blocks That Support Bus Signal Initialization

You can initialize bus signal values that input to a block if that block meets both of these conditions:

• Has an initial value or initial condition block parameter
• Supports bus signals

These blocks support bus signal initialization:

• Data Store Memory
• Memory
• Merge
• Outport (when the block is inside a conditionally executed context)
• Rate Transition
• Unit Delay

For example, the Unit Delay block is a bus-capable block. Its Block Parameters dialog box has an Initial conditions parameter.
You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

**Set Diagnostics to Support Bus Initialization**

To enable bus signal initialization, before you start a simulation, set the “Underspecified initialization detection” configuration parameter to simplified.

**Create Initial Condition Structures**

You can create partial or full initial condition structures to represent initial values for a bus signal. To create an initial condition structure, use one of these approaches:

- Define a MATLAB structure in the MATLAB base or Simulink model workspace. You can manually define the structure, or alternatively for full structures, you can use the `Simulink.Bus.createMATLABstruct` function.
- In the Block Parameters dialog box for a block that supports bus signal initialization, for the initial condition parameter specify an expression that evaluates to a structure.

For information about defining MATLAB structures, see “Create Structure Array” (MATLAB).

The field that you specify in an initial condition structure must match these data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the initial condition structure, define the value to initialize that bus element to be a real [2x2] double array.

Explicitly specify fields in the initial condition structure for every bus element that has an enumerated (enum) data type.
Control Data Types of Structure Fields

If any of the signal elements of the target bus use a data type other than double, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 72-137.

Create Full Structures for Initialization

A full initial condition structure provides an initial value for every element of a bus signal. The initial condition structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

Specifying full structures during code generation offers these advantages:

• Generates more readable code
• Supports a modeling style that explicitly initializes all signals

Use the Simulink.Bus.createMATLABStruct function to streamline the creation of a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus signal. This function fills all of the elements that you do not specify with ground values for those elements.

You can use several different kinds of input with the function, including:

• A bus object name
• An array of port handles

You can invoke the function from the Bus Editor. Select the bus object for which you want to create a full MATLAB structure, and then select the File > Create a MATLAB structure menu item.

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus, use the Model Advisor.

1 On the Modeling tab, click Model Advisor.
2 Click OK.
3 Select By Task > Modeling Signals and Parameters using Buses > “Check structure parameter usage with bus signals”.

72-81
Click the Run This Check button.

The Model Advisor identifies partial initial condition structures.

After you create the structure, you can edit it in the MATLAB Editor.

Create Partial Structures for Initialization

A partial initial condition structure provides initial values for a subset of the elements of a bus signal. If you use a partial initial condition structure, during simulation, Simulink creates a full initial condition structure to represent all the bus signal elements. Simulink assigns the respective ground value to each element for which the partial initial condition structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

When you define a partial initial condition structure:

- Include only fields that are in the bus.
- Omit one or more fields that are in the bus.
- Make the field in the initial condition structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, optionally specify the structure fields in a different order than the bus elements.

Note The value of an initial condition structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking when you do an update diagram or simulate the model.

Suppose that you have a bus, Top, composed of three elements: A, B, and C, with these characteristics:

- A is a nested bus, with two signal elements.
- B is a single signal.
• C is a nested bus that includes bus A as a nested bus.

The `ex_bus_initial_conditions` model includes the nested Top bus. This is how the model appears after it has been updated.

Here is a summary of the Top bus hierarchy and the data type, dimension, and complexity of the bus elements.

**Top**

- A (sub1)
  - A1 (double)
  - A2 (int8, 5x1, complex)
- B (double)
- C (sub2)
  - C1 (int16)
  - C2 (sub1)
    - A1 (double)
    - A2 (int8, 5x1, complex)
In these examples, \( K \) is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the \texttt{ex_bus_initial_conditions} model. Here are some valid initial condition specifications.

<table>
<thead>
<tr>
<th>Valid Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( K.A.A1 = 3 )</td>
<td>Initialize the bus element ( \text{Top.A.A1} ) using the value 3.</td>
</tr>
</tbody>
</table>
| \( K = \text{struct('C',struct('C1',
int16(4))}) \) | The bus element \( \text{Top.C.C1} \) is \text{int16}. The corresponding structure field explicitly specifies \text{int16(4)}. Alternatively, you could specify the field value as 4 without specifying an explicit data type. |
| \( K = \text{struct('B',3,'A',struct('A1',4))} \) | Bus elements \( \text{Top.B} \) and \( \text{Top.A} \) are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter. |

**Invalid Partial Initial Condition Structures**

In the following examples, \( K \) is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the \texttt{ex_bus_initial_conditions} model.

These three initial condition specifications are \textit{not} valid:

<table>
<thead>
<tr>
<th>Invalid Syntax</th>
<th>Reason the Syntax Is Invalid</th>
</tr>
</thead>
<tbody>
<tr>
<td>( K.A.A2 = 3 )</td>
<td>Value dimension and complexity do not match. The bus element ( \text{Top.A.A2} ) is ( 5 \times 1 ), but ( K.A.A2 ) is ( 1 \times 1 ); ( \text{Top.A.A2} ) is complex, but ( K.A.A2 ) is real.</td>
</tr>
<tr>
<td>( K.C.C2 = 3 )</td>
<td>You cannot use a scalar value to initialize initial condition substructures.</td>
</tr>
<tr>
<td>( K = \text{struct('B',3,'X',4)} )</td>
<td>You cannot specify fields that are not in the bus (( X ) does not exist in the bus).</td>
</tr>
</tbody>
</table>
Initialize Bus Signals Using Block Parameters

Initialize a bus signal by setting the initial condition parameter for a block that receives a bus signal as input and that supports bus initialization (see “Blocks That Support Bus Signal Initialization” on page 72-79).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

![Function Block Parameters: Unit Delay](image)

For a block that supports bus signal initialization, you can replace the default value of 0 using one of these approaches:

- “MATLAB Structure for Initialization” on page 72-86
- “MATLAB Variable for Initialization” on page 72-86
- “Simulink.Parameter For Initialization” on page 72-87

All three approaches require that you define an initial condition structure (see “Create Initial Condition Structures” on page 72-80). You cannot specify a nonzero scalar value or any other type of value other than 0, an initial condition structure, or Simulink.Parameter object to initialize a bus signal.

Defining an initial condition structure as a MATLAB variable, rather than specifying the initial condition structure directly in the Block Parameters dialog box offers several advantages, including:
• Reuse of the initial condition structure for multiple blocks
• Using the initial condition structure as a tunable parameter in the generated code

**MATLAB Structure for Initialization**

You can initialize a bus signal using a MATLAB structure that explicitly defines the initial conditions for the bus signal.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure.

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:

**MATLAB Variable for Initialization**

You can initialize a bus signal using a MATLAB variable that you define as an initial condition structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:
Simulink.Parameter For Initialization

You can initialize a bus signal using a Simulink.Parameter object that uses an initial condition structure for the Value property.

For example, you could define the partial structure P in the base workspace (reflecting the ex_bus_initial_conditions model discussed in the previous section):

```matlab
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the P structure as the **Initial conditions** parameter of the Unit Delay block:

Combine Buses into an Array of Buses

**Tip** Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see “Types of Composite Signals” on page 72-2.

**What Is an Array of Buses?**

An array of nonvirtual buses is an array whose elements are buses. Each bus object has the same signal name, hierarchy, and attributes for its bus elements.

An example of using an array of buses is to model a multi-channel system, such as a communications system. You can model all the channels using the same bus object, although each of the channels could have a different value.

To use an array of buses:

- Use a bus object as a data type (see “Specify a Bus Object Data Type” on page 66-48).
- Specify dimensions for the bus and bus elements.

For an example of a model that uses an array of buses, open the sldemo_bus_arrays model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. Here is the diagram after you update it:
The model uses the array of buses with:

- An Assignment block, to assign a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

**Benefits of an Array of Buses**

Use an array of buses to:

- Represent structured data compactly.
  - Reduce model complexity.
  - Reduce maintenance by centralizing algorithms used for processing multiple buses.
- Streamline iterative processing of multiple buses of the same type, for example, by using a For Each Subsystem with the array of buses.
- Simplify changing the number of buses, without your having to restructure the rest of the model or make updates in multiple places in the model.
• Use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type. Using a array of buses avoids the need for you to create custom S-functions to manage packing and unpacking structure signals.

• Use the combined bus data across subsystem boundaries, model reference boundaries, and into or out of a MATLAB Function block.

• Keep all the logic in the Simulink model, rather than splitting the logic between C code and the Simulink model. This approach supports integrated consistency and correctness checking, maintaining metadata in the model, and avoids the need to manage model components in two different environments.

• Generate code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures. This approach simplifies indexing into an array for Simulink computations, using a for loop on indexed structures.

Define an Array of Buses

For information about the kinds of buses that you can combine into an array of buses, see “Bus Requirements” on page 72-97.

To define an array of buses, use a Concatenate block. The table describes the array of buses input requirements and output for each of the Vector Concatenate and the Matrix Concatenate versions of the Concatenate block.

<table>
<thead>
<tr>
<th>Block</th>
<th>Bus Signal Input Requirement</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Concatenate</td>
<td>Vectors, row vectors, or columns vectors</td>
<td>If any of the inputs are row or column vectors, output is a row or column vector.</td>
</tr>
<tr>
<td>Matrix Concatenate</td>
<td>Signals of any dimensionality (scalars, vectors, and matrices)</td>
<td>Trailing dimensions are assumed to be 1 for lower dimensionality inputs. Concatenation is on the dimension that you specify with the Concatenate dimension parameter.</td>
</tr>
</tbody>
</table>

**Note** Do not use a Mux block or a Bus Creator block to define an array of buses. Instead, use a Bus Creator block to create scalar bus signals.
Define one bus object for all of the buses that you want to combine into an array of buses. For information about defining bus objects, see “Specify Bus Properties with Bus Objects” on page 72-55.

The **sldemo_bus_arrays** model defines an **sldemo_bus_arrays_busobject** bus object, which both of the Bus Creator blocks use for the input bus signals (Scalar Bus) for the array of buses.

Add a Vector Concatenate or Matrix Concatenate block to the model and open the Block Parameters dialog box.

The **sldemo_bus_arrays_busobject** model uses a Vector Concatenate block, because the inputs are scalars.

Set the **Number of inputs** parameter to be the number of buses that you want to be in the array of buses.

The block icon displays the number of input ports that you specify.

Set the **Mode** parameter to match the type of the input bus data.

In the **sldemo_bus_arrays** model, the input bus data is scalar, so the **Mode** setting is **Vector**.

If you use a Matrix Concatenation block, set the **Concatenate dimension** parameter to specify the output dimension along which to concatenate the input arrays. Enter one of the following values:

- 1 — concatenate input arrays vertically
- 2 — concatenate input arrays horizontally
- A higher dimension than 2 — perform multidimensional concatenation on the inputs

Connect to the Concatenate block all the buses that you want to be in the array of buses.

Group Constant Signals into an Array of Buses

You can use a Constant block to compactly represent multiple constant-valued signals as an array of buses. You can use this technique to reduce the number of signal lines in a model and the number of variables that the model uses, especially when the model repeats an algorithm with different parameter values.
To generate a constant-valued array of bus signals, use an array of MATLAB structures in a Constant block. The block output is an array of buses, and each field in the array of structures provides the simulation value for the corresponding signal element.

You can also use an array of structures to specify the Value property of a Simulink.Parameter object, and use the parameter object in a Constant block.

1. Open the example model `ex_constantbus_array`.

   The variables `ParamBus` and `const_param_struct` appear in the base workspace. The variable `const_param_struct` contains a structure whose field names match the elements of the bus type that `ParamBus` defines.

2. Update the diagram to view the signal line widths.

   The output of the Constant block is a single scalar bus of type `ParamBus`. The structure variable `const_param_struct` specifies the constant value in the block.

3. At the command prompt, create an array of two structures by copying the structure `const_param_struct`. Customize the field values by indexing into the individual structures in the array.

   ```matlab
   const_struct_array =... 
   [const_param_struct const_param_struct];
   const_struct_array(2).Offset = 158;
   const_struct_array(2).Gain = 3.83;
   const_struct_array(2).Threshold = 1039.77
   
   const_struct_array =
   1x2 struct array with fields:
     Offset
     Gain
     Threshold
   ```

4. In the Constant block dialog box, set **Constant value** to `const_struct_array`.

5. Add two Selector blocks to the model, and connect the Constant block as shown.
6 In the Selector block dialog box, set **Index** to 1 and **Input port size** to 2.
7 In the Selector1 block dialog box, set **Index** to 2 and **Input port size** to 2.
8 Copy the block algorithm in the model, and connect the blocks as shown.
Update the diagram. The signal line width and style indicate that the output of the Constant block is an array of buses. The Selector blocks each extract one of the buses in the array.

Each copy of the algorithm uses the constant values provided by the corresponding structure in the variable `const_struct_array`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`. You can also use this technique to create an array of structures if you do not have a scalar structure that you can copy.

Use Arrays of Buses in Models

Array of Buses Requirements and Limitations

Bus Requirements

All buses combined into an array of buses must:

- Be nonvirtual
- Have the same bus type (that is, same name, hierarchies, and attributes for the bus elements)
- Have no variable-size signals or frame-based signals

Blocks That Support Arrays of Buses

These blocks support arrays of buses:

- Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 37-2)
- These nonvirtual blocks:
  - Data Store Memory
  - Data Store Read
  - Data Store Write
  - Memory
  - Merge
  - Multiport Switch
  - Rate Transition
  - Switch
  - Unit Delay
  - Zero-Order Hold
- Assignment
- MATLAB Function
- Matrix Concatenate
- Selector
• Signal Conversion
• Vector Concatenate
• Width
• Two-Way Connection (a Simscape block)

**Note** You can use an array of buses as an input to an In Bus Element block, but you cannot use that block to select individual buses. The block passes through the whole array of buses signal.

**Block Parameter Settings**

Using an array of buses signal with some blocks requires specific block parameter settings.

This information is also in the reference pages for each of these blocks. For usage information for bus-related blocks, see “Work with Arrays of Buses” on page 72-102.

</table>

**Structure Parameter Requirements**

To initialize an array of buses with structure parameters, you can use:

- The number 0. In this case, all the individual signals in the array of buses use the initial value 0.

- A scalar struct that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.

- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

If you use an array of structures, all the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
• Numeric data type, such as single or int32
• Complexity
• Dimensions

You cannot use partial structures.

For more information about specifying initial conditions for bus signals, see “Initialize Arrays of Buses” on page 72-107.

Signal Logging Limitation

Simulink software does not log arrays of buses inside referenced models in rapid accelerator mode.

Stateflow Limitations

Stateflow action language does not support arrays of buses.

Bus Creator Blocks

A Bus Creator block can accept an array of buses as input, but cannot have an array of buses as output.

Signal Line Style

After model simulation, the line style for the array of buses signal is a thicker version of the signal line style for a nonvirtual bus signal.

For example, in the sldemo_bus_arrays model, the Scalar Bus signal is a nonvirtual bus signal, and the Bus Array output signal of the Concatenate block is an array of buses signal.

Work with Arrays of Buses

Set Up Model for Arrays of Buses

Setting up a model to use an array of buses usually involves these basic tasks:

1. Define the array of buses (see “Define an Array of Buses” on page 72-91).
2. Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a For Each Subsystem block or an Iterator block. Connect the array of buses signal from the Concatenate block to the iterative processing subsystem. See “Perform Iterative Processing” on page 72-103.
3. Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).
   
   a. Operate on the array of buses (using Selector and Assignment blocks).
   
   b. Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a scalar bus within the subsystem.

   See “Assign Values into an Array of Buses” on page 72-103 and “Select Bus Elements from an Array of Buses” on page 72-105.
4. Optionally, import or log array of buses data. See “Import Array of Buses Data” on page 72-106 and “Log Arrays of Buses” on page 72-106

The resulting model includes these components.
Perform Iterative Processing

You can perform iterative processing on the bus signal data of an array of buses using blocks such as a For Each Subsystem block, a While Iterator Subsystem block, or a For Iterator Subsystem block. You can use one of these blocks to perform the same kind of processing on:

- Each bus in the array of buses
- A selected subset of buses in the array of buses

Assign Values into an Array of Buses

To assign a value to a signal within an array of buses, use:

1. A Bus Assignment block to assign a value to a bus element
2. An Assignment block to assign the bus to the array of buses

Use an Assignment block to assign values to specified elements in a bus array.

For example, in the sldemo_bus_arrays model, the Assignment block assigns the value to the first element of the array of buses.
To assign bus elements within a bus signal, use the Bus Assignment block. The input for the Bus Assignment block must be a scalar bus signal.

**Assign into Arrays of Buses**

You can use a Bus Assignment block to assign or fully replace a nested bus that is an array of buses. To assign the data for a nested bus inside an array of buses or to make a partial assignment to certain elements with the array of buses, you can use a MATLAB Function block.

For example, suppose that you have this bus structure:
The bus has a `children` element, which is a sub-bus array. This example shows how to assign to element `c` and to element `a`. The Inport and Outport blocks use the `Parent` bus object. To define the assignments, this example uses a MATLAB Function block, because you cannot assign into element `a` using a Bus Assignment or Assignment block.

The MATLAB Function block uses this function code for making the assignments:

```matlab
function y = fcn(u)

y = u;
y.c = false;
for idx = 1:length(y.children)
    y.children(idx).a = int32(zeros(5, 1));
end
```

**Select Bus Elements from an Array of Buses**

To select a signal within an array of buses, use a:

1. Selector block to find the appropriate bus within the array of buses.
2. Bus Selector block to select the signal.

Use a Selector block to select elements of an array of buses. The input array of buses can have any dimension. The output bus signal of the Selector block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses Selector blocks to select elements from the array of buses signal that the Assignment and For Each Subsystem blocks outputs. In this example, here is the Block Parameters dialog box for the Selector block that selects the first element:
To select bus elements within a bus signal, use the Bus Selector block. The input for the Bus Selector block must be a scalar bus signal.

**Import Array of Buses Data**

Use a root Inport block to import (load) an array of structures of MATLAB timeseries objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 68-171.

You cannot use a From Workspace or From File block to import data for an array of buses.

**Log Arrays of Buses**

To export an array of buses signal, mark the signal for signal logging. For more information, see “Save Run-Time Data from Simulation”.

**Note** Simulink does not log signals inside referenced models in rapid accelerator mode.
To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 68-32.

**Initialize Arrays of Buses**

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

Here is an example that shows how to initialize an array of buses. Suppose that you define the bus types `MyData` and `PressureBus`.

```
initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;
initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;
initValues(3).temperature = int16(35);
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.
The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as Unit Delay.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all the buses in the array.

```matlab
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, 15, for the signal element `temperature`. Similarly, the buses use the initial value 10.32 for the element `pressure.s1` and the value 9.46 for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

This example shows how to initialize a nested array of buses. Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

1. In the Bus Editor, create the bus objects `MyData` and `PressureBus`.
2. In the hierarchy pane, select the bus element `pressure`. Set the **Dimensions** property to `[1 3]`.
3. Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all the individual signals to the ground value, 0.

   ```matlab
   initStruct=Simulink.Bus.createMATLABStruct('MyData',[],[1 4]);
   ```
4 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

The four structures in the array each have the fields `temperature` and `pressure`.

5 To inspect a `pressure`, double-click one of the fields.

The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

6 To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```matlab
initStruct(3).pressure(2).s1 = 15.35;
```

**Code Generation**

Code generation for arrays of buses produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 72-144.

Convert Models to Use Arrays of Buses

There are several reasons to convert a model to use an array of buses (see “Benefits of an Array of Buses” on page 72-90). For example:

• The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
• The model has grown in complexity.

General Conversion Approach

Here is a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For details about these techniques, see “Combine Buses into an Array of Buses” on page 72-89 and “Use Arrays of Buses in Models” on page 72-97.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.
In the original modeling pattern:

- The target bus signal to be converted is named `MainBus`, and it has three elements, each of type `BusObject`.
- The `ScalarAlgorithm1`, `ScalarAlgorithm2`, and `ScalarAlgorithm3` subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.
- A Bus Selector block picks out each element of `MainBus` to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:
• A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
• Adding another element to `MainBus` involves changing the bus object definition and the Bus Selector block, and adding a subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

1 Identify the target bus and associated algorithm that you want to convert. Typically, the target bus signal is a bus of buses, where each element bus signal is of the same type.
   • The bus that you convert must be a nonvirtual bus. If all elements of the target bus have the same sample time (or if the sample time is inherited), you can convert a virtual bus to a nonvirtual bus.
   • The target bus cannot have variable-dimensioned and frame-based elements.

2 Use a Concatenate block to convert the original bus of buses signal to an array of buses.

   In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus signal is `BusObject`. The new model eliminates the wrapper bus signal (`MainBus`).

3 Replace all identical copies of the algorithm subsystem with a single For Each subsystem that encapsulates the scalar algorithm. Connect the array of buses signal to the For Each subsystem.

   The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

4 Configure the For Each Subsystem block to iterate over the input array of buses signal and concatenate the output bus signal.

   The scalar algorithm within the For Each subsystem cannot have continuous states. For additional limitations, see the For Each Subsystem block documentation.

- “Repeat an Algorithm Using a For Each Subsystem” on page 72-114
Repeat an Algorithm Using a For Each Subsystem

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. At the same time, many variables can crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This example shows how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

Explore Example Model

1. Open the example model `ex_repeat_algorithm`. The model creates about 30 variables in the base workspace.
2. Inspect the subsystem Burner_1_Analysis. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as Constant and Discrete-Time Integrator.
3. Inspect the subsystems Burner_2_Analysis and Burner_3_Analysis. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
4. Inspect the three Analysis_Delay subsystems. These subsystems repeat a different algorithm from the one in the Analysis subsystems.
5. Return to the top level of the model. The Memory blocks delay the input signals before they enter the Analysis_Delay subsystems.
6. Look at the Data Import/Export pane of the Configuration Parameters dialog box. The model uses the variables SensorsInput and t as simulation inputs.

   During simulation, each of the nine columns in the matrix variable SensorsInput provides input data for an Inport block at the top level of the model.

Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.
Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with For Each Subsystem blocks.

1. Open the Bus Editor.
   
   buseditor

2. Create a bus type SensorData with three signal elements: sensor1, sensor2, and sensor3.

3. Delete the blocks as shown in the figure, leaving only the Burner_1_Sensor1 and Burner_1_Delay1 blocks as inputs to the two remaining subsystems.
4 On the **Signal Attributes** tab of the Burner_1_Sensor1 Inport block dialog box, set **Data type** to Bus: SensorData.

The output of the block is a bus signal that contains the three signal elements *sensor1*, *sensor2*, and *sensor3*.

5 Open the subsystem Burner_1_Analysis. Delete the signal output lines of the three Inport blocks. Delete the In2 and In3 Inport blocks.

6 Add a Bus Selector block to the right of the In1 Inport block. Connect the Inport block output to the Bus Selector block.

7 In the Bus Selector block dialog box, select the signals *sensor1*, *sensor2*, and *sensor3*. 

---

---
The Bus Selector block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

In the subsystem, connect the blocks as shown.
9 In the subsystem Burner_1_Analysis_Delay, use a Bus Selector block to extract the signals in the bus. Use the same technique as you did in the subsystem Burner_1_Analysis.

**Repeat an Algorithm**

A For Each Subsystem block partitions an input signal, and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use For Each subsystems to repeat an algorithm in an iterative fashion. This approach improves model readability and makes it easy to change the repeated algorithm.

1 Add two For Each Subsystem blocks to the model. Name one of the subsystems Burner_Analysis. Name the other subsystem Burner_Analysis_Delay.

2 Copy the contents of the subsystem Burner_1_Analysis into the subsystem Burner_Analysis. Before you paste the blocks, delete the Inport and Outport blocks in the For Each subsystem.

3 In the For Each block dialog box in the Burner_Analysis subsystem, select the check box to partition the input In1.

4 Copy the contents of the subsystem Burner_1_Analysis_Delay into the subsystem Burner_Analysis_Delay.
In the For Each block dialog box in the Burner_Analysis_Delay subsystem, select the check box to partition the input In1.

At the top level of the model, delete the subsystems Burner_1_Analysis and Burner_1_Analysis_Delay. Connect the new For Each Subsystem blocks in their place.

On the Signal Attributes tab of the Burner_1_Sensor1 Inport block dialog box, set Port dimensions to 3.

The block output is a three-element array of buses. The For Each subsystems in the model repeat an algorithm for each of the three buses in the array.

Create a Simulink.SimulationData.Dataset object that the Inport block can use to import the simulation data. You can use this code to create the object and store it in the variable SensorsInput.

```matlab
% First, create an array of structures whose field values are timeseries objects

for i = 1:3 % Burner number
    % Sensor 1
    eval(
        ['tempInput(1, ' num2str(i) ') . sensor1 = ' ...
        'timeseries(SensorsInput(:, num2str(3*(i-1)+1)), t);'])

    % Sensor 2
    eval(
        ['tempInput(1, ' num2str(i) ') . sensor2 = ' ...
        'timeseries(SensorsInput(:, num2str(3*(i-1)+2)), t);'])

    % Sensor 3
    eval(
        ['tempInput(1, ' num2str(i) ') . sensor3 = ' ...
        'timeseries(SensorsInput(:, num2str(3*(i-1)+3)), t);'])

end

% Create the Dataset object.
SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput, tempInput, 'element1');

clear tempInput t i
```

The code first creates a variable tempInput that contains an array of three structures. Each structure has three fields that correspond to the signal elements in the bus type SensorData, and each field stores a MATLAB timeseries object. Each
timeseries object stores one of the nine columns of data from the variable SensorsInput, which stored the simulation input data for each of the sensors.

The code then overwrites SensorsInput with a new Simulink.SimulationData.Dataset object, and adds tempInput as an element of the object.

9 Set the **Input** configuration parameter to SensorsInput.

Since SensorsInput provides simulation input data in the form of timeseries objects, you do not need to specify a variable that contains time data.

10 Create an array of structures that initializes the remaining Memory block, and store the array in the variable initForDelay. Specify the structure fields with the values of the existing initialization variables such as initDelay_1_sensor1.

```matlab
for i = 1:3 % Burner number
    % Sensor 1
    eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
    'initDelay_' num2str(i) '_sensor1;'])

    % Sensor 2
    eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
    'initDelay_' num2str(i) '_sensor2;'])

    % Sensor 3
    eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
    'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable initForDelay, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: sensor1, sensor2, and sensor3.
11. In the Memory block dialog box, set **Initial condition** to `initForDelay`.

    The Memory block output is an array of buses that requires initialization. Each signal
    element in the array of buses acquires an initial value from the corresponding field in
    the array of structures.

---

**Organize Parameters into Arrays of Structures**

The base workspace contains many variables that the example model uses for block
parameters. To reduce the number of workspace variables, package them into arrays of
structures, and use the individual structure fields to specify block parameters.

A For Each Subsystem block can partition an array of values that you specify as a mask
parameter. Each iteration of the subsystem uses a single partition of the array to specify
block parameters. If you specify the parameter as an array of structures, each iteration of
the subsystem can use one of the structures in the array.

1. Create an array of structures that parameterizes the Burner_Analysis For Each
subsystem, and store the array in the variable `paramsNormal`. Specify the structure
fields by using the values of existing parameter variables such as `gainNormal_1`,
`offsetNormal_1`, and `initDelayed_1`.

    ```matlab
    for i = 1:3
        eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';'])
        eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';'])
        eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';'])
    end
    ```

    The variable contains an array of three structures that each has three fields: `gain`,
`offset, and `init`.

2. In the model, right-click the Burner_Analysis For Each subsystem and select **Mask >
Create Mask**.

3. On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**.
For the new mask parameter, set **Prompt** to Parameter structure and **Name** to
paramStruct. Click **OK**.

4. In the mask for the Burner_Analysis subsystem, set **Parameter structure** to
paramsNormal.

5. Open the subsystem. In the For Each block dialog box, on the **Parameter Partition**
pane, select the check box to partition the parameter paramStruct. Set **Partition
dimension** to 2.
For the blocks in the subsystem, set these parameters.

<table>
<thead>
<tr>
<th>Block</th>
<th>Parameter Name</th>
<th>Parameter Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gain</td>
<td>Gain</td>
<td>paramStruct.gain</td>
</tr>
<tr>
<td>Discrete-Time Integrator</td>
<td>Initial condition</td>
<td>paramStruct.init</td>
</tr>
<tr>
<td>Constant</td>
<td>Constant value</td>
<td>paramStruct.offset</td>
</tr>
</tbody>
</table>

Create an array of structures that parameterizes the Burner_Analysis_Delay For Each subsystem, and store the array in the variable paramsForDelay.

```matlab
for i = 1:3
    eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';'])
end
```

At the top level of the model, right-click the Burner_Analysis_Delay For Each subsystem and select **Mask > Create Mask**.

On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to Parameter structure and **Name** to paramStruct. Click **OK**.

In the mask for the For Each Subsystem block, set **Parameter structure** to paramsForDelay.

Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter paramStruct. Set **Partition dimension** to 2.

For the blocks in the subsystem, set these parameters.

<table>
<thead>
<tr>
<th>Block</th>
<th>Parameter Name</th>
<th>Parameter Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gain</td>
<td>Gain</td>
<td>paramStruct.gain</td>
</tr>
<tr>
<td>Discrete-Time Integrator</td>
<td>Initial condition</td>
<td>paramStruct.init</td>
</tr>
<tr>
<td>Constant</td>
<td>Constant value</td>
<td>paramStruct.offset</td>
</tr>
</tbody>
</table>

Clear the unnecessary variables from the base workspace.

```matlab
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```
The model requires few variables in the base workspace.

**Inspect the Converted Model**

To view the new signal and subsystem organization, update the diagram.

The model input is an array of three bus signals. The model uses two For Each subsystems to execute the two algorithms on each of the three bus signals in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all the old variables.

**Tip** You can log nonbus signals in a For Each subsystem. However, you cannot use signal logging for buses or arrays of buses from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals that you want to log or add an Outport block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 68-110.
Examples of Working with For Each Subsystems

Vectorize Algorithms Using For Each Subsystems

This example shows how to simplify modeling of vectorized algorithms. Using For Each Subsystem blocks simplifies a model where three input signals are filtered by three identical Transfer Fcn blocks. This example also shows how to add more control to the filters by changing their coefficients for each iteration of the subsystem.

This model uses identical Transfer Fcn blocks to independently process each element of the input sine wave signal. A Vector Concatenate block concatenates the resulting output signals. This repetitive process is graphically complex and difficult to maintain. Also, adding another element to the signal requires significant reworking of the model.

You can simplify this model by replacing the repetitive operations with a single For Each Subsystem block.
The For Each subsystem block contains a For Each block and a model representing the algorithm of the three blocks it replaces by way of the Transfer Fcn block. The For Each block specifies how to partition the input signal vector into individual elements and how to concatenate the processed signals to form the output signal vector. Every block that has a state maintains a separate set of states for each input element processed during a given execution step.

For this example, the input signal is selected for partitioning. The **Partition Dimension** and the **Partition Width** parameters on the For Each block are both set to 1 for the input.
You can scale up this approach to add more signals without having to change the model significantly. This approach is considered easily scalable and graphically simpler.

**Model Parameter Variation Without Changing Model Structure**

This example shows how to model parameter variation in an algorithm. It uses the For Each Subsystem partitioning model from Vectorize Algorithms Using For Each Subsystems and creates different filters for each input signal while retaining model simplicity. You feed an array of filter coefficients to the For Each subsystem block as a mask parameter marked for partitioning. In each iteration of the For Each subsystem block, a partition of the filter coefficients is fed to the Transfer Fcn block.
1  Open the model `ex_ForEachSubsystem_Partitioning`. Create a mask for the For Each Subsystem block and add an editable mask parameter. Set the name to `FilterCoeffs` and the prompt to `Filter Coefficient Matrix`. For information on how to add a mask parameter, see “Create a Simple Mask” on page 40-8.

![Mask Editor: For Each Subsystem](image)

2  Open the For Each subsystem block. Inside the subsystem, open the For Each block dialog box.

3  In the Parameter Partition tab, select the check box next to the `FilterCoeffs` parameter to enable partitioning of this parameter. Keep the Partition Width and Partition Dimension parameters at their default value of 1.
4 Double-click the For Each Subsystem block and enter your filter coefficient matrix, having one row of filter coefficients for each input signal. For example, enter

\[
\begin{bmatrix}
0.0284 & 0.2370 & 0.4692 & 0.2370 & 0.0284; \\
-0.0651 & 0 & 0.8698 & 0 & -0.0651; \\
0.0284 & -0.2370 & 0.4692 & -0.2370 & 0.0284
\end{bmatrix}
\]

to implement different fourth-order filters for each input signal.

5 In the For Each Subsystem block, double-click the Transfer Fcn block and enter FilterCoeffs for the Denominator Coefficients parameter. This setting causes the block to get its coefficients from the mask parameter.

The For Each Subsystem block slices the input parameter into horizontal partitions of width 1, which is equivalent to one row of coefficients. The parameter of coefficients transforms from a single array

\[
\begin{bmatrix}
0.0284 & 0.2370 & 0.4692 & 0.2370 & 0.0284; \\
-0.0651 & 0.0000 & 0.8698 & 0.0000 & -0.0651; \\
0.0284 & -0.2370 & 0.4692 & -0.2370 & 0.0284
\end{bmatrix}
\]
into three rows of parameters:

\[
\begin{bmatrix}
0.0284 & 0.2370 & 0.4692 & 0.2370 & 0.0284 \\
-0.0651 & 0.0000 & 0.8698 & 0.0000 & -0.0651 \\
0.0284 & -0.2370 & 0.4692 & -0.2370 & 0.0284 \\
\end{bmatrix}
\]

**Improved Code Reuse Using For Each Subsystems**

This example shows how you can improve code reuse when you have two or more identical For Each Subsystem blocks. Consider the following model, `rtwdemo_foreachreuse`.

The intent is for the three subsystems — Vector SS1, Vector SS2, and Vector SS3 — to apply the same processing to each scalar element of the vector signal at their respective inputs. Because these three subsystems perform the same processing, it is desirable for them to produce a single shared Output (and Update) function for all three subsystems in the code generated for this model. For example, the Vector SS3 subsystem contains the these blocks.
To generate a single shared function for the three subsystems, the configuration of the partitioning they perform on their input signals must be the same. For Vector SS1 and Vector SS3, this configuration is straightforward because you can set the partition dimension and width to 1. However, in order for Vector SS2 to also partition its input signal along dimension 1, you must insert a Math Function block to transpose the 1-by-8 row vector into an 8-by-1 column vector. You can then convert the output of the subsystem back to a 1-by-8 row vector using a second Math Function block set to the transpose operator.

If you press Ctrl+B to generate code, the resulting code uses a single output function. This function is shared by all three For Each Subsystem instances.

```c
/*
 * Output and update for iterator system:
 *    '<Root>/Vector SS1'
 *    '<Root>/Vector SS2'
 *    '<Root>/Vector SS3'
 */
void VectorProcessing(int32_T NumIters, const real_T rtu_In1[],
                      real_T rty_Out1[],
                      rtDW_VectorProcessing *localDW)
```

The function has an input parameter NumIters that indicates the number of independent scalars that each For Each Subsystem is to processes. This function is called three times with the parameter NumIters set to 10, 8, and 7, respectively.
The remaining two subsystems in this model show how reusable code can also be generated for matrix signals that are processed using the For Each Subsystem block. Again, pressing Ctrl+B to generate the code provides code reuse of a single function.

Bus Data Crossing Model Reference Boundaries

A model reference boundary is the boundary between a model that contains a Model block and the referenced model. If bus data passes to a Model block, then that data crosses the boundary to the referenced model. Bus data input for the Model block must be consistent with the bus data that the referenced model requires.

For bus data that crosses model reference boundaries, decide whether to use a virtual or nonvirtual bus. Using a virtual bus can be simpler than using a nonvirtual bus. Using a nonvirtual bus provides a well-defined data interface for code generation. To learn the differences between virtual and nonvirtual buses, see “Types of Composite Signals” on page 72-2. If you use a virtual bus, you can use In Bus Element blocks to avoid the need for a bus object. If you use a nonvirtual bus, you must define it with a bus object by following the instructions in “Create and Specify Bus Objects” on page 72-58.

Multirate Bus Input for Referenced Models

You can pass a virtual multirate bus into a referenced model by using In Bus Element blocks. To pass a nonvirtual multirate bus into a referenced model, use an Inport block and add blocks in the parent and referenced model as follows:

1. In the parent model: To convert the multirate bus to a single-rate bus, insert a Rate Transition block. Inport blocks can only pass single-rate buses into referenced models. The Rate Transition block must specify a rate in its Block Parameters > Output port sample time field unless one of the following is true:
   - The Configuration Parameters > Solver pane specifies a rate with these settings:
     - The Periodic sample time constraint parameter is set to Specified.
     - The Sample time properties parameter contains the specified rate.
     - The Inport block that accepts the bus in the referenced model specifies a rate in its Block Properties > Signal Attributes > Sample time field.

2. In the referenced model: Use a Bus Selector block to pick out signals of interest, and use Rate Transition blocks to convert the signals to the desired rates.

Model Reference Requirements for Nonvirtual Buses

If you use a bus as an input to or an output from a referenced model:
• Only a nonvirtual bus can contain variable-size signal elements.
• For code generation, you can only configure the I/O arguments step method style of C++ class interface for the referenced model when using a nonvirtual bus or when using the Default style of C++ class interface.
• For code generation, you can only configure function prototype control for the referenced model when using a nonvirtual bus.

Use these Upgrade Advisor checks to fix models saved before R2016a that engage these limitations:
• Check for virtual bus across model reference boundaries
• “Analyze model hierarchy and continue upgrade sequence”

Bus Conversion

When updating a diagram prior to simulation or code generation, Simulink automatically converts a virtual bus to a nonvirtual bus (and a nonvirtual bus to a virtual buses) in cases such as when the virtual bus is an input to, or output from:

- An S-Function block
- A Stateflow chart

When you pass a bus signal into a referenced model, Simulink makes the bus a virtual or nonvirtual bus to match the type of bus specified for the input block it feeds. Bus signal outputs are virtual or nonvirtual, based on the specification for the output block. For bus signals driving a root-level output block, Simulink performs a similar conversion. For more information, see “Bus Data Crossing Model Reference Boundaries” on page 72-132.

The conversion consists of inserting hidden Signal Conversion blocks into the model where needed. If no bus object is specified at the port to which the virtual bus connects, conversion to a nonvirtual bus fails.

To avoid the need for automatic bus conversion, manually insert a Signal Conversion block. For details, see the Signal Conversion documentation.

Buses and Libraries

When you define a library block, the block can input, process, and output buses just as an ordinary subsystem can.

Provide the appropriate input bus signal if:

• You have a bus routing block (Bus Creator, Bus Selector, or Bus Assignment) block that is in a library.
• That block depends on signals that are input to the library.

To change that block in a library, perform these steps. For details about modifying library links, see “Custom Libraries”.

1. Copy the library block that uses that block to a model that connects an input bus.
2. Disable the link to the library block in this model.
3. Edit the bus routing block within the context of the outside model.
4. Resolve the link to the library.
5. In the Link Tool, in **Push/Restore Mode**, select Push to place the edited content into the library.
6. Save the library.

Alternatively, to have the library supply an appropriate bus signal, use a bus object to lock in the data type at the interface of a library subsystem block.

Generate Code for Bus Signals

If you have Simulink Coder, the various techniques for defining buses are essentially equivalent for simulation, but the techniques can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, here is the generated code for the Bus Creator block in the ex_bus_logging model.

```matlab
/* BusCreator: 'Root/COUNTERBUSCreator' incorporates:
 * BusCreator: 'Root/LIMITBUSCreator'
 * Constant: 'Root/lower_saturation_limit'
 * Constant: 'Root/upper_saturation_limit'
 */
ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
```

A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.

To group signals into structures in the generated code, use nonvirtual buses. See “Organize Data into Structures in Generated Code” (Simulink Coder).

When you create a MATLAB structure to initialize a bus that contains non-double signal elements, you need to set the values of structure fields. The technique that you choose to set the values can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 72-137.

When you generate code for a bus signal that is input to or output from a referenced model, there are some code generation limitations. See “Limitations for Virtual Buses Crossing Model Reference Boundaries” on page 72-144.

Code generation for arrays of buses produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 72-144.
Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See “Specify Initial Conditions for Bus Signals” on page 72-79.

If the signal elements of the target bus use numeric data types other than double, in general:

- To avoid manually matching the field data types with the data types of the signal elements, use untyped expressions to set the field values. As you develop and rapidly prototype a model, use this technique for convenience.
- To generate more efficient production code and to avoid floating-point storage in the code, match the data types of the structure fields with the data types of the corresponding signal elements.

The technique that you choose can influence the efficiency and readability of the generated code.

For examples and more information about tunable initial conditions in the generated code, see “Control Signal and State Initialization in the Generated Code” (Simulink Coder).

Inline Numeric Values of Structure Fields in the Generated Code

If you set the Default parameter behavior configuration parameter to Inlined, by default, the field values of the initial condition structure appear in the generated code as inlined numbers (non-tunable). For these structures, use untyped expressions to set the field values in Simulink. The field values do not require data types because the structure is not tunable in the generated code.

However, if you later set Default parameter behavior to Tunable or apply a storage class to the structure by using a Simulink.Parameter object, the code can contain floating-point storage and inefficient explicit typecasts and bit shifts. To avoid these issues, consider matching the data types of the structure fields with the data types of the corresponding signal elements.

Generate Tunable Structure Specified Directly in a Block Dialog Box

Suppose that you specify an initial condition structure directly in a block dialog box, or in a Simulink.Signal object, with an expression such as

\[
\text{struct('signal1',5,'signal2',7.2)}
\]

(instead of storing the structure in a variable
or Simulink.Parameter object). In this case, to generate a tunable structure in the code, you set **Default parameter behavior** to Tunable.

Use the table to decide how to control the data types of the fields in these initial condition structures.

<table>
<thead>
<tr>
<th>Goal</th>

<td>Match the structure field data types with the signal element types. Store the data type information in the struct by using typed expressions to set the field values.</td>
</tr>
</tbody>
</table>

**Generate Tunable Structure Stored in a Variable or Parameter Object**

Suppose that you store an initial condition structure in a variable or Simulink.Parameter object that you create in the base workspace or a data dictionary. For example, you use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to Inlined. In this case, use the table to decide how to control the data types of the fields in the initial condition structure.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avoid manually matching the field data types with those of the signal elements.</td>
<td>Use untyped expressions to set the field values. In the generated code, the structure fields use the data type double. The generated algorithm uses explicit typecasts to reconcile the data type mismatches.</td>
</tr>
<tr>
<td><strong>Goal</strong></td>
<td><strong>Technique</strong></td>
</tr>
<tr>
<td>----------</td>
<td>---------------</td>
</tr>
</tbody>
</table>
| Generate more efficient code and avoid floating-point storage. | Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a Simulink.Bus object to control the data types of the fields and the signal elements simultaneously. 
To use the Model Advisor to check your model for potentially expensive data type mismatches, see “Check structure parameter usage with bus signals”. |
| Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the Model block. | Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a Simulink.Bus object to control the data types of the structure fields and the signal elements simultaneously. 
If you do not pass the structure to the referenced model as a model argument, follow the other guidelines for nonvirtual buses to decide how to control the data types. |

**Use Untyped Expressions to Set Field Values**

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus signal, the method that you use to apply the initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus signal `myBusSig` with these signal elements. Each element uses a specific data type.

```plaintext
myBusSig
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```
Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```matlab
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See “Use `Simulink.Bus.createMATLABStruct` to Create Structure” on page 72-141.

### Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

### Use Typed Expressions to Set Field Values

Suppose that you create a bus signal `myBusSig` with this hierarchy of signal elements. Each element uses a specific data type.

```matlab
myBusSig
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```matlab
initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.
To match a fixed-point data type, set the field value by using a `fi` object.

**Change Field Value by Preserving Data Type Information**

Suppose that you change the value of a field in an existing initial condition structure. To preserve the data type information in the field you can use subscripted assignment, with the syntax `( )`.

```plaintext
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```plaintext
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```plaintext
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

**Use Simulink.Bus.createMATLABStruct to Create Structure**

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically 0. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.
Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a Simulink.Bus object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to match the field data types manually when you change the data types of the signal elements. To control the data types of the fields and the signal elements, use the DataType property of the elements in the bus object.

Suppose that you use a Bus Creator block to create a bus signal myBusSig with these signal elements.

myBusSig
  signalElement1 (int32)
  signalElement2 (boolean)
  signalElement3 (single)

1 Open the Bus Editor.

2 Create a bus object, myBus, that corresponds to the bus signal.

3 Create an initial condition structure initStruct. Used untyped expressions to set the field values. To enhance readability of the field signalElement2, use the Boolean value false instead of 0.

   initStruct.signalElement1 = 3;
   initStruct.signalElement2 = false;
   initStruct.signalElement3 = 17.35;

4 To represent the structure, create a Simulink.Parameter object.

   initStruct = Simulink.Parameter(initStruct);
5 Use the parameter object to specify an initial condition for the bus signal. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

6 Use the bus object to specify the data type of the parameter object.

   ```matlab
   initStruct.DataType = 'Bus: myBus';
   ```

7 Use the bus object to specify the data type of the bus signal. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the bus object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the bus object.

For basic information about bus objects, see “Specify Bus Properties with Bus Objects” on page 72-55.

**Configure Data Types for Existing Structure**

To remove data type information from all the fields of a structure, you can write a custom function that replaces the field values with `double` numbers. Use the example function `castStructToDbl` as a template.

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function `castStructFromDbl` as a template.

**Check for Mismatched Data Types with Model Advisor**

To detect when the data types of structure fields are not consistent with associated bus elements, use the Model Advisor.

1 On the **Modeling** tab, click **Model Advisor**.
2 Click **OK**.
3 Select **By Task > Modeling Signals and Parameters using Buses > “Check structure parameter usage with bus signals”**.
4 Click the **Run This Check** button.
Limitations for Virtual Buses Crossing Model Reference Boundaries

If you use a bus signal as an input to or an output from a referenced model (Model block):

- You cannot configure the I/O arguments step method style of C++ class interface for the referenced model.

  As a workaround, use a nonvirtual bus instead. Alternatively, use the Default style of C++ class interface.

- You cannot configure function prototype control for the referenced model.

  As a workaround, use a nonvirtual bus instead.

For more information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 72-132. For more information about bus virtuality, see “Types of Composite Signals” on page 72-2.

Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a typedef that represents the underlying bus type appears in the *_types.h file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) is generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```c
typedef struct {
    real_T a;
    real_T b;
} BusObject;
/* Block signals (auto storage) */
typedef struct {
    BusObject ForEachSubsystem_IterInp_0[2];
} BlockIO_aob1;
```
For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

About Variable-Size Signals

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. For information about these types of signals, see “Signal Basics” on page 71-2 in the Simulink User’s Guide.

A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

Creating Variable-Size Signals

You can create variable-size signals in your Simulink model by using:

• Switch or Multiport Switch blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.

• A selector block and the Starting and ending indices (port) indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.

• The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.
How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

  Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

  Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.

---

**Discrete 2-Tap Filter**

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the states of
the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

“Mode-Dependent Variable-Size Signals” on page 73-14 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

**Programmatically Determine Whether Signal Line Has Variable Size**

This example shows how to use commands at the command prompt or in a script to determine whether a signal line has a variable size. In a large model or hierarchy of subsystems or referenced models, use this technique to determine whether a signal has a variable size due to an upstream block.

The example model sldemo_varsize_basic contains a signal \( a \) that is downstream of a Switch block. Use commands at the command prompt to determine whether \( a \) has a variable size.

1. Open the example model.
2. Select the Sum block whose output signal is labeled \( a \).
3. At the command prompt, set the model to a compiled state (similar to a diagram update).

   ```matlab
   sldemo_varsize_basic([],[],[],'compile')
   ```
4. Get a handle to the block output port.

   ```matlab
   portHandles = get_param(gcb,'portHandles');
   outPortHandle = portHandles.Outport;
   ```
5. Query the programmatic parameter `CompiledPortDimensionsMode` of the output port.

   ```matlab
   varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
   ```

   ```matlab
   varSize =
   1
   ```

The value of the variable `varSize` is 1, which indicates that the signal \( a \) has variable size.
The value 0 indicates that a signal does not have variable size.

6 Terminate the model compilation.

\[ \text{sldemo_varsize_basic([],[],[],'term')} \]

### Empty Signals

An empty signal is a signal with a length of 0. For example, signals with size \([0]\), \([0 \times 3]\), \([2 \times 0]\), and \([2 \times 0 \times 3]\) are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

### Subsystem Initialization of Variable-Size Signals

The initial signal size from an Outport block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the Propagate sizes of variable-size signals parameter in the parent subsystem to During execution, the Initial output parameter for the Output block must not exceed the maximum size of the input port. If the Initial output parameter value is:

<table>
<thead>
<tr>
<th>Initial output parameter</th>
<th>Initial output signal size</th>
</tr>
</thead>
<tbody>
<tr>
<td>A nonscalar matrix</td>
<td>The initial output signal size is the size of the Initial output parameter.</td>
</tr>
<tr>
<td>A scalar</td>
<td>The initial output signal size is a scalar.</td>
</tr>
<tr>
<td>The default []</td>
<td>The initial output size is an empty signal (dimensions are all zeros).</td>
</tr>
</tbody>
</table>

If you set the Propagate sizes of variable-size signals parameter in the parent subsystem to Only when enabling, the Initial output parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Outport block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the Initial output parameter is the default value [], Simulink treats the initial output as a grounded value.
• If the model does not activate the parent subsystem at start time \( t = 0 \), the current size of the subsystem output corresponding to the Outport block is set to maximum size.

• When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

Simulink Models Using Variable-Size Signals

In this section...

“Variable-Size Signal Generation and Operations” on page 73-7
“Variable-Size Signal Length Adaptation” on page 73-11
“Mode-Dependent Variable-Size Signals” on page 73-14

Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals” on page 73-24.

1  In the MATLAB Command Window, type

   sldemo_varsize_basic

2  In the Simulink Editor, on the Debug tab, select Information Overlays > Signal Dimensions. Run a simulation or press Ctrl-D.

   The Simulink Editor displays the signal dimensions and line styles. See “Signal Basics” on page 71-2 for an interpretation of signal line styles.

3  So that you can see the names of the blocks in the model, on the Format tab, clear Auto > Hide Automatic Block Names.
Creating a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.
Output from the Switch block is a 2-D variable-size signal with a maximum size of 3x2. When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

**Saving Variable-Size Signal Data**

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2`. The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```matlab
simout2.signals.values
```

```
ans(:,:,1) =
    1   -1
   -2    2
   -3    3

ans(:,:,2) =
    1   -1
   -2    2
   -3    3

ans(:,:,3) =
     0   NaN
    NaN   NaN
    NaN   NaN
```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```matlab
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

```
ans =
   3   2
```
Creating a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a 3x4 matrix. The Pulse Generator represents a control signal that selects a starting and ending index value ( [1 2] or [1 3]). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.

Viewing Changes in Signal Size

The output from the Selector block is either a 2x2 or 3x3 matrix. Because the maximum dimension for a variable-size signal is the 3x4 matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

Processing Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain, Sum, Math Function, and Matrix Concatenate blocks. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.
Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 73-24.

To open the example model, in the MATLAB Command Window, type:

sldemo_varsize_dataLengthAdapt

So that you can see the names of the blocks, in the model, on the Format tab, clear Auto > Hide Automatic Block Names.

Creating a Variable-Size Signal by Adapting the Length of a Data Signal

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

[1:9].'

ans =
  1
  2
  3
The Size Selection subsystem determines the quality of the data signal and outputs a quality value (1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.
**Processing a Variable-Size Signal**

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks shows various manipulations you can do with variable-size signals.

**Visualizing a Variable-Size Signal**

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.
Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

`sldemo_varsize_multimode`
So that you can see the names of the blocks, in the model, on the Format tab, clear Auto > Hide Automatic Block Names.

**Creating a Variable-Size Signal Based on Mode**

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value (1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are [1 3], [1 2], and [1 1].
The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3x3, 2x2, and 1x1.

The dimensions of the raw data signal (Constant block) is a 3x3. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values
```

```
ans(:,:,1) =
    1     4     7
    2     5     8
    3     6     9
```

The variable-size signal generated from the Data subsystem is also a 3x3 matrix. For shorter signals, the matrix is padded with NaNs.
simout.signals.values

ans(:,:,1) =

1   NaN   NaN
NaN   NaN   NaN
NaN   NaN   NaN

ans(:,:,2) =

1     4   NaN
2     5   NaN
NaN   NaN   NaN

ans(:,:,3) =

1     4     7
2     5     8
3     6     9

**Processing a Variable-Size Signal with a Conditionally Executed Subsystem**

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the Propagate sizes of variable-size signals list, choose Only when enabling. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 73-3.
The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repopagates the signal sizes within the Process subsystem.

**Visualizing Data**

Use the Probe block to visualize signal size and signal dimension.
Since the signals are $n \times n$ matrices, the signal dimension lines overlap in the Scope display.

You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

S-Functions Using Variable-Size Signals

In this section...

“Level-2 MATLAB S-Function with Variable-Size Signals” on page 73-21
“C S-Function with Variable-Size Signals” on page 73-22

Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to **Variable**. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

`msfcndemo_varsize`
The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by $1:n$ where $n$ is the input value.

### C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcndemo_varsize
```

The enabled subsystems have two S-Functions:

- `sfun_varsize_holdStatesUntilReset` is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.
• sfun_varsizer_concat1D is a C S-function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

Simulink Block Data Type Support

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

1. Open a Simulink model.
2. In the MATLAB command line, enter `showblockdatatypetable`.

   A separate window with the Simulink Block Data Type Support table opens.

An X in the **Variable-Size Support** column indicates support for that block.

**Tip** You can also view the table by entering `showblockdatatypetable` at the command prompt.

Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to **During execution**, **Only when execution is resumed** (Action Port), and **Only when enabling** (Enable and Trigger or Function-Call).
• Action Port
• Enable
• Trigger — **Trigger type** set to function-call

**Switching Blocks**

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the
Allow different data input sizes parameter for these blocks on the Signal Attributes pane to either on or off.

- Switch
- Multiport Switch
- Manual Switch

You can add commands and submenus to a menu bar and context menus for the Simulink Editor and Stateflow Editor.

To add an item to a menu:

• For each item, create a function, called a schema function, that defines the item (see “Define Menu Items” on page 74-4).
• Register the menu customizations with the Simulink customization manager at startup, e.g., in an sl_customization.m file on the MATLAB path (see “Register Menu Customizations” on page 74-9).
• Create callback functions that implement the commands triggered by the items that you add to the menus.

Code for Adding Menu Items

The following sl_customization.m file adds four items to the Simulink Editor Tools menu.

function sl_customization(cm)

    %% Register custom menu function.
    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
    schemaFcns = {@getItem1, ...
                  @getItem2, ...
                  {@getItem3,3}, ... %% Pass 3 as user data to getItem3.
                  @getItem4};
%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
    schema = sl_action_schema;
    schema.label = 'Item One';
    schema.userdata = 'item one';
    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
% Make a submenu label 'Item Two' with
% the menu item above three times.
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
% Create a menu item whose label is
% 'Item Three: 3', with the 3 being passed
% from getMyItems above.
    schema = sl_action_schema;
    schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
        set_param(gcs, 'ScreenColor', 'red');
    else
        set_param(gcs, 'ScreenColor', 'white');
    end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
    schema = sl_toggle_schema;
    schema.label = 'Red Screen';
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
        schema.checked = 'checked';
    else
        schema.checked = 'unchecked';
    end
    schema.callback = @myToggleCallback;
end
Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- “Defining Menu Items That Trigger Custom Commands” on page 74-4
- “Defining Custom Submenus” on page 74-7

Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see “Callback Info Object” on page 74-10) and create and return an action schema object (see “Action Schema Object” on page 74-4) that specifies the item label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```matlab
function schema = getItem1(callbackInfo)
    % Create an instance of an action schema.
    schema = sl_action_schema;

    % Specify the menu item label.
    schema.label = 'My Item 1';
    schema.userdata = 'item1';
    % Specify the menu item callback function.
    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata ' was called']);
end
```

Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked...
when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include:

- **tag**
  
  Optional character vector that identifies this action, for example, so that it can be referenced by a filter function.

- **label**
  
  Character vector specifying the label that appears on a menu item that triggers this action.

- **state**
  
  Property that specifies the state of this action. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.

- **statustip**
  
  Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this action.

- **userdata**
  
  Data that you specify. May be of any type.

- **accelerator**
  
  Character vector specifying a Ctrl and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, Ctrl+D is an accelerator for Update Diagram in the Simulink Editor, so you cannot redefine it.

  To specify this value, use the form 'Ctrl+K', where K is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down Ctrl and Alt and pressing T.

- **callback**
  
  Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- **autoDisableWhen**
Property that controls when a menu item is automatically disabled.

<table>
<thead>
<tr>
<th>Setting</th>
<th>When Menu Items Are Disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Locked'</td>
<td>(default) When the active editor is locked or when the model is busy</td>
</tr>
<tr>
<td>'Busy'</td>
<td>Only if the model is busy</td>
</tr>
<tr>
<td>'Never'</td>
<td>Never</td>
</tr>
</tbody>
</table>

**Toggle Schema Object**

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include:

- **tag**
  
  Optional character vector that identifies this toggle action, for example, so that it can be referenced by a filter function.

- **label**
  
  Character vector specifying the label that appears on a menu item that triggers this toggle action.

- **checked**
  
  Specify whether the menu item displays a check mark. Valid values are 'unchecked' (default) and 'checked'.

- **state**
  
  State of this toggle action, specified as 'Enabled' (default), 'Disabled', and 'Hidden'.

- **statustip**
  
  Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this toggle action.

- **userdata**
  
  Data that you specify. May be of any type.

- **accelerator**
  
  Customizing the Simulink User Interface
Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.

To specify this value, use the form 'Ctrl+K', where K is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.

- **callback**

  Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- **autoDisableWhen**

  Property that controls when a menu item is automatically disabled.

<table>
<thead>
<tr>
<th>Setting</th>
<th>When Menu Items Are Disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Locked'</td>
<td>(default) When the active editor is locked or when the model is busy</td>
</tr>
<tr>
<td>'Busy'</td>
<td>Only if the model is busy</td>
</tr>
<tr>
<td>'Never'</td>
<td>Never</td>
</tr>
</tbody>
</table>

**Defining Custom Submenus**

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see “Container Schema Object” on page 74-8) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in “Defining Menu Items That Trigger Custom Commands” on page 74-4.

```matlab
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```
**Container Schema Object**

A container schema object specifies a submenu label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- **tag**
  
  Optional character vector that identifies this submenu.

- **label**
  
  Character vector specifying the submenu label.

- **state**
  
  Character vector that specifies the state of this submenu. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.

- **statustip**
  
  Character vector specifying text to appear in the editor status bar when the user selects this submenu.

- **childrenFcns**
  
  Cell array that specifies the contents of the submenu. Each entry in the cell array can be

  - A pointer to a schema function that defines an item on the submenu (see “Define Menu Items” on page 74-4)
  
  - A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see “Callback Info Object” on page 74-10) passed to the schema function
  
  - `'separator'`, which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, 'SEPARATOR' and 'Separator' are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).

For example, the following cell array specifies two submenu entries:

```
{getItem1, 'separator', {getItem2, 1}}
```
In this example, a 1 is passed to `getItem2` via a callback info object.

- **generateFcn**

  Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

  **Note** The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

- **userdata**

  Data of any type that is passed to `generateFcn`.

- **autoDisableWhen**

  Property that controls when a menu item is automatically disabled.

<table>
<thead>
<tr>
<th>Setting</th>
<th>When Menu Items Are Disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Locked'</td>
<td>(default) When the active editor is locked or when the model is busy</td>
</tr>
<tr>
<td>'Busy'</td>
<td>Only if the model is busy</td>
</tr>
<tr>
<td>'Never'</td>
<td>Never</td>
</tr>
</tbody>
</table>

**Register Menu Customizations**

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Registering Customizations” on page 74-25) to perform this task. In particular, for each menu that you want to customize, your system `sl_customization` function must invoke the customization manager `addCustomMenuFcn` method. Each invocation should pass the tag of the menu (see “Menu Tags” on page 74-11) to be customized and a custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 74-10). For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```matlab
function sl_customization(cm)  
    % Register custom menu function.  
    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);  
```
Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 74-4). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 74-10) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```matlab
function schemas = getMyItems(callbackInfo)
    schemas = {@getItem1, ...
                @getItem2, ...
                {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`
  - Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.
- `model`
  - Method to get the handle to the model being displayed in the editor window.
- `userdata`
  - User data property. The value of this property can be any type of data.

Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive or the
menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

**Menu Tags**

A menu tag identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know the tag for a menu to add custom items to it (see “Register Menu Customizations” on page 74-9).

<table>
<thead>
<tr>
<th>Tag</th>
<th>What It Adds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simulink tags</td>
<td></td>
</tr>
<tr>
<td>Simulink:MenuBar</td>
<td>Menu to the Simulink Editor menu bar</td>
</tr>
<tr>
<td>Simulink:PreContextMenu</td>
<td>Item to the beginning of a Simulink Editor context menu</td>
</tr>
<tr>
<td>Simulink:ContextMenu</td>
<td>Item to the end of a Simulink Editor context menu</td>
</tr>
<tr>
<td>Simulink:FileMenu</td>
<td>Item to the end of a Simulink Editor File menu</td>
</tr>
<tr>
<td>Simulink:EditMenu</td>
<td>Item to the end of a Simulink Editor Edit menu</td>
</tr>
<tr>
<td>Simulink:ViewMenu</td>
<td>Item to the end of a Simulink Editor View menu</td>
</tr>
<tr>
<td>Simulink:DisplayMenu</td>
<td>Item to the end of a Simulink Editor Display menu</td>
</tr>
<tr>
<td>Simulink:DiagramMenu</td>
<td>Item to the end of a Simulink Editor Diagram menu</td>
</tr>
<tr>
<td>Simulink:SimulationMenu</td>
<td>Item to the end of a Simulink Editor Simulation menu</td>
</tr>
<tr>
<td>Simulink:AnalysisMenu</td>
<td>Item to the end of a Simulink Editor Analysis menu</td>
</tr>
<tr>
<td>Simulink:CodeMenu</td>
<td>Item to the end of a Simulink Editor Code menu</td>
</tr>
<tr>
<td>Simulink:ToolsMenu</td>
<td>Item to the end of a Simulink Editor Tools menu</td>
</tr>
<tr>
<td>Simulink:HelpMenu</td>
<td>Item to the end of a Simulink Editor Help menu</td>
</tr>
<tr>
<td>Stateflow tags</td>
<td></td>
</tr>
<tr>
<td>Stateflow:MenuBar</td>
<td>Menu to the Stateflow Editor menu bar</td>
</tr>
<tr>
<td>Stateflow:PreContextMenu</td>
<td>Item to the beginning of a Stateflow Editor context menu.</td>
</tr>
</tbody>
</table>
### Simulink and Stateflow Editor Menu Customization

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

Disable and Hide Model Editor Items

You can disable items that appear on the Simulink Toolstrip and context menus. You can also hide items that appear on context menus. To disable or hide an item, you must:

- Create a filter function that disables or hides the item (see “Create a Filter Function” on page 74-14).
- Register the filter function with the customization manager (see “Register a Filter Function” on page 74-15).

Example: Disable the New Model Command in the Simulink Toolstrip

```matlab
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
    state = 'Disabled';
end
```

Create a Filter Function

Your filter function must accept a callback info object and return the state that you want to assign to the item. Valid states are:

- 'Hidden'
- 'Disabled'
- 'Enabled'

Your filter function may have to compete with other filter functions and with Simulink itself to assign a state to an item. Who succeeds depends on the strength of the state that each assigns to the item.

- 'Hidden' is the strongest state. If any filter function or Simulink assigns 'Hidden' to a menu item, it is hidden. For Simulink Toolstrip items, specifying 'Hidden' disables the item instead of hiding it.
- 'Disabled' overrides 'Enabled', but is itself overridden by 'Hidden'.
• 'Enabled' is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign 'Enabled' to the item.

### Register a Filter Function

Use the customization manager `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or item to be filtered and a pointer to the filter function itself. For example, the following code registers a filter function for the **New Model** item on the Simulink Toolstrip.

```matlab
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

</tr>
<tr>
<td>“Register Control Customization Callback Functions” on page 74-19</td>
</tr>
</tbody>
</table>

About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as widgets), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a dialog box is customizable, open the dialog box, enable dialog and widget ID display (see “Widget IDs” on page 74-18), and hover over a widget. If a widget ID appears, you can customize the dialog box.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see “Write Control Customization Callback Functions” on page 74-17) and registering the callback functions using the customization manager (see “Register Control Customization Callback Functions” on page 74-19). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

Disable a Button on a Dialog Box

This sl_customization.m file disables the Browse button on the Code Generation pane of the Configuration Parameters dialog box for any model whose name contains engine.
function sl_customization(cm)
% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);
end

function disableRTWBrowseButton(dialogH)
    hSrc   = dialogH.getSource;  % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName   = get_param(hModel,'Name');

    if ~isempty(strfind(modelName,'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'STF_Browser'})
    end
end

To test this customization:

1. Save the sl_customization.m file on the MATLAB path.
2. Refresh the customizations by entering sl_refresh_customizations at the command line or by restarting MATLAB (see “Registering Customizations” on page 74-25).
3. Open the sldemo_engine model, for example, by entering the command sldemo_engine at the command prompt.
4. Open the Configuration Parameters dialog box and look at the Code Generation pane to see if the Browse button is disabled.

**Write Control Customization Callback Functions**

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the Browse button on the Code Generation pane of the Configuration Parameters dialog box for any model whose name contains engine.

function disableRTWBrowseButton(dialogH)
hSrc = dialogH.getSource; \% Simulink.RTWCC
hModel = hSrc.getModel;
modelName = get_param(hModel,'Name');

if ~isempty(strfind(modelName,'engine'))
    \% Takes a cell array of widget Factory ID.
    dialogH.disableWidgets({'STF_Browser'})
end

**Dialog Box Methods**

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

`widgetIDs` is a cell array of widget identifiers (see “Widget IDs” on page 74-18) that specify the widgets to disable or hide.

**Widget IDs**

Widget IDs identify a control on a Simulink dialog box. To determine the widget ID for a particular control, execute the following code at the command line:

```matlab
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the widget ID. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the widget ID for the **Start time** field is `StartTime`. 

---

74-18
Note The tooltip displays not customizable for controls that are not customizable.

Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation `sl_customization.m` file (see “Registering Customizations” on page 74-25) that invokes the `configset.dialog.Customizer.addCustomization` method on the callbacks.

This method takes as an argument a pointer to the callback function to register. Invoking this method causes the registered function to be invoked before the dialog box is opened.
This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see “Write Control Customization Callback Functions” on page 74-17).

```matlab
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton, cm);

end
```

**Note** Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

Customize Library Browser Appearance

Reorder Libraries

The library name and sort priority determines its order in the tree view of the Library Browser. Libraries appear in ascending order of priority. Libraries that have the same priority are sorted alphabetically.

The Simulink library has a sort priority of -1 by default. All other libraries have a sort priority of 0 by default. These sort priorities cause the Simulink library to display first in the Library Browser by default.

You can reorder libraries by changing their sort priorities. To change library sort priorities, add code in this form to an sl_customization.m file on the MATLAB path:

```matlab
cm.LibraryBrowserCustomizer.applyOrder({'LIBNAME1',PRIORITY1, ...
  'LIBNAME2',PRIORITY2, ...
  ...
  'LIBNAMEn',PRIORITYn});
```

LIBNAMEn is the name of the library (or its model file) and PRIORITYn is an integer indicating the library sort priority. For example, this code moves the Simulink Extras library to the top of the Library Browser tree view.

```matlab
cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras',-2});
```

After adding or modifying the sl_customization.m file, enter

```
sl_refresh_customizations
```

at the MATLAB command prompt to see the customizations take effect.

For more information on the customization functions, see “Registering Customizations” on page 74-25.
**Disable and Hide Libraries**

To disable or hide libraries, sublibraries, or library blocks, insert code in this form in an `sl_customization.m` file (see “Registering Customizations” on page 74-25) on the MATLAB path. Blocks that you disable or hide in a library also do not appear on the quick insert menu that you invoke in the model.

```matlab
cm.LibraryBrowserCustomizer.applyFilter({
    'Item1','State', ...
    'Item2','State', ...
    .
    .
    'ItemN','State'});
```

- **ItemN** is the library, sublibrary, or block to disable or hide. Specify the item in the form `'LibraryName/Sublibrary/Block'`.
  - **LibraryName** is the library name as it appears in the browser. For a custom library, you set this value in the `slblocks.m` file with the `Browser.Name` property.
  - **Sublibrary** is the name of the sublibrary or, for a custom library, a Subsystem block. You can specify a block inside the subsystem in your library or in a library that you open by way of the subsystem `OpenFcn` callback. See “Create a Custom Library” on page 42-2.
  - **Block** is the block name.
- **'State'** is 'Disabled' or 'Hidden'.

For example, this code hides the Sources sublibrary of the Simulink library and disables the Sinks sublibrary.

```matlab
cm.LibraryBrowserCustomizer.applyFilter({
    'Simulink/Sources','Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({
    'Simulink/Sinks','Disabled'});
```

This code disables the Sqrt block in the sublibrary opened by way of the Subsystem2 block in the custom library 'My Library'.

```matlab
cm.LibraryBrowserCustomizer.applyFilter(...
    {'My Library/Subsystem2/Sqrt','Disabled'});```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.
Expand or Collapse Library in Browser Tree

You can add a customization to expand or collapse any library in the Library Browser tree by default. For example, the Simulink library is expanded by default. You can specify to instead collapse it by default. Add code in this form to your `sl_customization.m` file:

```matlab
cm.LibraryBrowserCustomizer.applyNodePreference(...
    {'libraryName',logical});
```

Use `true` to expand the library and `false` to collapse it.

For example, this code collapses the Simulink library and expands the Simscape library:

```matlab
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference(...
        {'Simulink',false,'Simscape',true});
end
```

This code collapses a custom library named 'My Library'.

```matlab
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference(...
        {'My Library',false});
end
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Improve Quick Block Insert Results

You can double-click the end of a signal line that you draw from an existing block to add a block. A menu of possible blocks to insert appears. For example, at the end of a signal line out of a Gain block, the menu suggests other math blocks. Simulink comes with default suggestions.

You can improve the suggestions on this menu by updating the engine with information about your models. To do so, run a command on a single model or on all the models in a folder. Information about your model designs updates the engine. You can also remove this customization using a command.

Registering Customizations

About Registering Customizations in Simulink

Register your customizations using the MATLAB function `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file take effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations are loading as expected, refresh the customizations, as described in “Reading and Refreshing the Customization File” on page 74-26.

The `sl_customization` function accepts one argument: a handle to the customization manager object, that is, `cm`. For example:

```matlab
function sl_customization(cm)
```

In your `sl_customization` function, use customization manager object properties and methods specific to your application to register customizations. You can use customization properties and methods to:

- “Add Items to Model Editor Menus” on page 74-2
- “Disable and Hide Model Editor Items” on page 74-14
- “Disable and Hide Dialog Box Controls” on page 74-16
- “Add Libraries to the Library Browser” on page 42-9
- “Customize Library Browser Appearance” on page 74-21
- “Customize Bus Object Import and Export” on page 72-70
- “Import Lookup Table Data from MATLAB” on page 39-30

Additional MathWorks products use the customization manager object and the `sl_customization.m` file. Refer to your product documentation to learn about the methods and properties that apply to your product.
Reading and Refreshing the Customization File

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side-effects of running `sl_refresh_customizations` include:

- Rebuilding the Simulink Toolstrip
- Rebuilding all Simulink Editor menus
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Viewers and Generators Manager data

Print Frames

In this section...

“What Are Print Frames?” on page 75-2
“PrintFrame Editor” on page 75-3
“Single Use or Multiple Use Print Frames” on page 75-4
“Text and Variable Content” on page 75-5

What Are Print Frames?

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells.

For example, the print frame below includes:

• An additional row at the top of the frame for a title
• A middle row, which includes the block diagram
• A bottom row, in which one cell has the path to the subsystem and another cell has the page number

PrintFrame Editor

Use the **PrintFrame Editor** to create and edit print frames.

To open the **PrintFrame Editor**, at the MATLAB command line, enter the `frameedit` command.
Use the **PrintFrame Editor** to:

- Set up the printed page
- Add or remove rows and cells in the print frame
- Add content to cells, such as text, the date, and page numbers
- Format cell content

To open an existing print frame, use `frameedit` command with the `filename` parameter, where `filename` is an existing print frame (a .fig file).

**Single Use or Multiple Use Print Frames**

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.
Text and Variable Content

In cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

• “Print Using Print Frames” on page 75-13
Create a Print Frame

1. At the MATLAB prompt, type `frameedit` to open the **PrintFrame Editor**.
2. In the **PrintFrame Editor**, select **File > Page Setup**.
   
   If necessary, change default page setup for the print frame, which is:
   
   - Paper type — *usletter*
   - Orientation — *landscape*

   **Note** The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the **PrintFrame Editor**. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.
   
   - Margins — .75 inches on all sides

3. Set up the layout of the print frame and add content. See:
   
   - “Add Rows and Cells to Print Frames” on page 75-7
   - “Add Content to Print Frame Cells” on page 75-9

4. Save the print frame as a `.fig` file. Select **File > Save As**.

- “Print Frames” on page 75-2
Add Rows and Cells to Print Frames

In this section…

“Add and Remove Rows” on page 75-7
“Add and Remove Cells” on page 75-7
“Resize Rows and Cells” on page 75-8

Tip Specify the print frame page setup before you create rows and cells or add content (see “Create a Print Frame” on page 75-6).

Add and Remove Rows

You can add a row above the row that you select.

1. Click in a cell to select a row.

   When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

2. Click Add Row.

   The new row appears above the row that you selected.

To remove a row, select the row and click Delete Row.

Add and Remove Cells

You can add cells within a row.

1. Select the cell that you want to split.

2. Click Split Cell.

   The cell splits into two cells.

To remove a cell, select the cell and click Delete Cell.
Resize Rows and Cells

You can change the dimensions of a row or cell by selecting the bordering line.

1. Click the line you want to move.
   
   A handle appears on both ends of the line.

2. Drag the line to resize the row or cell.

For example, to make a row taller, click on the top line that forms the row. Then drag the line up and the height of the row increases.

To change the overall dimensions of the print frame, see “Create a Print Frame” on page 75-6.

Add Content to Print Frame Cells

In this section...

“Types of Content” on page 75-9
“Add Content to Cells” on page 75-9
“Block Diagram” on page 75-10
“Variables” on page 75-10
“Text” on page 75-11
“Format Content in Cells” on page 75-12

Types of Content

You can add text or variables, or both, to a cell.

You must add a Block Diagram variable to one of the cells.

For details about the types of content, see:

• “Block Diagram” on page 75-10
• “Variables” on page 75-10
• “Text” on page 75-11

Add Content to Cells

1. Select the cell that you want to add content to.
2. From the list, select the type of content that you want to add.
3. Click Add.

The type of content that you added appears in the cell.

Tip If you click Add and nothing happens, it might be because you did not select a cell first.

4. If you add text, select the edit box and type in the text. For details, see “Text” on page 75-11.
**Tip** To make it easier to read and edit the content that you add, you can click the **Zoom in** + button.

**Include Multiple Entries in a Cell**

1. Select a cell that has a content entry.
2. Add another content type item from the list.

   The new entry is added after the last entry in that cell.

You can also add descriptive text to any of the variable entries without using the **Text** item.

1. Double-click in the cell.
2. Type text in the edit box before or after the entry.
3. To end editing mode, click outside of the cell.

**Note** You cannot include multiple entries or text in the cell that contains the **Block Diagram** variable. %<blockdiagram> must be the only content in that cell.

**Block Diagram**

Use the **Block Diagram** variable to indicate the cell in which to print the block diagram. Every print frame must include one **Block Diagram** variable. If you do not specify a **Block Diagram** in one of the cells, you cannot save the print frame and cannot print a block diagram with it.

Do not add any other content in a cell that contains a **Block Diagram** variable.

**Variables**

In addition to the **Block Diagram** variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

Variable entries include:

- **Block Diagram** — Add this variable in the cell in which you want the block diagram to print. For details, see “Block Diagram” on page 75-10.
• **Date** — The date that the block diagram and print frame are printed, in **dd-mmm-yyyy** format.

• **Time** — The time that the block diagram and print frame are printed, in **hh:mm** format.

• **Page Number** — The page of the block diagram being printed.

• **Total Pages** — The total number of pages being printed for the block diagram, which depends on the printing options specified.

• **System Name** — The name of the block diagram being printed.

• **Full System Name** — The name of the block diagram being printed, including its position from the root system through the current system, for example, *engine/Throttle & Manifold*.

• **FileName** — The file name of the block diagram, for example, *sldemo_engine.mdl*.

• **Full File Name** — The full path and file name for the block diagram, for example, `\matlab\toolbox\simulink\simdemos\automotive\sldemo_engine.mdl`.

When you enter a variable, the cell displays the type of content in brackets, `<>` , preceded by a percent sign, `%`. For example, if you add a **Page Number** variable, it appears as `%<page>`.

**Note** Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints, instead of the actual page number.

**Text**

For **Text** content, type the text that you want to include in that cell (for example, the name of your organization). To type additional text on a new line, press the **Enter** key. When you are finished editing, click outside of the edit box.

You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.

To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the **text** command **String** property (in **Text**).
**Format Content in Cells**

You can align cell contents using the left, center, and right alignment buttons. (Block diagrams are always center aligned.)

You can change font properties, such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

- “Print Frames” on page 75-2
Print Using Print Frames

To print using a print frame, you specify an existing print frame. If you want to build a print frame, see “Create a Print Frame” on page 75-6.

**Note** If you enable the print frame option, then Simulink does not use tiled printing.

1. In the Simulink Editor or Stateflow Editor, on the **Simulation** tab, click **Print**.
2. In the Print Model dialog box, select the **Frame** check box.

3. Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the **...** button and select a print frame file you saved using the **PrintFrame Editor**. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
4. Specify other printing options in the Print Model dialog box.

**Note** The paper orientation you specify with the **PrintFrame Editor** does not control the paper orientation used for printing. For example, assume you specify a
landscape-oriented print frame in the **PrintFrame Editor**. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

5 Click **OK**.

The block diagram prints with the print frame that you specify.

Overview of Using External Mode

You can use External mode to tune parameters and monitor a model running on your target hardware.

External mode enables you to tune model parameters and evaluate the effects of different parameter values on model results in real time. Doing so helps you find the optimal values to achieve desired performance. This process is called parameter tuning.

External mode accelerates parameter tuning because you do not have to rerun the model each time you change parameters. You can also use External mode to develop and validate your model using the actual data and hardware for which it is designed. This software-hardware interaction is not available solely by simulating a model.

This workflow lists the tasks usually required to tune parameters with External mode:

1. In the model on your host computer, enable External mode.
2. (Optional) Place one or more sink blocks in your model. For example, use Display or Scope blocks to visualize data, or use a To File block to log signal data.
3. Give the Simulink software command to run the model on the target hardware.
4. (Optional) Observe the data External mode sends from the target hardware to sink blocks in the model on the host computer.
5. Change and apply parameter values in the model on your host computer.
6. Find the optimal parameter values by making adjustments and observing the results.
7. Save the new parameter values, disable External mode, and save the model.
Run Your Simulink Model in External Mode

**Note** If you have the Embedded Coder or Simulink Coder software, you can use External mode with a model that contains Model blocks (uses the “Model reference”).

1. Connect the target hardware to your host computer.
   
   Different types of target hardware can use different types of connections. Check the External mode topic for your target hardware to determine which type of connection to use.

2. On the Simulation tab, set Simulation Mode to External.

3. Set the Stop Time parameter. The default value is 10.0 seconds. To run the model for an indefinite period, enter inf.

4. Click the Run button.
   
   If your model does not contain a sink block, the MATLAB Command Window displays a warning message. For example:

   Warning: No data has been selected for uploading.  
   > In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\realtime\realtime\+realtime\extModeAutoConnect.p>extModeAutoConnect at 17
   In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\realtime\realtime\sl_customization.p>myRunCallback at 149

   You can disregard this warning or add a sink block to the model.

   After several minutes, Simulink starts running your model on the board.

5. Change parameter values in the model on your host computer.
   
   Observe the corresponding changes in the model running on the hardware.

   Any Simulink Sinks blocks in your model receive data from the hardware and display it on your host computer.

**Note** External mode increases the processing burden of the model running on the board, and can cause overruns.
Stop External Mode

To stop the model running in External mode, on the Simulation tab, click the Stop button.

This action stops the process for the model running on the target hardware, and stops the model simulation running on your host computer.

If the Stop Time parameter is set to a specific number of seconds, External mode stops when that time elapses.

When you are finished using External mode, set Simulation Mode back to Normal.

External Mode Control Panel

Using External Mode Control Panel provides additional control of External mode operations, including:

- Connect or disconnect the model on the host computer to/from the model running on the target hardware.
- Start and stop the model running on the target hardware.
- Gather changes to parameter values in a batch before applying them concurrently to the model running on the target hardware.

To open the External Mode Control Panel dialog box, in the model window, on the Apps tab, under Apps, click Run on Custom Hardware. Then on the Hardware tab, click Control Panel.
The **Connect/Disconnect** button connects or disconnects the model on your host computer to/from the model running on the target hardware. If the model is not running on the target hardware, clicking **Connect** automatically deploys and runs the model on the target hardware.

- **The **Start Real-Time Code/Stop Real-Time Code** button starts or stops the model running on the target hardware.

- **Batch download** enables you to gather changes before using the **Download** button to simultaneously apply those changes to the model running on the hardware:
  - While **Batch download** is disabled, clicking **OK** or **Apply** in a block dialog box sends updated block parameter values from the block to the model running on the target hardware.
  - When you enable **Batch download**, clicking **OK** or **Apply** in a block dialog box stores updated block parameter values on the host computer. You can complete a set of changes before clicking **Download** to simultaneously send all of the updated values to the model running on the target hardware. This feature is useful for avoiding error conditions when a model contains blocks whose parameter values must be changed concurrently.

External Mode Control Panel displays **Parameter changes pending...** to the right of the **Download** button until the model running on the target hardware has applied the new parameter values.

Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

This is the expected behavior.

For example, in a model, on the Simulation tab, if you select Normal in the Simulate section, and then click Run, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, on the Modeling tab, click Model Settings. In the Configuration Parameters dialog box, select Hardware Implementation. Then, in the Simulink Editor, on the Hardware tab, select Build Stand-Alone > Build, Deploy & Start.

To use External mode, in the Hardware Implementation pane of the Configuration Parameters dialog box, select your hardware board from the drop-down list. Then expand Target hardware resources, and under Groups select External mode. Then click Run.

Running Simulations in Fast Restart

- “How Fast Restart Improves Iterative Simulations” on page 77-2
- “Get Started with Fast Restart” on page 77-5
How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

1. Compiles the model
2. Simulates the model
3. Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and root inputs and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

Limitations

These are the limitations to simulating in fast restart.

- Fast restart does not support these modes:
  - Rapid Accelerator
When a model is in the reinitialized state, you cannot:

- Make structural changes.
- Make changes to nontunable parameters such as sample time.
- Save changes to the model. You must turn off fast restart to save any changes to the model.

You cannot turn on fast restart in a model if it contains blocks that do not support `ModelOperatingPoint` object. These blocks include:

- Legacy (pre-R2016a) SimEvents blocks
- Simscape Multibody First Generation blocks
- MATLAB function blocks that contain system objects
- S-functions that do not implement the model operating point `get` and `set` methods but have `Pwork` vectors declared
- From Multimedia File
- To Multimedia File
- From Audio Device
- To Audio Device
- Multipath Rician Fading Channel
- Multipath Rayleigh Fading Channel
- Derepeat
- DC Blocker
- Stack
- Queue
- Read Binary File
- Write Binary File
- Video Viewer
- Frame Rate Display
- Video From Workspace
- Video To Workspace

Between simulations, fast restart does not handle changes to design data, such as bus properties.
- Parameter tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 38-49.

- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.

- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.

- When there are multiple model references to the same referenced model, you cannot change the model visibility when the model is in the reinitialized state.

- Fast restart is not compatible with these tools:
  - Simulink Profiler
  - Simulink Debugger

- When simulating a model in fast restart, you cannot run checks using Model Advisor.

- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.

- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.

- “Save and Restore Simulation Operating Point” on page 26-48
Get Started with Fast Restart

In this section...

“Prepare a Model to Use Fast Restart” on page 77-6
“Fast Restart Methodology” on page 77-8

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again. Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. A generic workflow using fast restart involves the following steps.

1. Turn on fast restart using the **Fast Restart** button on the Simulink Toolstrip or from the command line.

2. Simulate the model. The first simulation requires the model to compile, initialize and save a **ModelOperatingPoint** object. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.

3. Perform any of these actions:

   - Change tunable parameters.
   - Tune root-level inputs.
   - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
   - Change inputs to From File and From Workspace blocks.
   - Change the **Initial state** parameter for the next simulation.
   - Using the Signal Builder block, change data, rename signals and signal groups, and add new groups.
   - Change the signal logging override values for the model programmatically by using the `set_param` command and the **DataLoggingOverride** parameter. See “Override Signal Logging Settings from MATLAB” on page 68-99.

Once you have initialized a model in fast restart, you cannot

   - Change the dimension, type, or complexity of a signal or variable.
   - Make changes to a nontunable parameter such as sample time.
   - Make structural changes such as adding or deleting blocks or connections.
These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.

4 Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.

5 Once you have achieved the desired response, turn off fast restart.

**Note** When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

### Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `ModelOperatingPoint` object.
- The simulation mode is Normal or Accelerator mode.

**Note** When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

### Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type `set_param(model,'FastRestart','on')`
Simulate a Model using Fast Restart

After you load your model and turn on fast restart, simulate the model.

1  Simulate the model by calling `sim` or clicking the Run button in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `ModelOperatingPoint` object.

Once the simulation is complete, the status bar shows that the model is initialized in fast restart.

2  Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.

3  Simulate the model again. This time, the model does not compile. When you click the Play button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.

4  When you are satisfied with your results, turn off fast restart by clicking the Fast restart button off.

5  To keep your changes, save the model.

Note  After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

Stop a Simulation

When you click Stop in the middle of a fast restart simulation:

- Simulation does not terminate.
• The model is in the initialized state.
• You can now change tunable parameters in the model
• You can terminate the simulation and exit fast restart by clicking the Fast restart button off.

**Exit Fast Restart**

You can exit fast restart only when the model is in the initialized state. After simulating, click the Fast restart button off. To do this programmatically, type:

```matlab
set_param(model,'FastRestart','off')
```

• Simulink terminates simulation.
• Simulink discards any compiled information about the model.
• The model must compile again the next time you simulate.

**Fast Restart Methodology**

**Tuning Parameters Between Simulations**

• When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the Data Import/Export and Solver panes in the Configuration Parameters dialog box (on the Simulation tab, under Prepare, click Model Settings).
• Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the IC block
  - **Initial Output** parameter of the Merge block
  - **Data** parameter of the From Workspace block
  - **Signal** parameter and signal groups of the Signal Builder block.

**Model Methods and Callbacks in Fast Restart**

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

1. Call model InitFcn callback.
2. Call model SetupRuntimeResources method.
a Call mdlSetupRuntimeResources S-function method.

3 Call model Start method.

a Call mdlStart S-function method.

4 Call model Initialize method.

a Call mdlInitializeConditions S-function method.

**Note** Use the ssIsFirstInitCond flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.

5 Call model and block StartFcn callbacks.

**Note** Steps 1–5 apply to all simulations in Simulink (with or without fast restart).

6 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (ModelOperatingPoint) and information related to logged data and visualization blocks. As part of the snapshot capture, call ModelOperatingPoint S-function method.

7 This is a standard execution phase of any simulation, with or without fast restart.

- Call model Outputs.
- Call model Update.
- Call model Derivatives.
- Repeat these steps in a loop until stop time or a stop is requested.

8 Call model Terminate method.

a Call mdlTerminate S-function method.

9 After simulation ends, call model and block StopFcn callbacks. This is a standard phase of any simulation, with or without fast restart.

10 Restore the simulation snapshot taken for fast restart. As part of the restore, call set S-function method.

11 Wait in a reinitialized state until one of these actions:

- To run another simulation (programmatically or using the Simulink Editor) in fast restart, return to step 3.
To end Fast Restart mode and uncompile the model:

a Call the model method `CleanupRuntimeResources` and the `mdlCleanupRuntimeResources` S-function method.

b Do not call `StopFcn` callbacks again at this point.

In some cases, the `Start` and `Terminate` methods are only called once and not for each successive Fast Restart simulation. In these cases, these method calls are combined with calls to `SetupRuntimeResources` and `CleanupRuntimeResources`, respectively. These cases are as follows:

- When an S-function contains custom `ModelOperatingPoint` save and restore methods.
- When an S-function sets the flag `SS_OPTION_CALL_TERMINATE_ON_EXIT`.
- When an S-function is placed inside the accelerated mode of a referenced model.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-61.

**Operating Point and Initial State Values**

You can change initial state values, including `ModelOperatingPoint`, in between fast restart simulations.

When a `ModelOperatingPoint` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `ModelOperatingPoint` object. Thereafter, on the first step forward, Simulink checks to see if a `ModelOperatingPoint` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `ModelOperatingPoint` object.

**Analyze Data Using the Simulation Data Inspector**

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name `<modelname> fast restart run <number>`. The value of `number` increments for each simulation.

**Custom Code in the Initialize Function**

When you place custom code in the `Configuration Parameters > Simulation Target > Custom Code > Initialize function` pane in the `Model Configuration Parameters` dialog box, this gets called only during the first simulation in fast restart.

Model Component Testing
Component Verification
Component Verification

**In this section...**

| "Workflow for Component Verification" on page 78-2 |
| "Test a Component in Isolation" on page 78-4 |
| "Test a Model Block Included in a Larger Model" on page 78-5 |

You can test a component of your model in isolation, or as part of a larger model. Testing in isolation is useful for debugging the component algorithm and ensuring readiness for component reuse. Testing as part of a larger model considers component behavior in response to particular application inputs and outputs.

This topic is a broad overview of verification activities, including tools in additional products you can use in your verification workflow.

**Workflow for Component Verification**

This graphic illustrates component verification testing in closed- and open-loop configurations.
1 Choose your approach for component verification:

- For closed-loop simulations, verify a component within the context of its container model by logging the signals to that component and storing them in a data file. If those signals do not constitute a complete test suite, generate a harness model and add or modify the test cases in the Signal Builder.

- For open-loop simulations, verify a component independently of the container model by extracting the component from its container model and creating a harness model for the extracted component. Add or modify test cases in the Signal Builder and log the signals to the component in the harness model.

2 Prepare component for verification.

3 Create and log test cases. You can also merge the test case data into a single data file.

The data file contains the test case data for simulating the component. If you cannot achieve the expected results with a certain set of test cases, add new test cases or modify existing test cases in the data file, and merge them into a single data file.
Continue adding or modifying test cases until you achieve a test suite that satisfies the goals of your analysis.

4 Execute the test cases in software-in-the-loop or processor-in-the-loop mode.

5 After you have a complete test suite, you can:

- Simulate the model and execute the test cases to:
  - Record coverage using Simulink Coverage.
  - Record output values to make sure that you get the expected results.
- Invoke the Code Generation Verification (CGV) API to execute the generated code for the model that contains the component in simulation, software-in-the-loop (SIL), or processor-in-the-loop (PIL) mode.

**Note** To execute a model in different modes of execution, you use the CGV API to verify the numerical equivalence of results. For more information about the CGV API, see “Programmatic Code Generation Verification” (Embedded Coder).

**Test a Component in Isolation**

This workflow illustrates common steps to test reusable components such as:

- Model blocks
- Atomic subsystems
- Stateflow atomic subcharts

1 Depending on the type of component, take one of the following actions:

- Model blocks — Open the referenced model.
- Atomic subsystems — Extract the contents of the subsystem into its own Simulink model.
- Atomic subcharts — Extract the contents of the Stateflow atomic subchart into its own Simulink model.

2 Create a harness model for:

- The referenced model
- The extracted model that contains the contents of the atomic subsystem or atomic subchart
Add or modify test cases in the Signal Builder in the harness model.

Log the input signals from the Signal Builder to the test unit.

Repeat steps 3 and 4 until you are satisfied with the test suite.

Merge the test case data into a single file.

Depending on your goals, take one of the following actions:

- Execute the test cases to:
  - Record coverage.
  - Record output values and make sure that they equal the expected values.
  - Invoke the Code Generation Verification (CGV) API to execute the test cases in software-in-the-loop (SIL) or processor-in-the-loop (PIL) mode on the generated code for the model that contains the component.

If the test cases do not achieve the expected results, repeat steps 3 through 5.

**Test a Model Block Included in a Larger Model**

Use system analysis to:

- Verify a Model block in the context of the block's container model.
- Analyze a closed-loop controller.

Log the input signals to the component by simulating the container model or analyze the model using the Simulink Design Verifier software.

If you want to add test cases to your test suite or modify existing test cases, create a harness model with the logged signals.

Add or modify test cases in the Signal Builder in the harness model.

Log the input signals from the Signal Builder to the test unit.

Repeat steps 3 and 4 until you are satisfied with the test suite.

Merge the test case data into a single file.

Depending on your goals, do one of the following:

- Execute the test cases to:
  - Record coverage.
• Record output values and make sure that they equal the expected values.
• Invoke the Code Generation Verification (CGV) API to execute the test cases in software-in-the-loop (SIL) or processor-in-the-loop (PIL) mode on the generated code for the model.

If the test cases do not achieve the expected results, repeat steps 3 through 5.

Simulink Model Verification library blocks assess time-domain signals in your model, according to the specifications that you assign to the blocks. Model verification blocks return an assertion when signals fall outside the specified limit or range. During simulation, when the signal crosses the limit, the verification block can:

- Stop the simulation and bring immediate focus to that part of the model.
- Report the failure with a logical signal. If the simulation does not fail, the signal output is true. If the simulation fails, the signal output is false.

For reference information on individual model verification blocks, see “Model Verification”.

If you use a Signal Builder block to provide test signals for your model, you can enable and disable Model Verification blocks through the Verification Manager graphical interface. To open the Verification Manager, on the Signal Builder dialog box toolbar, select the **Show Verification Settings** icon.

**Use Model Verification Block to Check for Out-of-Bounds Signal**

This example uses a Check Static Lower Bound block to stop the model simulation when a signal from a Sine Wave block crosses its lower bound limit.

In the model, the Check Static Lower Bound block has a **Lower bound** parameter of -0.8. The assertion is disabled, so the block appears crossed out.
1. Double-click the Check Static Lower Bound block and select the **Enable assertion** check box. This parameter enables the assertion of the verification block. In the model, the block is no longer crossed out.

2. Run the simulation. After 1.29517 seconds, when the signal from the Sine Wave block reaches the lower bound of -0.8, the verification block stops the simulation with this diagnostic message:

   An error occurred while running the simulation and the simulation was terminated
   Caused by:
   Assertion detected in 'ex_model_verif_block_check_static_lower_errwarn/Check Static

3. To verify the signal value, double-click the Scope block.
View Model Verification Blocks in Verification Manager

This model contains a Signal Builder block that feeds five test signals to Model Verification blocks. The first four signals connect directly to Check Static Upper Bound blocks.
The fifth signal connects to a subsystem that contains a Check Static Upper Bound block.

Only the assertion for the Check Static Upper Bound3 block is enabled. The other Model Verification blocks appear crossed out in the model because their assertions are disabled.

To open the Verification Manager, double-click the Signal Builder block and select the Show Verification Settings icon.
Manage Verification Blocks and Requirement Links

The Verification Manager consists of the Verification block settings pane and the Requirements pane.

The Verification block settings pane lists all Model Verification blocks in the model, grouped by subsystem. For example, in the ex_verif_mgr_test_signals model, the
**Verification block settings** pane displays five Check Static Upper Bound blocks. Four are in the top level of the model, and one is in a subsystem.

- To display all of the Model Verification blocks, click the **Show verification block hierarchy** icon.
- To display only the blocks that are enabled for the current signal group, click the **List enabled verifications** icon.

You can select additional options for viewing Model Verification blocks by right-clicking in the **Verification block settings** pane:

- **Display > Tree format** — List the blocks as they appear in the model hierarchy.
- **Display > Overridden blocks only** — List only the blocks that are not enabled for all test groups.
- **Display > Active blocks only** — List only the blocks that are enabled for the current signal group.

The **Requirements** pane lists the requirements document links for the current signal group. If you have Simulink Requirements, you can link requirements documents to test cases and their corresponding Model Verification blocks through this pane.

- To open or close the **Requirements** pane, click the **Requirements display** icon.
- To link a requirements document to a test case, in the **Requirements** pane, right-click and select **Open Outgoing Links Dialog** from the context menu. In the Outgoing Links dialog box, you can browse and select a requirements document. For more information, see “Link Test Cases to Requirements Documents” (Simulink Requirements).

**Enable and Disable Individual Model Verification Blocks**

In the Verification Manager, each verification block has a status node that indicates whether its assertion is enabled or disabled. The status node also indicates whether the enabled setting applies universally or only to the current active group. This table describes the different types of status nodes and the context menu options that are available when you right-click a node.
When you use the Verification Manager to enable a model verification block for the current active group, in the model, the block displays an **Override** label. For example, in the `ex_verif_mgr_test_signals` model, when you select **Group 2** from the **Active Group** list, the Verification Manager shows that the Check Static Upper Bound1 block is enabled.

In the model, the Check Static Upper Bound1 block is not crossed out, but displays an **Override** label.
Enable and Disable Model Verification Blocks by Subsystem

If your model contains many verification blocks, it is tedious to enable and disable blocks individually. Using the Verification Manager, you can enable and disable all blocks in a subsystem. In the Verification block settings pane, right-click the subsystem node and select from these context menu options:

- **Contents enable for all groups** — Enable all verification blocks in this subsystem for all test groups.
- **Contents enable by group** — Restore the individually enabled/disabled settings to each verification block in this subsystem for all test groups.
• **Contents group enable** — Individually enable all verification blocks in this subsystem for the current active group.

• **Contents group disable** — Individually disable all verification blocks in this subsystem for the current active group.

For example, in the `ex_verif_mgr_test_signals` model, you can enable all of the verification blocks for all test groups by double-clicking the `ex_verif_mgr_test_signals` node and selecting **Contents enable for all groups**. In the Verification Manager, all nodes change to enabled for all groups.

To restore the individually enabled/disabled settings for each verification block in each group, double-click the `ex_verif_mgr_test_signals` node and select **Contents enable by group**.

**Linear System Modeling Blocks in Simulink Control Design**

If you have Simulink Control Design, you can:

• Monitor time-domain and frequency-domain characteristics.
• Specify bounds on linear system characteristics.
• Check that the bounds are satisfied during simulation.

For reference information on individual blocks, see “Model Verification” (Simulink Control Design).
