- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMModel` and by conducting 10-fold cross-validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2073.
- If the classes are perfectly separable, then the transformation function is the step function on page 32-2073.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2195. The `fitPosterior` function is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:
• Displays a warning
• Resets the original transformation function to 'none' before estimating the new one

**Alternative Functionality**

You can also fit the optimal score-to-posterior-probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

fitrensemble

Fit ensemble of learners for regression

Syntax

Mdl = fitrensemble(Tbl,ResponseVarName)
Mdl = fitrensemble(Tbl,formula)
Mdl = fitrensemble(Tbl,Y)
Mdl = fitrensemble(X,Y)
Mdl = fitrensemble(____,Name,Value)

Description

Mdl = fitrensemble(Tbl,ResponseVarName) returns the trained regression ensemble model object (Mdl) that contains the results of boosting 100 regression trees using LSBoost and the predictor and response data in the table Tbl. ResponseVarName is the name of the response variable in Tbl.

Mdl = fitrensemble(Tbl,formula) applies formula to fit the model to the predictor and response data in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl. For example, ‘Y~X1+X2+X3’ fits the response variable Tbl.Y as a function of the predictor variables Tbl.X1, Tbl.X2, and Tbl.X3.

Mdl = fitrensemble(Tbl,Y) treats all variables in the table Tbl as predictor variables. Y is the vector of responses that is not in Tbl.

Mdl = fitrensemble(X,Y) uses the predictor data in the matrix X and response data in the vector Y.

Mdl = fitrensemble(____,Name,Value) uses additional options specified by one or more Name,Value pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Regression Ensemble

Create a regression ensemble that predicts the fuel economy of a car given the number of cylinders, volume displaced by the cylinders, horsepower, and weight. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the carsmall data set. Store the variables to be used in training in a table.

load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);

Train a regression ensemble.
Mdl1 = fitrensemble(Tbl,'MPG');

Mdl1 is a RegressionEnsemble model. Some notable characteristics of Mdl1 are:

- The ensemble aggregation algorithm is 'LSBoost'.
- Because the ensemble aggregation method is a boosting algorithm, regression trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Because MPG is a variable in the MATLAB® Workspace, you can obtain the same result by entering

Mdl1 = fitrensemble(Tbl,MPG);

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

pMPG = predict(Mdl1,[4 200 150 3000])
pMPG = 25.6467

Train a new ensemble using all predictors in Tbl except Displacement.

formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitrensemble(Tbl,formula);

Compare the resubstitution MSEs between Mdl1 and Mdl2.

mse1 = resubLoss(Mdl1)
mse1 = 0.3096

mse2 = resubLoss(Mdl2)
mse2 = 0.5861

The in-sample MSE for the ensemble that trains on all predictors is lower.

### Speed Up Training by Binning Numeric Predictor Values

Train an ensemble of boosted regression trees by using fitrensemble. Reduce training time by specifying the 'NumBins' name-value pair argument to bin numeric predictors. After training, you can reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

Generate a sample data set.

rng('default') % For reproducibility
N = 1e6;
X1 = randi([-1,5],[N,1]);
X2 = randi([5,10],[N,1]);
X3 = randi([0,5],[N,1]);
X4 = randi([1,10],[N,1]);
X = [X1 X2 X3 X4];
y = X1 + X2 + X3 + X4 + normrnd(0,1,[N,1]);
Train an ensemble of boosted regression trees using least-squares boosting (LSBoost, the default value). Time the function for comparison purposes.

tic
Mdl1 = fitrensemble(X,y);
toc

Elapsed time is 78.662954 seconds.

Speed up training by using the 'NumBins' name-value pair argument. If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

tic
Mdl2 = fitrensemble(X,y,'NumBins',50);
toc

Elapsed time is 43.353208 seconds.

The process is about two times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the regression errors by resubstitution.

rsLoss = resubLoss(Mdl1)
rsLoss = 1.0134

rsLoss2 = resubLoss(Mdl2)
rsLoss2 = 1.0133

In this example, binning predictor values reduces training time without a significant loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

X = Mdl2.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of an ensemble of boosted regression trees.

Load the carsmall data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

load carsmall
X = [Cylinders Displacement Horsepower Weight];

Cross-validate an ensemble of regression trees using 10-fold cross-validation. Using a decision tree template, specify that each tree should be a split once only.

rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitrensemble(X,MPG,'Learners',t,'CrossVal','on');

Mdl is a RegressionPartitionedEnsemble model.

Plot the cumulative, 10-fold cross-validated, mean-squared error (MSE). Display the estimated generalization error of the ensemble.

kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold cross-validated MSE');
oxlabel('Learning cycle');
estGenError = kflc(end)
estGenError = 25.6818

kfoldLoss returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves an MSE of around 23.5 after accumulating about 30 weak learners.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters such as the maximum number of decision splits per tree and the number of learning cycles.

**Optimize Regression Ensemble**

This example shows how to optimize hyperparameters automatically using fitrensemble. The example uses the carsmall data.

Load the data.

load carsmall
You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

\[
\text{Mdl} = \text{fitrensemble}([\text{Horsepower,Weight}], \text{MPG}, \text{''OptimizeHyperparameters''}, \text{''auto''})
\]

In this example, for reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function. Also, for reproducibility of random forest algorithm, specify the 'Reproducible' name-value pair argument as true for tree learners.

\[
\text{rng('default')}
\]
\[
\text{t} = \text{templateTree('Reproducible',true)};
\]
\[
\text{Mdl} = \text{fitrensemble}([\text{Horsepower,Weight}], \text{MPG}, \text{''OptimizeHyperparameters''}, \text{''auto''}, \text{''Learners'', t, ... 'HyperparameterOptimizationOptions', struct(' AcquisitionFunctionName', 'expected-improvement-plus')})
\]

        UseObsForLearner: [94×491 logical]
```

Properties, Methods

The optimization searched over the methods for regression (Bag and LSBoost), over NumLearningCycles, over the LearnRate for LSBoost, and over the tree learner MinLeafSize. The output is the ensemble regression with the minimum estimated cross-validation loss.

**Optimize Regression Ensemble Using Cross-Validation**

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the 'KFold' name-value pair argument) and the kfoldLoss function. Alternatively, you can use the 'OptimizeHyperparameters' name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 32-2080.
Load the carsmall data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```matlab
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

The default values of the tree depth controllers for boosting regression trees are:

- 10 for MaxNumSplits.
- 5 for MinLeafSize
- 10 for MinParentSize

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most \( n - 1 \) splits. \( n \) is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.

2. Estimate the cross-validated mean-squared error (MSE) for each ensemble.

3. For tree-complexity level \( j \), \( j = 1 \ldots J \), compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.

4. Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```matlab
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off', ... 'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on', ... 'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence \( \{2^0, 2^1, \ldots, 2^m\} \). \( m \) is such that \( 2^m \) is no greater than \( n - 1 \).
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set \( \{0.1, 0.25, 0.5, 1\} \).

```matlab
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
umLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
umMNS = numel(maxNumSplits);
umTrees = 150;
Mdl = cell(numMNS,numLR);
for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
```
Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees, ...
   'Learners',t,'KFold',5,'LearnRate',learnRate(k));
end

Estimate the cumulative, cross-validated MSE of each ensemble.

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the
curves with respect to learning rate on the same plot, and plot separate plots for varying tree-
complexity levels. Choose a subset of tree complexity levels to plot.

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'.b','LineWidth',2)
    plot(h.XLim,[errorStump errorStump],'.r','LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'.--k')
    h.YLim = [10 50];
    xlabel('Number of trees')
    ylabel('Cross-validated MSE')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate','Learning Rate = %0.2f')); ...
   'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;
Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```matlab
[minErr, minErrIdxLin] = min(error(:));
[idxNumTrees, idxMNS, idxLR] = ind2sub(size(error), minErrIdxLin);
fprintf('
Min. MSE = %0.5f', minErr)
Min. MSE = 17.00516
fprintf('
Optimal Parameter Values:
Num. Trees = %d', idxNumTrees);
Optimal Parameter Values:
Num. Trees = 38
fprintf('
MaxNumSplits = %d
Learning Rate = %0.2f
', maxNumSplits(idxMNS), learnRate(idxLR))
MaxNumSplits = 4
Learning Rate = 0.10
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```matlab
tFinal = templateTree('MaxNumSplits', maxNumSplits(idxMNS), 'Surrogate', 'on');
MdlFinal = fitrensemble(Tbl, 'MPG', 'NumLearningCycles', idxNumTrees, ...
    'Learners', tFinal, 'LearnRate', learnRate(idxLR))
```
MdlFinal =
  classreg.learning.regr.RegressionEnsemble
    PredictorNames: {'Cylinders'  'Displacement'  'Horsepower'  'Weight'}
    ResponseName: 'MPG'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 38
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training cycles.'
    FitInfo: [38×1 double]
    FitInfoDescription: {2×1 cell}
    Regularization: []

Properties, Methods

MdlFinal is a RegressionEnsemble. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and MdlFinal to predict.

Instead of searching optimal values manually by using the cross-validation option ('KFold') and the kfoldLoss function, you can use the 'OptimizeHyperparameters' name-value pair argument. When you specify 'OptimizeHyperparameters', the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using 'OptimizeHyperparameters' can be different from those obtained using manual search.

t = templateTree('Surrogate','on');
mdl = fitrensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{'NumLearningCycles','LearnRate','MaxNumSplits'})

Properties, Methods

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using ResponseVarName.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using formula.
- If Tbl does not contain the response variable, then specify the response data using Y. The length of response variable and the number of rows of Tbl must be equal.

**Note** To save memory and execution time, supply X and Y instead of Tbl.

Data Types: table

ResponseVarName — Response variable name

name of response variable in Tbl

Response variable name, specified as the name of the response variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if Tbl.Y is the response variable, then specify ResponseVarName as 'Y'. Otherwise, fitrensemble treats all columns of Tbl as predictor variables.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables

character vector | string scalar
Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

Data Types: char | string

**X — Predictor data**
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

**Y — Response**
numeric vector

Response, specified as a numeric vector. Each element in Y is the response to the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.
Example:
'NumLearningCycles',500,'Method','Bag','Learners',templateTree(),'CrossVal','on' cross-validates an ensemble of 500 bagged regression trees using 10-fold cross-validation.

**General Ensemble Options**

**Method — Ensemble aggregation method**

<table>
<thead>
<tr>
<th>Value</th>
<th>Method</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LSBoost'</td>
<td>Least-squares boosting (LSBoost)</td>
<td>You can specify the learning rate for shrinkage by using the 'LearnRate' name-value pair argument.</td>
</tr>
<tr>
<td>'Bag'</td>
<td>Bootstrap aggregation (bagging, for example, random forest[2])</td>
<td>fitrensemble uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose 'NumVariablesToSample' value is 'all'.</td>
</tr>
</tbody>
</table>

For details about ensemble aggregation algorithms and examples, see “Algorithms” on page 32-2103, “Ensemble Algorithms” on page 18-38, and “Choose an Applicable Ensemble Aggregation Method” on page 18-31.

Example: 'Method','Bag'

**NumLearningCycles — Number of ensemble learning cycles**

100 (default) | positive integer

Number of ensemble learning cycles, specified as the comma-separated pair consisting of 'NumLearningCycles' and a positive integer. At every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles*numel(Learners) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-2103.

Example: 'NumLearningCycles',500

Data Types: single | double

**Learners — Weak learners to use in ensemble**

'tree' (default) | tree template object | cell vector of tree template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of 'Learners' and 'tree', a tree template object, or a cell vector of tree template objects.
• 'tree' (default) — fitrensemble uses default regression tree learners, which is the same as using templateTree(). The default values of templateTree() depend on the value of 'Method'.

• For bagged decision trees, the maximum number of decision splits ('MaxNumSplits') is \( n - 1 \), where \( n \) is the number of observations. The number of predictors to select at random for each split ('NumVariablesToSample') is one third of the number of predictors. Therefore, fitrensemble grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.

• For boosted decision trees, 'MaxNumSplits' is 10 and 'NumVariablesToSample' is 'all'. Therefore, fitrensemble grows shallow decision trees. You can grow deeper trees for better accuracy.

See templateTree for the default settings of a weak learner.

• Tree template object — fitrensemble uses the tree template object created by templateTree. Use the name-value pair arguments of templateTree to specify settings of the tree learners.

• Cell vector of \( m \) tree template objects — fitrensemble grows \( m \) regression trees per learning cycle (see NumLearningCycles). For example, for an ensemble composed of two types of regression trees, supply \{t1 t2\}, where t1 and t2 are regression tree template objects returned by templateTree.

For details on the number of learners to train, see NumLearningCycles and “Tips” on page 32-2103.

Example: 'Learners',templateTree('MaxNumSplits',5)

**NPrint — Printout frequency**

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of weak learners or folds that fitrensemble trained so far, specify a positive integer. That is, if you specify the positive integer \( m \):

• Without also specifying any cross-validation option (for example, CrossVal), then fitrensemble displays a message to the command line every time it completes training \( m \) weak learners.

• And a cross-validation option, then fitrensemble displays a message to the command line every time it finishes training \( m \) folds.

If you specify 'off', then fitrensemble does not display a message when it completes training weak learners.

**Tip** When training an ensemble of many weak learners on a large data set, specify a positive integer for NPrint.

Example: 'NPrint',5

Data Types: single | double | char | string

**NumBins — Number of bins for numeric predictors**

[](empty) (default) | positive integer scalar
Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then fitrensemble bins the predictor into u bins.
  - fitrensemble does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the BinEdges property.

Example: 'NumBins',50

Data Types: single | double

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of</td>
</tr>
<tr>
<td></td>
<td>the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or</td>
</tr>
<tr>
<td></td>
<td>Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must</td>
</tr>
<tr>
<td></td>
<td>match the entries in PredictorNames. Pad the names with extra blanks so</td>
</tr>
<tr>
<td></td>
<td>each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell</td>
<td>Each element in the array is the name of a predictor variable. The names</td>
</tr>
<tr>
<td>array of character vectors</td>
<td>must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitrensemble assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fitrensemble assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors
Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitrensemble uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{ 'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}
Data Types: string | cell

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

**ResponseTransform — Response transformation**

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform',myfunction.
Data Types: char | string | function_handle
Cross-Validation Options

CrossVal — Cross-validation flag
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval or crossval.

Example: 'Crossval','on'

CVPartition — Cross-validation partition
[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

Holdout — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

KFold — Number of folds
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:
Randomly partition the data into \( k \) sets.

For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.

Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`  

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `Leaveout` and `'on'` or `'off'`. If you specify `Leaveout`, `'on'`, then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.
2. Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

**Other Regression Options**

**Weights — Observation weights**

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `Weights` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of \( X \) or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of \( X \) or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector \( W \) is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n,1)`, where \( n \) is the number of observations in \( X \) or `Tbl`.

Data Types: `double` | `single` | `char` | `string`
Sampling Options

FResample — Fraction of training set to resample
1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.
Example: 'FResample',0.75
Data Types: single | double

Replace — Flag indicating to sample with replacement
'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.
Example: 'Replace','off'

Resample — Flag indicating to resample
'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off'(default) specifies to reweight observations at every learning iteration.
  - If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

LSBoost Method Options

LearnRate — Learning rate for shrinkage
1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].
To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: single | double

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Method','NumLearningCycles','LearnRate'} along with the default parameters for the specified Learners:
  - Learners = 'tree' (default) — {'MinLeafSize'}

**Note** For hyperparameter optimization, Learners must be a single argument, not a string array or cell array.

- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter name names.
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitrensemble by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrensemble are:

- **Method** — Eligible methods are 'Bag' or 'LSBoost'.
- **NumLearningCycles** — fitrensemble searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — fitrensemble searches among positive reals, by default log-scaled with range [1e-3,1].
- **MinLeafSize** — fitrensemble searches among integers log-scaled in the range [1,max(2,floor(NumObservations/2))].
- **MaxNumSplits** — fitrensemble searches among integers log-scaled in the range [1,max(2,NumObservations-1)].
- **NumVariablesToSample** — fitrensemble searches among integers in the range [1,max(2,NumPredictors)].
Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load carsmall
params = hyperparameters('fitrensemble',[Horsepower,Weight],MPG,'Tree');
params(4).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Regression Ensemble” on page 32-2080.

Example: `'OptimizeHyperparameters',
{"Method","NumLearningCycles","LearnRate","MinLeafSize","MaxNumSplits"}`

**HyperparameterOptimizationOptions — Options for optimization**

Structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optimizer</td>
<td>• <code>'bayesopt'</code> — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • <code>'gridsearch'</code> — Use grid search with <code>NumGridDivisions</code> values per dimension. • <code>'randomsearch'</code> — Search at random among <code>MaxObjectiveEvaluations</code> points. <code>'gridsearch'</code> searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</td>
<td><code>'bayesopt'</code></td>
</tr>
<tr>
<td>Field Name</td>
<td>Values</td>
<td>Default</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>----------------------------------------------</td>
</tr>
</tbody>
</table>
| AcquisitionFunctionName | • 'expected-improvement-per-second-plus'  
• 'expected-improvement'  
• 'expected-improvement-plus'  
• 'expected-improvement-per-second'  
• 'lower-confidence-bound'  
• 'probability-of-improvement' | 'expected-improvement-per-second-plus'        |
|                         | Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see "Acquisition Function Types" on page 10-3. |                                              |
| MaxObjectiveEvaluations | Maximum number of objective function evaluations.                        | 30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch' |
| MaxTime                 | Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations. | Inf                                          |
| NumGridDivisions        | For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables. | 10                                           |
| ShowPlots               | Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters. | true                                         |
| SaveIntermediateResults | Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object. | false                                        |
Field Name | Values | Default
--- | --- | ---
Verbose | Display to the command line.  
• 0 — No iterative display  
• 1 — Iterative display  
• 2 — Iterative display with extra information  
For details, see the `bayesopt Verbose` name-value pair argument. | 1

UseParallel | Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7. | false

Repartition | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization.  
true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false

Use no more than one of the following three field names.

CVPartition | A `cvpartition` object, as created by `cvpartition`. | 'Kfold',5 if you do not specify any cross-validation field

Holdout | A scalar in the range (0,1) representing the holdout fraction. | |

Kfold | An integer greater than 1. | |

Example:  
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

### Output Arguments

**Md1 — Trained regression ensemble model**  
`RegressionBaggedEnsemble` model object | `RegressionEnsemble` model object | `RegressionPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

<table>
<thead>
<tr>
<th>Model Object</th>
<th>Specify Any Cross-Validation Options?</th>
<th>Method Setting</th>
<th>Resample Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegressionBaggedEnsemble</td>
<td>No</td>
<td>'Bag'</td>
<td>'on'</td>
</tr>
</tbody>
</table>
The name-value pair arguments that control cross-validation are CrossVal, Holdout, KFold, Leaveout, and CVPartition.

To reference properties of Mdl, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter Mdl.Trained at the command line.

**Tips**

- **NumLearningCycles** can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume`.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-38.

- If you specify `'Method','LSBoost'`, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.

**References**

Extended Capabilities

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `HyperparameterOptions`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2016b**
fitrsvm

Fit a support vector machine regression model

Syntax

Mdl = fitrsvm(Tbl,ResponseVarName)
Mdl = fitrsvm(Tbl,formula)
Mdl = fitrsvm(Tbl,Y)
Mdl = fitrsvm(X,Y)
Mdl = fitrsvm(____,Name,Value)

Description

fitrsvm trains or cross-validates a support vector machine (SVM) regression model on a low-through moderate-dimensional predictor data set. fitrsvm supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or L1 soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM regression model on a high-dimensional data set, that is, data sets that include many predictor variables, use fitrlinear instead.

To train an SVM model for binary classification, see fitcsvm for low-through moderate-dimensional predictor data sets, or fitclinear for high-dimensional data sets.

Mdl = fitrsvm(Tbl,ResponseVarName) returns a full, trained support vector machine (SVM) regression model Mdl trained using the predictors values in the table Tbl and the response values in Tbl.ResponseVarName.

Mdl = fitrsvm(Tbl,formula) returns a full SVM regression model trained using the predictors values in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl.

Mdl = fitrsvm(Tbl,Y) returns a full, trained SVM regression model trained using the predictors values in the table Tbl and the response values in the vector Y.

Mdl = fitrsvm(X,Y) returns a full, trained SVM regression model trained using the predictors values in the matrix X and the response values in the vector Y.

Mdl = fitrsvm(____,Name,Value) returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

Examples

Train Linear Support Vector Machine Regression Model

Train a support vector machine (SVM) regression model using sample data stored in matrices.
Load the `carsmall` data set.

```matlab
load carsmall
rng 'default'  % For reproducibility
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```matlab
X = [Horsepower,Weight];
Y = MPG;
```

Train a default SVM regression model.

```matlab
Md1 = fitrsvm(X,Y)
```

```matlab
Md1 = RegressionSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Alpha: [76x1 double]
    Bias: 43.1920
    KernelParameters: [1x1 struct]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [93x1 logical]
    Solver: 'SMO'
```

Properties, Methods

Md1 is a trained `RegressionSVM` model.

Check the model for convergence.

```matlab
Md1.ConvergenceInfo.Converged
```

```matlab
ans = logical
0
```

0 indicates that the model did not converge.

Retrain the model using standardized data.

```matlab
Md1Std = fitrsvm(X,Y,'Standardize',true)
```

```matlab
Md1Std = RegressionSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Alpha: [77x1 double]
    Bias: 22.9131
    KernelParameters: [1x1 struct]
    Mu: [109.3441 2.9625e+03]
    Sigma: [45.3545 805.9668]
    NumObservations: 93
```
Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name `abalone.csv`.

```matlab
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```matlab
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...
              'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `Sex`, which is a categorical variable with possible values ‘M’ (for males), ‘F’ (for females), and ‘I’ (for infants). The goal is to predict the number of rings (stored in `Rings`) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```matlab
rng default  % For reproducibility
Mdl = fitrsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...
              'Standardize',true)
```

Mdl =
RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Rings'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    NumObservations: 4177
    BoxConstraints: [4177x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [4177x1 logical]
    Solver: 'SMO'

The Command Window shows that Mdl is a trained RegressionSVM model and displays a property list.

Display the properties of Mdl using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

    conv = Mdl.ConvergenceInfo.Converged
    iter = Mdl.NumIterations

    conv =
        logical
        1

    iter =
        2759

The returned results indicate that the model converged after 2759 iterations.

Cross-Validate SVM Regression Model

Load the carsmall data set.

    load carsmall
    rng 'default'  % For reproducibility

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

    X = [Horsepower Weight];
    Y = MPG;
Cross-validate two SVM regression models using 5-fold cross-validation. For both models, specify to standardize the predictors. For one of the models, specify to train using the default linear kernel, and the Gaussian kernel for the other model.

```matlab
MdlLin = fitrsvm(X,Y,'Standardize',true,'KFold',5)
```

```matlab
MdlLin = 
    classreg.learning.partition.RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    NumObservations: 94
    KFold: 5
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'

Properties, Methods
```

```matlab
MdlGau = fitrsvm(X,Y,'Standardize',true,'KFold',5,'KernelFunction','gaussian')
```

```matlab
MdlGau = 
    classreg.learning.partition.RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    NumObservations: 94
    KFold: 5
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'

Properties, Methods
```

```matlab
MdlLin.Trained
ans=5x1 cell array
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
```

`MdlLin` and `MdlGau` are `RegressionPartitionedSVM` cross-validated models. The `Trained` property of each model is a 5-by-1 cell array of `CompactRegressionSVM` models. The models in the cell store the results of training on 4 folds of observations, and leaving one fold of observations out.

Compare the generalization error of the models. In this case, the generalization error is the out-of-sample mean-squared error.

```matlab
mseLin = kfoldLoss(MdlLin)
```

```matlab
mseLin = 17.4417
```

```matlab
mseGau = kfoldLoss(MdlGau)
```

```matlab
mseGau = 32.2109
```
mseGau = 16.7333

The SVM regression model using the Gaussian kernel performs better than the one using the linear kernel.

Create a model suitable for making predictions by passing the entire data set to fitrsvm, and specify all name-value pair arguments that yielded the better-performing model. However, do not specify any cross-validation options.

MdlGau = fitrsvm(X,Y,'Standardize',true,'KernelFunction','gaussian');

To predict the MPG of a set of cars, pass Mdl and a table containing the horsepower and weight measurements of the cars to predict.

Optimize SVM Regression

This example shows how to optimize hyperparameters automatically using fitrsvm. The example uses the carsmall data.

Load the carsmall data set.

load carsmall

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

X = [Horsepower Weight];
Y = MPG;

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

rng default
Mdl = fitrsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))

</table>
Optimization completed.
MaxObjectiveEvaluations of 30 reached.
Total function evaluations: 30
Total elapsed time: 67.1005 seconds.
Total objective function evaluation time: 38.0678

Best observed feasible point:
BoxConstraint  KernelScale  Epsilon
997.3          317.41       3.7696

Observed objective function value = 2.8666
Estimated objective function value = 2.8683
Function evaluation time = 0.50424

Best estimated feasible point (according to models):
BoxConstraint  KernelScale  Epsilon
997.3          317.41       3.7696

Estimated objective function value = 2.8683
Estimated function evaluation time = 0.44423

Mdl =
RegressionSVM
Properties, Methods

The optimization searched over `BoxConstraint`, `KernelScale`, and `Epsilon`. The output is the regression with the minimum estimated cross-validation loss.

**Input Arguments**

**Tbl** — Predictor data

`table`  
Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

If a row of `Tbl` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in `Tbl`, use the `PredictorNames` name-value pair argument.

Data Types: `table`

**ResponseVarName** — Response variable name

`name of variable in Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.
You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers.

You can verify the variable names in `Tbl` by using the `isvarname` function. The following code returns logical `1` (`true`) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in `Tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

Data Types: `char` | `string`

`Y` — Response data
numeric vector

Response data, specified as an `n`-by-1 numeric vector. The length of `Y` and the number of rows of `Tbl` or `X` must be equal.

If a row of `Tbl` or `X`, or an element of `Y`, contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

`X` — Predictor data
numeric matrix

Predictor data to which the SVM regression model is fit, specified as an `n`-by-`p` numeric matrix. `n` is the number of observations and `p` is the number of predictor variables.

The length of `Y` and the number of rows of `X` must be equal.

If a row of `X` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments.
To specify the names of the predictors in the order of their appearance in \( X \), use the \texttt{PredictorNames} name-value pair argument.

Data Types: \texttt{single} | \texttt{double}

### Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

**Note** You cannot use any cross-validation name-value pair argument along with the \texttt{'OptimizeHyperparameters'} name-value pair argument. You can modify the cross-validation for \texttt{'OptimizeHyperparameters'} only by using the \texttt{'HyperparameterOptimizationOptions'} name-value pair argument.

Example: \texttt{'KernelFunction','gaussian','Standardize',true,'CrossVal','on'} trains a 10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

### Support Vector Machine Options

#### BoxConstraint — Box constraint

Positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of \texttt{'BoxConstraint'} and a positive scalar value.

The absolute value of the \texttt{Alpha} coefficients cannot exceed the value of \texttt{BoxConstraint}.

The default \texttt{BoxConstraint} value for the \texttt{'gaussian'} or \texttt{'rbf'} kernel function is \( \text{iqr}(Y)/1.349 \), where \( \text{iqr}(Y) \) is the interquartile range of response variable \( Y \). For all other kernels, the default \texttt{BoxConstraint} value is \( 1 \).

Example: \texttt{BoxConstraint,10}

Data Types: \texttt{single} | \texttt{double}

#### KernelFunction — Kernel function

\texttt{'linear'} (default) | \texttt{'gaussian'} | \texttt{'rbf'} | \texttt{'polynomial'} | function name

Kernel function used to compute the Gram matrix on page 32-1689, specified as the comma-separated pair consisting of \texttt{'KernelFunction'} and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{'gaussian'} or \texttt{'rbf'}</td>
<td>Gaussian or Radial Basis Function (RBF) kernel</td>
<td>( G(x_j, x_k) = \exp(-|x_j - x_k|^2) )</td>
</tr>
<tr>
<td>\texttt{'linear'}</td>
<td>Linear kernel</td>
<td>( G(x_j, x_k) = x_j'x_k )</td>
</tr>
<tr>
<td>\texttt{'polynomial'}</td>
<td>Polynomial kernel. Use \texttt{'PolynomialOrder',p} to specify a polynomial kernel of order ( p ).</td>
<td>( G(x_j, x_k) = (1 + x_j'x_k)^q )</td>
</tr>
</tbody>
</table>
You can set your own kernel function, for example, `kernel`, by setting `KernelFunction`, `'kernel'`. `kernel` must have the following form:

```matlab
function G = kernel(U,V)
```

where:

- `U` is an `m`-by-`p` matrix.
- `V` is an `n`-by-`p` matrix.
- `G` is an `m`-by-`n` Gram matrix of the rows of `U` and `V`.

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction','gaussian'`

Data Types: `char` | `string`

**KernelScale — Kernel scale parameter**

1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `KernelScale` and `'auto'` or a positive scalar. The software divides all elements of the predictor matrix `X` by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, `'KernelFunction','kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char` | `string`

**PolynomialOrder — Polynomial kernel function order**

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `PolynomialOrder` and a positive integer.

If you set `PolynomialOrder` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double` | `single`

**KernelOffset — Kernel offset parameter**

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of `KernelOffset` and a nonnegative scalar.
The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver','SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver','ISDA')

Example: `KernelOffset',0
Data Types: double | single

**Epsilon — Half the width of epsilon-insensitive band**

`iqr(Y)/13.49` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value.

The default Epsilon value is `iqr(Y)/13.49`, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y. If `iqr(Y)` is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon',0.3
Data Types: single | double

**Standardize — Flag to standardize predictor data**

`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see "Algorithms" on page 32-1693). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the model using the standardized predictor matrix, but stores the unstandardized data in the model property X.

Example: 'Standardize',true
Data Types: logical

**Solver — Optimization routine**

'SFDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ISDA'</td>
<td>Iterative Single Data Algorithm (see [30])</td>
</tr>
</tbody>
</table>
Value | Description
---|---
'\text{L1QP}' | Uses \text{quadprog} to implement L1 soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
'SMO' | Sequential Minimal Optimization (see [17])

The defaults are:
- 'ISDA' if you set 'OutlierFraction' to a positive value
- 'SMO' otherwise

Example: 'Solver','ISDA'

**Alpha** — Initial estimates of alpha coefficients

numeric vector

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector. The length of Alpha must be equal to the number of rows of \(X\).

- Each element of Alpha corresponds to an observation in \(X\).
- Alpha cannot contain any NaNs.
- If you specify Alpha and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If \(Y\) contains any missing values, then remove all rows of \(Y\), \(X\), and Alpha that correspond to the missing values. That is, enter:

```matlab
idx = ~isnan(Y);
Y = Y(idx);
X = X(idx,:);
alpha = alpha(idx);
```

Then, pass \(Y\), \(X\), and Alpha as the response, predictors, and initial alpha estimates, respectively.

The default is \(\text{zeros(size}(Y,1))\).

Example: 'Alpha',0.1*ones(size(X,1),1)

Data Types: single | double

**CacheSize** — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire \(n\)-by-\(n\) Gram matrix on page 32-1689.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of memory for training the model.
Example: 'CacheSize','maximal'
Data Types: double | single | char | string

ClipAlphas — Flag to clip alpha coefficients
true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation $j$ is $\alpha_j$ and the box constraint of observation $j$ is $C_j$, $j = 1,...,n$, where $n$ is the training sample size.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>At each iteration, if $\alpha_j$ is near 0 or near $C_j$, then MATLAB sets $\alpha_j$ to 0 or to $C_j$, respectively.</td>
</tr>
<tr>
<td>false</td>
<td>MATLAB does not change the alpha coefficients during optimization.</td>
</tr>
</tbody>
</table>

MATLAB stores the final values of $\alpha$ in the Alpha property of the trained SVM model object.

ClipAlphas can affect SMO and ISDA convergence.

Example: 'ClipAlphas',false
Data Types: logical

NumPrint — Number of iterations between optimization diagnostic message output
1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint',500
Data Types: NumPrint', double | single

OutlierFraction — Expected proportion of outliers in training data
0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1). fitrsvm removes observations with large gradients, ensuring that fitrsvm removes the fraction of observations specified by OutlierFraction by the time convergence is reached. This name-value pair is only valid when 'Solver' is 'ISDA'.

Example: 'OutlierFraction',0.1
Data Types: single | double

RemoveDuplicates — Flag to replace duplicate observations with single observations
false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.
If `RemoveDuplicates` is true, then `fitrsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

**Tip** If your data set contains many duplicate observations, then specifying `'RemoveDuplicates',true` can decrease convergence time considerably.

**Data Types:** logical

**Verbose — Verbosity level**

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display or save convergence information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument <code>'NumPrint'</code>.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays diagnostic messages and saves convergence criteria at every iteration.</td>
</tr>
</tbody>
</table>

Example: `'Verbose',1`

**Data Types:** double | single

**Other Regression Options**

**CategoricalPredictors — Categorical predictors list**

`vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code>. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
String array or cell array of character vectors | Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
'all' | All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrsvm` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrsvm` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `CategoricalPredictors` name-value pair argument.

For the identified categorical predictors, `fitrsvm` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrsvm` uses only the predictor variables in `PredictorNames` and the response variable in training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula` only.

Example: `'PredictorNames',
{ 'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.
• If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
• If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

**ResponseTransform — Response transformation**

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform',myfunction.

Data Types: char | string | function_handle

**Weights — Observation weights**

ones(size(X,1),1) (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of numeric values. The size of Weights must equal the number of rows in X. fitrsvm normalizes the values of Weights to sum to 1.

Data Types: single | double

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, you can cross-validate the model later using the crossval method.

Example: 'CrossVal','on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using 
\[
\text{cvp} = \text{cvpartition}(500, \text{'KFold'}, 5)
\]
Then, you can specify the cross-validated model by using 
\[
\text{'CVPartition'}, \text{cvp}
\]

**Holdout — Fraction of data for holdout validation**

Scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 
\text{'Holdout'} and a scalar value in the range (0,1). If you specify 
\text{'Holdout'}, \text{p}, then the software completes these steps:

1. Randomly select and reserve \text{p} \times 100\% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 
\text{CVPartition, Holdout, KFold, or Leaveout}.

Example: 
\text{'Holdout', 0.1}

Data Types: double | single

**KFold — Number of folds**

10 (default) | Positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 
\text{'KFold'} and a positive integer value greater than 1. If you specify 
\text{'KFold'}, \text{k}, then the software completes these steps:

1. Randomly partition the data into \text{k} sets.
2. For each set, reserve the set as validation data, and train the model using the other \text{k} - 1 sets.
3. Store the \text{k} compact, trained models in the cells of a \text{k}-by-1 cell vector in the Trained property 
of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 
\text{CVPartition, Holdout, KFold, or Leaveout}.

Example: 
\text{'KFold', 5}

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

\text{'off'} (default) | \text{'on'}

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 
\text{'Leaveout'} and \text{'on'} or \text{'off'}. If you specify 
\text{'Leaveout'}, \text{'on'}, then, for each of the \text{n} observations (where \text{n} 
is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \text{n} - 1 
observations.
2. Store the \text{n} compact, trained models in the cells of an \text{n}-by-1 cell vector in the Trained property 
of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Convergence Controls**

**DeltaGradientTolerance — Tolerance for gradient difference**

Tolerance for gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

Example: 'DeltaGradientTolerance',1e-4

Data Types: single | double

**GapTolerance — Feasibility gap tolerance**

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If GapTolerance is 0, then fitrsvm does not use this parameter to check convergence.

Example: 'GapTolerance',1e-4

Data Types: single | double

**IterationLimit — Maximal number of numerical optimization iterations**

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. Mdl.ConvergenceInfo contains convergence information.

Example: 'IterationLimit',1e8

Data Types: double | single

**KKTTolerance — Tolerance for KKT violation**

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar value.

This name-value pair applies only if 'Solver' is 'SMO' or 'ISDA'.

If KKTTolerance is 0, then fitrsvm does not use this parameter to check convergence.

Example: 'KKTTolerance',1e-4

Data Types: single | double

**ShrinkagePeriod — Number of iterations between reductions of active set**

Data Types: single | double
Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000

Data Types: double | single

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'venone' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

• 'none' — Do not optimize.
• 'auto' — Use {'BoxConstraint','KernelScale','Epsilon'}.  
• 'all' — Optimize all eligible parameters.
• String array or cell array of eligible parameter names.
• Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrsvm by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrsvm are:

• BoxConstraint — fitrsvm searches among positive values, by default log-scaled in the range [1e-3,1e3].
• KernelScale — fitrsvm searches among positive values, by default log-scaled in the range [1e-3,1e3].
• Epsilon — fitrsvm searches among positive values, by default log-scaled in the range [1e-3,1e2]*iqr(Y)/1.349.
• KernelFunction — fitrsvm searches among 'gaussian', 'linear', and 'polynomial'.
• PolynomialOrder — fitrsvm searches among integers in the range [2,4].
• Standardize — fitrsvm searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

load carsmall
params = hyperparameters('fitrsvm',[Horsepower,Weight],MPG);
params(1).Range = [1e-4,1e6];

Pass params as the value of OptimizeHyperparameters.
By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize SVM Regression” on page 32-2110.

Example: 'OptimizeHyperparameters','auto'

**HyperparameterOptimizationOptions — Options for optimization**
structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

Example:

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

Mdl — Trained SVM regression model
RegressionSVM model | RegressionPartitionedSVM cross-validated model

Trained SVM regression model, returned as a RegressionSVM model or RegressionPartitionedSVM cross-validated model.

If you set any of the name-value pair arguments KFold, Holdout, Leaveout, CrossVal, or CVPartition, then Mdl is a RegressionPartitionedSVM cross-validated model. Otherwise, Mdl is a RegressionSVM model.

Limitations

fitrsvm supports low- through moderate-dimensional data sets. For high-dimensional data set, use fitrlinear instead.

Tips

- Unless your data set is large, always try to standardize the predictors (see Standardize). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM model generalizes.
- Sparsity in support vectors is a desirable property of an SVM model. To decrease the number of support vectors, set the BoxConstraint name-value pair argument to a large value. This action also increases the training time.
• For optimal training time, set CacheSize as high as the memory limit on your computer allows.

• If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active-set using the name-value pair argument 'ShrinkagePeriod'. It is good practice to use 'ShrinkagePeriod',1000.

• Duplicate observations that are far from the regression line do not affect convergence. However, just a few duplicate observations that occur near the regression line can slow down convergence considerably. To speed up convergence, specify 'RemoveDuplicates',true if:
  \[ \text{Your data set contains many duplicate observations.} \]
  \[ \text{You suspect that a few duplicate observations can fall near the regression line.} \]

However, to maintain the original data set during training, \texttt{fitrsvm} must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify true for data sets containing few duplicates, then \texttt{fitrsvm} consumes close to double the memory of the original data.

• After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

• For the mathematical formulation of linear and nonlinear SVM regression problems and the solver algorithms, see “Understanding Support Vector Machine Regression” on page 25-2.

• NaN, <undefined>, empty character vector (' '), empty string ('"'), and <missing> values indicate missing data values. \texttt{fitrsvm} removes entire rows of data corresponding to a missing response. When normalizing weights, \texttt{fitrsvm} ignores any weight corresponding to an observation with at least one missing predictor. Consequently, observation box constraints might not equal BoxConstraint.

• \texttt{fitrsvm} removes observations that have zero weight.

• If you set 'Standardize',true and 'Weights', then \texttt{fitrsvm} standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, \texttt{fitrsvm} standardizes predictor \( j \) (\( x_j \)) using

\[
x^*_j = \frac{x_j - \mu^*_j}{\sigma^*_j}.
\]

\[
\mu^*_j = \frac{1}{\sum_k w_k} \sum_k w_k x^*_j.
\]

\( x^*_j \) is observation \( k \) (row) of predictor \( j \) (column).

\[
(\sigma^*_j)^2 = \frac{v_1}{v_2 - v_1} \sum_k w_k (x^*_j - \mu^*_j)^2.
\]

\[
v_1 = \sum_j w_j.
\]

\[
v_2 = \sum_j (w_j)^2.
\]
• If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.

• The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 array of character vectors containing the original names of the predictor variables.

• The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

• Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.

• The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are `m` support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an `m`-by-5 matrix.

• The `X` property stores the training data as originally input. It does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.

• For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.

• For a variable having `k` ordered levels, the software creates `k` - 1 dummy variables. The `j`th dummy variable is -1 for levels up to `j`, and +1 for levels `j` + 1 through `k`.

• The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores `k` - 1 additional predictor names for the dummy variables, including the names of levels 2, 3, ..., `k`.

• All solvers implement `L1` soft-margin minimization.

• Let `p` be the proportion of outliers that you expect in the training data. If you set `'OutlierFraction',p`, then the software implements robust learning. In other words, the software attempts to remove 100`p`% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics
“Understanding Support Vector Machine Regression” on page 25-2

Introduced in R2015b
fitrtree

Fit binary decision tree for regression

Syntax

tree = fitrtree(Tbl,ResponseVarName)
tree = fitrtree(Tbl,formula)
tree = fitrtree(Tbl,Y)
tree = fitrtree(X,Y)
tree = fitrtree(___,Name,Value)

Description

tree = fitrtree(Tbl,ResponseVarName) returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table Tbl and the output (response) contained in Tbl.ResponseVarName. The returned tree is a binary tree where each branching node is split based on the values of a column of Tbl.

tree = fitrtree(Tbl,formula) returns a regression tree based on the input variables contained in the table Tbl. The input formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit tree.

tree = fitrtree(Tbl,Y) returns a regression tree based on the input variables contained in the table Tbl and the output in vector Y.

tree = fitrtree(X,Y) returns a regression tree based on the input variables X and the output Y. The returned tree is a binary tree where each branching node is split based on the values of a column of X.

tree = fitrtree(___,Name,Value) specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify observation weights or train a cross-validated model.

Examples

Construct Regression Tree

Load the sample data.
load carsmall

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

tree = fitrtree([Weight, Cylinders],MPG,...
                 'CategoricalPredictors',2,'MinParentSize',20,...
                 'PredictorNames',{'W','C'})

            tree = RegressionTree
Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

MPG4Kpred = predict(tree, [4000 4; 4000 6; 4000 8])

MPG4Kpred = 3×1
         19.2778
         19.2778
         14.3889

Control Regression Tree Depth

fitrtree grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time. To control the depth of trees, use the 'MaxNumSplits', 'MinLeafSize', or 'MinParentSize' name-value pair arguments.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];

The default values of the tree-depth controllers for growing regression trees are:

- n - 1 for MaxNumSplits. n is the training sample size.
- 1 for MinLeafSize.
- 10 for MinParentSize.

These default values tend to grow deep trees for large training sample sizes.

Train a regression tree using the default values for tree-depth control. Cross-validate the model using 10-fold cross-validation.

rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');

Draw a histogram of the number of imposed splits on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
view(MdlDefault.Trained{1}, 'Mode', 'graph')
The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross-validate the model using 10-fold cross-validation.

\[
\text{Mdl7} = \text{fitrtree}(X, \text{MPG}, \text{'MaxNumSplits'}, 7, \text{'CrossVal'}, \text{'on'})
\]

view(Mdl7.Trained{1}, \text{'Mode'}, \text{'graph'})
Compare the cross-validation mean squared errors (MSEs) of the models.

```matlab
mseDefault = kfoldLoss(MdlDefault)
mseDefault = 25.7383
mse7 = kfoldLoss(Mdl7)
mse7 = 26.5031
```

*Mdl7* is much less complex and performs only slightly worse than *MdlDefault*.

**Optimize Regression Tree**

Optimize hyperparameters automatically using `fitrtree`.

Load the `carsmall` data set.

```matlab
load carsmall
```
Use Weight and Horsepower as predictors for MPG. Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
X = [Weight,Horsepower];
Y = MPG;
rng default
Mdl = fitrtree(X,Y,'OptimizeHyperparameters','auto',
               'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

Unbiased Predictor Importance Estimates

Load the carsmall data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider Cylinders, Mfg, and Model_Year as categorical variables.

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
  Model_Year,Weight,MPG);

Display the number of categories represented in the categorical variables.

numCylinders = numel(categories(Cylinders))
numCylinders = 3
numMfg = numel(categories(Mfg))
numMfg = 28
numModelYear = numel(categories(Model_Year))
numModelYear = 3

Because there are 3 categories only in Cylinders and Model_Year, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.
Mdl = fitrtree(X, 'MPG', 'PredictorSelection', 'curvature', 'Surrogate', 'on');

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';

In this case, Displacement is the most important predictor, followed by Horsepower.

**Control Maximum Tree Depth on Tall Array**

fitrtree grows deep decision trees by default. Build a shallower tree that requires fewer passes through a tall array. Use the 'MaxDepth' name-value pair argument to control the maximum tree depth.
When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays `X` and `MPG` to tall arrays.

```matlab
tx = tall(X);
```

Starting parallel pool (parpool) using the 'local' profile ... Connected to the parallel pool (number of workers: 6).

```matlab
ty = tall(MPG);
```

Grow a regression tree using all observations. Allow the tree to grow to the maximum possible depth.

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```matlab
rng('default')
tallrng('default')
Mdl = fitrtree(tx,ty);
```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 2: Completed in 3.3 sec
- Pass 2 of 2: Completed in 1 sec
Evaluation completed in 6.8 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 6: Completed in 1.4 sec

- Pass 6 of 7: Completed in 1.5 sec
View the trained tree Mdl.

view(Mdl,'Mode','graph')
Mdl is a tree of depth 8.

Estimate the in-sample mean squared error.

\[ \text{MSE}_{\text{Mdl}} = \text{gather}(\text{loss}(\text{Mdl}, \text{tx}, \text{ty})) \]

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.1 sec
Evaluation completed in 3.7 sec
\[ \text{MSE}_{\text{Mdl}} = 4.9078 \]

Grow a regression tree using all observations. Limit the tree depth by specifying a maximum tree depth of 4.

\[ \text{Mdl2} = \text{fitrtree}(\text{tx}, \text{ty}, '\text{MaxDepth}', 4); \]

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 2: Completed in 0.38 sec
- Pass 2 of 2: Completed in 0.35 sec
Evaluation completed in 1.2 sec
Evaluating tall expression using the Parallel Pool 'local':
View the trained tree Mdl2.

```matlab
view(Mdl2, 'Mode', 'graph')
```
Estimate the in-sample mean squared error.

\[ \text{MSE}_{\text{Mdl2}} = \text{gather} (\text{loss} (\text{Mdl2}, tx, ty)) \]

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 0.86 sec
Evaluation completed in 1.3 sec

\[ \text{MSE}_{\text{Mdl2}} = 9.3903 \]

\( \text{Mdl2} \) is a less complex tree with a depth of 4 and an in-sample mean squared error that is higher than the mean squared error of \( \text{Mdl} \).

**Optimize Regression Tree on Tall Array**

Optimize hyperparameters of a regression tree automatically using a tall array. The sample data set is the \textit{carsmall} data set. This example converts the data set to a tall array and uses it to run the optimization procedure.
When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the mapreducer function.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays X and MPG to tall arrays.

```matlab
tx = tall(X);
ty = tall(MPG);
```

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'MinLeafSize' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'MinLeafSize'.) For reproducibility, use the 'expected-improvement-plus' acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```matlab
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrtree(tx,ty,...
    'OptimizeHyperparameters','auto',... 
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,... 
    'AcquisitionFunctionName','expected-improvement-plus'))
```

The results are as follows:

```matlab

Min objective vs. Number of function evaluations

- Min observed objective
- Estimated min objective

Function evaluations vs. Min objective
Optimization completed.
MaxObjectiveEvaluations of 30 reached.
Total function evaluations: 30
Total elapsed time: 921.4644 seconds.
Total objective function evaluation time: 898.6512

Best observed feasible point:
MinLeafSize

6

Observed objective function value = 2.9048
Estimated objective function value = 2.9122
Function evaluation time = 34.7142

Best estimated feasible point (according to models):
MinLeafSize

6

Estimated objective function value = 2.9122
Estimated function evaluation time = 35.77

32-2164
Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.
If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl. The response variable must be a numeric vector.

You must specify ResponseVarName as a character vector or string scalar. For example, if Tbl stores the response variable Y as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

Data Types: char | string

Y — Response data
numeric column vector

Response data, specified as a numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

The software considers NaN values in Y to be missing values. fitrtree does not use observations with missing values for Y in the fit.

Data Types: single | double
**X — Predictor data**  
**numeric matrix**

Predictor data, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

fitrtree considers NaN values in X as missing values. fitrtree does not use observations with all missing values for X in the fit. fitrtree uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'CrossVal','on','MinParentSize',30 specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

**Model Parameters**

**CategoricalPredictors — Categorical predictors list**  
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitrtree assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fitrtree assumes that all predictors are
To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**MaxDepth — Maximum tree depth**

positive integer

Maximum tree depth, specified as the comma-separated pair consisting of `'MaxDepth'` and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitrtree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

**Note** This option applies only when you use `fitrtree` on tall arrays. See Tall Arrays on page 32-2183 for more information.

**MergeLeaves — Leaf merge flag**

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and `'on'` or `'off'`.

If `MergeLeaves` is `'on'`, then `fitrtree`:

- Merges leaves that originate from the same parent node and yield a sum of risk values greater than or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, `fitrtree` does not merge leaves.

Example: `'MergeLeaves','off'`

**MinParentSize — Minimum number of branch node observations**

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize).

Example: `'MinParentSize',8`

Data Types: `single` | `double`

**NumBins — Number of bins for numeric predictors**

`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then the software does not bin any predictors.
• If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.

• If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then fitrtree bins the predictor into u bins.

• fitrtree does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the BinEdges property.

Example: 'NumBins',50

Data Types: single | double

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

• If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.

  • The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.

  • By default, PredictorNames is {'x1','x2',...}.

• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitrtree uses only the predictor variables in PredictorNames and the response variable in training.

  • PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.

  • By default, PredictorNames contains the names of all predictor variables.

  • A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**PredictorSelection — Algorithm used to select the best split predictor**

'allsplits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allsplits'</td>
<td>Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].</td>
</tr>
<tr>
<td>'curvature'</td>
<td>Curvature test on page 32-2178 — Selects the split predictor that minimizes the $p$-value of chi-square tests of independence between each predictor and the response [2]. Training speed is similar to standard CART.</td>
</tr>
<tr>
<td>'interaction-curvature'</td>
<td>Interaction test on page 32-2179 — Chooses the split predictor that minimizes the $p$-value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the $p$-value of a chi-square test of independence between each pair of predictors and response [2]. Training speed can be slower than standard CART.</td>
</tr>
</tbody>
</table>

For 'curvature' and 'interaction-curvature', if all tests yield $p$-values greater than 0.05, then `fitrtree` stops splitting nodes.

**Tip**

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance` and “Introduction to Feature Selection” on page 15-49.
  - Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test.
  - Prediction speed is unaffected by the value of 'PredictorSelection'.

For details on how `fitrtree` selects split predictors, see “Node Splitting Rules” on page 32-2180 and “Choose Split Predictor Selection Technique” on page 19-14.

Example: 'PredictorSelection','curvature'

**Prune — Flag to estimate optimal sequence of pruned subtrees**

'on' (default) | 'off'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If Prune is 'on', then `fitrtree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitrtree` grows the regression tree without estimating the optimal sequence of pruned subtrees.
To prune a trained regression tree, pass the regression tree to prune.

Example: 'Prune','off'

**PruneCriterion — Pruning criterion**

'mse' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

**QuadraticErrorTolerance — Quadratic error tolerance**

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. The function stops splitting nodes when the weighted mean squared error per node drops below QuadraticErrorTolerance*ε, where ε is the weighted mean squared error of all n responses computed before growing the decision tree.

\[
\varepsilon = \frac{1}{n} \sum_{i=1}^{n} w_i (y_i - \bar{y})^2.
\]

w_i is the weight of observation i, given that the weights of all the observations sum to one \((\sum_{i=1}^{n} w_i = 1)\), and

\[
\bar{y} = \frac{1}{n} \sum_{i=1}^{n} w_i y_i
\]

is the weighted average of all the responses.

For more details on node splitting, see Node Splitting Rules on page 32-2180.

Example: 'QuadraticErrorTolerance',1e-4

**Reproducible — Flag to enforce reproducibility**

false (logical 0) (default) | true (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of 'Reproducible' and either false or true.

If 'NumVariablesToSample' is not 'all', then the software selects predictors at random for each split. To reproduce the random selections, you must specify 'Reproducible',true and set the seed of the random number generator by using rng. Note that setting 'Reproducible' to true can slow down training.

Example: 'Reproducible',true

Data Types: logical

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.
• If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
• If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

ResponseTransform — Response transformation

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform',myfunction.
Data Types: char | string | function_handle

SplitCriterion — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.
Example: 'SplitCriterion','MSE'

Surrogate — Surrogate decision splits flag

'off' (default) | 'on' | 'all' | positive integer

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer:
• When 'on', fitrtree finds at most 10 surrogate splits at each branch node.
• When set to a positive integer, fitrtree finds at most the specified number of surrogate splits at each branch node.
• When set to 'all', fitrtree finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.
Example: ‘Surrogate','on'
Data Types: single | 'on' | char | string

Weights — Observation weights

ones(size(X,1),1) (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The software weights the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.
If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors when training the model.

fitrtree normalizes the weights in each class to add up to 1.

Data Types: single | double | char | string

Cross-Validation

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', fitrtree grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Example: 'CrossVal','on'

CVPartition — Partition for cross-validation tree
cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Holdout — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

KFold — Number of folds

10 (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.
Example: 'KFold',8
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross-validation by setting to 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

**Hyperparameters**

**MaxNumSplits — Maximal number of decision splits**

`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. fitrtree splits MaxNumSplits or fewer branch nodes. For more details on splitting behavior, see “Tree Depth Control” on page 32-2182.

Example: 'MaxNumSplits',5
Data Types: single | double

**MinLeafSize — Minimum number of leaf node observations**

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitrtree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize,2*MinLeafSize).

Example: 'MinLeafSize',3
Data Types: single | double

**NumVariablesToSample — Number of predictors to select at random for each split**

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' as 'all'. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using rng and specify 'Reproducible',true.

Example: 'NumVariablesToSample',3
Data Types: char | string | single | double
Hyperparameter Optimization

**OptimizeHyperparameters — Parameters to optimize**

- 'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'MinLeafSize'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrtree by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrtree are:

- **MaxNumSplits** — fitrtree searches among integers, by default log-scaled in the range \([1, \max(2, \text{NumObservations}-1)]\).
- **MinLeafSize** — fitrtree searches among integers, by default log-scaled in the range \([1, \max(2, \floor{\text{NumObservations}/2})]\).
- **NumVariablesToSample** — fitrtree does not optimize over this hyperparameter. If you pass NumVariablesToSample as a parameter name, fitrtree simply uses the full number of predictors. However, fitrensemble does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

```matlab
load carsmall
params = hyperparameters('fitrtree',[Horsepower,Weight],MPG);
params(1).Range = [1,30];
```

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Regression Tree” on page 32-2136.

Example: 'auto'
HyperparameterOptimizationOptions — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of
'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of
the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

<table>

Data Types: struct

**Output Arguments**

**tree — Regression tree**
regression tree object

Regression tree, returned as a regression tree object. Using the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

**More About**

**Curvature Test**

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

1. If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2. For each level in the partitioned predictor $j = 1...J$ and class in the response $k = 1,...,K$, compute the weighted proportion of observations in class $k$

   $$\hat{\pi}_{jk} = \sum_{i=1}^{n} I\{y_i = k\}w_i.$$ 

   $w_i$ is the weight of observation $i$, $\sum w_i = 1$, $I$ is the indicator function, and $n$ is the sample size. If all observations have the same weight, then $\hat{\pi}_{jk} = \frac{n_{jk}}{n}$, where $n_{jk}$ is the number of observations in level $j$ of the predictor that are in class $k$.

3. Compute the test statistic

   $$t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \left( \frac{\hat{\pi}_{jk} - \hat{\pi}_{j} + \hat{\pi}_{k}}{\hat{\pi}_{j} + \hat{\pi}_{k}} \right)^2$$

32-2178
\[ \hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}, \text{ that is, the marginal probability of observing the predictor at level } j. \]
\[ \hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}, \]
that is, the marginal probability of observing class \( k \). If \( n \) is large enough, then \( t \) is distributed as a \( \chi^2 \) with \((K - 1)(J - 1)\) degrees of freedom.

4 If the \( p \)-value for the test is less than 0.05, then reject the null hypothesis that there is no association between \( x \) and \( y \).

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant \( p \)-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

For more details on how the curvature test applies to growing regression trees, see “Node Splitting Rules” on page 32-2180 and [3].

Interaction Test

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables \( x_1 \) and \( x_2 \) with respect to \( y \) is conducted using this process.

1 If \( x_1 \) or \( x_2 \) is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2 Create the nominal variable \( z \) with \( J = J_1 J_2 \) levels that assigns an index to observation \( i \) according to which levels of \( x_1 \) and \( x_2 \) it belongs. Remove any levels of \( z \) that do not correspond to any observations.

3 Conduct a curvature test on page 32-2178 between \( z \) and \( y \).

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-2178, “Node Splitting Rules” on page 32-2180 and [2].

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose \( x_j \) and \( x_k \) are predictor variables \( j \) and \( k \), respectively, and \( j \neq k \). At node \( t \), the predictive measure of association between the optimal split \( x_j < u \) and a surrogate split \( x_k < v \) is
\[ \lambda_{jk} = \frac{\min(P_L, P_R) - \left(1 - P_{LjLk} - P_{RjRk}\right)}{\min(P_L, P_R)}. \]

- \( P_L \) is the proportion of observations in node \( t \), such that \( x_j < u \). The subscript \( L \) stands for the left child of node \( t \).
- \( P_R \) is the proportion of observations in node \( t \), such that \( x_j \geq u \). The subscript \( R \) stands for the right child of node \( t \).
- \( P_{LjLk} \) is the proportion of observations at node \( t \), such that \( x_j < u \) and \( x_k < v \).
- \( P_{RjRk} \) is the proportion of observations at node \( t \), such that \( x_j \geq u \) and \( x_k \geq v \).
- Observations with missing values for \( x_j \) or \( x_k \) do not contribute to the proportion calculations.

\( \lambda_{jk} \) is a value in \((-\infty,1]\). If \( \lambda_{jk} > 0 \), then \( x_k < v \) is a worthwhile surrogate split for \( x_j < u \).

**Surrogate Decision Splits**

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2179.

**Tip**

- By default, Prune is 'on'. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to prune.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

**Node Splitting Rules**

`fitrtree` uses these processes to determine how to split node \( t \).

- For standard CART (that is, if `PredictorSelection` is 'allpairs') and for all predictors \( x_i \), \( i = 1,\ldots,p \):
  1. `fitrtree` computes the weighted mean squared error (MSE) of the responses in node \( t \) using

\[ \varepsilon_t = \sum_{j \in T} w_j (y_j - \bar{y}_t)^2. \]

  \( w_j \) is the weight of observation \( j \), and \( T \) is the set of all observation indices in node \( t \). If you do not specify `Weights`, then \( w_j = 1/n \), where \( n \) is the sample size.
  2. `fitrtree` estimates the probability that an observation is in node \( t \) using
\[
P(T) = \sum_{j \in T} w_j.
\]

3. \texttt{fitrtree} sorts \(x_i\) in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. \texttt{fitrtree} records any indices corresponding to missing values in the set \(T_U\), which is the unsplit set.

4. \texttt{fitrtree} determines the best way to split node \(t\) using \(x_i\) by maximizing the reduction in MSE (\(\Delta I\)) over all splitting candidates. That is, for all splitting candidates in \(x_i\):
   
   a. \texttt{fitrtree} splits the observations in node \(t\) into left and right child nodes (\(t_L\) and \(t_R\), respectively).
   
   b. \texttt{fitrtree} computes \(\Delta I\). Suppose that for a particular splitting candidate, \(t_L\) and \(t_R\) contain observation indices in the sets \(T_L\) and \(T_R\), respectively.
      
      - If \(x_i\) does not contain any missing values, then the reduction in MSE for the current splitting candidate is
        \[
        \Delta I = P(T)\epsilon_t - P(T_L)\epsilon_{t_L} - P(T_R)\epsilon_{t_R}.
        \]
      
      - If \(x_i\) contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is
        \[
        \Delta I_U = P(T - T_U)\epsilon_t - P(T_L)\epsilon_{t_L} - P(T_R)\epsilon_{t_R}.
        \]

   \(T - T_U\) is the set of all observation indices in node \(t\) that are not missing.

   - If you use surrogate decision splits on page 32-2180, then:
      
      i. \texttt{fitrtree} computes the predictive measures of association on page 32-2179 between the decision split \(x_i < u\) and all possible decision splits \(x_i < v, j \neq k\).
      
      ii. \texttt{fitrtree} sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
      
      iii. \texttt{fitrtree} decides the child node assignments for observations with a missing value for \(x_i\) using the surrogate split. If the surrogate predictor also contains a missing value, then \texttt{fitrtree} uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for \texttt{fitrtree} to split two different observations at node \(t\) using two different surrogate splits. For example, suppose the predictors \(x_1\) and \(x_2\) are the best and second best surrogates, respectively, for the predictor \(x_i\), \(i \notin \{1, 2\}\), at node \(t\). If observation \(m\) of predictor \(x_i\) is missing (i.e., \(x_{mi}\) is missing), but \(x_{m1}\) is not missing, then \(x_1\) is the surrogate predictor for observation \(x_{mi}\). If observations \(x_{(m+1),1}\) and \(x_{(m+1),2}\) are missing, but \(x_{(m+1),2}\) is not missing, then \(x_2\) is the surrogate predictor for observation \(m + 1\).
      
      iv. \texttt{fitrtree} uses the appropriate MSE reduction formula. That is, if \texttt{fitrtree} fails to assign all missing observations in node \(t\) to children nodes using surrogate splits, then the MSE reduction is \(\Delta I_U\). Otherwise, \texttt{fitrtree} uses \(\Delta I\) for the MSE reduction.

   c. \texttt{fitrtree} chooses the candidate that yields the largest MSE reduction.

\texttt{fitrtree} splits the predictor variable at the cut point that maximizes the MSE reduction.

- For the curvature test (that is, if \texttt{PredictorSelection} is 'curvature'): 

32-2181
fitrtree computes the residuals \( r_{ti} = y_{ti} - \bar{y}_t \) for all observations in node \( t \).
\[
\bar{y}_t = \frac{1}{\sum_i w_i} \sum_i w_i y_{ti},
\]
which is the weighted average of the responses in node \( t \). The weights are the observation weights in Weights.

fitrtree assigns observations to one of two bins according to the sign of the corresponding residuals. Let \( z_t \) be a nominal variable that contains the bin assignments for the observations in node \( t \).

fitrtree conducts curvature tests on page 32-2178 between each predictor and \( z_t \). For regression trees, \( K = 2 \).

- If all \( p \)-values are at least 0.05, then fitrtree does not split node \( t \).
- If there is a minimal \( p \)-value, then fitrtree chooses the corresponding predictor to split node \( t \).
- If more than one \( p \)-value is zero due to underflow, then fitrtree applies standard CART to the corresponding predictors to choose the split predictor.

If fitrtree chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

For the interaction test (that is, if PredictorSelection is 'interaction-curvature'):

1. For observations in node \( t \), fitrtree conducts curvature tests on page 32-2178 between each predictor and the response and interaction tests on page 32-2179 between each pair of predictors and the response.
   - If all \( p \)-values are at least 0.05, then fitrtree does not split node \( t \).
   - If there is a minimal \( p \)-value and it is the result of a curvature test, then fitrtree chooses the corresponding predictor to split node \( t \).
   - If there is a minimal \( p \)-value and it is the result of an interaction test, then fitrtree chooses the split predictor using standard CART on the corresponding pair of predictors.
   - If more than one \( p \)-value is zero due to underflow, then fitrtree applies standard CART to the corresponding predictors to choose the split predictor.

2. If fitrtree chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If MergeLeaves is 'on' and PruneCriterion is 'mse' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using MSE. This specification amounts to merging leaves coming from the same parent node whose MSE is at most the sum of the MSE of its two leaves.
- To accommodate MaxNumSplits, fitrtree splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds MaxNumSplits, fitrtree follows this procedure:

1. Determine how many branch nodes in the current layer must be unsplit so that there are at most MaxNumSplits branch nodes.
2. Sort the branch nodes by their impurity gains.
3. Unsplit the number of least successful branches.
4. Return the decision tree grown so far.
This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
  - There are MaxNumSplits branch nodes.
  - A proposed split causes the number of observations in at least one branch node to be fewer than MinParentSize.
  - A proposed split causes the number of observations in at least one leaf node to be fewer than MinLeafSize.
  - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see PruneCriterion), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
  - For values 'curvature' or 'interaction-curvature' of PredictorSelection, all tests yield p-values greater than 0.05.

MaxNumSplits and MinLeafSize do not affect splitting at their default values. Therefore, if you set 'MaxNumSplits', splitting might stop due to the value of MinParentSize, before MaxNumSplits splits occur.

**Parallelization**

**References**

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - tree = fitrtree(Tbl,Y)
  - tree = fitrtree(X,Y)
  - tree = fitrtree(___,Name,Value)
  - [tree,FitInfo,HyperparameterOptimizationResults] = fitrtree(___,Name,Value) — fitrtree returns the additional output arguments FitInfo and HyperparameterOptimizationResults when you specify the 'OptimizeHyperparameters' name-value pair argument.
tree is a CompactRegressionTree object; therefore, it does not include the data used in training the regression tree.

- The FitInfo output argument is an empty structure array currently reserved for possible future use.
- The HyperparameterOptimizationResults output argument is a BayesianOptimization object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

'HyperparameterOptimizationResults' is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty at the time you create the model. The values in 'HyperparameterOptimizationResults' depend on the value you specify for the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model.

- If you specify 'bayesopt' (default), then HyperparameterOptimizationResults is an object of class BayesianOptimization.
- If you specify 'gridsearch' or 'randomsearch', then HyperparameterOptimizationResults is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

- Supported name-value pair arguments are:
  - 'CategoricalPredictors'
  - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitrtree(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
  - 'MaxNumSplits' — For tall optimization, fitrtree searches among integers, log-scaled (by default) in the range \([1, \max(2, \min(10000, \text{NumObservations}-1))]\).
  - 'MergeLeaves'
  - 'MinLeafSize' — For tall optimization, fitrtree searches among integers, log-scaled (by default) in the range \([1, \max(2, \floor(\text{NumObservations}/2))]\).
  - 'MinParentSize'
  - 'NumVariablesToSample' — For tall optimization, fitrtree searches among integers in the range \([1, \max(2, \text{NumPredictors})]\).
  - 'OptimizeHyperparameters'
  - 'PredictorNames'
  - 'QuadraticErrorTolerance'
  - 'ResponseName'
  - 'ResponseTransform'
  - 'SplitCriterion'
  - 'Weights'

- This additional name-value pair argument is specific to tall arrays:
  - 'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of fitrtree takes one pass
through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Topics**
“Splitting Categorical Predictors in Classification Trees” on page 19-25

**Introduced in R2014a**
**fitSVMPosterior**

Fit posterior probabilities

**Syntax**

ScoreSVMModel = fitSVMPosterior(SVMModel)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)

ScoreSVMModel = fitSVMPosterior(____,Name,Value)

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(____)

**Description**

**ScoreSVMModel = fitSVMPosterior(SVMModel)** returns **ScoreSVMModel**, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier **SVMModel**, and by cross validation using the stored predictor data (**SVMModel.X**) and the class labels (**SVMModel.Y**). The transformation function computes the posterior probability that an observation is classified into the positive class (**SVMModel.Classnames(2)**).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2194.
- If the classes are perfectly separable, the transformation function is the step function on page 32-2194.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2195. **fitSVMPosterior** is not appropriate for one-class learning.
- If **SVMModel** is a **ClassificationSVM** classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, **SVMModel** must be a **ClassificationPartitionedModel** classifier. **SVMModel** specifies the cross-validation method.
- The software stores the optimal transformation function in **ScoreSVMModel.ScoreTransform**.

**ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)** returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier **SVMModel**. The software estimates the score transformation function using predictor data in the table **TBL** and class labels **TBL.ResponseVarName**.

**ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)** returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier **SVMModel**. The software estimates the score transformation function using predictor data in the table **TBL** and class labels **Y**.
ScoreSVMMModel = fitSVMPosterior(SVMModel,X,Y) returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier SVMModel. The software estimates the score transformation function using predictor data X and class labels Y.

ScoreSVMMModel = fitSVMPosterior(___ ,Name,Value) uses additional options specified by one or more Name,Value pair arguments provided SVMModel is a ClassificationSVM classifier. For example, you can specify the number of folds to use in k-fold cross validation.

[ScoreSVMMModel,ScoreTransform] = fitSVMPosterior( ___ ) additionally returns the transformation function parameters (ScoreTransform) using any of the input arguments in the previous syntaxes.

Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);

gscatter(X(:,1),X(:,2),y);
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```matlab
rng(1);
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
CVSVMModel
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```matlab
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

`fitSVMPosterior` does the following:

- Uses the data that the software stored in `CVSVMModel` to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in `ScoreCVSVMModel.ScoreTransform`

Display the score function type and its parameter values.

```matlab
ScoreParameters
```

`ScoreParameters = struct with fields:`

```
    Type: 'step'
```
ScoreParameters is a structure array with four fields:

- The score transformation function type (Type)
- The score corresponding to the negative class boundary (LowerBound)
- The score corresponding to the positive class boundary (UpperBound)
- The positive class probability (PositiveClassProbability)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the ionosphere data set.

```matlab
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```matlab
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true,...
    'CrossVal','on');
ScoreTransform = CVSVMModel.ScoreTransform
```

ScoreTransform = 'none'

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```matlab
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
```

ScoreTransform = '@(S)sigmoid(S,-9.481576e-01,-1.218300e-01)'

ScoreParameters

```matlab
ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -0.9482
    Intercept: -0.1218
```
ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing ScoreCVSVMModel to kfoldPredict.

## Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```matlab
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```matlab
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

CVSVMModel is a trained ClassificationPartitionedModel cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```matlab
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

ScoreCVSVMModel is a trained ClassificationPartitionedModel cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```matlab
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

Input Arguments

**SVMModel — Trained SVM classifier**

- **ClassificationSVM classifier**
- **CompactClassificationSVM classifier**
- **ClassificationPartitionedModel classifier**

Trained SVM classifier, specified as a `ClassificationSVM`, `CompactClassificationSVM`, or `ClassificationPartitionedModel` classifier.

If `SVMModel` is a `ClassificationSVM` classifier, then you can set optional name-value pair arguments.

If `SVMModel` is a `CompactClassificationSVM` classifier, then you must input predictor data `X` and class labels `Y`.

**TBL — Sample data**

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all of the predictors used to train `SVMModel`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMModel` using sample data contained in a table, then the input data for `fitSVMPosterior` must also be in a table.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `table`

**X — Predictor data**

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows in `X` must be equal.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: `double` | `single`
**ResponseVarName — Response variable name**

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify ResponseVarName as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.Response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'KFold',8 performs 8-fold cross validation when SVMModel is a ClassificationSVM classifier.

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

The crossval name-value pair argument of fitcsvm splits the data into subsets using cvpartition.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)
Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout',0.1

Data Types: double | single

KFold — Number of folds
10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold',8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag
'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'Leaveout','on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout','on'

Output Arguments

ScoreSVMModel — Trained SVM classifier
ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The ScoreSVMModel classifier type is the same as the SVMModel classifier type.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize',true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters
structure array
Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field \textit{Type} is:

- \textit{sigmoid}, then \textit{ScoreTransform} has these fields:
  - \textit{Slope} — The value of $A$ in the sigmoid function on page 32-2194
  - \textit{Intercept} — The value of $B$ in the sigmoid function
- \textit{step}, then \textit{ScoreTransform} has these fields:
  - \textit{PositiveClassProbability}: the value of $\pi$ in the step function on page 32-2194. $\pi$ represents:
    - The probability that an observation is in the positive class.
    - The posterior probability that a score is in the interval $(\text{LowerBound}, \text{UpperBound})$.
  - \textit{LowerBound}: the value $\max_{y_n = -1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class \textit{PositiveClassProbability} to scores. Any observation with a score less than \textit{LowerBound} has posterior probability of being the positive class 0.
  - \textit{UpperBound}: the value $\min_{y_n = +1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class \textit{PositiveClassProbability}. Any observation with a score greater than \textit{UpperBound} has posterior probability of being the positive class 1.
- \textit{constant}, then \textit{ScoreTransform.PredictedClass} contains the name of the class prediction.

This result is the same as \textit{SVMModel.ClassNames}. The posterior probability of an observation being in \textit{ScoreTransform.PredictedClass} is always 1.

\textbf{More About}

\textbf{Sigmoid Function}

The sigmoid function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$ 

If the value of the \textit{Type} field of \textit{ScoreTransform} is \textit{sigmoid}, then parameters $A$ and $B$ correspond to the fields \textit{Scale} and \textit{Intercept} of \textit{ScoreTransform}, respectively.

\textbf{Step Function}

The step function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \begin{cases} 
  0; & s < \max_{y_k = -1} s_k \\
  \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k \\
  1; & s_j > \min_{y_k = +1} s_k 
\end{cases}.$$
where:

- $s_j$ is the score of observation $j$.
- +1 and -1 denote the positive and negative classes, respectively.
- $\pi$ is the prior probability that an observation is in the positive class.

If the value of the Type field of ScoreTransform is step, then

$$
\max_{y_k = -1} s_k \quad \text{and} \quad \min_{y_k = +1} s_k
$$

correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

- This process describes one way to predict positive class posterior probabilities.
  
1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.

2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

   If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to ‘none’ before estimating the new one.

Introduced in R2014a
fitted

Class: GeneralizedLinearMixedModel
Fitted responses from generalized linear mixed-effects model

Syntax

mufit = fitted(glme)
mufit = fitted(glme,Name,Value)

Description

mufit = fitted(glme) returns the fitted conditional response of the generalized linear mixed-effects model glme.

mufit = fitted(glme,Name,Value) returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Conditional — Indicator for conditional response
true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Contributions from both fixed effects and random effects (conditional)</td>
</tr>
<tr>
<td>false</td>
<td>Contribution from only fixed effects (marginal)</td>
</tr>
</tbody>
</table>

To obtain fitted marginal response values, fitted computes the conditional mean of the response with the empirical Bayes predictor vector of random effects $b$ set equal to 0. For more information, see “Conditional and Marginal Response” on page 32-2200

Example: 'Conditional',false

32-2197
Output Arguments

**mufit — Fitted response values**

*n*-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

**Plot Observed Versus Fitted Values**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (**A**, **B**, or **C**) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as ‘effects’, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_\text{C}_{ij} + \beta_5 \text{supplier}_\text{B}_{ij} + b_i, \]

where
• defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
• \( \mu_{ij} \) is the mean number of defects corresponding to factory i (where i = 1, 2, \ldots, 20) during batch j (where j = 1, 2, \ldots, 5).
• newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
• supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
• \( b_i \sim N(0, \sigma^2_i) \) is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme}(\text{mfr},'\text{defects} - 1 + \text{newprocess} + \text{time_dev} + \text{temp_dev} + \text{supplier} + (1|\text{factory}),' \%
\text{Distribution}','\text{Poisson}',\text{Link}','\text{log}',\text{FitMethod}','\text{Laplace}','\text{DummyVarCoding}','\text{effects}');
\]

Generate the fitted conditional mean values for the model.

\[
mufit = \text{fitted}(\text{glme});
\]

Create a scatterplot of the observed values versus fitted values.

\[
\text{figure} \text{scatter(}\text{mfr.defects},\text{mufit})
\text{title('Residuals versus Fitted Values')} \text{xlabel('Fitted Values')} \text{ylabel('Residuals')}
\]
More About

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an \( n \)-by-\( p \) fixed-effects design matrix \( X \) and an \( n \)-by-\( q \) random-effects design matrix \( Z \). Also, suppose the estimated \( p \)-by-1 fixed-effects vector is \( \hat{\beta} \), and the \( q \)-by-1 empirical Bayes predictor vector of random effects is \( \hat{b} \).

The fitted conditional response corresponds to the ‘Conditional’,true name-value pair argument, and is defined as

\[
\hat{\mu}_{\text{cond}} = g^{-1}(\widehat{\eta}_{\text{ME}}),
\]

where \( \widehat{\eta}_{\text{ME}} \) is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

\[
\widehat{\eta}_{\text{ME}} = X\hat{\beta} + Z\hat{b} + \delta.
\]

The fitted marginal response corresponds to the ‘Conditional’,false name-value pair argument, and is defined as
\[
\hat{\mu}_{mar} = g^{-1}(\hat{\eta}_{FE}),
\]

where \( \hat{\eta}_{FE} \) is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

\[
\hat{\eta}_{FE} = X\hat{\beta} + \delta.
\]

fitted

Class: LinearMixedModel

Fitted responses from a linear mixed-effects model

Syntax

yfit = fitted(lme)
yfit = fitted(lme,Name,Value)

Description

yfit = fitted(lme) returns the fitted conditional response on page 32-2207 from the linear mixed-effects model lme.

yfit = fitted(lme,Name,Value) returns the fitted response from the linear mixed-effects model lme with additional options specified by one or more Name,Value pair arguments.

For example, you can specify if you want to compute the fitted marginal response on page 32-2207.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Conditional — Indicator for conditional response
true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

true

Contribution from both fixed effects and random effects (conditional)

false

Contribution from only fixed effects (marginal)

Example: 'Conditional',false

Data Types: logical
Output Arguments

yfit — Fitted response values
n-by-1 vector

Fitted response values, returned as an n-by-1 vector, where n is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate','IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Region is a categorical variable. You can specify the contrasts for categorical variables using the DummyVarCoding name-value pair argument when fitting the model. When you do not specify the contrasts, fitlme uses the 'reference' contrast by default. Because the model has an intercept, fitlme takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, [MidAtl] is the dummy variable representing the region MidAtl. For details, see “Dummy Variables” on page 2-48.

The corresponding model is

\[ y_{im} = \beta_0 + \beta_1 [\text{MidAtl}]_i + \beta_2 [\text{ENCentral}]_i + \beta_3 [\text{WNCentral}]_i + \beta_4 [\text{SAtl}]_i \\
+ \beta_5 [\text{ESCentral}]_i + \beta_6 [\text{WSCentral}]_i + \beta_7 [\text{Mtn}]_i + \beta_8 [\text{Pac}]_i + b_{0m} + \epsilon_{im}, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( \beta_j \), \( j = 0, 1, \ldots, 8 \), are the fixed-effects coefficients, with \( \beta_0 \) being the coefficient for region NE. \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution, \( b_{0m} \sim N(0, \sigma_b^2) \) and the error term has the distribution, \( \epsilon_{im} \sim N(0, \sigma^2) \).

lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')

0.37191     -0.055948      0.14929
0.0022936    -0.033621      0.14929

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
Name1                  Name2                  Type           Estimate
{'(Intercept)'}        {'(Intercept)'}        {'std'}        0.6443

Lower     Upper
0.5297    0.78368

Group: Error
Name                        Estimate Lower     Upper
{'Res Std'}         0.26627 0.24878 0.285

The p-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions WNCentral and ESCentral are significantly different relative to the flu rates in region NE.
The confidence limits for the standard deviation of the random-effects term, $\sigma_b$, do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the compare method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region WNCentral in week 10/9/2005 is

$$\hat{Y}_{\text{WNCentral}, 10/9/2005} = \hat{\beta}_0 + \hat{\beta}_3 I_{\text{WNCentral}} + \hat{b}_{10/9/2005} = 1.2233 + 0.23687 - 0.1718 = 1.28837.$$  

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```matlab
beta = fixedEffects(lme);  
[-,,-,STATS] = randomEffects(lme);  
STATS.Level = nominal(STATS.Level);  
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
y_hat = 1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for $\beta_0$ and `beta(4)` corresponds to the estimate for $\beta_3$. You can simply display the fitted value using the `fitted` method.

```matlab
F = fitted(lme);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
ans = 1.2884
```

The estimated marginal response for region WNCentral in week 10/9/2005 is

$$\hat{Y}_{\text{WNCentral}, 10/9/2005}^{(\text{marginal})} = \hat{\beta}_0 + \hat{\beta}_3 I_{\text{WNCentral}} = 1.2233 + 0.23687 = 1.46017.$$  

Compute the fitted marginal response.

```matlab
F = fitted(lme,'Conditional',false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
ans = 1.4602
```

### Plot Residuals vs. Fitted Values

Load the sample data.

```matlab
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.
Store the data in a table. Define Subject and Program as categorical variables.

```MATLAB
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```MATLAB
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```MATLAB
F = fitted(lme);
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```MATLAB
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```MATLAB
figure()
gscatter(F,R,Program)
```
More About

**Fitted Conditional and Marginal Response**

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, \( \text{lmee} \), has an \( n \)-by-\( p \) fixed-effects design matrix \( X \) and an \( n \)-by-\( q \) random-effects design matrix \( Z \). Also, suppose the \( p \)-by-1 estimated fixed-effects vector is \( \hat{\beta} \), and the \( q \)-by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \( \hat{b} \). The fitted conditional response is

\[
\hat{y}_{\text{Cond}} = X\hat{\beta} + Z\hat{b},
\]

and the fitted marginal response is

\[
\hat{y}_{\text{Mar}} = X\hat{\beta}.
\]

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

beta = fixedEffects(glme)
[beta,betanames] = fixedEffects(glme)
[beta,betanames,stats] = fixedEffects(glme)
[___] = fixedEffects(glme,Name,Value)

Description

beta = fixedEffects(glme) returns the estimated fixed-effects coefficients, beta, of the generalized linear mixed-effects model glme.

[beta,betanames] = fixedEffects(glme) also returns the names of estimated fixed-effects coefficients in betanames. Each name corresponds to a fixed-effects coefficient in beta.

[beta,betanames,stats] = fixedEffects(glme) also returns a table of statistics, stats, related to the estimated fixed-effects coefficients of glme.

[___] = fixedEffects(glme,Name,Value) returns any of the output arguments in previous syntaxes using additional options specified by one or more Name,Value pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the t-statistic.

Input Arguments

glme -- Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Alpha — Significance level
0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α, the confidence level is 100 × (1 – α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.
Example: 'Alpha',0.01
Data Types: single | double

**DFMethod — Method for computing approximate degrees of freedom**

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'residual'</td>
<td>The degrees of freedom value is assumed to be constant and equal to n - p, where n is the number of observations and p is the number of fixed effects.</td>
</tr>
<tr>
<td>'none'</td>
<td>The degrees of freedom is set to infinity.</td>
</tr>
</tbody>
</table>

Example: 'DFMethod','none'

**Output Arguments**

**beta — Estimated fixed-effects coefficients**

vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model glme, returned as a vector.

**betanames — Names of fixed-effects coefficients**

table

Names of fixed-effects coefficients in beta, returned as a table.

**stats — Fixed-effects estimates and related statistics**

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the fixed-effects coefficient</td>
</tr>
<tr>
<td>Estimate</td>
<td>Estimated coefficient value</td>
</tr>
<tr>
<td>SE</td>
<td>Standard error of the estimate</td>
</tr>
<tr>
<td>tStat</td>
<td>t-statistic for a test that the coefficient is 0</td>
</tr>
<tr>
<td>DF</td>
<td>Estimated degrees of freedom for the t-statistic</td>
</tr>
<tr>
<td>pValue</td>
<td>p-value for the t-statistic</td>
</tr>
<tr>
<td>Lower</td>
<td>Lower limit of a 95% confidence interval for the fixed-effects coefficient</td>
</tr>
<tr>
<td>Upper</td>
<td>Upper limit of a 95% confidence interval for the fixed-effects coefficient</td>
</tr>
</tbody>
</table>

When fitting a model using fitglme and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), if you specify the 'CovarianceMethod' name-value pair argument as
'conditional', then SE does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify 'CovarianceMethod' as 'JointHessian'.

When fitting a GLME model using fitglme and one of the pseudo likelihood fit methods ('MPL' or 'REML'), fixedEffects bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

**Examples**

**Estimate Fixed-Effects Coefficients**

Load the sample data.

```matlab
load mfr

In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_{devij} + \beta_3 \text{temp}_{devij} + \beta_4 \text{supplier}_{Ci} + \beta_5 \text{supplier}_{Bij} + b_i,
\]

where
• defects\(i_j\) is the number of defects observed in the batch produced by factory \(i\) during batch \(j\).

• \(\mu_{i_j}\) is the mean number of defects corresponding to factory \(i\) (where \(i = 1, 2, \ldots , 20\)) during batch \(j\) (where \(j = 1, 2, \ldots , 5\)).

• newprocess\(i_j\), time_dev\(i_j\), and temp_dev\(i_j\) are the measurements for each variable that correspond to factory \(i\) during batch \(j\). For example, newprocess\(i_j\) indicates whether the batch produced by factory \(i\) during batch \(j\) used the new process.

• supplier\(_C_{ij}\) and supplier\(_B_{ij}\) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \(i\) during batch \(j\).

• \(b_i \sim N(0, \sigma^2_b)\) is a random-effects intercept for each factory \(i\) that accounts for factory-specific variation in quality.

```
% fitglme.mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...  
'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta,betanames,stats] = fixedEffects(glme);
```

```
stats

ans =

Fixed effect coefficients: DFMethod = 'residual', Alpha = 0.05

Name                  Estimate  SE       tStat    DF  pValue
{'(Intercept)'}       1.4689   0.15988   9.1875  94    9.8194e-15
{'newprocess'}        -0.3677   0.17755  -2.0708  94    0.041122
{'time_dev'}          -0.09452  0.82849  -0.11409 94   0.90941
{'temp_dev'}          -0.2832    0.9617  -0.29444 94    0.76907
{'supplier_C'}       -0.0719    0.07802  -0.9211  94    0.35936
{'supplier_B'}        0.07107   0.07739   0.91836 94    0.36078

Lower     Upper
   1.1515  1.7864
-0.72019  -0.01513
-1.7395  1.5505
-2.1926  1.6263
-0.22679  0.22679
-0.08258  0.22473
```

The returned results indicate, for example, that the estimated coefficient for temp\(_{dev}\) is -0.28317. Its large \(p\)-value, 0.76907, indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries Lower and Upper indicate that the 95% confidence interval for the coefficient for temp\(_{dev}\) is [-2.1926 , 1.6263]. This interval contains 0, which supports the conclusion that temp\(_{dev}\) is not statistically significant at the 5% significance level.

fixedEffects

Class: LinearMixedModel

Estimates of fixed effects and related statistics

Syntax

\[
\begin{align*}
\beta &= \text{fixedEffects}(\text{lme}) \\
[\beta, \text{betanames}] &= \text{fixedEffects}(\text{lme}) \\
[\beta, \text{betanames}, \text{stats}] &= \text{fixedEffects}(\text{lme}) \\
[\beta, \text{betanames}, \text{stats}] &= \text{fixedEffects}(\text{lme}, \text{Name, Value})
\end{align*}
\]

Description

\(\beta = \text{fixedEffects}(\text{lme})\) returns the estimated fixed-effects coefficients, \(\beta\), of the linear mixed-effects model \(\text{lme}\).

\([\beta, \text{betanames}] = \text{fixedEffects}(\text{lme})\) also returns the names of estimated fixed-effects coefficients in \(\text{betanames}\). Each name corresponds to a fixed-effects coefficient in \(\beta\).

\([\beta, \text{betanames}, \text{stats}] = \text{fixedEffects}(\text{lme})\) also returns the estimated fixed-effects coefficients of the linear mixed-effects model \(\text{lme}\) and related statistics in \(\text{stats}\).

\([\beta, \text{betanames}, \text{stats}] = \text{fixedEffects}(\text{lme}, \text{Name, Value})\) also returns the estimated fixed-effects coefficients of the linear mixed-effects model \(\text{lme}\) and related statistics with additional options specified by one or more \text{Name, Value} pair arguments.

Input Arguments

\text{lme} — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmmatrix.

Name-Value Pair Arguments

Specify optional comma-separated pairs of \text{Name, Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \text{Name1, Value1, ..., NameN, ValueN}.

\text{Alpha} — Significance level
0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of \text{'Alpha'} and a scalar value in the range 0 to 1. For a value \(\alpha\), the confidence level is 100*(1-\(\alpha\))%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: \text{'Alpha', 0.01}
Data Types: single | double

**DFMethod — Method for computing approximate degrees of freedom**

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for the t-statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

- 'residual': Default. The degrees of freedom are assumed to be constant and equal to \( n - p \), where \( n \) is the number of observations and \( p \) is the number of fixed effects.
- 'satterthwaite': Satterthwaite approximation.
- 'none': All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod','satterthwaite'

**Output Arguments**

**beta — Fixed-effects coefficients estimates**

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model lme, returned as a vector.

**betanames — Names of fixed-effects coefficients**

table

Names of fixed-effects coefficients in beta, returned as a table.

**stats — Fixed-effects estimates and related statistics**

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

- **Name**: Name of the fixed effect coefficient
- **Estimate**: Estimated coefficient value
- **SE**: Standard error of the estimate
- **tStat**: \( t \)-statistic for a test that the coefficient is zero
- **DF**: Estimated degrees of freedom for the \( t \)-statistic
- **pValue**: \( p \)-value for the \( t \)-statistic
- **Lower**: Lower limit of a 95% confidence interval for the fixed-effect coefficient
- **Upper**: Upper limit of a 95% confidence interval for the fixed-effect coefficient
Examples

Display Fixed-Effects Coefficient Estimates and Names

Load the sample data.

load('weight.mat');

The data set weight contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define Subject and Program as categorical variables.

tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

[beta,betanames] = fixedEffects(lme)

beta = 9×1

    {'Program_C' }    
    {'Program_D' }    
    {'Week' }         
    {'Program_B:Week'} 
    {'Program_C:Week'} 
    {'Program_D:Week'}
Compute Coefficient Estimates and Related Statistics

Load the sample data.

load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

tbl = table(Acceleration,Horsepower,Model_Year,MPG);

Fit the model.

lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');

Compute the fixed-effects coefficients estimates and related statistics.

[~,~,stats] = fixedEffects(lme)

stats =

Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05

<table>
<thead>
<tr>
<th>Name</th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>DF</th>
</tr>
</thead>
<tbody>

1.7075e-05  -0.84661    -0.31992
5.188e-76   -0.18382    -0.15527

The small \( p \)-values (under \( p \)Value) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Load the sample data.

load('shift.mat');

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.
Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```matlab
[-,-,stats] = fixedEffects(lme,'alpha',0.01)
```

```matlab
stats =
   Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01

     Name               Estimate     SE       tStat      DF    pValue
           '(Intercept)'     3.1196    0.88681     3.5178    12    0.0042407
          'Shift_Morning'   -0.3868     0.48344    -0.80009    12    0.43921
          'Shift_Night'     1.9856     0.48344      4.1072    12    0.0014535

    Lower    Upper
  0.41081    5.8284
-1.8635    1.0899
 0.5089    3.4623
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```matlab
[-,-,stats] = fixedEffects(lme,'DFMethod','satterthwaite','alpha',0.01)
```

```matlab
stats =
   Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01

     Name               Estimate     SE       tStat      DF    pValue
           '(Intercept)'     3.1196    0.88681     3.5178    6.123    0.01214
          'Shift_Morning'   -0.3868     0.48344    -0.80009       10    0.44225
          'Shift_Night'     1.9856     0.48344      4.1072       10    0.00212

    Lower    Upper
-0.14122    6.3804
-1.919    1.1454
 0.45343    3.5178
```

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger p-values (pValue) and larger confidence intervals (see Lower and Upper).

fpdf

F probability density function

Syntax

Y = fpdf(X,V1,V2)

Description

Y = fpdf(X,V1,V2) computes the F pdf at each of the values in X using the corresponding numerator degrees of freedom V1 and denominator degrees of freedom V2. X, V1, and V2 can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. V1 and V2 parameters must contain real positive values, and the values in X must lie on the interval [0 Inf].

The probability density function for the F distribution is

\[ y = f(x | \nu_1, \nu_2) = \frac{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right)}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{2}\right)^{\nu_1/2} \left(\frac{\nu_2}{2}\right)^{-\nu_2/2} \frac{x^{\nu_1/2} - 2^{-\nu_1/2}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)x\right]^{(\nu_1 + \nu_2)/2}} \]

Examples

\[
y = fpdf(1:6,2,2)
\]
\[
y =
\begin{align*}
0.2500 & 0.1111 & 0.0625 & 0.0400 & 0.0278 & 0.0204 \\
\end{align*}
\]

\[
z = fpdf(3,5:10,5:10)
\]
\[
z =
\begin{align*}
0.0689 & 0.0659 & 0.0620 & 0.0577 & 0.0532 & 0.0487 \\
\end{align*}
\]

“F Distribution” on page B-45

Introduced before R2006a
fracfact

Fractional factorial design

Syntax

\[ X = \text{fracfact}(\text{gen}) \]
\[ [X,\text{conf}] = \text{fracfact}(\text{gen}) \]
\[ [X,\text{conf}] = \text{fracfact}(\text{gen},\text{Name,Value}) \]

Description

\( X = \text{fracfact}(\text{gen}) \) creates the two-level fractional factorial design defined by the generator gen.

\([X,\text{conf}] = \text{fracfact}(\text{gen})\) returns a cell array of character vectors containing the confounding pattern for the design.

\([X,\text{conf}] = \text{fracfact}(\text{gen},\text{Name,Value})\) creates a fractional factorial designs with additional options specified by one or more Name,Value pair arguments.

Input Arguments

\text{gen}

Either a string array or cell array of character vectors where each element contains one “word,” or a character array or string scalar consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents value 1, 'b' represents value 2, ..., 'A' represents value 27, ..., 'Z' represents value 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a \(2^K\) full-factorial design. \(K\) is the number of letters of the alphabet in \text{gen}.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

\text{FactorNames}

String array or cell array specifying the name for each factor.

\textbf{Default}: \{'X1','X2',\ldots\}

\text{MaxInt}

Positive integer setting the maximum level of interaction to include in the confounding output.

\textbf{Default}: 2
Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

• N = 2^K, where K is the number of letters of the alphabet in gen.
• P is the number of words in gen.

Because X is a two-level design, the components of X are ±1. For the meaning of X, see “Fractional Factorial Designs” on page 27-5.

conf

Cell array of character vectors containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

x = fracfact('a b c abc')

x =

-1 -1 -1 -1
-1 -1 1 1
-1 1 -1 1
-1 1 1 -1
1 -1 -1 1
1 -1 1 -1
1 1 -1 -1
1 1 1 1

Find generators for a six-factor design that uses four factors and achieves resolution IV using fracfactgen. Use the result to specify the design:

generators = fracfactgen('a b c d e f',4, ... % 4 factors
4) % resolution 4

generators =
'a'
'b'
'c'
'd'
'bcd'
'acd'

x = fracfact(generators)

x =

-1 -1 -1 -1 -1 -1
-1 -1 -1 1 1 1
-1 1 -1 1 1 1
-1 1 -1 1 1 -1
1 1 -1 1 -1 1
1 1 1 1 1 1

32-2219
-1 1 1 -1 -1 1
-1 1 1 1 1 -1
1 -1 -1 -1 -1 1
1 -1 -1 1 1 -1
1 -1 1 -1 1 -1
1 -1 1 1 -1 1
1 1 -1 -1 1 1
1 1 -1 1 -1 -1
1 1 1 -1 -1 -1
1 1 1 1 1 1

“Fractional Factorial Designs” on page 27-5

Introduced before R2006a
fracfactgen

Fractional factorial design generators

Syntax

generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)

Description

generators = fracfactgen(terms) uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by terms. terms is a character vector or string scalar consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a'- 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, terms = 'a b c ab ac'. Single-letter words indicate main effects to be estimated; multiple-letter words indicate interactions. Alternatively, terms is an m-by-n matrix of 0s and 1s where m is the number of model terms to be estimated and n is the number of factors. For example, if terms contains rows [0 1 0 0] and [1 0 0 1], then the factor b and the interaction between factors a and d are included in the model. generators is a cell array of character vectors with one generator per cell. Pass generators to fracfact to produce the fractional-factorial design and corresponding confounding pattern.

generators = fracfactgen(terms,k) returns generators for a two-level fractional-factorial design with 2^k-runs, if possible. If k is [], fracfactgen finds the smallest design.

generators = fracfactgen(terms,k,R) finds a design with resolution R, if possible. The default resolution is 3.

A design of resolution R is one in which no n-factor interaction is confounded with any other effect containing less than R - n factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If fracfactgen is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

generators = fracfactgen(terms,k,R,basic) also accepts a vector basic specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in terms.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require 2^4 = 16 runs. The fracfactgen function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only 2^3 = 8 runs:
generators = fracfactgen('a b c d',3,4)
generators =
' a'
'b'
'c'
'abc'

The more economical design and the corresponding confounding pattern are returned by fracfact:

[dfF, confounding] = fracfact(generators)
dfF =
-1 -1 -1 -1
-1 -1 1 1
-1 1 -1 1
-1 1 1 -1
1 -1 -1 1
1 -1 1 -1
1 1 -1 -1
1 1 1 1

confounding =
'Term'     'Generator'    'Confounding'
'X1'       'a'            'X1'
'X2'       'b'            'X2'
'X3'       'c'            'X3'
'X4'       'abc'          'X4'
'X1*X2'    'ab'           'X1*X2 + X3*X4'
'X1*X3'    'ac'           'X1*X3 + X2*X4'
'X1*X4'    'bc'           'X1*X4 + X2*X3'
'X2*X3'    'bc'           'X1*X4 + X2*X3'
'X2*X4'    'ac'           'X1*X3 + X2*X4'
'X3*X4'    'ab'           'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between \( X_1 \) and \( X_2 \) is confounded by the two-way interaction between \( X_3 \) and \( X_4 \).

Topics

“Fractional Factorial Designs” on page 27-5

Introduced in R2006a
friedman

Friedman's test

Syntax

\[
p = \text{friedman}(x,\text{reps})
\]
\[
p = \text{friedman}(x,\text{reps,displayopt})
\]
\[
[p,tbl] = \text{friedman}(\_\_)
\]
\[
[p,tbl,stats] = \text{friedman}(\_\_)
\]

Description

\[
p = \text{friedman}(x,\text{reps})\] returns the \( p \)-value for the nonparametric Friedman's test to compare column effects in a two-way layout. friedman tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

\[
p = \text{friedman}(x,\text{reps,displayopt})\] enables the ANOVA table display when displayopt is 'on' (default) and suppresses the display when displayopt is 'off'.

\[
[p,tbl] = \text{friedman}(\_\_)\] returns the ANOVA table (including column and row labels) in cell array tbl.

\[
[p,tbl,stats] = \text{friedman}(\_\_)\] also returns a structure stats that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

\[
\text{load popcorn}
\]
\[
\text{popcorn}
\]
\[
\text{popcorn} = 6\times3
\]
\[
\begin{array}{ccc}
5.5000 & 4.5000 & 3.5000 \\
5.5000 & 4.5000 & 4.0000 \\
6.0000 & 4.0000 & 3.0000 \\

7.0000 & 5.5000 & 5.0000 \\
7.0000 & 5.0000 & 4.5000
\end{array}
\]

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix popcorn are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.
Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

\[ p = \text{friedman}(\text{popcorn}, 3) \]

Test for column effects after row effects are removed

\[ p = 0.0010 \]

The small value of \( p = 0.001 \) indicates the popcorn brand affects the yield of popcorn.

**Input Arguments**

\( x \) — Sample data matrix

Sample data for the hypothesis test, specified as a matrix. The columns of \( x \) represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input 
\( \text{reps} \) indicates the number of replicates in each “cell,” which must be constant.

Data Types: \text{single} | \text{double}

\( \text{reps} \) — Number of replicates per cell

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: \text{single} | \text{double}

\( \text{displayopt} \) — ANOVA table display option

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If \( \text{displayopt} \) is 'on', then \text{friedman} displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if \( \text{reps} \) is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:
The first shows the source of the variability.
The second shows the Sum of Squares (SS) due to each source.
The third shows the degrees of freedom (df) associated with each source.
The fourth shows the Mean Squares (MS), which is the ratio SS/df.
The fifth shows Friedman's chi-square statistic.
The sixth shows the $p$ value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the Edit menu.

**Output Arguments**

$p$ — $p$-value  
scalar value in the range $[0,1]$

$p$-value of the test, returned as a scalar value in the range $[0,1]$. $p$ is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of $p$ cast doubt on the validity of the null hypothesis.

tbl — ANOVA table  
cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the $p$ value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the Edit menu.

stats — Test data  
structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

**More About**

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects.
Friedman’s test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest. The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each “cell,” which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively:

\[
\begin{bmatrix}
    x_{111} & x_{121} & x_{131} \\
    x_{112} & x_{122} & x_{132} \\
    x_{211} & x_{221} & x_{231} \\
    x_{212} & x_{222} & x_{232} \\
\end{bmatrix}
\]

Friedman’s test assumes a model of the form

\[x_{ijk} = \mu + \alpha_i + \beta_j + \epsilon_{ijk}\]

where \(\mu\) is an overall location parameter, \(\alpha_i\) represents the column effect, \(\beta_j\) represents the row effect, and \(\epsilon_{ijk}\) represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The \(p\) that `friedman` returns is the \(p\) value for the null hypothesis that \(\alpha_i = 0\). If the \(p\) value is near zero, this casts doubt on the null hypothesis. A sufficiently small \(p\) value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical \(p\) value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the \(p\) value is less than 0.05 or 0.01.

Friedman’s test makes the following assumptions about the data in \(X\):

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

Introduced before R2006a
frnd

$F$ random numbers

Syntax

$R = \text{frnd}(V1,V2)$
$R = \text{frnd}(V1,V2,m,n,...)$
$R = \text{frnd}(V1,V2,[m,n,...])$

Description

$R = \text{frnd}(V1,V2)$ generates random numbers from the $F$ distribution with numerator degrees of freedom $V1$ and denominator degrees of freedom $V2$. $V1$ and $V2$ can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for $V1$ or $V2$ is expanded to a constant array with the same dimensions as the other input. $V1$ and $V2$ parameters must contain real positive values.

$R = \text{frnd}(V1,V2,m,n,...)$ or $R = \text{frnd}(V1,V2,[m,n,...])$ generates an $m$-by-$n$-by-... array containing random numbers from the $F$ distribution with parameters $V1$ and $V2$. $V1$ and $V2$ can each be scalars or arrays of the same size as $R$.

Examples

$n1 = \text{frnd}(1:6,1:6)$
$n1 = [0.0022 
    0.3121 
    3.0528 
    0.3189 
    0.2715 
    0.9539]$

$n2 = \text{frnd}(2,2,[2 3])$
$n2 = [0.3186 
    0.9727 
    3.0268 
    0.2052 
    148.5816 
    0.2191]$

$n3 = \text{frnd}([1 2 3;4 5 6],1,2,3)$
$n3 = [0.6233 
    0.2322 
    31.5458 
    2.5848 
    0.2121 
    4.4955]$

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.
For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**

“F Distribution” on page B-45

**Introduced before R2006a**
**fscchi2**

Univariate feature ranking for classification using chi-square tests

**Syntax**

```plaintext
idx = fscchi2(Tbl,ResponseVarName)
idx = fscchi2(Tbl,formula)
idx = fscchi2(Tbl,Y)
idx = fscchi2(X,Y)
idx = fscchi2(____,Name,Value)
[idx,scores] = fscchi2(____)
```

**Description**

`idx = fscchi2(Tbl,ResponseVarName)` ranks features (predictors) using chi-square tests on page 32-2238. The table `Tbl` contains predictor variables and a response variable, and `ResponseVarName` is the name of the response variable in `Tbl`. The function returns `idx`, which contains the indices of predictors ordered by predictor importance, meaning `idx(1)` is the index of the most important predictor. You can use `idx` to select important predictors for classification problems.

`idx = fscchi2(Tbl,formula)` specifies a response variable and predictor variables to consider among the variables in `Tbl` by using `formula`.

`idx = fscchi2(Tbl,Y)` ranks predictors in `Tbl` using the response variable `Y`.

`idx = fscchi2(X,Y)` ranks predictors in `X` using the response variable `Y`.

`idx = fscchi2(____,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify prior probabilities and observation weights.

`[idx,scores] = fscchi2(____)` also returns the predictor scores `scores`. A large score value indicates that the corresponding predictor is important.

**Examples**

**Rank Predictors in Matrix**

Rank predictors in a numeric matrix and create a bar plot of predictor importance scores.

Load the sample data.

```plaintext
load ionosphere
```

`ionosphere` contains predictor variables (`X`) and a response variable (`Y`).

Rank the predictors using chi-square tests.
[idx,scores] = fscchi2(X,Y);

The values in scores are the negative logs of the p-values. If a p-value is smaller than \( \text{eps}(0) \), then the corresponding score value is Inf. Before creating a bar plot, determine whether scores includes Inf values.

\[
\text{find(isinf(scores))}
\]

\[
\text{ans} =
\]

1x0 empty double row vector

scores does not include Inf values. If scores includes Inf values, you can replace Inf by a large numeric number before creating a bar plot for visualization purposes. For details, see “Rank Predictors in Table” on page 32-2231.

Create a bar plot of the predictor importance scores.

\[
\text{bar(scores(idx))}
\]
\[
\text{xlabel('Predictor rank')}
\]
\[
\text{ylabel('Predictor importance score')}
\]

Select the top five most important predictors. Find the columns of these predictors in X.

\[
\text{idx}(1:5)
\]

\[
\text{ans} = 1x5
\]
The fifth column of \( X \) is the most important predictor of \( Y \).

**Rank Predictors in Table**

Rank predictors in a table and create a bar plot of predictor importance scores.

If your data is in a table and \texttt{fscchi2} ranks a subset of the variables in the table, then the function indexes the variables using only the subset. Therefore, a good practice is to move the predictors that you do not want to rank to the end of the table. Move the response variable and observation weight vector as well. Then, the indexes of the output arguments are consistent with the indexes of the table.

Load the census1994 data set.

```matlab
load census1994
```

The table \texttt{adultdata} in \texttt{census1994} contains demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. Display the first three rows of the table.

```matlab
head(adultdata,3)
```

In the table \texttt{adultdata}, the third column \texttt{fnlwgt} is the weight of the samples, and the last column \texttt{salary} is the response variable. Move \texttt{fnlwgt} to the left of \texttt{salary} by using the \texttt{movevars} function.

```matlab
adultdata = movevars(adultdata,'fnlwgt','before','salary');
head(adultdata,3)
```

Rank the predictors in \texttt{adultdata}. Specify the column \texttt{salary} as a response variable, and specify the column \texttt{fnlwgt} as observation weights.

```matlab
[idx,scores] = fscchi2(adultdata,'salary','Weights','fnlwgt');
```

The values in \texttt{scores} are the negative logs of the \( p \)-values. If a \( p \)-value is smaller than \texttt{eps(0)}, then the corresponding score value is \texttt{Inf}. Before creating a bar plot, determine whether \texttt{scores} includes \texttt{Inf} values.
idxInf = find(isinf(scores))
idxInf = 1x8
1 3 4 5 6 7 10 12

scores includes eight Inf values.

Create a bar plot of predictor importance scores. Use the predictor names for the x-axis tick labels.

figure
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
xticklabels(strrep(adultdata.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)

The bar function does not plot any bars for the Inf values. For the Inf values, plot bars that have the same length as the largest finite score.

hold on
bar(scores(idx(length(idxInf)+1))*ones(length(idxInf),1))
legend('Finite Scores','Inf Scores')
hold off

The bar graph displays finite scores and Inf scores using different colors.
Input Arguments

Tbl — Sample data
table

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

- If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName. If Tbl also contains the observation weights, then you can specify the weights by using Weights.
- If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify the subset of variables by using formula.
- If Tbl does not contain the response variable, then specify a response variable by using Y. The response variable and Tbl must have the same number of rows.

If fscchi2 uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The values in the 'CategoricalPredictors' name-value pair argument and the output argument idx do not count the predictors that the function does not rank.

fscchi2 considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Tbl for a response variable to be missing values. fscchi2 does not use observations with missing values for a response variable.

Data Types: table

ResponseVarName — Response variable name
character vector or string scalar containing name of variable in Tbl

Response variable name, specified as a character vector or string scalar containing the name of a variable in Tbl.

For example, if a response variable is the column Y of Tbl (Tbl.Y), then specify ResponseVarName as 'Y'.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y ~ X1 + X2 + X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors, use a formula. If you specify a formula, then fscchi2 does not rank any variables in Tbl that do not appear in formula.
The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers. For details, see “Tips” on page 32-2237.

Data Types: char | string

**Y — Response variable**
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors. Each row of Y represents the labels of the corresponding row of X.

fscchi2 considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. fscchi2 does not use observations with missing values for Y.

Data Types: single | double | categorical | logical | char | string | cell

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'NumBins',20,'UseMissing',true sets the number of bins as 20 and specifies to use missing values in predictors for ranking.

**CategoricalPredictors — List of categorical predictors**
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

List of categorical predictors, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the names in Tbl. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the names in Tbl.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fscchi2 assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fscchi2 assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

If fscchi2 uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the predictors that the function does not rank.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**ClassNames — Names of classes to use for ranking**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for ranking, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y` or the response variable in Tbl.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Specify the order of the `Prior` dimensions that corresponds to the class order.
- Select a subset of classes for ranking. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To rank predictors using observations from classes `a` and `c` only, specify `'ClassNames',{'a','c'}`.

The default value for `'ClassNames'` is the set of all distinct class names in `Y` or the response variable in Tbl. The default `'ClassNames'` value has mathematical ordering if the response variable is ordinal. Otherwise, the default value has alphabetical ordering.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**NumBins — Number of bins for binning continuous predictors**

10 (default) | positive integer scalar

Number of bins for binning continuous predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

Example: `'NumBins',50`

Data Types: `single` | `double`
**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- Character vector or string scalar.
  - 'empirical' determines class probabilities from class frequencies in the response variable in Y or Tbl. If you pass observation weights, fscchi2 uses the weights to compute the class probabilities.
  - 'uniform' sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of 'Prior', also specify the ClassNames name-value pair argument.
- Structure S with two fields.
  - S.ClassNames contains the class names as a variable of the same type as the response variable in Y or Tbl.
  - S.ClassProbs contains a vector of corresponding probabilities.

If you set values for both 'Weights' and 'Prior', fscchi2 normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

**UseMissing — Indicator for whether to use or discard missing values in predictors**

false (default) | true

Indicator for whether to use or discard missing values in predictors, specified as the comma-separated pair consisting of 'UseMissing' and either true to use or false to discard missing values in predictors for ranking.

fscchi2 considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values to be missing values.

If you specify 'UseMissing',true, then fscchi2 uses missing values for ranking. For a categorical variable, fscchi2 treats missing values as an extra category. For a continuous variable, fscchi2 places NaN values in a separate bin for binning.

If you specify 'UseMissing',false, then fscchi2 does not use missing values for ranking. Because fscchi2 computes importance scores individually for each predictor, the function does not discard an entire row when values in the row are partially missing. For each variable, fscchi2 uses all values that are not missing.

Example: 'UseMissing',true

Data Types: logical

**Weights — Observation weights**

ones(size(X,1),1) (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The function weights the observations in each row of X.
or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weight vector is the column W of Tbl (Tbl.W), then specify 'Weights,'W'.

fscchi2 normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: single | double | char | string

Output Arguments

idx — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in X or Tbl ordered by predictor importance, returned as a 1-by-\( r \) numeric vector, where \( r \) is the number of ranked predictors.

If fscchi2 uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. For example, suppose Tbl includes 10 columns and you specify the last five columns of Tbl as the predictor variables by using formula. If \( \text{idx}(3) \) is 5, then the third most important predictor is the 10th column in Tbl, which is the fifth predictor in the subset.

scores — Predictor scores
numeric vector

Predictor scores, returned as a 1-by-\( r \) numeric vector, where \( r \) is the number of ranked predictors.

A large score value indicates that the corresponding predictor is important.

- If you use X to specify the predictors or use all the variables in Tbl as predictors, then the values in scores have the same order as the predictors in X or Tbl.
- If you specify a subset of variables in Tbl as predictors, then the values in scores have the same order as the subset.

For example, suppose Tbl includes 10 columns and you specify the last five columns of Tbl as the predictor variables by using formula. Then, \( \text{score}(3) \) contains the score value of the 8th column in Tbl, which is the third predictor in the subset.

Tips

- If you specify the response variable and predictor variables by using the input argument formula, then the variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

\[
\text{cellfun(@(isvarname,Tbl.Properties.VariableNames)}
\]

32-2237
If the variable names in Tbl are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

**Algorithms**

**Univariate Feature Ranking Using Chi-Square Tests**

- fscchi2 examines whether each predictor variable is independent of a response variable by using individual chi-square tests. A small \( p \)-value of the test statistic indicates that the corresponding predictor variable is dependent on the response variable, and, therefore is an important feature.
- The output scores is \(-\log(p)\). Therefore, a large score value indicates that the corresponding predictor is important. If a \( p \)-value is smaller than \( \text{eps}(0) \), then the output is \( \text{Inf} \).
- fscchi2 examines a continuous variable after binning, or discretizing, the variable. You can specify the number of bins using the 'NumBins' name-value pair argument.

**Topics**

“Introduction to Feature Selection” on page 15-49

**Introduced in R2020a**
fscmrmr

Rank features for classification using minimum redundancy maximum relevance (MRMR) algorithm

Syntax

idx = fscmrmr(Tbl,ResponseVarName)
idx = fscmrmr(Tbl,formula)
idx = fscmrmr(Tbl,Y)
idx = fscmrmr(X,Y)
idx = fscmrmr(____,Name,Value)
[idx,scores] = fscmrmr(____)

Description

idx = fscmrmr(Tbl,ResponseVarName) ranks features (predictors) using the MRMR algorithm on page 32-2249. The table Tbl contains predictor variables and a response variable, and ResponseVarName is the name of the response variable in Tbl. The function returns idx, which contains the indices of predictors ordered by predictor importance. You can use idx to select important predictors for classification problems.

idx = fscmrmr(Tbl,formula) specifies a response variable and predictor variables to consider among the variables in Tbl by using formula.

idx = fscmrmr(Tbl,Y) ranks predictors in Tbl using the response variable Y.

idx = fscmrmr(X,Y) ranks predictors in X using the response variable Y.

idx = fscmrmr(____,Name,Value) specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify prior probabilities and observation weights.

[idx,scores] = fscmrmr(____) also returns the predictor scores scores. A large score value indicates that the corresponding predictor is important.

Examples

Rank Predictors by Importance

Load the sample data.
load ionosphere

Rank the predictors based on importance.
[idx,scores] = fscmrmr(X,Y);

Create a bar plot of the predictor importance scores.
The drop in score between the first and second most important predictors is large, while the drops after the sixth predictor are relatively small. A drop in the importance score represents the confidence of feature selection. Therefore, the large drop implies that the software is confident of selecting the most important predictor. The small drops indicate that the difference in predictor importance are not significant.

Select the top five most important predictors. Find the columns of these predictors in $X$.

```matlab
idx(1:5)
ans = 1x5
      5     4     1     7    24
```

The fifth column of $X$ is the most important predictor of $Y$. 

```matlab
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
```
Select Features and Compare Accuracies of Two Classification Models

Find important predictors by using fscmrmr. Then compare the accuracies of the full classification model (which uses all the predictors) and a reduced model that uses the five most important predictors by using testckfold.

Load the census1994 data set.

classificationmodels = load('census1994')

The table adultdata in census1994 contains demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. Display the first three rows of the table.

head(adultdata,3)

ans=3×15 table
  age    workClass          fnlwgt      education    education_num      marital_status         occupation        relationship     race     sex     capital_gain    capital_loss    hours_per_week    native_country    salary
  __    ________________    __________    _________    _____________    __________________    _________________    _____________    _____    ____    ____________    ____________    ______________    ______________    ______
  39    State-gov                77516    Bachelors         13          Never-married         Adm-clerical         Not-in-family    White    Male        2174             0                40          United-States     <=50K
  50    Self-emp-not-inc         83311    Bachelors         13          Married-civ-spouse    Exec-managerial      Husband          White    Male           0             0                13          United-States     <=50K
  38    Private             2.1565e+05    HS-grad            9          Divorced              Handlers-cleaners    Not-in-family    White    Male           0             0                40          United-States     <=50K

The output arguments of fscmrmr include only the variables ranked by the function. Before passing a table to the function, move the variables that you do not want to rank, including the response variable and weight, to the end of the table so that the order of the output arguments is consistent with the order of the table.

In the table adultdata, the third column fnlwgt is the weight of the samples, and the last column salary is the response variable. Move fnlwgt to the left of salary by using the movevars function.

adultdata = movevars(adultdata,'fnlwgt','before','salary');
head(adultdata,3)

ans=3×15 table
  age    workClass        education    education_num      marital_status         occupation        relationship     race     sex     capital_gain    capital_loss    hours_per_week    native_country       fnlwgt      salary
  __    ________________    _________    _____________    __________________    _________________    _____________    _____    ____    ____________    ____________    ______________    ______________    __________    ______
  39    State-gov           Bachelors         13          Never-married         Adm-clerical         Not-in-family    White    Male        2174             0                40          United-States        77516   <=50K
  50    Self-emp-not-inc    Bachelors         13          Married-civ-spouse    Exec-managerial      Husband          White    Male           0             0                13          United-States        83311   <=50K
  38    Private             HS-grad            9          Divorced              Handlers-cleaners    Not-in-family    White    Male           0             0                40          United-States     2.1565e+05    <=50K

Rank the predictors in adultdata. Specify the column salary as the response variable.

[idx,scores] = fscmrmr(adultdata,'salary','Weights','fnlwgt');

Create a bar plot of predictor importance scores. Use the predictor names for the x-axis tick labels.

bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
exticklabels(strrep(adultdata.Properties.VariableNames(idx),'_','_'))
extickangle(45)
The five most important predictors are relationship, capital_loss, capital_gain, education, and hours_per_week.

Compare the accuracy of a classification tree trained with all predictors to the accuracy of one trained with the five most important predictors.

Create a classification tree template using the default options.

\[ C = \text{templateTree}; \]

Define the table tbl1 to contain all predictors and the table tbl2 to contain the five most important predictors.

\[
\begin{align*}
\text{tbl1} &= \text{adultdata}(:,\text{adultdata.Properties.VariableNames(idx(1:13))}); \\
\text{tbl2} &= \text{adultdata}(:,\text{adultdata.Properties.VariableNames(idx(1:5)))};
\end{align*}
\]

Pass the classification tree template and the two tables to the testckfold function. The function compares the accuracies of the two models by repeated cross-validation. Specify 'Alternative','greater' to test the null hypothesis that the model with all predictors is, at most, as accurate as the model with the five predictors. The 'greater' option is available when 'Test' is '5x2t' (5-by-2 paired t test) or '10x10t' (10-by-10 repeated cross-validation t test).

\[
\begin{align*}
[h,p] &= \text{testckfold}(C,C,tbl1,tbl2,\text{adultdata.salary},'Weights',\text{adultdata.fnlwgt},'Alternative','greater',
\end{align*}
\]

\[ h = \text{logical} \]

0
p = 0.9966

h equals 0 and the p-value is almost 1, indicating failure to reject the null hypothesis. Using the model with the five predictors does not result in loss of accuracy compared to the model with all the predictors.

Now train a classification tree using the selected predictors.

mdl = fitctree(adultdata,'salary ~ relationship + capital_loss + capital_gain + education + hours_per_week',...
'Weights',adultdata.fnlwgt)

mdl =  
    ClassificationTree
    PredictorNames: {1x5 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [1 2]
    ClassNames: [<=50K  >50K]
    ScoreTransform: 'none'
    NumObservations: 32561

Properties, Methods

Input Arguments

Tbl — Sample data
     table

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

• If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName. If Tbl also contains the observation weights, then you can specify the weights by using Weights.

• If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify the subset of variables by using formula.

• If Tbl does not contain the response variable, then specify a response variable by using Y. The response variable and Tbl must have the same number of rows.

If fscmrmr uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The values in the 'CategoricalPredictors' name-value pair argument and the output argument idx do not count the predictors that the function does not rank.
fscmrmr considers NaN, "" (empty character vector), "" (empty string), <missing>, and <undefined> values in Tbl for a response variable to be missing values. fscmrmr does not use observations with missing values for a response variable.

Data Types: table

ResponseVarName — Response variable name
character vector or string scalar containing name of variable in Tbl

Response variable name, specified as a character vector or string scalar containing the name of a variable in Tbl.

For example, if a response variable is the column Y of Tbl (Tbl.Y), then specify ResponseVarName as 'Y'.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y ~ X1 + X2 + X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors, use a formula. If you specify a formula, then fscmrmr does not rank any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers. For details, see “Tips” on page 32-2248.

Data Types: char | string

Y — Response variable
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors. Each row of Y represents the labels of the corresponding row of X.

fscmrmr considers NaN, "" (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. fscmrmr does not use observations with missing values for Y.

Data Types: single | double | categorical | logical | char | string | cell

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: single | double
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'CategoricalPredictors',[1 2],'Verbose',2 specifies the first two predictor variables as categorical variables and specifies the verbosity level as 2.

CategoricalPredictors — List of categorical predictors

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

List of categorical predictors, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the names in Tbl. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the names in Tbl.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fscmrmr assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fscmrmr assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

If fscmrmr uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The 'CategoricalPredictors' values do not count the predictors that the function does not rank.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

ClassNames — Names of classes to use for ranking

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for ranking, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y or the response variable in Tbl.

If ClassNames is a character array, then each element must correspond to one row of the array.
Use 'ClassNames' to:

- Specify the order of the Prior dimensions that corresponds to the class order.
- Select a subset of classes for ranking. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To rank predictors using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for 'ClassNames' is the set of all distinct class names in Y or the response variable in Tbl. The default 'ClassNames' value has mathematical ordering if the response variable is ordinal. Otherwise, the default value has alphabetical ordering.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- Character vector or string scalar.
  - 'empirical' determines class probabilities from class frequencies in the response variable in Y or Tbl. If you pass observation weights, fscmrmr uses the weights to compute the class probabilities.
  - 'uniform' sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of 'Prior', also specify the ClassNames name-value pair argument.
- Structure S with two fields.
  - S.ClassNames contains the class names as a variable of the same type as the response variable in Y or Tbl.
  - S.ClassProbs contains a vector of corresponding probabilities.

If you set values for both 'Weights' and 'Prior', fscmrmr normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

UseMissing — Indicator for whether to use or discard missing values in predictors

false (default) | true

Indicator for whether to use or discard missing values in predictors, specified as the comma-separated pair consisting of 'UseMissing' and either true to use or false to discard missing values in predictors for ranking.

fscmrmr considers NaN, '', (empty character vector), "" (empty string), <missing>, and <undefined> values to be missing values.

If you specify 'UseMissing', true, then fscmrmr uses missing values for ranking. For a categorical variable, fscmrmr treats missing values as an extra category. For a continuous variable, fscmrmr places NaN values in a separate bin for binning.
If you specify 'UseMissing',false, then fscmrmr does not use missing values for ranking. Because fscmrmr computes mutual information for each pair of variables, the function does not discard an entire row when values in the row are partially missing. fscmrmr uses all pair values that do not include missing values.

Example: 'UseMissing',true
Data Types: logical

Verbose — Verbosity level
0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and a nonnegative integer. The value of Verbose controls the amount of diagnostic information that the software displays in the Command Window.

- 0 — fscmrmr does not display any diagnostic information.
- 1 — fscmrmr displays the elapsed times for computing “Mutual Information” on page 32-2248 and ranking predictors.
- ≥ 2 — fscmrmr displays the elapsed times and more messages related to computing mutual information. The amount of information increases as you increase the 'Verbose' value.

Example: 'Verbose',1
Data Types: single | double

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The function weights the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weight vector is the column W of Tbl (Tbl.W), then specify 'Weights,'W'.

fscmrmr normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: single | double | char | string

Output Arguments

idx — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in X or Tbl ordered by predictor importance, returned as a 1-by-r numeric vector, where r is the number of ranked predictors.

If fscmrmr uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. For example, suppose Tbl includes 10 columns and you specify the last five
columns of Tbl as the predictor variables by using formula. If \( \text{idx}(3) = 5 \), then the third most important predictor is the 10th column in Tbl, which is the fifth predictor in the subset.

**scores — Predictor scores**

numeric vector

Predictor scores, returned as a 1-by-\( n \) numeric vector, where \( n \) is the number of ranked predictors.

A large score value indicates that the corresponding predictor is important. Also, a drop in the feature importance score represents the confidence of feature selection. For example, if the software is confident of selecting a feature \( x \), then the score value of the next most important feature is much smaller than the score value of \( x \).

- If you use \( X \) to specify the predictors or use all the variables in Tbl as predictors, then the values in scores have the same order as the predictors in \( X \) or Tbl.
- If you specify a subset of variables in Tbl as predictors, then the values in scores have the same order as the subset.

For example, suppose Tbl includes 10 columns and you specify the last five columns of Tbl as the predictor variables by using formula. Then, score(3) contains the score value of the 8th column in Tbl, which is the third predictor in the subset.

**More About**

**Mutual Information**

The mutual information between two variables measures how much uncertainty of one variable can be reduced by knowing the other variable.

The mutual information \( I \) of the discrete random variables \( X \) and \( Z \) is defined as

\[
I(X, Z) = \sum_{i,j} P(X = x_i, Z = z_j) \log \frac{P(X = x_i, Z = z_j)}{P(X = x_i)P(Z = z_j)}
\]

If \( X \) and \( Z \) are independent, then \( I \) equals 0. If \( X \) and \( Z \) are the same random variable, then \( I \) equals the entropy of \( X \).

The fscmrmr function uses this definition to compute the mutual information values for both categorical (discrete) and continuous variables. fscmrmr discretizes a continuous variable into 256 bins or the number of unique values in the variable if it is less than 256. The function finds optimal bivariate bins for each pair of variables using the adaptive algorithm [2].

**Tips**

- If you specify the response variable and predictor variables by using the input argument formula, then the variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

\[
\text{cellfun(@(isvarname,Tbl.Properties.VariableNames)}
\]
If the variable names in `Tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

**Algorithms**

**Minimum Redundancy Maximum Relevance (MRMR) Algorithm**

The MRMR algorithm[1] finds an optimal set of features that is mutually and maximally dissimilar and can represent the response variable effectively. The algorithm minimizes the redundancy of a feature set and maximizing the relevance of a feature set to the response variable. The algorithm quantifies the redundancy and relevance using the mutual information of variables—pairwise mutual information of features and mutual information of a feature and the response. You can use this algorithm for classification problems.

The goal of the MRMR algorithm is to find an optimal set $S$ of features that maximizes $V_S$, the relevance of $S$ with respect to a response variable $y$, and minimizes $W_S$, the redundancy of $S$, where $V_S$ and $W_S$ are defined with mutual information on page 32-2248:

$$V_S = \frac{1}{|S|} \sum_{x \in S} I(x, y),$$

$$W_S = \frac{1}{|S|^2} \sum_{x, z \in S} I(x, z).$$

$|S|$ is the number of features in $S$.

Finding an optimal set $S$ requires considering all $2^{|\Omega|}$ combinations, where $\Omega$ is the entire feature set. Instead, the MRMR algorithm ranks features through the forward addition scheme, which requires $O(|\Omega|\cdot|S|)$ computations, by using the mutual information quotient (MIQ) value.

$$MIQ_x = \frac{V_x}{W_x},$$

where $V_x$ and $W_x$ are the relevance and redundancy of a feature, respectively:

$$V_x = I(x, y),$$

$$W_x = \frac{1}{|S|} \sum_{z \in S} I(x, z).$$

The `fscmrmr` function ranks all features in $\Omega$ and returns `idx` (the indices of features ordered by feature importance) using the MRMR algorithm. Therefore, the computation cost becomes $O(|\Omega|^2)$. The function quantifies the importance of a feature using a heuristic algorithm and returns `score`. A large score value indicates that the corresponding predictor is important. Also, a drop in the feature importance score represents the confidence of feature selection. For example, if the software is confident of selecting a feature $x$, then the score value of the next most important feature is much smaller than the score value of $x$. You can use the outputs to find an optimal set $S$ for a given number of features.

`fscmrmr` ranks features as follows:

1. Select the feature with the largest relevance, $\max_{x \in \Omega} V_x$. Add the selected feature to an empty set $S$. 

---

32-2249
Find the features with nonzero relevance and zero redundancy in the complement of $S$, $S^c$.

- If $S^c$ does not include a feature with nonzero relevance and zero redundancy, go to step 4.
- Otherwise, select the feature with the largest relevance, $\max_{x \in S^c} V_x$. Add the selected feature to the set $S$.

Repeat Step 2 until the redundancy is not zero for all features in $S^c$.

Select the feature that has the largest MIQ value with nonzero relevance and nonzero redundancy in $S^c$, and add the selected feature to the set $S$.

$$\max_{x \in S^c} \text{MIQ}_x = \max_{x \in S^c} \frac{I(x, y)}{\sum_{z \in S} I(x, z)}.$$  

Repeat Step 4 until the relevance is zero for all features in $S^c$.

Add the features with zero relevance to $S$ in random order.

The software can skip any step if it cannot find a feature that satisfies the conditions described in the step.

**Compatibility Considerations**

Specify `'UseMissing',true` to use missing values in predictors for ranking.

*Behavior changed in R2020a*

Starting in R2020a, you can specify whether to use or discard missing values in predictors for ranking by using the `'UseMissing'` name-value pair argument. The default value of `'UseMissing'` is `false` because most classification training functions in Statistics and Machine Learning Toolbox do not use missing values for training.

In R2019b, `fscmrmr` used missing values in predictors by default. To update your code, specify `'UseMissing',true`.

**Topics**

“Introduction to Feature Selection” on page 15-49
“Sequential Feature Selection” on page 15-61

**Introduced in R2019b**
**fscnca**

Feature selection using neighborhood component analysis for classification

**Syntax**

```matlab
mdl = fscnca(X,Y)
mdl = fscnca(X,Y,Name,Value)
```

**Description**

`mdl = fscnca(X,Y)` performs feature selection for classification using the predictors in `X` and responses in `Y`. `fscnca` learns the feature weights by using a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fscnca(X,Y,Name,Value)` performs feature selection for classification with additional options specified by one or more name-value pair arguments.

**Examples**

**Detect Relevant Features in Data Using NCA for Classification**

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```matlab
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = -ones(N,1);
y(X(:,3).*X(:,9)./X(:,15) < 0.4) = 1;
```

Fit the neighborhood component analysis model for classification.

```matlab
mdl = fscnca(X,y,'Solver','sgd','Verbose',1);
```

<td></td>
</tr>
<tr>
<td>obs</td>
<td>216x4000</td>
<td>345600</td>
<td>single</td>
<td></td>
</tr>
</tbody>
</table>

This example uses the high-resolution ovarian cancer data set that was generated using the WCX2 protein array. The data is from the FDA-NCI Clinical Proteomics Program Databank. After some preprocessing steps, the data set has two variables: obs and grp. The obs variable consists 216 observations with 4000 features. Each element in grp defines the group to which the corresponding row of obs belongs.

Divide data into training and test sets

Use cvpartition to divide data into a training set of size 160 and a test set of size 56. Both the training set and the test set have roughly the same group proportions as in grp.

fscnca correctly detects the relevant features.
rng(1); % For reproducibility

cvp = cvpartition(grp,'holdout',56)

cvp =  
Hold-out cross validation partition  
NumObservations: 216  
NumTestSets: 1  
TrainSize: 160  
TestSize: 56

Xtrain = obs(cvp.training,:);
ytrain = grp(cvp.training,:);
Xtest  = obs(cvp.test,:);
ytest  = grp(cvp.test,:);

**Determine if feature selection is necessary**

Compute generalization error without fitting.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','none');
L = loss(nca,Xtest,ytest)
```

```
L = 0.0893
```

This option computes the generalization error of the neighborhood component analysis (NCA) feature selection model using the initial feature weights (in this case the default feature weights) provided in `fscnca`.

Fit NCA without regularization parameter (Lambda = 0)

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Lambda',0,...
             'Solver','sgd','Standardize',true);
L = loss(nca,Xtest,ytest)
```

```
L = 0.0714
```

The improvement on the loss value suggests that feature selection is a good idea. Tuning the $\lambda$ value usually improves the results.

**Tune the regularization parameter for NCA using five-fold cross-validation**

Tuning $\lambda$ means finding the $\lambda$ value that produces the minimum classification loss. To tune $\lambda$ using cross-validation:

1. Partition the training data into five folds and extract the number of validation (test) sets. For each fold, `cvpartition` assigns four-fifths of the data as a training set, and one-fifth of the data as a test set.

   ```
cvp = cvpartition(ytrain,'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign $\lambda$ values and create an array to store the loss function values.

```
n = length(ytrain);
lambdavals = linspace(0,20,20)/n;
lossvals = zeros(length(lambdavals),numvalidsets);
```

2. Train the NCA model for each $\lambda$ value, using the training set in each fold.
3. Compute the classification loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this process for all folds and all $\lambda$ values.

```matlab
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fscnca(X,y,'FitMethod','exact', ...  
                      'Solver','sgd','Lambda',lambdavals(i), ...  
                      'IterationLimit',30,'GradientTolerance',1e-4, ...  
                      'Standardize',true);

        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','classiferror');
    end
end

Compute the average loss obtained from the folds for each $\lambda$ value.

meanloss = mean(lossvals,2);

Plot the average loss values versus the $\lambda$ values.

figure()
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```
Find the best lambda value that corresponds to the minimum average loss.

```
[~,idx] = min(meanloss) % Find the index
idx = 2
bestlambda = lambdavals(idx) % Find the best lambda value
bestlambda = 0.0066
bestloss = meanloss(idx)
bestloss = 0.0250
```

**Fit the nca model on all data using best \( \lambda \) and plot the feature weights**

Use the solver lbfgs and standardize the predictor values.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Solver','sgd',...  'Lambda',bestlambda,'Standardize',true,'Verbose',1);
```

```

Compute the classification loss using the test set.

```matlab
L = loss(nca,Xtest,ytest)
L = 0.0179
```

**Classify observations using the selected features**

Extract the features with feature weights greater than 0 from the training data.
features = Xtrain(:,selidx);

Apply a support vector machine classifier using the selected features to the reduced training set.

svmMdl = fitcsvm(features,ytrain);

Evaluate the accuracy of the trained classifier on the test data which has not been used for selecting features.

\[ L = \text{loss}(\text{svmMdl},Xtest(:,selidx),ytest) \]

\[ L = \text{single}\]
\[ 0 \]

**Input Arguments**

**X — Predictor variable values**

\( n \)-by-\( p \) matrix

Predictor variable values, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables.

Data Types: `single` | `double`

**Y — Class labels**

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length \( n \) | character matrix with \( n \) rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length \( n \), or character matrix with \( n \) rows, where \( n \) is the number of observations. Element \( i \) or row \( i \) of \( Y \) is the class label corresponding to row \( i \) of \( X \) (observation \( i \)).

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','sgd','Weights',W,'Lambda',0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector \( W \), and sets the regularization parameter at \( 0.0003 \).

**Fitting Options**

**FitMethod — Method for fitting the model**

'exact' (default) | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of `FitMethod` and one of the following:

- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`. 
- 'average' — Divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the NumPartitions name-value pair argument.

Example: 'FitMethod','none'

**NumPartitions — Number of partitions**

\[
\max(2, \min(10, n)) \text{ (default)} \mid \text{integer between 2 and } n
\]

Number of partitions to split the data for using with 'FitMethod','average' option, specified as the comma-separated pair consisting of 'NumPartitions' and an integer value between 2 and \( n \), where \( n \) is the number of observations.

Example: 'NumPartitions',15

Data Types: double | single

**Lambda — Regularization parameter**

\( \frac{1}{n} \text{ (default)} \mid \text{nonnegative scalar} \)

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of 'Lambda' and a nonnegative scalar.

As the number of observations \( n \) increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Identify Relevant Features for Classification” on page 32-2253 and “Tune Regularization Parameter to Detect Features Using NCA for Classification” to learn how to tune the regularization parameter.

Example: 'Lambda',0.002

Data Types: double | single

**LengthScale — Width of the kernel**

1 (default) \mid \text{positive real scalar}

Width of the kernel, specified as the comma-separated pair consisting of 'LengthScale' and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in \( X \) are of very different magnitudes, then consider standardizing the predictor values using 'Standardize',true and setting 'LengthScale',1.

Example: 'LengthScale',1.5

Data Types: double | single

**InitialFeatureWeights — Initial feature weights**

\( \text{ones}(p,1) \text{ (default)} \mid p\text{-by-}1 \text{ vector of real positive scalars} \)

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a \( p\)-by-1 vector of real positive scalars, where \( p \) is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using \( \text{rand}(p,1) \) can give better quality solutions.
Data Types: double | single

Weights — Observation weights
n-by-1 vector of 1s (default) | n-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: double | single

Prior — Prior probabilities for each class
'empirical' (default) | 'uniform' | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'empirical' — fscnca obtains the prior class probabilities from class frequencies.
- 'uniform' — fscnca sets all class probabilities equal.
- Structure with two fields:
  - ClassProbs — Vector of class probabilities. If these are numeric values with a total greater than 1, fscnca normalizes them to add up to 1.
  - ClassNames — Class names corresponding to the class probabilities in ClassProbs.

Example: 'Prior','uniform'

Standardize — Indicator for standardizing predictor data
false (default) | true

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either false or true. For more information, see “Impact of Standardization” on page 15-102.

Example: 'Standardize',true

Data Types: logical

Verbose — Verbosity level indicator
0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose',1

Data Types: double | single
**Solver** — Solver type

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for \( n \leq 1000 \), and 'sgd' for \( n > 1000 \).

Example: 'solver','minibatch-lbfgs'

**LossFunction** — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following.

- 'classiferror' — Misclassification error
  
  \[
  l(y_i, y_j) = \begin{cases} 
  1 & \text{if } y_i \neq y_j, \\
  0 & \text{otherwise}.
  \end{cases}
  \]

- @lossfun — Custom loss function handle. A loss function has this form.

  ```plaintext
  function L = lossfun(Yu,Yv)
  % calculation of loss
  ...
  
  Yu is a u-by-1 vector and Yv is a v-by-1 vector. L is a u-by-v matrix of loss values such that \( L(i,j) \) is the loss value for \( Yu(i) \) and \( Yv(j) \).
  
  The objective function for minimization includes the loss function \( l(y_i, y_j) \) as follows:
  
  \[
  f(w) = \frac{1}{n} \sum_{i=1}^{n} \sum_{j \neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{p} w_r^2,
  \]

  where \( w \) is the feature weight vector, \( n \) is the number of observations, and \( p \) is the number of predictor variables. \( p_{ij} \) is the probability that \( x_i \) is the reference point for \( x_j \). For details, see “NCA Feature Selection for Classification” on page 15-99.

  Example: 'LossFunction',@lossfun

**CacheSize** — Memory size

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize',1500MB

Data Types: double | single
**LBFGS Options**

**HessianHistorySize** — Size of history buffer for Hessian approximation
15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20
Data Types: double | single

**InitialStepSize** — Initial step size
'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

**LineSearchMethod** — Line search method
'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

**MaxLineSearchIterations** — Maximum number of line search iterations
20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25
Data Types: double | single

**GradientTolerance** — Relative convergence tolerance
1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar.

Example: 'GradientTolerance',0.000002
Data Types: double | single
**SGD Options**

**InitialLearningRate — Initial learning rate for 'sgd' solver**

`'auto'` (default) | positive real scalar

Initial learning rate for the 'sgd' solver, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive real scalar.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

The default 'auto' means that the initial learning rate is determined using experiments on small subsets of data. Use the NumTuningIterations name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the TuningSubsetSize name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type 'minibatch-lbfgs', you can set 'InitialLearningRate' to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the Iteration versus the Objective values saved in the mdl.FitInfo property.

You can use the refit method with 'InitialFeatureWeights' equal to mdl.FeatureWeights to start from the current solution and run additional iterations.

Example: 'InitialLearningRate', 0.9

Data Types: double | single

**MiniBatchSize — Number of observations to use in each batch for the 'sgd' solver**

`min(10,n)` (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n.

Example: 'MiniBatchSize', 25

Data Types: double | single

**PassLimit — Maximum number of passes for solver 'sgd'**

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit', 10

Data Types: double | single

**NumPrint — Frequency of batches for displaying convergence summary**

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when
the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

**NumTuningIterations — Number of tuning iterations**

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

**TuningSubsetSize — Number of observations to use for tuning initial learning rate**

min(100,n) (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to n. This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'TuningSubsetSize',25

Data Types: double | single

**SGD or LBFGS Options**

**IterationLimit — Maximum number of iterations**

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: 'IterationLimit',250

Data Types: double | single

**StepTolerance — Convergence tolerance on the step size**

1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance',0.000005

Data Types: double | single

**Mini-Batch LBFGS Options**

**MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step**

10 (default) | positive integer
Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for classification
FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

Introduced in R2016b
fsrnca

Feature selection using neighborhood component analysis for regression

Syntax

mdl = fsrnca(X,Y)
mdl = fsrnca(X,Y,Name,Value)

Description

mdl = fsrnca(X,Y) performs feature selection for regression using the predictors in X and responses in Y.

fsrnca learns the feature weights by a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

mdl = fsrnca(X,Y,Name,Value) performs feature selection for regression with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Regression

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = 1 + X(:,3)*5 + sin(X(:,9)./X(:,15) + 0.25*randn(N,1));

Fit the neighborhood component analysis model for regression.

mdl = fsrnca(X,y,'Verbose',1,'Lambda',0.5/N);

o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

Infinity norm of the final gradient = 2.596e-07
Two norm of the final step = 1.111e-04, TolX = 1.000e-06
Relative infinity norm of the final gradient = 2.596e-07, TolFun = 1.000e-06
EXIT: Local minimum found.

Plot the selected features. The weights of the irrelevant features should be close to zero.

```matlab
figure()
plot(mdl.FeatureWeights,'ro')
grid on
xlabel('Feature index')
ylabel('Feature weight')
```
fsrnca correctly detects the relevant predictors for this response.

**Tune Regularization Parameter in NCA for Regression**

Load the sample data.

```matlab
load robotarm.mat
```

The `robotarm` (pumadyn32nm) dataset is created using a robot arm simulator with 7168 training observations and 1024 test observations with 32 features [1][2]. This is a preprocessed version of the original data set. The data are preprocessed by subtracting off a linear regression fit, followed by normalization of all features to unit variance.

Perform neighborhood component analysis (NCA) feature selection for regression with the default $\lambda$ (regularization parameter) value.

```matlab
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ... 'Solver','lbfgs');
```

Plot the selected values.

```matlab
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature index')
```
ylabel('Feature weight')
grid on

More than half of the feature weights are nonzero. Compute the loss using the test set as a measure of the performance by using the selected features.

\[ L = \text{loss(nca,Xtest,ytest)} \]
\[ L = 0.0837 \]

Try improving the performance. Tune the regularization parameter \( \lambda \) for feature selection using five-fold cross-validation. Tuning \( \lambda \) means finding the \( \lambda \) value that produces the minimum regression loss. To tune \( \lambda \) using cross-validation:

1. Partition the data into five folds. For each fold, \( \text{cvpartition} \) assigns 4/5th of the data as a training set, and 1/5th of the data as a test set.

\[
\text{rng}(1) \quad \text{\% For reproducibility} \\
n = \text{length(ytrain)}; \\
cvp = \text{cvpartition(length(ytrain),'kfold',5)}; \\
\text{numvalidsets} = \text{cvp.NumTestSets};
\]

Assign the \( \lambda \) values for the search. Multiplying response values by a constant increases the loss function term by a factor of the constant. Therefore, including the \( \text{std(ytrain)} \) factor in the \( \lambda \) values balances the default loss function ('mad', mean absolute deviation) term and the regularization term in the objective function. In this example, the \( \text{std(ytrain)} \) factor is one because the loaded sample data is a preprocessed version of the original data set.
The code snippet above describes a process for evaluating a model using cross-validation and lambda values. Here's a breakdown of the steps:

1. **Lambda Values Creation**: The lambda values are created using `linspace` function to generate an array of lambda values, denoted as `lambdavals`.
   ```matlab
   lambdavals = linspace(0,50,20)*std(ytrain)/n;
   ``

2. **Loss Values Array Creation**: An array `lossvals` is created to store the loss values for each lambda value.
   ```matlab
   lossvals = zeros(length(lambdavals),numvalidsets);
   ``

3. **Model Training and Loss Computation**:
   - The NCA model is trained for each lambda value using the training set in each fold.
   - The regression loss is computed for the corresponding test set in the fold using the NCA model.
   ```matlab
   for i = 1:length(lambdavals)
     for k = 1:numvalidsets
       X = Xtrain(cvp.training(k),:);
       y = ytrain(cvp.training(k),:);
       Xvalid = Xtrain(cvp.test(k),:);
       yvalid = ytrain(cvp.test(k),:);

       nca = fsrnca(X,y,'FitMethod','exact', ...
                   'Solver','minibatch-lbfgs','Lambda',lambdavals(i), ...
                   'GradientTolerance',1e-4,'IterationLimit',30);

       lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','mse');
     end
   end
   ``

4. **Average Loss Computation**:
   - The average loss obtained from the folds is computed for each lambda value.
   ```matlab
   meanloss = mean(lossvals,2);
   ``

5. **Plotting the Loss Values**:
   - The mean loss is plotted against the lambda values.
   ```matlab
   figure
   plot(lambdavals,meanloss,'ro-')
   xlabel('Lambda')
   ylabel('Loss (MSE)')
   grid on
   ```
Find the $\lambda$ value that gives the minimum loss value.

\[
[-, \text{idx}] = \min(\text{meanloss})
\]

\[
\text{idx} = 17
\]

\[
\text{bestlambda} = \text{lambdavals}(\text{idx})
\]

\[
\text{bestlambda} = 0.0059
\]

\[
\text{bestloss} = \text{meanloss}(\text{idx})
\]

\[
\text{bestloss} = 0.0590
\]

Fit the NCA feature selection model for regression using the best $\lambda$ value.

\[
\text{nca} = \text{fsrnca(Xtrain,ytrain,'FitMethod','exact', ...}
\]

\[
\quad '\text{Solver}','lbfgs','\text{Lambda}',\text{bestlambda});
\]

Plot the selected features.

\[
\text{figure}
\]

\[
\text{plot(nca.FeatureWeights,'ro')}
\]

\[
\text{xlabel('Feature Index')}
\]

\[
\text{ylabel('Feature Weight')}
\]

\[
\text{grid\ on}
\]
Most of the feature weights are zero. \texttt{fsrnca} identifies the four most relevant features.

Compute the loss for the test set.

\begin{verbatim}
L = loss(nca,Xtest,ytest)
L = 0.0571
\end{verbatim}

Tuning the regularization parameter, $\lambda$, eliminated more of the irrelevant features and improved the performance.

\textbf{Compare NCA and ARD Feature Selection}

This example uses the Abalone data [3][4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

\begin{verbatim}
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height', ...
    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
\end{verbatim}

\texttt{ans=7x9 table}

\begin{verbatim}
    Sex  Length  Diameter  Height  WWeight  SWeight  VWeight  ShWeight  NoShellRings
    5     1.0    0.043    0.15     0.51     0.52     3.22      0.41       2
    4     1.0    0.05     0.15     0.47     0.46     3.14      0.45       2
    4     1.0    0.058    0.15     0.55     0.47     3.25      0.46       2
    5     1.0    0.046    0.15     0.46     0.46     3.15      0.45       2
    5     1.0    0.046    0.15     0.46     0.46     3.15      0.45       2
    4     1.0    0.052    0.15     0.51     0.51     3.18      0.46       2
    4     1.0    0.052    0.15     0.51     0.51     3.18      0.46       2
\end{verbatim}
The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, the number of shell rings, shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Prepare the predictor and response variables for `fsrnca`. The last column of `tbl` contains the number of shell rings, which is the response variable. The first predictor variable, sex, is categorical. You must create dummy variables.

```matlab
y = table2array(tbl(:,end));
X(:,1:3) = dummyvar(categorical(tbl.Sex));
X = [X,table2array(tbl(:,2:end-1))];
```

Use four-fold cross-validation to tune the regularization parameter in the NCA model. First partition the data into four folds.

```matlab
rng('default') % For reproducibility
n = length(y);
cvp = cvpartition(n,'kfold',4);
numtestsets = cvp.NumTestSets;

cvpartition divides the data into four partitions (folds). In each fold, about three-fourths of the data is assigned as a training set and one-fourth is assigned as a test set.

Generate a variety of \( \lambda \) (regularization parameter) values for fitting the model to determine the best \( \lambda \) value. Create a vector to collect the loss values from each fit.

```matlab
lambdavals = linspace(0,25,20)*std(y)/n;
lossvals = zeros(length(lambdavals),numtestsets);
The rows of `lossvals` corresponds to the \( \lambda \) values and the columns correspond to the folds.

Fit the NCA model for regression using `fsrnca` to the data from each fold using each \( \lambda \) value. Compute the loss for each model using the test data from each fold.

```matlab
for i = 1:length(lambdavals)
    for k = 1:numtestsets
        Xtrain = X(cvp.training(k),:);
ytrain = y(cvp.training(k),:);
        Xtest = X(cvp.test(k),:);
ytest = y(cvp.test(k),:);

        nca = fsrnca(Xtrain,ytrain,'FitMethod','exact',...        
            'Solver','lbfgs','Lambda',lambdavals(i),'Standardize',true);

        lossvals(i,k) = loss(nca,Xtest,ytest,'LossFunction','mse');
    end
end
```
Compute the average loss for the folds, that is, compute the mean in the second dimension of `lossvals`.

```matlab
meanloss = mean(lossvals,2);
```

Plot the $\lambda$ values versus the mean loss from the four folds.

```matlab
figure
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```

Find the $\lambda$ value that minimizes the mean loss.

```matlab
[~,idx] = min(meanloss);
bestlambda = lambdavals(idx)
bestlambda = 0.0071
```

Compute the best loss value.

```matlab
bestloss = meanloss(idx)
bestloss = 4.7799
```

Fit the NCA model on all of the data using the best $\lambda$ value.
nca = fsrnca(X,y,'FitMethod','exact','Solver','lbfgs', ...  'Verbose',1,'Lambda',bestlambda,'Standardize',true);

Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

Properties, Methods

Compute the regression loss on the training data (resubstitution loss) for the trained model.

L = resubLoss(gprMdl)
L = 4.0306

The smallest cross-validated loss using fsrnca is comparable to the loss obtained using a GPR model with an ARD kernel.

**Input Arguments**

**X** — Predictor variable values
n-by-p matrix

Predictor variable values, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables.

Data Types: single | double

**Y** — Response values
numeric real vector of length n

Response values, specified as a numeric real vector of length n, where n is the number of observations.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Solver','sgd','Weights',W,'Lambda',0.0003 specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector W, and sets the regularization parameter at 0.0003.

**Fitting Options**

**FitMethod** — Method for fitting the model
'exact' (default) | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following:
- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to fsrnca.
- 'average' — Divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the NumPartitions name-value pair argument.

Example: 'FitMethod','none'

NumPartitions — Number of partitions

max(2, min(10, n)) (default) | integer between 2 and n

Number of partitions to split the data for using with 'FitMethod','average' option, specified as the comma-separated pair consisting of 'NumPartitions' and an integer value between 2 and n, where n is the number of observations.

Example: 'NumPartitions',15

Data Types: double | single

Lambda — Regularization parameter

1/n (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of 'Lambda' and a nonnegative scalar.

As the number of observations n increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Tune Regularization Parameter in NCA for Regression” on page 32-2269 to learn how to tune the regularization parameter.

Example: 'Lambda',0.002

Data Types: double | single

LengthScale — Width of the kernel

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of 'LengthScale' and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using 'Standardize',true and setting 'LengthScale',1.

Example: 'LengthScale',1.5

Data Types: double | single

InitialFeatureWeights — Initial feature weights

ones(p,1) (default) | p-by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p-by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1
generally works well, but in some cases, random initialization using \( \text{rand}(p,1) \) can give better quality solutions.

Data Types: double | single

**Weights — Observation weights**
n-by-1 vector of 1s (default) | n-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: double | single

**Standardize — Indicator for standardizing predictor data**
false (default) | true

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either false or true. For more information, see “Impact of Standardization” on page 15-102.

Example: 'Standardize',true

Data Types: logical

**Verbose — Verbosity level indicator**
0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- >1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose',1

Data Types: double | single

**Solver — Solver type**
'lbgfs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for \( n \leq 1000 \), and 'sgd' for \( n > 1000 \).

Example: 'solver','minibatch-lbfgs'
**LossFunction — Loss function**

- 'mad' (default) | 'mse' | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following:

- 'mad' — Mean absolute deviation
  \[ l(y_i, y_j) = |y_i - y_j| . \]
- 'mse' — Mean squared error
  \[ l(y_i, y_j) = (y_i - y_j)^2 . \]
- 'epsiloninsensitive' — ε-insensitive loss function
  \[ l(y_i, y_j) = \max(0, |y_i - y_j| - \epsilon) . \]

  This loss function is more robust to outliers than mean squared error or mean absolute deviation.

- @lossfun — Custom loss function handle. A loss function has this form.

  ```matlab
  function L = lossfun(Yu,Yv)
  % calculation of loss
  ...
  
  Yu is a \( u \)-by-1 vector and Yv is a \( v \)-by-1 vector. L is a \( u \)-by-\( v \) matrix of loss values such that \( L(i,j) \) is the loss value for \( Yu(i) \) and \( Yv(j) \).
  ```

The objective function for minimization includes the loss function \( l(y_i, y_j) \) as follows:

\[
f(w) = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{p} w_r^2,
\]

where \( w \) is the feature weight vector, \( n \) is the number of observations, and \( p \) is the number of predictor variables. \( p_{ij} \) is the probability that \( x_j \) is the reference point for \( x_i \). For details, see “NCA Feature Selection for Regression” on page 15-101.

Example: 'LossFunction', @lossfun

**Epsilon — Epsilon value**

- iqr(Y)/13.49 (default) | nonnegative real scalar

Epsilon value for the 'LossFunction','epsiloninsensitive' option, specified as the comma-separated pair consisting of 'LossFunction' and a nonnegative real scalar. The default value is an estimate of the sample standard deviation using the interquartile range of the response variable.

Example: 'Epsilon', 0.1

Data Types: double | single

**CacheSize — Memory size**

- 1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize', 1500MB

---

32-2281
Data Types: double | single

**LBFGS Options**

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20
Data Types: double | single

**InitialStepSize — Initial step size**

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

**LineSearchMethod — Line search method**

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

**MaxLineSearchIterations — Maximum number of line search iterations**

20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25
Data Types: double | single

**GradientTolerance — Relative convergence tolerance**

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar.

Example: 'GradientTolerance',0.000002
Data Types: double | single
SGD Options

**InitialLearningRate — Initial learning rate for 'sgd' solver**

'auto' (default) | positive real scalar

Initial learning rate for the 'sgd' solver, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive real scalar.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

The default 'auto' means that the initial learning rate is determined using experiments on small subsets of data. Use the NumTuningIterations name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the TuningSubsetSize name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type 'minibatch-lbfgs', you can set 'InitialLearningRate' to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the Iteration versus the Objective values saved in the mdl.FitInfo property.

You can use the refit method with 'InitialFeatureWeights' equal to mdl.FeatureWeights to start from the current solution and run additional iterations.

Example: 'InitialLearningRate',0.9
Data Types: double | single

**MiniBatchSize — Number of observations to use in each batch for the 'sgd' solver**

min(10,n) (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n.

Example: 'MiniBatchSize',25
Data Types: double | single

**PassLimit — Maximum number of passes for solver 'sgd'**

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit',10
Data Types: double | single

**NumPrint — Frequency of batches for displaying convergence summary**

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when
the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint', 5

Data Types: double | single

NumTuningIterations — Number of tuning iterations
20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations', 15

Data Types: double | single

TuningSubsetSize — Number of observations to use for tuning initial learning rate
min(100, n) (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to n. This option is valid only for 'InitialLearningRate','auto'.

Example: 'TuningSubsetSize', 25

Data Types: double | single

SGD or LBFGS Options

IterationLimit — Maximum number of iterations
positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: 'IterationLimit', 250

Data Types: double | single

StepTolerance — Convergence tolerance on the step size
1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance', 0.000005

Data Types: double | single

Mini-batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step
10 (default) | positive integer
Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.
Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for regression
FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, returned as a FeatureSelectionNCARegression object.

Introduced in R2016b
fsrfstest

Univariate feature ranking for regression using F-tests

Syntax

idx = fsrfstest(Tbl,ResponseVarName)
idx = fsrfstest(Tbl,formula)
idx = fsrfstest(Tbl,Y)
idx = fsrfstest(X,Y)
idx = fsrfstest(____,Name,Value)
[idx,scores] = fsrfstest(____)

Description

idx = fsrfstest(Tbl,ResponseVarName) ranks features (predictors) using F-tests on page 32-2294. The table Tbl contains predictor variables and a response variable, and ResponseVarName is the name of the response variable in Tbl. The function returns idx, which contains the indices of predictors ordered by predictor importance, meaning idx(1) is the index of the most important predictor. You can use idx to select important predictors for regression problems.

idx = fsrfstest(Tbl,formula) specifies a response variable and predictor variables to consider among the variables in Tbl by using formula.

idx = fsrfstest(Tbl,Y) ranks predictors in Tbl using the response variable Y.

idx = fsrfstest(X,Y) ranks predictors in X using the response variable Y.

idx = fsrfstest(____,Name,Value) specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify categorical predictors and observation weights.

[idx,scores] = fsrfstest(____) also returns the predictor scores scores. A large score value indicates that the corresponding predictor is important.

Examples

Rank Predictors in Matrix

Rank predictors in a numeric matrix and create a bar plot of predictor importance scores.

Load the sample data.

load robotarm.mat

The robotarm data set contains 7168 training observations (Xtrain and ytrain) and 1024 test observations (Xtest and ytest) with 32 features [1][2].

Rank the predictors using the training observations.
[idx,scores] = fsrftest(Xtrain,ytrain);

The values in scores are the negative logs of the $p$-values. If a $p$-value is smaller than eps(0), then the corresponding score value is Inf. Before creating a bar plot, determine whether scores includes Inf values.

find(isinf(scores))
ans =
    1x0 empty double row vector

scores does not include Inf values. If scores includes Inf values, you can replace Inf by a large numeric number before creating a bar plot for visualization purposes. For details, see “Rank Predictors in Table” on page 32-2288.

Create a bar plot of the predictor importance scores.

bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')

Select the top five most important predictors. Find the columns of these predictors in Xtrain.

idx(1:5)
ans = 1x5
The 30th column of $X_{train}$ is the most important predictor of $y_{train}$.

### Rank Predictors in Table

Rank predictors in a table and create a bar plot of predictor importance scores.

If your data is in a table and `fsrftest` ranks a subset of the variables in the table, then the function indexes the variables using only the subset. Therefore, a good practice is to move the predictors that you do not want to rank to the end of the table. Move the response variable and observation weight vector as well. Then, the indexes of the output arguments are consistent with the indexes of the table. You can move variables in a table using the `movevars` function.

This example uses the Abalone data [3][4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data in a table.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height', ... 
    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};```

Preview the first few rows of the table.

```matlab
head(tbl)
ans=8×9 table
    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRings
    ______    ______    ________    ______    _______    _______    _______    ________    ____________
    {'M'}    0.455      0.365      0.095      0.514     0.2245      0.101       0.15           15
    {'M'}     0.35      0.265       0.09     0.2255     0.0995     0.0485       0.07            7
    {'F'}     0.53       0.42      0.135      0.677     0.2565     0.1415       0.21            9
    {'M'}     0.44      0.365      0.125      0.516     0.2155      0.114      0.155           10
    {'I'}     0.33      0.255       0.08      0.205     0.0895     0.0395      0.055            7
    {'I'}   0.425      0.25         0.95     0.3515      0.141     0.0775       0.12            8
    {'F'}     0.53      0.415       0.15     0.7775      0.237     0.1415       0.33           20
    {'F'}   0.545      0.425      0.125      0.768      0.294     0.1495       0.26           16

The last variable in the table is a response variable.

Rank the predictors in `tbl`. Specify the last column `NoShellRings` as a response variable.

```matlab
[idx,scores] = fsrftest(tbl,'NoShellRings')
idx = 1×8
     3     4     5     7     8     2     6     1
scores = 1×8
    Functions
32-2288

32-2288
The values in `scores` are the negative logs of the p-values. If a p-value is smaller than \( \text{eps}(0) \), then the corresponding score value is Inf. Before creating a bar plot, determine whether `scores` includes Inf values.

```matlab
dxInf = find(isinf(scores))
dxInf = 1x5
   3  4  5  7  8
```

`scores` includes five Inf values.

Create a bar plot of predictor importance scores. Use the predictor names for the x-axis tick labels.

```matlab
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
xticklabels(strrep(tbl.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)
```

The `bar` function does not plot any bars for the Inf values. For the Inf values, plot bars that have the same length as the largest finite score.

```matlab
hold on
bar(scores(idx(length(idxInf)+1))*ones(length(idxInf),1))
legend('Finite Scores','Inf Scores')
hold off
```
The bar graph displays finite scores and Inf scores using different colors.

**Input Arguments**

**Tbl — Sample data**

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`. If `Tbl` also contains the observation weights, then you can specify the weights by using `Weights`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify the subset of variables by using `formula`.  

32-2290
• If Tbl does not contain the response variable, then specify a response variable by using Y. The response variable and Tbl must have the same number of rows.

If fsrftest uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The values in the 'CategoricalPredictors' name-value pair argument and the output argument idx do not count the predictors that the function does not rank.

fsrftest considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Tbl for a response variable to be missing values. fsrftest does not use observations with missing values for a response variable.

Data Types: table

ResponseVarName — Response variable name
character vector or string scalar containing name of variable in Tbl

Response variable name, specified as a character vector or string scalar containing the name of a variable in Tbl.

For example, if a response variable is the column Y of Tbl (Tbl.Y), then specify ResponseVarName as 'Y'.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y ~ X1 + X2 + X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors, use a formula. If you specify a formula, then fsrftest does not rank any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers. For details, see “Tips” on page 32-2294.

Data Types: char | string

Y — Response variable
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector; a character or string array, or a cell array of character vectors. Each row of Y represents the labels of the corresponding row of X.

fsrftest considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. fsrftest does not use observations with missing values for Y.

Data Types: single | double | categorical | logical | char | string | cell

X — Predictor data
numeric matrix
Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example: ‘NumBins’, 20, ‘UseMissing’, true sets the number of bins as 20 and specifies to use missing values in predictors for ranking.

CategoricalPredictors — List of categorical predictors
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

List of categorical predictors, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the names in Tbl. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the names in Tbl.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fsrftest assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fsrftest assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

If fsrftest uses a subset of variables in Tbl as predictors, then the function indexes the predictors using only the subset. The 'CategoricalPredictors' values do not count the predictors that the function does not rank.

Example: 'CategoricalPredictors', 'all'

Data Types: single | double | logical | char | string | cell

NumBins — Number of bins for binning continuous predictors
10 (default) | positive integer scalar

Number of bins for binning continuous predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar.
Example: 'NumBins', 50
Data Types: single | double

UseMissing — Indicator for whether to use or discard missing values in predictors
false (default) | true

Indicator for whether to use or discard missing values in predictors, specified as the comma-
separated pair consisting of 'UseMissing' and either true to use or false to discard missing
values in predictors for ranking.

`fsrftest` considers NaN, '' (empty character vector), "" (empty string), <missing>, and
<undefined> values to be missing values.

If you specify 'UseMissing',true, then `fsrftest` uses missing values for ranking. For a
categorical variable, `fsrftest` treats missing values as an extra category. For a continuous variable,
`fsrftest` places NaN values in a separate bin for binning.

If you specify 'UseMissing',false, then `fsrftest` does not use missing values for ranking.
Because `fsrftest` computes importance scores individually for each predictor, the function does not
discard an entire row when values in the row are partially missing. For each variable, `fsrftest` uses
all values that are not missing.

Example: 'UseMissing',true
Data Types: logical

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of
scalar values or the name of a variable in Tbl. The function weights the observations in each row of X
or Tbl with the corresponding value in Weights. The size of Weights must equal the number of
rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that
contains a numeric vector. In this case, you must specify Weights as a character vector or string
scalar. For example, if the weight vector is the column W of Tbl (Tbl.W), then specify
'Weights', 'W'.

`fsrftest` normalizes the weights to add up to one.

Data Types: single | double | char | string

Output Arguments

idx — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in X or Tbl ordered by predictor importance, returned as a 1-by-\textit{r} numeric
vector, where \textit{r} is the number of ranked predictors.

If `fsrftest` uses a subset of variables in Tbl as predictors, then the function indexes the predictors
using only the subset. For example, suppose Tbl includes 10 columns and you specify the last five
columns of Tbl as the predictor variables by using `formula`. If `idx(3)` is 5, then the third most
important predictor is the 10th column in Tbl, which is the fifth predictor in the subset.
scores — Predictor scores
numeric vector

Predictor scores, returned as a 1-by-\(r\) numeric vector, where \(r\) is the number of ranked predictors. A large score value indicates that the corresponding predictor is important.

- If you use \(X\) to specify the predictors or use all the variables in \(Tbl\) as predictors, then the values in scores have the same order as the predictors in \(X\) or \(Tbl\).
- If you specify a subset of variables in \(Tbl\) as predictors, then the values in scores have the same order as the subset.

For example, suppose \(Tbl\) includes 10 columns and you specify the last five columns of \(Tbl\) as the predictor variables by using formula. Then, score(3) contains the score value of the 8th column in \(Tbl\), which is the third predictor in the subset.

Tips

- If you specify the response variable and predictor variables by using the input argument formula, then the variable names in the formula must be both variable names in \(Tbl\) (\(Tbl.Properties.VariableNames\)) and valid MATLAB identifiers.

  You can verify the variable names in \(Tbl\) by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

  ```matlab
  cellfun(@isvarname,Tbl.Properties.VariableNames)
  ```

  If the variable names in \(Tbl\) are not valid, then convert them by using the matlab.lang.makeValidName function.

  ```matlab
  Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
  ```

Algorithms

Univariate Feature Ranking Using F-Tests

- fsrftest examines the importance of each predictor individually using an F-test. Each F-test tests the hypothesis that the response values grouped by predictor variable values are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same. A small \(p\)-value of the test statistic indicates that the corresponding predictor is important.
- The output scores is \(-\log(p)\). Therefore, a large score value indicates that the corresponding predictor is important. If a \(p\)-value is smaller than eps(0), then the output is Inf.
- fsrftest examines a continuous variable after binning, or discretizing, the variable. You can specify the number of bins using the 'NumBins' name-value pair argument.

**Topics**

"Introduction to Feature Selection" on page 15-49

**Introduced in R2020a**
**fstat**

*F* mean and variance

**Syntax**

```
[M,V] = fstat(V1,V2)
```

**Description**

```
[M,V] = fstat(V1,V2)
```

returns the mean of and variance for the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of *M* and *V*. A scalar input for *V1* or *V2* is expanded to a constant arrays with the same dimensions as the other input. *V1* and *V2* parameters must contain real positive values.

The mean of the *F* distribution for values of *ν*₂ greater than 2 is

\[ \frac{ν₂}{ν₂ - 2} \]

The variance of the *F* distribution for values of *ν*₂ greater than 4 is

\[ \frac{2ν₂ν₁ + ν₂ - 2}{ν₁(ν₂ - 2)²(ν₂ - 4)} \]

The mean of the *F* distribution is undefined if *ν*₂ is less than 3. The variance is undefined for *ν*₂ less than 5.

**Examples**

*fstat* returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
m = NaN NaN 3.0000 2.0000 1.6667
v = NaN NaN NaN NaN 8.8889
```

**Extended Capabilities**

- **C/C++ Code Generation**
  Generate C and C++ code using MATLAB® Coder™.

- **GPU Arrays**
  Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“F Distribution” on page B-45

Introduced before R2006a
**fsulaplacian**

Rank features for unsupervised learning using Laplacian scores

**Syntax**

```matlab
idx = fsulaplacian(X)
idx = fsulaplacian(X,Name,Value)
[idx,scores] = fsulaplacian(____)
```

**Description**

`idx = fsulaplacian(X)` ranks features (variables) in `X` using the Laplacian scores on page 32-2304. The function returns `idx`, which contains the indices of features ordered by feature importance. You can use `idx` to select important features for unsupervised learning.

`idx = fsulaplacian(X,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `'NumNeighbors',10` to create a similarity graph on page 32-2303 using 10 nearest neighbors.

`[idx,scores] = fsulaplacian(____)` also returns the feature scores `scores`, using any of the input argument combinations in the previous syntaxes. A large score value indicates that the corresponding feature is important.

**Examples**

**Rank Features by Importance**

Load the sample data.

```matlab
load ionosphere
```

Rank the features based on importance.

```matlab
[idx,scores] = fsulaplacian(X);
```

Create a bar plot of the feature importance scores.

```matlab
bar(scores(idx))
xlabel('Feature rank')
ylabel('Feature importance score')
```
Select the top five most important features. Find the columns of these features in $X$.

```matlab
idx(1:5)
ans = 1x5
    15   13   17   21   19
```

The 15th column of $X$ is the most important feature.

---

**Rank Features Using Specified Similarity Matrix**

Compute a similarity matrix from Fisher's iris data set and rank the features using the similarity matrix.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Find the distance between each pair of observations in `meas` by using the `pdist` and `squareform` functions with the default Euclidean distance metric.

```matlab
D = pdist(meas);
Z = squareform(D);
```
Construct the similarity matrix and confirm that it is symmetric.

\[ S = \exp(-Z.^2); \]
\[ \text{issymmetric}(S) \]
\[ \text{ans} = \text{logical} \]
\[ 1 \]

Rank the features.

\[ \text{idx} = \text{fsulaplacian}(	ext{meas}, '\text{Similarity}', S) \]
\[ \text{idx} = 1\times4 \]
\[ 3 \quad 4 \quad 1 \quad 2 \]

Ranking using the similarity matrix \( S \) is the same as ranking by specifying 'NumNeighbors' as \( \text{size}(	ext{meas},1) \).

\[ \text{idx2} = \text{fsulaplacian}(	ext{meas}, '\text{NumNeighbors}', \text{size}(	ext{meas},1)) \]
\[ \text{idx2} = 1\times4 \]
\[ 3 \quad 4 \quad 1 \quad 2 \]

**Input Arguments**

\( X \) — Input data
numeric matrix

Input data, specified as an \( n \)-by-\( p \) numeric matrix. The rows of \( X \) correspond to observations (or points), and the columns correspond to features.

The software treats NaNs in \( X \) as missing data and ignores any row of \( X \) containing at least one NaN.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'NumNeighbors',10,'KernelScale','auto' specifies the number of nearest neighbors as 10 and the kernel scale factor as 'auto'.

**Similarity** — Similarity matrix
[] (empty matrix) (default) | symmetric matrix

Similarity matrix, specified as the comma-separated pair consisting of 'Similarity' and an \( n \)-by-\( n \) symmetric matrix, where \( n \) is the number of observations. The similarity matrix (or adjacency matrix) represents the input data by modeling local neighborhood relationships among the data points. The values in a similarity matrix represent the edges (or connections) between nodes (data points) that
are connected in a similarity graph on page 32-2303. For more information, see “Similarity Matrix” on page 32-2304.

If you specify the 'Similarity' value, then you cannot specify any other name-value pair argument. If you do not specify the 'Similarity' value, then the software computes a similarity matrix using the options specified by the other name-value pair arguments.

**Data Types:** single | double

**Distance — Distance metric**

character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a character vector, string scalar, or function handle, as described in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>

<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values)</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
@distfun | Custom distance function handle. A distance function has the form

```matlab
function D2 = distfun(ZI,ZJ)
% calculation of distance
...
```

where

- ZI is a 1-by-n vector containing a single observation.
- ZJ is an m2-by-n matrix containing multiple observations. `distfun` must accept a matrix ZJ with an arbitrary number of observations.
- D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For more information, see “Distance Metrics” on page 18-11.

When you use the 'seuclidean', 'minkowski', or 'mahalanobis' distance metric, you can specify the additional name-value pair argument 'Scale', 'P', or 'Cov', respectively, to control the distance metrics.

Example: 'Distance','minkowski','P',3 specifies to use the Minkowski distance metric with an exponent of 3.

**P — Exponent for Minkowski distance metric**

| 2 (default) | positive scalar |

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

**Cov — Covariance matrix for Mahalanobis distance metric**

| nancov(X) (default) | positive definite matrix |

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix.

This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov',eye(4)

Data Types: single | double

**Scale — Scaling factors for standardized Euclidean distance metric**

| nanstd(X) (default) | numeric vector of nonnegative values |

Scaling factors for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a numeric vector of nonnegative values.
Scale has length \( p \) (the number of columns in \( X \)), because each dimension (column) of \( X \) has a corresponding value in Scale. For each dimension of \( X \), fsulaplacian uses the corresponding value in Scale to standardize the difference between observations.

This argument is valid only if 'Distance' is 'seuclidean'.

Data Types: single | double

**NumNeighbors — Number of nearest neighbors**

\( \log(\text{size}(X,1)) \) (default) | positive integer

Number of nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer.

Example: 'NumNeighbors',10

Data Types: single | double

**KernelScale — Scale factor**

1 (default) | 'auto' | positive scalar

Scale factor for the kernel, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software uses the scale factor to transform distances to similarity measures. For more information, see “Similarity Graph” on page 32-2303.

- The 'auto' option is supported only for the 'euclidean' and 'seuclidean' distance metrics.
- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. To reproduce results, set a random number seed using rng before calling fsulaplacian.

Example: 'KernelScale','auto'

**Output Arguments**

**idx — Indices of features ordered by feature importance**

numeric vector

Indices of the features in \( X \) ordered by feature importance, returned as a numeric vector. For example, if \( \text{idx}(3) \) is 5, then the third most important feature is the fifth column in \( X \).

**scores — Feature scores**

numeric vector

Feature scores, returned as a numeric vector. A large score value in scores indicates that the corresponding feature is important. The values in scores have the same order as the features in \( X \).

**More About**

**Similarity Graph**

A similarity graph models the local neighborhood relationships between data points in \( X \) as an undirected graph. The nodes in the graph represent data points, and the edges, which are directionless, represent the connections between the data points.
If the pairwise distance $\text{Dist}_{i,j}$ between any two nodes $i$ and $j$ is positive (or larger than a certain threshold), then the similarity graph connects the two nodes using an edge [2]. The edge between the two nodes is weighted by the pairwise similarity $S_{i,j}$, where $S_{i,j} = \exp\left(-\frac{(\text{Dist}_{i,j})^2}{\sigma^2}\right)$, for a specified kernel scale $\sigma$ value.

`fsulaplacian` constructs a similarity graph using the nearest neighbor method. The function connects points in $X$ that are nearest neighbors. Use `'NumNeighbors'` to specify the number of nearest neighbors.

**Similarity Matrix**

A similarity matrix is a matrix representation of a similarity graph on page 32-2303. The $n$-by-$n$ matrix $S = (S_{i,j})_{i,j=1,...,n}$ contains pairwise similarity values between connected nodes in the similarity graph. The similarity matrix of a graph is also called an adjacency matrix.

The similarity matrix is symmetric because the edges of the similarity graph are directionless. A value of $S_{i,j} = 0$ means that nodes $i$ and $j$ of the similarity graph are not connected.

**Degree Matrix**

A degree matrix $D_g$ is an $n$-by-$n$ diagonal matrix obtained by summing the rows of the similarity matrix on page 32-2304 $S$. That is, the $i$th diagonal element of $D_g$ is $D_g(i,i) = \sum_{j=1}^{n} S_{i,j}$.

**Laplacian Matrix**

A Laplacian matrix, which is one way of representing a similarity graph on page 32-2303, is defined as the difference between the degree matrix on page 32-2304 $D_g$ and the similarity matrix on page 32-2304 $S$.

$$L = D_g - S.$$  

**Algorithms**

**Laplacian Score**

The `fsulaplacian` function ranks features using Laplacian scores[1] obtained from a nearest neighbor similarity graph on page 32-2303.

`fsulaplacian` computes the values in `scores` as follows:

1. For each data point in $X$, define a local neighborhood using the nearest neighbor method, and find pairwise distances $\text{Dist}_{i,j}$ for all points $i$ and $j$ in the neighborhood.
2. Convert the distances to the similarity matrix on page 32-2304 $S$ using the kernel transformation $S_{i,j} = \exp\left(-\frac{(\text{Dist}_{i,j})^2}{\sigma^2}\right)$, where $\sigma$ is the scale factor for the kernel as specified by the `'KernelScale'` name-value pair argument.
3. Center each feature by removing its mean.

$$\bar{x}_r = x_r - \frac{x_r^T D_g 1}{1^T D_g 1},$$
where \( x_r \) is the \( r \)th feature, \( D_g \) is the degree matrix on page 32-2304, and \( 1^T = [1, \ldots, 1]^T \).

4 Compute the score \( s_r \) for each feature.

\[
s_r = \frac{x_r^T S x_r}{x_r^T D_g x_r}.
\]

Note that [1] defines the Laplacian score as

\[
L_r = \frac{x_r^T L x_r}{x_r^T D_g x_r} = 1 - \frac{x_r^T S x_r}{x_r^T D_g x_r},
\]

where \( L \) is the Laplacian matrix on page 32-2304, defined as the difference between \( D_g \) and \( S \). The \texttt{fsulaplacian} function uses only the second term of this equation for the score value of \( s_r \) so that a large score value indicates an important feature.

Selecting features using the Laplacian score is consistent with minimizing the value

\[
\sum_{i,j} \frac{(x_{ir} - x_{jr})^2 S_{i,j}}{\text{Var}(x_r)},
\]

where \( x_{ir} \) represents the \( i \)th observation of the \( r \)th feature. Minimizing this value implies that the algorithm prefers features with large variance. Also, the algorithm assumes that two data points of an important feature are close if and only if the similarity graph has an edge between the two data points.

**Topics**

“Introduction to Feature Selection” on page 15-49

**Introduced in R2019b**
**fsurfht**

Interactive contour plot

**Syntax**

```matlab
fsurfht(fun,xlims,ylims)
fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)
```

**Description**

`fsurfht(fun,xlims,ylims)` is an interactive contour plot of the function specified by the text variable `fun`. The x-axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y-axis limits are specified by `ylims` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z-values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x-axis and y-axis.

**Examples**

Plot the Gaussian likelihood function for the `gas.mat` data.

```matlab
load gas
Create a function containing the following commands, and name it `gauslike.m`.

```matlab
function z = gauslike(mu,sigma,p1)
n = length(p1);
z = ones(size(mu));
for i = 1:n
    z = z .* (normpdf(p1(i),mu,sigma));
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters µ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```matlab
fsurfht('gauslike',[112 118],[3 5],price1)
```
The sample mean is the x value at the maximum, but the sample standard deviation is \textit{not} the y value at the maximum.

\[
m_{\text{max}} = \text{mean(price1)} \\
m_{\text{max}} = 115.1500 \\
s_{\text{max}} = \text{std(price1)} \times \sqrt{\frac{19}{20}} \\
s_{\text{max}} = 3.7719
\]

\textbf{Introduced before R2006a}
fullfact

Full factorial design

Syntax

dFF = fullfact(levels)

Description

dFF = fullfact(levels) gives factor settings dFF for a full factorial design with \( n \) factors, where the number of levels for each factor is given by the vector levels of length \( n \). dFF is \( m \)-by-\( n \), where \( m \) is the number of treatments in the full-factorial design. Each row of dFF corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

dFF = fullfact([2 4])
dFF =
   1   1
   2   1
   1   2
   2   2
   1   3
   2   3
   1   4
   2   4

ff2n

Introduced before R2006a
**gagerr**

Gage repeatability and reproducibility study

**Syntax**

```matlab
gagerr(y,{part,operator})
gagerr(y,GROUP)
gagerr(y,part)
gagerr(...,param1,val1,param2,val2,...)
[TABLE, stats] = gagerr(...)
```

**Description**

`gagerr(y,{part,operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, string arrays, or cell arrays of character vectors. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If NDC > 5, the measurement system is capable.
- If NDC < 2, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If PRR < 10%, the measurement system is capable.
- If PRR > 30%, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y,GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y,part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(...,param1,val1,param2,val2,...)` performs a gage R&R study using one or more of the following parameter name/value pairs:
• 'spec' — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

• If PTR < 0.1, the measurement system is capable.
• If PTR > 0.3, the measurement system is not capable.
• Otherwise, the measurement system may be acceptable.

• 'printtable' — A value 'on' or 'off' that indicates whether the tabular output should be printed in the command window or not. The default value is 'on'.
• 'printgraph' — A value 'on' or 'off' that indicates whether the bar graph should be plotted or not. The default value is 'on'.
• 'randomoperator' — A logical value, true or false, that indicates whether the effect of operator is random or not. The default value is true.
• 'model' — The model to use, specified by one of:
  • 'linear' — Main effects only (default)
  • 'interaction' — Main effects plus two-factor interactions
  • 'nested' — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

• ndc — Number of distinct categories
• prr — Percentage of gage R&R of total variations
• ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y, operators do on the parts.

rng(1234,'twister')               % for reproducibility
y = randn(100,1);                 % measurements
part = ceil(3*rand(100,1));       % parts
operator = ceil(4*rand(100,1));   % operators

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

gagerr(y,{part, operator},'randomoperator',true)

Introduced in R2006b
gamcdf

Gamma cumulative distribution function

Syntax

p = gamcdf(x,a)
p = gamcdf(x,a,b)

[p,pLo,pUp] = gamcdf(x,a,b,pCov)
[p,pLo,pUp] = gamcdf(x,a,b,pCov,alpha)

___  = gamcdf( ___ ,'upper')

Description

p = gamcdf(x,a) returns the cumulative distribution function (cdf) of the standard gamma
distribution with the shape parameters in a, evaluated at the values in x.

p = gamcdf(x,a,b) returns the cdf of the gamma distribution with the shape parameters in a and
scale parameters in b, evaluated at the values in x.

[p,pLo,pUp] = gamcdf(x,a,b,pCov) also returns the 95% confidence interval [pLo,pUp] of p
when a and b are estimates. pCov is the covariance matrix of the estimated parameters.

[p,pLo,pUp] = gamcdf(x,a,b,pCov,alpha) specifies the confidence level for the confidence
interval [pLo,pUp] to be 100(1–alpha)%.

___  = gamcdf( ___ ,'upper') returns the complement of the cdf, evaluated at the values in x,
using an algorithm that more accurately computes the extreme upper-tail probabilities than
subtracting the lower tail value from 1. 'upper' can follow any of the input argument combinations
in the previous syntaxes.

Examples

Compute Gamma Distribution cdf

Compute the cdf of the mean of the gamma distribution, which is equal to the product of the
parameters ab.

a = 1:6;
b = 5:10;
prob = gamcdf(a.*b,a,b)

prob = 1×6

0.6321    0.5940    0.5768    0.5665    0.5595    0.5543

As ab increases, the distribution becomes more symmetric, and the mean approaches the median.
Confidence Interval of Gamma cdf Value

Find a confidence interval estimating the probability that an observation is in the interval \([0, 10]\) using gamma distributed data.

Generate a sample of 1000 gamma distributed random numbers with shape 2 and scale 5.

```matlab
x = gamrnd(2,5,1000,1);
```

Compute estimates for the parameters.

```matlab
[params,~] = gamfit(x)
params = 1x2
    2.1089    4.8147
```

Store the parameters as \(a_{hat}\) and \(b_{hat}\).

```matlab
ahat = params(1);
bhat = params(2);
```

Find the covariance of the parameter estimates.

```matlab
[~,nCov] = gamlike(params,x)
nCov = 2x2
    0.0077   -0.0176
   -0.0176    0.0512
```

Create a confidence interval estimating the probability that an observation is in the interval \([0, 10]\).

```matlab
[prob,pLo,pUp] = gamcdf(10,ahat,bhat,nCov)
prob = 0.5830
pLo = 0.5587
pUp = 0.6069
```

Complementary cdf (Tail Distribution)

Determine the probability that an observation from the gamma distribution with shape parameter 2 and scale parameter 3 will be in the interval \([150, \text{Inf}]\).

```matlab
p1 = 1 - gamcdf(150,2,3)
p1 = 0
```

\(\text{gamcdf}(150, 2, 3)\) is nearly 1, so \(p1\) becomes 0. Specify ‘upper’ so that \(\text{gamcdf}\) computes the extreme upper-tail probabilities more accurately.
p2 = gamcdf(150,2,3,'upper')
p2 = 9.8366e-21

**Input Arguments**

**x** — **Values at which to evaluate cdf**
nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the cdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `x` must be a scalar value.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`
Data Types: `single` | `double`

**a** — **Shape parameter**
positive scalar value | array of positive scalar values

Shape of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 2 3 5]`
Data Types: `single` | `double`

**b** — **Scale parameter**
1 (default) | positive scalar value | array of positive scalar values

Scale of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array
inputs. Each element in \( p \) is the cdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).

Example: \([1\ 1\ 2\ 2]\)

Data Types: single | double

\( pCov \) — Covariance of estimates
2-by-2 numeric matrix

Covariance of the estimates \( a \) and \( b \), specified as a 2-by-2 matrix.

If you specify \( pCov \) to compute the confidence interval \([pLo\ pUp]\), then \( x \), \( a \), and \( b \) must be scalar values.

You can estimate \( a \) and \( b \) by using \texttt{gamfit} or \texttt{mle}, and estimate the covariance of \( a \) and \( b \) by using \texttt{gamlike}. For an example, see “Confidence Interval of Gamma cdf Value” on page 32-2314.

Data Types: single | double

\( alpha \) — Significance level
0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is \( 100(1-alpha) \)% where \( alpha \) is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

Output Arguments

\( p \) — cdf values
scalar value | array of scalar values

cdf values evaluated at the values in \( x \), returned as a scalar value or an array of scalar values. \( p \) is the same size as \( x \), \( a \), and \( b \) after any necessary scalar expansion. Each element in \( p \) is the cdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).

\( pLo \) — Lower confidence bound for \( p \)
scalar value | array of scalar values

Lower confidence bound for \( p \), returned as a scalar value or an array of scalar values. \( pLo \) has the same size as \( p \).

\( pUp \) — Upper confidence bound for \( p \)
scalar value | array of scalar values

Upper confidence bound for \( p \), returned as a scalar value or an array of scalar values. \( pUp \) has the same size as \( p \).
More About

Gamma cdf

The gamma distribution is a two-parameter family of curves. The parameters $a$ and $b$ are shape and scale, respectively.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt.$$

The result $p$ is the probability that a single observation from a gamma distribution with parameters $a$ and $b$ falls in the interval $[0,x]$.

The gamma cdf is related to the incomplete gamma function `gamfit` by

$$f(x | a, b) = \text{gammainc}(\frac{x}{b}, a).$$

The standard gamma distribution occurs when $b = 1$, which coincides with the incomplete gamma function precisely.

For more information, see “Gamma Distribution” on page B-47.

Alternative Functionality

- `gamcdf` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gamcdf` is faster than the generic function `cdf`.

- Use the Probability Distribution Function app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Gamma Distribution” on page B-47
Introduced before R2006a
**gamfit**

Gamma parameter estimates

**Syntax**

```matlab
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

**Description**

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns 100(1 - alpha)% confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The `gamfit` function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

**Examples**

Fit a gamma distribution to random data generated from a specified gamma distribution:

```matlab
a = 2; b = 4;
data = gamrnd(a,b,100,1);
[p,ci] = gamfit(data)
p = 
  2.1990   3.7426
ci = 
  1.6840  2.8298  
  2.7141  4.6554
```

Topics
“Gamma Distribution” on page B-47

Introduced before R2006a
gaminv

Gamma inverse cumulative distribution function

**Syntax**

\[
x = \text{gaminv}(p,a)
\]
\[
x = \text{gaminv}(p,a,b)
\]
\[
[x,xLo,xUp] = \text{gaminv}(p,a,b,pCov)
\]
\[
[x,xLo,xUp] = \text{gaminv}(p,a,b,pCov,alpha)
\]

**Description**

\( x = \text{gaminv}(p,a) \) returns the inverse cumulative distribution function (icdf) of the standard gamma distribution with the shape parameter \( a \), evaluated at the values in \( p \).

\( x = \text{gaminv}(p,a,b) \) returns the icdf of the gamma distribution with shape parameter \( a \) and the scale parameter \( b \), evaluated at the values in \( p \).

\( [x,xLo,xUp] = \text{gaminv}(p,a,b,pCov) \) also returns the 95% confidence interval \([xLo,xUp]\) of \( x \) when \( a \) and \( b \) are estimates. \( pCov \) is the covariance matrix of the estimated parameters.

\( [x,xLo,xUp] = \text{gaminv}(p,a,b,pCov,alpha) \) specifies the confidence level for the confidence interval \([xLo,xUp]\) to be \( 100(1-\alpha)\% \).

**Examples**

**Compute Gamma icdf**

Find the median of the gamma distribution with shape parameter 3 and scale parameter 5.

\[
x = \text{gaminv}(0.5,3,5)
\]
\[
x = 13.3703
\]

**Confidence Interval of Gamma icdf Value**

Find a confidence interval estimating the median using gamma distributed data.

Generate a sample of 500 gamma distributed random numbers with shape 2 and scale 5.

\[
x = \text{gamrnd}(2,5,500,1);
\]

Compute estimates for the parameters.

\[
\text{params} = \text{gaminv}(x)
\]
\[
\text{params} = 1\times2
\]
Store the estimates for the parameters as \( \hat{a} \) and \( \hat{b} \).

\[
\hat{a} = \text{params}(1);
\hat{b} = \text{params}(2);
\]

Compute the covariance of the parameter estimates.

\[
[-,nCov] = \text{gamlike}(\text{params},x)
\]

\[
nCov = \begin{bmatrix}
0.0135 & -0.0346 \\
-0.0346 & 0.1141
\end{bmatrix}
\]

Create a confidence interval estimating \( x \).

\[
[x,xLo,xUp] = \text{gaminv}(0.50,\hat{a},\hat{b},nCov)
\]

\[
x = 8.4021 \\
xLo = 7.8669 \\
xUp = 8.9737
\]

**Input Arguments**

- **p** — Probability values at which to evaluate icdf
  
  | scalar value in \([0,1]\) | array of scalar values |
  
  Probability values at which to evaluate the inverse cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range \([0,1]\).

  If you specify \( p \) to compute the confidence interval \([xLo,xUp]\), then \( p \) must be a scalar value (not an array).

  - To evaluate the icdf at multiple values, specify \( p \) using an array.
  - To evaluate the icdfs of multiple distributions, specify \( a \) and \( b \) using arrays.

  If one or more of the input arguments \( p, a, \) and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gaminv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( p \).

  Example: \([0.1,0.5,0.9]\)

  Data Types: single | double

- **a** — Shape Parameter
  
  | positive scalar value | array of positive scalar values |
  
  Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.
To evaluate the icdf at multiple values, specify \( p \) using an array.

To evaluate the icdfs of multiple distributions, specify \( a \) and \( b \) using arrays.

If one or more of the input arguments \( p \), \( a \), and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gaminv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( p \).

Example: \([1 \ 2 \ 3 \ 5]\)

Data Types: \text{single} \mid \text{double}

\textbf{b — Scale Parameter}

1 (default) \mid \text{positive scalar value} \mid \text{array of positive scalar values}

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the icdf at multiple values, specify \( p \) using an array.

To evaluate the icdfs of multiple distributions, specify \( a \) and \( b \) using arrays.

If one or more of the input arguments \( p \), \( a \), and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gaminv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( p \).

Example: \([1 \ 1 \ 2 \ 2]\)

Data Types: \text{single} \mid \text{double}

\textbf{pCov — Covariance of estimates}

2-by-2 numeric matrix

Covariance of the estimates \( a \) and \( b \), specified as a 2-by-2 matrix.

If you specify \( pCov \) to compute the confidence interval \([xLo, xUp]\), then \( p \), \( a \), and \( b \) must be scalar values.

You can estimate \( a \) and \( b \) by using \text{gamfit} or \text{mle}, and estimate the covariance of \( a \) and \( b \) by using \text{gamlike}. For an example, see “Confidence Interval of Gamma icdf Value” on page 32-2321.

Data Types: \text{single} \mid \text{double}

\textbf{alpha — Significance level}

0.05 (default) \mid \text{scalar in the range (0,1)}

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is \( 100(1-\alpha)\% \), where \( \alpha \) is the probability that the confidence interval does not contain the true value.

Example: \(0.01\)

Data Types: \text{single} \mid \text{double}
**Output Arguments**

**x — icdf values**
scalar value | array of scalar values

icdf values evaluated at the probability values in p, returned as a scalar value or an array of scalar values. x is the same size as p, a, and b, after any necessary scalar expansion. Each element in x is the icdf value of the distribution specified by the corresponding elements in a and b, evaluated at the corresponding element in p.

**xLo — Lower confidence bound for x**
scalar value | array of scalar values

Lower confidence bound for x, returned as a scalar value or an array of scalar values. xLo has the same size as x.

**xUp — Upper confidence bound for x**
scalar value | array of scalar values

Upper confidence bound for x, returned as a scalar value or an array of scalar values. xUp has the same size as x.

**More About**

**Gamma icdf**

The gamma distribution is a two-parameter family of curves. The parameters a and b are shape and scale, respectively.

The gamma inverse function in terms of the gamma cdf is

\[ x = F^{-1}(p | a, b) = \{ x : F(x | a, b) = p \}, \]

where

\[ p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-t/b} dt. \]

The result x is the value such that an observation from the gamma distribution with parameters a and b falls in [0,x] with probability p.

For more information, see “Gamma Distribution” on page B-47.

**Algorithms**

No known analytical solution exists for the integral equation shown in “Gamma icdf” on page 32-2324. gaminv uses an iterative approach (Newton’s method) to converge on the solution.

**Alternative Functionality**

- gaminv is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function icdf, which supports various probability distributions. To use
icdf, create a GammaDistribution probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function gaminv is faster than the generic function icdf.

Extended Capabilities

Topics
“Gamma Distribution” on page B-47

Introduced before R2006a
**gamlike**

Gamma negative log-likelihood

**Syntax**

```matlab
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

**Description**

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters. The parameters in `params` must all be positive.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...,] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...,] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

**Examples**

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```matlab
a = 2; b = 3;
r = gamrnd(a,b,100,1);
[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
   267.5648
AVAR =
   0.0788  -0.1104
  -0.1104   0.1955
```

**Extended Capabilities**

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.
This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a
gampdf

Gamma probability density function

Syntax

\[ y = \text{gampdf}(x,a) \]
\[ y = \text{gampdf}(x,a,b) \]

Description

\[ y = \text{gampdf}(x,a) \] returns the probability density function (pdf) of the standard gamma distribution with the shape parameter \( a \), evaluated at the values in \( x \).

\[ y = \text{gampdf}(x,a,b) \] returns the pdf of the gamma distribution with the shape parameter \( a \) and the scale parameter \( b \), evaluated at the values in \( x \).

Examples

Compute Gamma pdf

Compute the density of the observed value 5 in the standard gamma distribution with shape parameter 2.

\[ y1 = \text{gampdf}(5,2) \]
\[ y1 = 0.0337 \]

Compute the density of the observed value 5 in the gamma distributions with shape parameter 2 and scale parameters 1 through 5.

\[ y2 = \text{gampdf}(5,2,1:5) \]
\[ y2 = 1\times5 
\begin{bmatrix}
0.0337 & 0.1026 & 0.1049 & 0.0895 & 0.0736
\end{bmatrix} \]

Input Arguments

\( x \) — Values at which to evaluate pdf
nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify \( x \) using an array.
- To evaluate the pdfs of multiple distributions, specify \( a \) and \( b \) using arrays.
If one or more of the input arguments \( x, a, \) and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gampdf} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).

**Example:** \([3 4 7 9]\)

**Data Types:** single | double

\( a \) — Shape parameter

*positive scalar value | array of positive scalar values*

Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify \( x \) using an array.
- To evaluate the pdfs of multiple distributions, specify \( a \) and \( b \) using arrays.

If one or more of the input arguments \( x, a, \) and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gampdf} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).

**Example:** \([1 2 3 5]\)

**Data Types:** single | double

\( b \) — Scale parameter

*1 (default) | positive scalar value | array of positive scalar values*

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify \( x \) using an array.
- To evaluate the pdfs of multiple distributions, specify \( a \) and \( b \) using arrays.

If one or more of the input arguments \( x, a, \) and \( b \) are arrays, then the array sizes must be the same. In this case, \( \text{gampdf} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).

**Example:** \([1 1 2 2]\)

**Data Types:** single | double

**Output Arguments**

\( y \) — pdf values

*scalar value | array of scalar values*

Pdf values evaluated at the values in \( x \), returned as a scalar value or an array of scalar values. \( y \) is the same size as \( x, a, \) and \( b \) after any necessary scalar expansion. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( a \) and \( b \), evaluated at the corresponding element in \( x \).
More About

Gamma pdf

The gamma distribution is a two-parameter family of curves. The parameters \( a \) and \( b \) are shape and scale, respectively.

The gamma pdf is

\[
y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}},
\]

where \( \Gamma(\cdot) \) is the Gamma function.

The standard gamma distribution occurs when \( b = 1 \).

For more information, see “Gamma Distribution” on page B-47.

Alternative Functionality

- `gampdf` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. Topics

“Gamma Distribution” on page B-47

Introduced before R2006a
**gamrnd**

Gamma random numbers

**Syntax**

\[ r = \text{gamrnd}(a,b) \]

\[ r = \text{gamrnd}(a,b,sz1,\ldots,szN) \]

\[ r = \text{gamrnd}(a,b,sz) \]

**Description**

\[ r = \text{gamrnd}(a,b) \] generates a random number from the gamma distribution with the shape parameter \( a \) and the scale parameter \( b \).

\[ r = \text{gamrnd}(a,b,sz1,\ldots,szN) \] generates an array of random numbers from the gamma distribution, where \( sz1,\ldots,szN \) indicates the size of each dimension.

\[ r = \text{gamrnd}(a,b,sz) \] generates an array of random numbers from the gamma distribution, where vector \( sz \) specifies \( \text{size}(r) \).

**Examples**

**Generate Gamma Random Number**

Generate a single random number from the gamma distribution with shape 5 and scale 7.

\[ r = \text{gamrnd}(5,7) \]

\[ r = 68.9857 \]

**Generate Array of Gamma Random Numbers**

Generate five random numbers from the gamma distributions with shape parameter values 1 through 5 and scale parameter 2.

\[ a1 = 1:5; \]
\[ b1 = 2; \]
\[ r1 = \text{gamrnd}(a1,b1) \]

\[ r1 = 1\times5 \]

\[
\begin{array}{cccccc}
7.1297 & 6.0918 & 2.1010 & 8.7253 & 29.5447
\end{array}
\]

By default, `gamrnd` generates an array that is the same size as \( a \) and \( b \) after any necessary scalar expansion so that all scalars are expanded to match the dimensions of the other inputs.
If you specify array dimensions \( sz_1, \ldots, sz_N \) or \( sz \), they must match the dimensions of \( a \) and \( b \) after any necessary scalar expansion.

Generate a 2-by-3 array of random numbers from the gamma distribution with shape parameter 3 and scale parameter 7.

\[
\begin{align*}
\text{sz} &= [2 \ 3]; \\
r2 &= \text{gamrnd}(3,7,\text{sz}) \\
r2 &= 2\times3 \\
&= \begin{bmatrix}
17.9551 & 41.3983 & 7.9865 \\
16.4204 & 40.0048 & 44.1909
\end{bmatrix}
\end{align*}
\]

Generate six random numbers from the gamma distributions with shape parameter values 1 through 6 and scale parameter values 5 through 10 respectively.

\[
\begin{align*}
a3 &= 1:6; \\
b3 &= 5:10; \\
r3 &= \text{gamrnd}(a3,b3,1,6) \\
r3 &= 1\times6 \\
&= \begin{bmatrix}
\end{bmatrix}
\end{align*}
\]

**Input Arguments**

**a — Shape parameter**

Positive scalar value | array of positive scalar values

Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify \( a \) and \( b \) using arrays. If both \( a \) and \( b \) are arrays, then the array sizes must be the same. If either \( a \) or \( b \) is a scalar, then \( \text{gamrnd} \) expands the scalar argument into a constant array of the same size as the other argument. Each element in \( r \) is the random number generated from the distribution specified by the corresponding elements in \( a \) and \( b \).

Example: \([3 \ 4 \ 7 \ 9]\)

Data Types: single | double

**b — Scale parameter**

Positive scalar value | array of positive scalar values

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify \( a \) and \( b \) using arrays. If both \( a \) and \( b \) are arrays, then the array sizes must be the same. If either \( a \) or \( b \) is a scalar, then \( \text{gamrnd} \) expands the scalar argument into a constant array of the same size as the other argument. Each element in \( r \) is the random number generated from the distribution specified by the corresponding elements in \( a \) and \( b \).
Example: [1 1 2 2]
Data Types: single | double

sz1,...,szN — Size of each dimension (as separate arguments)

Size of each dimension, specified as separate arguments of integers.

If either a or b is an array, then the specified dimensions sz1,...,szN must match the common dimensions of a and b after any necessary scalar expansion. The default values of sz1,...,szN are the common dimensions.

• If you specify a single value sz1, then r is a square matrix of size sz1-by-sz1.
• If the size of any dimension is 0 or negative, then r is an empty array.
• Beyond the second dimension, gamrnd ignores trailing dimensions with a size of 1. For example, gamrnd(2,5,3,1,1,1) produces a 3-by-1 vector of random numbers from the gamma distribution with shape 2 and scale 5.

Example: 2,4
Data Types: single | double

sz — Size of each dimension (as a row vector)

Size of each dimension, specified as a row vector of integers.

If either a or b is an array, then the specified dimensions sz must match the common dimensions of a and b after any necessary scalar expansion. The default values of sz are the common dimensions.

• If you specify a single value [sz1], then r is a square matrix of size sz1-by-sz1.
• If the size of any dimension is 0 or negative, then r is an empty array.
• Beyond the second dimension, gamrnd ignores trailing dimensions with a size of 1. For example, gamrnd(2,5,[3 1 1 1]) produces a 3-by-1 vector of random numbers from the gamma distribution with shape 2 and scale 5.

Example: [2 4]
Data Types: single | double

Output Arguments

r — Gamma random numbers

nonnegative scalar value | array of nonnegative scalar values

Gamma random numbers, returned as a nonnegative scalar value or an array of nonnegative scalar values with the dimensions specified by sz1,...,szN or sz. Each element in r is the random number generated from the distribution specified by the corresponding elements in a and b.

Alternative Functionality

• gamrnd is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function random, which supports various probability distributions. To use
random, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gamrnd` is faster than the generic function `random`.

- Use `randg` to generate random numbers from the standard gamma distribution (unit scale).
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

**References**

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

gamstat

Gamma mean and variance

Syntax

[M,V] = gamstat(A,B)

Description

[M,V] = gamstat(A,B) returns the mean of and variance for the gamma distribution with shape parameters in A and scale parameters in B. A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V. A scalar input for A or B is expanded to a constant array with the same dimensions as the other input. The parameters in A and B must be positive.

The mean of the gamma distribution with parameters A and B is AB. The variance is AB².

Examples

[m,v] = gamstat(1:5,1:5)
m =   1   4   9  16  25
v =   1   8  27  64  125

[m,v] = gamstat(1:5,1./(1:5))
m =   1   1   1   1   1
v = 1.0000 0.5000 0.3333 0.2500 0.2000

ge

Class: qrandstream
Greater than or equal relation for handles

Syntax

h1 >= h2

Description

h1 >= h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise >= result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = ge(h1, h2) stores the result in a logical array of the same dimensions.

See Also

eq | gt | le | lt | ne | qrandstream
**GeneralizedLinearMixedModel class**

Generalized linear mixed-effects model class

**Description**

A GeneralizedLinearMixedModel object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the predict function and generate random data at new design points using the random function.

**Construction**

You can fit a generalized linear mixed-effects (GLME) model to sample data using fitglme(tbl, formula). For more information, see fitglme.

**Input Arguments**

- **tbl** — Input data
table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using formula.

Data Types: table

- **formula** — Formula for model specification
character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For a full description, see Formula on page 32-2350.

Example: 'y ~ treatment +(1|block)'

**Properties**

- **Coefficients** — Estimates of fixed-effects coefficients
dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
• **SE** — Standard error of the estimate
• **tStat** — $t$-statistic for a test that the coefficient is equal to 0
• **DF** — Degrees of freedom associated with the $t$ statistic
• **pValue** — $p$-value for the $t$-statistic
• **Lower** — Lower confidence limit
• **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

**CoefficientCovariance** — Covariance of estimated fixed-effects vector matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

**CoefficientNames** — Names of fixed-effects coefficients

cell array of character vectors

Names of fixed-effects coefficients, stored as a cell array of character vectors. The label for the coefficient of the constant term is `(Intercept)`. The labels for other coefficients indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

**DFE** — Degrees of freedom for error

positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If $n$ is the number of observations and $p$ is the number of fixed-effects coefficients, then DFE is equal to $n - p$.

Data Types: `double`

**Dispersion** — Model dispersion parameter

scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation $i$, the conditional variance of the response $y_i$, given the conditional mean $\mu_i$ and the dispersion parameter $\sigma^2$, in a generalized linear mixed-effects model is

$$\text{var}(y_i \mid \mu_i, \sigma^2) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where $w_i$ is the $i$th observation weight and $v$ is the variance function for the specified conditional distribution of the response. The `Dispersion` property contains an estimate of $\sigma^2$ for the specified
GLME model. The value of Dispersion depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of Dispersion is equal to $\sigma^2 = 1.0$.

- If FitMethod is MPL or REMPL and the 'DispersionFlag' name-value pair argument in fitglme is true, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If FitMethod is ApproximateLaplace or Laplace, then the 'DispersionFlag' name-value pair argument in fitglme does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, Dispersion is estimated from data.

Data Types: double

DispersionEstimated — Flag indicating if dispersion parameter was estimated
true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If FitMethod is ApproximateLaplace or Laplace, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and DispersionEstimated is false. For other distributions, the dispersion parameter is estimated from the data, and DispersionEstimated is true.
- If FitMethod is MPL or REMPL, and the 'DispersionFlag' name-value pair argument in fitglme is specified as true, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and DispersionEstimated is true.
- If FitMethod is MPL or REMPL, and the 'DispersionFlag' name-value pair argument in fitglme is specified as false, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and DispersionEstimated is false. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and DispersionEstimated is true.

Data Types: logical

Distribution — Response distribution name
'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:
- 'Normal' — Normal distribution
- 'Binomial' — Binomial distribution
- 'Poisson' — Poisson distribution
- 'Gamma' — Gamma distribution
- 'InverseGaussian' — Inverse Gaussian distribution

FitMethod — Method used to fit the model
'MPL' | 'REMPL' | 'ApproximateLaplace' | 'Laplace'

Method used to fit the model, stored as one of the following:
- 'MPL' — Maximum pseudo likelihood
- 'REMPL' — Restricted maximum pseudo likelihood
• 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
• 'Laplace' — Maximum likelihood using the Laplace method

**Formula — Model specification formula**

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula on page 32-2350.

**Link — Link function characteristics**

Link function characteristics, stored as a structure containing the following fields. The link is a function $G$ that links the distribution parameter $\mu$ to the linear predictor $\eta$ as follows: $G(\mu) = \eta$.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the link function</td>
</tr>
<tr>
<td>Link</td>
<td>Function that defines $G$</td>
</tr>
<tr>
<td>Derivative</td>
<td>Derivative of $G$</td>
</tr>
<tr>
<td>SecondDerivative</td>
<td>Second derivative of $G$</td>
</tr>
<tr>
<td>Inverse</td>
<td>Inverse of $G$</td>
</tr>
</tbody>
</table>

Data Types: struct

**LogLikelihood — Log of likelihood function**

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.
- If you use 'MPL', then LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then LogLikelihood is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: double

**ModelCriterion — Model criterion**

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIC</td>
<td>Akaike information criterion</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BIC</td>
<td>Bayesian information criterion</td>
</tr>
</tbody>
</table>
| LogLikelihood| • For a model fit using 'Laplace' or 'ApproximateLaplace', LogLikelihood is the maximized log likelihood.  
• For a model fit using 'MPL', LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.  
• For a model fit using 'REML', LogLikelihood is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration. |
| Deviance     | ~2 times LogLikelihood                                                      |

**NumCoefficients — Number of fixed-effects coefficients**
positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumEstimatedCoefficients — Number of estimated fixed-effects coefficients**
positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumObservations — Number of observations**
positive integer value

Number of observations used in the fit, stored as a positive integer value. NumObservations is the number of rows in the table or dataset array tbl, minus rows excluded using the 'Exclude' name-value pair of fitglme or rows containing NaN values.

Data Types: double

**NumPredictors — Number of predictors**
positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumVariables — Total number of variables**
positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array tbl, then NumVariables is the total number of variables in tbl, including the response variable. NumVariables includes variables, if any, that are not used as predictors or as the response.
Data Types: double

**ObservationInfo — Information about the observations**

Information about the observations used in the fit, stored as a table.

ObservationInfo has one row for each observation and the following columns.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>The weight value for the observation. The default value is 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>If the observation was excluded from the fit using the 'Exclude' name-value pair argument in fitglme, then Excluded is true, or 1. Otherwise, Excluded is false, or 0.</td>
</tr>
<tr>
<td>Missing</td>
<td>If the observation was excluded from the fit because any response or predictor value is missing, then Missing is true. Otherwise, Missing is false.</td>
</tr>
<tr>
<td></td>
<td>Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the &lt;undefined&gt; value for categorical arrays.</td>
</tr>
<tr>
<td>Subset</td>
<td>If the observation was used in the fit, then Subset is true. If the observation was not used in the fit because it is missing or excluded, then Subset is false.</td>
</tr>
<tr>
<td>BinomSize</td>
<td>Binomial size for each observation. This column only applies when fitting a binomial distribution.</td>
</tr>
</tbody>
</table>

Data Types: table

**ObservationNames — Names of observations**

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array tbl that contains observation names, then ObservationNames uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then ObservationNames is an empty cell array.

Data Types: cell

**PredictorNames — Names of predictors**

Names of the variables used as predictors in the fit, stored as a cell array of character vectors that has the same length as NumPredictors.

Data Types: cell
**ResponseName — Name of response variable**

Character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

**Data Types:** char

**Rsquared — Proportion of variability in the response explained by the fitted model structure**

Proportion of variability in the response explained by the fitted model, stored as a structure. Rsquared contains the R-squared value of the fitted model, also known as the multiple correlation coefficient. Rsquared contains the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ordinary</td>
<td>R-squared value, stored as a scalar value in a structure. Rsquared.Ordinary = 1 – SSE./SST</td>
</tr>
<tr>
<td>Adjusted</td>
<td>R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. Rsquared.Adjusted = 1 – (SSE./SST)*(DFT./DFE), where DFE = n – p, DFT = n – 1, n is the total number of observations, and p is the number of fixed-effects coefficients.</td>
</tr>
</tbody>
</table>

**Data Types:** struct

**SSE — Error sum of squares**

Positive scalar value

Error sum of squares, stored as a positive scalar value. SSE is the weighted sum of the squared conditional residuals, and is calculated as

\[
SSE = \sum_{i=1}^{n} w_i^{\text{eff}}(y_i - f_i)^2,
\]

where \(n\) is the number of observations, \(w_i^{\text{eff}}\) is the \(i\)th effective weight, \(y_i\) is the \(i\)th response, and \(f_i\) is the \(i\)th fitted value.

The \(i\)th effective weight is calculated as

\[
w_i^{\text{eff}} = \frac{w_i}{v_i(\mu(\hat{\beta}, \hat{b}))},
\]

where \(v_i\) is the variance term for the \(i\)th observation, \(\hat{\beta}\) and \(\hat{b}\) are estimated values of \(\beta\) and \(b\), respectively.

The \(i\)th fitted value is calculated as

\[
f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),
\]
where \( x_i^T \) is the \( i \)th row of the fixed-effects design matrix \( X \), and \( z_i^T \) is the \( i \)th row of the random-effects design matrix \( Z \). \( \delta_i \) is the \( i \)th offset value.

**Data Types:** double

### SSR — Regression sum of squares

**positive scalar value**

Regression sum of squares, stored as a positive scalar value. SSR is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. SSR is calculated as

\[
SSR = \sum_{i=1}^{N} w_{\text{eff}}^i (f_i - \bar{f})^2,
\]

where \( n \) is the number of observations, \( w_{\text{eff}}^i \) is the \( i \)th effective weight, \( f_i \) is the \( i \)th fitted value, and \( \bar{f} \) is a weighted average of the fitted values.

The \( i \)th effective weight is calculated as

\[
w_{\text{eff}}^i = \left[ \frac{w_i}{\nu_i(\mu(\hat{\beta}, \hat{b}))} \right],
\]

where \( \hat{\beta} \) and \( \hat{b} \) are estimated values of \( \beta \) and \( b \), respectively.

The \( i \)th fitted value is calculated as

\[
f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),
\]

where \( x_i^T \) is the \( i \)th row of the fixed-effects design matrix \( X \), and \( z_i^T \) is the \( i \)th row of the random-effects design matrix \( Z \). \( \delta_i \) is the \( i \)th offset value.

The weighted average of fitted values is calculated as

\[
\bar{f} = \frac{\sum_{i=1}^{n} w_{\text{eff}}^i f_i}{\sum_{i=1}^{n} w_{\text{eff}}^i}.
\]

**Data Types:** double

### SST — Total sum of squares

**positive scalar value**

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as \( \text{SST} = \text{SSE} + \text{SSR} \).

**Data Types:** double

### VariableInfo — Information about the variables

table
Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Class of the variable ('double', 'cell', 'nominal', and so on).</td>
</tr>
<tr>
<td>Range</td>
<td>Value range of the variable.</td>
</tr>
<tr>
<td></td>
<td>• For a numerical variable, Range is a two-element vector of the form ([\text{min}, \text{max}]).</td>
</tr>
<tr>
<td></td>
<td>• For a cell or categorical variable, Range is a cell or categorical array containing all unique values of the variable.</td>
</tr>
<tr>
<td>InModel</td>
<td>If the variable is a predictor in the fitted model, InModel is true.</td>
</tr>
<tr>
<td></td>
<td>If the variable is not in the fitted model, InModel is false.</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then IsCategorical is true.</td>
</tr>
<tr>
<td></td>
<td>If the variable is a continuous predictor, then IsCategorical is false.</td>
</tr>
</tbody>
</table>

Data Types: table

`VariableNames — Names of the variables`

cell array of character vectors

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of character vectors.

Data Types: cell

`Variables — Variables`

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.
Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[
defects_{ij} \sim \text{Poisson}(\mu_{ij})
\]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_{devij} + \beta_3 \text{temp}_{devij} + \beta_4 \text{supplier}_{Cij} + \beta_5 \text{supplier}_{Bij} + b_i,
\]

where

- `defects_{ij}` is the number of defects observed in the batch produced by factory `i` during batch `j`.
- `\mu_{ij}` is the mean number of defects corresponding to factory `i` (where `i = 1, 2, \ldots, 20`) during batch `j` (where `j = 1, 2, \ldots, 5`).
- `newprocess_{ij}`, `time_{devij}`, and `temp_{devij}` are the measurements for each variable that correspond to factory `i` during batch `j`. For example, `newprocess_{ij}` indicates whether the batch produced by factory `i` during batch `j` used the new process.
- `supplier_{Cij}` and `supplier_{Bij}` are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory `i` during batch `j`.
- `b_i \sim N(0, \sigma_b^2)` is a random-effects intercept for each factory `i` that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Display the model.

```matlab
disp(glme)
```

Generalized linear mixed-effects model fit by ML

Model information:

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

**Formula** indicates the model specification using Wilkinson’s notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The **Fixed effects coefficients** table indicates that fitglme returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the t-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and p-value that correspond to the t-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

**Random effects covariance parameters** displays a table for each grouping variable (here, only factory), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, std indicates that fitglme returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.
The standard display generated by fitglme does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

**More About**

**Formula**

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms, respectively, and R is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:
- A response variable, y
- Predictor variables, $X_j$, which can be continuous or grouping variables
- Grouping variables, $g_1$, $g_2$, ..., $g_R$,

where the grouping variables in $X_j$ and $g_r$ can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, '$y \sim \text{fixed} + (\text{random}_1|\text{grouping}_1) + ... + (\text{random}_R|\text{grouping}_R)'$, the term `fixed` corresponds to a specification of the fixed-effects design matrix $X$, `random_1` is a specification of the random-effects design matrix $Z_1$ corresponding to grouping variable $g_1$, and similarly `random_R` is a specification of the random-effects design matrix $Z_R$ corresponding to grouping variable $g_R$. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>$X^k$, where $k$ is a positive integer</td>
<td>$X, X^2, ..., X^k$</td>
</tr>
<tr>
<td>$X1 + X2$</td>
<td>$X1, X2$</td>
</tr>
<tr>
<td>$X1*X2$</td>
<td>$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)</td>
</tr>
<tr>
<td>$X1:X2$</td>
<td>$X1.*X2$ only</td>
</tr>
<tr>
<td>- $X2$</td>
<td>Do not include $X2$</td>
</tr>
<tr>
<td>$X1*X2 + X3$</td>
<td>$X1, X2, X3, X1*X2$</td>
</tr>
<tr>
<td>$X1 + X2 + X3 + X1:X2$</td>
<td>$X1, X2, X3, X1*X2$</td>
</tr>
<tr>
<td>$X1<em>X2</em>X3 - X1:X2:X3$</td>
<td>$X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>$X1*(X2 + X3)$</td>
<td>$X1, X2, X3, X1<em>X2, X1</em>X3$</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.
**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>
<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (X1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>
</tbody>
</table>

“Generalized Linear Mixed-Effects Models” on page 12-48
GeneralizedLinearModel

Generalized linear regression model class

Description

GeneralizedLinearModel is a fitted generalized linear regression model. A generalized linear regression model is a special class of nonlinear models that describe a nonlinear relationship between a response and predictors. A generalized linear regression model has generalized characteristics of a linear regression model. The response variable follows a normal, binomial, Poisson, gamma, or inverse Gaussian distribution with parameters including the mean response $\mu$. A link function $f$ defines the relationship between $\mu$ and the linear combination of predictors.

Use the properties of a GeneralizedLinearModel object to investigate a fitted generalized linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the model.

Creation

Create a GeneralizedLinearModel object by using fitglm or stepwiseglm.

fitglm fits a generalized linear regression model to data using a fixed model specification. Use addTerms, removeTerms, or step to add or remove terms from the model. Alternatively, use stepwiseglm to fit a model using stepwise generalized linear regression.

Properties

Coefficient Estimates

CoefficientCovariance — Covariance matrix of coefficient estimates
numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a $p$-by-$p$ matrix of numeric values. $p$ is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-57.

Data Types: single | double

CoefficientNames — Coefficient names
cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.
Data Types: cell

**Coefficients — Coefficient values**

Table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t-statistic for a test that the coefficient is zero
- **pValue** — p-value for the t-statistic

Use `coefTest` to perform linear hypothesis tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```matlab
beta = mdl.Coefficients.Estimate
```

Data Types: table

**NumCoefficients — Number of model coefficients**

Positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: double

**NumEstimatedCoefficients — Number of estimated coefficients**

Positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: double

**Summary Statistics**

**Deviance — Deviance of fit**

Numeric value

This property is read-only.

Deviance of the fit, specified as a numeric value. The deviance is useful for comparing two models when one model is a special case of the other model. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of
estimated parameters between the two models. For more information, see “Deviance” on page 32-2367.

Data Types: single | double

**DFE — Degrees of freedom for error**

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: double

**Diagnostics — Observation diagnostics**

table

This property is read-only.

Observation diagnostics, specified as a table that contains one row for each observation and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leverage</td>
<td>Diagonal elements of HatMatrix</td>
<td>Leverage for each observation indicates to what extent the fit is determined by the observed predictor values. A value close to 1 indicates that the fit is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates that the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. A Leverage value greater than 2*P/N indicates high leverage.</td>
</tr>
<tr>
<td>CooksDistance</td>
<td>Cook's distance of scaled change in fitted values</td>
<td>CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance greater than three times the mean Cook's distance can be an outlier.</td>
</tr>
<tr>
<td>HatMatrix</td>
<td>Projection matrix to compute fitted from observed responses</td>
<td>HatMatrix is an N-by-N matrix such that Fitted = HatMatrix*Y, where Y is the response vector and Fitted is the vector of fitted response values.</td>
</tr>
</tbody>
</table>

The software computes these values on the scale of the linear combination of the predictors, stored in the LinearPredictor field of the Fitted and Residuals properties. For example, the software computes the diagnostic values by using the fitted response and adjusted response values from the model mdl.

Yfit = mdl.Fitted.LinearPredictor
YAdjusted = mdl.Fitted.LinearPredictor + mdl.Residuals.LinearPredictor

Diagnostics contains information that is helpful in finding outliers and influential observations. For more details, see “Leverage” on page 32-2366, “Cook’s Distance” on page 32-2366, and “Hat Matrix” on page 32-2366.

Use plotDiagnostics to plot observation diagnostics.
Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values in the `CooksDistance` column and zeros in the `Leverage` and `HatMatrix` columns.

To obtain any of these columns as an array, index into the property using dot notation. For example, obtain the hat matrix in the model `mdl`:

```matlab
HatMatrix = mdl.Diagnostics.HatMatrix;
```

Data Types: `table`

**Dispersion — Scale factor of variance of response**  
numeric scalar

This property is read-only.

Scale factor of the variance of the response, specified as a numeric scalar.

If the `'DispersionFlag'` name-value pair argument of `fitglm` or `stepwiseglm` is `true`, then the function estimates the `Dispersion` scale factor in computing the variance of the response. The variance of the response equals the theoretical variance multiplied by the scale factor. For example, the variance function for the binomial distribution is \( p(1-p)/n \), where \( p \) is the probability parameter and \( n \) is the sample size parameter. If `Dispersion` is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If `Dispersion` is larger than 1, the data set is “overdispersed” relative to the binomial distribution.

Data Types: `double`

**DispersionEstimated — Flag to indicate use of dispersion scale factor**  
logical value

This property is read-only.

Flag to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`, specified as a logical value. If `DispersionEstimated` is `false`, `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be `false` only for the binomial and Poisson distributions.
- Set `DispersionEstimated` by setting the `'DispersionFlag'` name-value pair argument of `fitglm` or `stepwiseglm`.

Data Types: `logical`

**Fitted — Fitted response values based on input data**  
table

This property is read-only.

Fitted (predicted) values based on the input data, specified as a table that contains one row for each observation and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response</td>
<td>Predicted values on the scale of the response</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LinearPredictor</td>
<td>Predicted values on the scale of the linear combination of the predictors (same as the link function applied to the Response fitted values)</td>
</tr>
<tr>
<td>Probability</td>
<td>Fitted probabilities (included only with the binomial distribution)</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the vector `f` of fitted values on the response scale in the model `mdl`:

```latex
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Data Types: `table`

**LogLikelihood — Loglikelihood**

numeric value

This property is read-only.

Loglikelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: `single` | `double`

**ModelCriterion — Criterion for model comparison**

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \log L + 2m$, where $\log L$ is the loglikelihood and $m$ is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + \left(2m^2(1 + \frac{1}{n - m - 1})\right)$, where $n$ is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2\log L + m\log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2\log L + m^*(\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```latex
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`
Residuals — Residuals for fitted model
table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw</td>
<td>Observed minus fitted values</td>
</tr>
<tr>
<td>LinearPredictor</td>
<td>Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors</td>
</tr>
<tr>
<td>Pearson</td>
<td>Raw residuals divided by the estimated standard deviation of the response</td>
</tr>
<tr>
<td>Anscombe</td>
<td>Residuals defined on transformed data with the transformation selected to remove skewness</td>
</tr>
<tr>
<td>Deviance</td>
<td>Residuals based on the contribution of each observation to the deviance</td>
</tr>
</tbody>
</table>

Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the ordinary raw residual vector r in the model mdl:

\[
 r = \text{mdl.Residuals.Raw}
\]

Data Types: table

Rsquared — R-squared value for model
structure

This property is read-only.

R-squared value for the model, specified as a structure with five fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients
- LLR — Loglikelihood ratio
- Deviance — Deviance
- AdjGeneralized — Adjusted generalized R-squared

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

\[
 \text{Rsquared} = \frac{\text{SSR}}{\text{SST}}
\]

To obtain any of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model mdl:

\[
 r2 = \text{mdl.Rsquared.Adjusted}
\]

Data Types: struct
**SSE — Sum of squared errors**
numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

Data Types: single | double

**SSR — Regression sum of squares**
numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

Data Types: single | double

**SST — Total sum of squares**
numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector \( y \) from the mean(y).

Data Types: single | double

**Fitting Information**

**Steps — Stepwise fitting information**
structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Formula representing the starting model</td>

</tr>
<tr>
<td></td>
<td>coefficient standard errors.</td>
</tr>
</tbody>
</table>

Data Types: struct

**Formula — Model information**

LinearFormula object

This property is read-only.
Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

```matlab
mdl.Formula
```

**Link — Link function**

This property is read-only.

Link function, specified as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the link function, specified as a character vector. If you specify the link function using a function handle, then <code>Name</code> is `''.</td>
</tr>
<tr>
<td>LinkFunction</td>
<td>Function $f$ that defines the link function, specified as a function handle</td>
</tr>
<tr>
<td>DevianceFunction</td>
<td>Derivative of $f$, specified as a function handle</td>
</tr>
<tr>
<td>VarianceFunction</td>
<td>Inverse of $f$, specified as a function handle</td>
</tr>
</tbody>
</table>

The link function is a function $f$ that links the distribution parameter $\mu$ to the fitted linear combination $Xb$ of the predictors:

$$f(\mu) = Xb.$$

Data Types: `struct`

**NumObservations — Number of observations**

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. `NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `'Exclude'` name-value pair argument) or rows with missing values.

Data Types: `double`

**NumPredictors — Number of predictor variables**

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: `double`

**NumVariables — Number of variables**

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.
NumVariables also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

**ObservationInfo — Observation information**

data table

This property is read-only.

Observation information, specified as an n-by-4 table, where n is equal to the number of rows of input data. ObservationInfo contains the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>Observation weights, specified as a numeric value. The default value is 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>Indicator of excluded observations, specified as a logical value. The value is true if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.</td>
</tr>
<tr>
<td>Missing</td>
<td>Indicator of missing observations, specified as a logical value. The value is true if the observation is missing.</td>
</tr>
<tr>
<td>Subset</td>
<td>Indicator of whether or not the fitting function uses the observation, specified as a logical value. The value is true if the observation is not excluded or missing, meaning the fitting function uses the observation.</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector w of the model mdl:

```matlab
w = mdl.ObservationInfo.Weights
```

Data Types: table

**ObservationNames — Observation names**

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array.

Data Types: cell

**Offset — Offset variable**

numeric vector

This property is read-only.

Offset variable, specified as a numeric vector with the same length as the number of rows in the data. Offset is passed from fitglm or stepwiseglm in the 'Offset' name-value pair argument. The fitting functions use Offset as an additional predictor variable with a coefficient value fixed at 1. In other words, the formula for fitting is
\[ f(\mu) \sim \text{Offset} + \text{(terms involving real predictors)} \]

where \( f \) is the link function. The Offset predictor has coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor \( A \). By using the log link function and by specifying \( \log(A) \) as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: double

**PredictorNames — Names of predictors used to fit model**
cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: cell

**ResponseName — Response variable name**
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

**VariableInfo — Information about variables**
table

This property is read-only.

Information about variables contained in Variables, specified as a table with one row for each variable and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'</td>
</tr>
<tr>
<td>Range</td>
<td>Variable range, specified as a cell array of vectors</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector ([min,max]), the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Vector of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Indicator of which variables are in the fitted model, specified as a logical vector. The value is true if the model includes the variable.</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Indicator of categorical variables, specified as a logical vector. The value is true if the variable is categorical.</td>
</tr>
</tbody>
</table>

VariableInfo also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table
**VariableNames — Names of variables**
cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1','x2',..., 'xn','y'}.

VariableNames also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: cell

**Variables — Input data**
table

This property is read-only.

Input data, specified as a table. Variables contains both predictor and response values. If the fit is based on a table or dataset array, Variables contains all the data from the table or dataset array. Otherwise, Variables is a table created from the input data matrix X and the response vector y.

Variables also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

**Object Functions**

**Create** CompactGeneralizedLinearModel
compact  Compact generalized linear regression model

**Add or Remove Terms from Generalized Linear Model**
addTerms  Add terms to generalized linear regression model
removeTerms  Remove terms from generalized linear regression model
step  Improve generalized linear regression model by adding or removing terms

**Predict Responses**
feval  Predict responses of generalized linear regression model using one input for each predictor
predict  Predict responses of generalized linear regression model
random  Simulate responses with random noise for generalized linear regression model

**Evaluate Generalized Linear Model**
coefCI  Confidence intervals of coefficient estimates of generalized linear regression model
coefTest  Linear hypothesis test on generalized linear regression model coefficients
devianceTest  Analysis of deviance for generalized linear regression model
Visualize Generalized Linear Model and Summary Statistics

- plotDiagnostics: Plot observation diagnostics of generalized linear regression model
- plotPartialDependence: Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
- plotResiduals: Plot residuals of generalized linear regression model
- plotSlice: Plot of slices through fitted generalized linear regression surface

Examples

Create Generalized Linear Regression Model

Fit a logistic regression model of the probability of smoking as a function of age, weight, and sex, using a two-way interaction model.

Load the hospital data set.

```matlab
load hospital
```

Convert the dataset array to a table.

```matlab
tbl = dataset2table(hospital);
```

Specify the model using a formula that includes two-way interactions and lower-order terms.

```matlab
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```matlab
mdl = fitglm(tbl,modelspec,'Distribution','binomial')
```

```matlab
mdl = Generalized linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial

Estimated Coefficients:

<table>

</table>
```

100 observations, 93 error degrees of freedom
Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large p-value indicates that the model might not differ statistically from a constant.
Create Generalized Linear Regression Model Using Stepwise Regression

Create response data using three of 20 predictor variables, and create a generalized linear model using stepwise regression from a constant model to see if `stepwiseglm` finds the correct predictors.

Generate sample data that has 20 predictor variables. Use three of the predictors to generate the Poisson response variable.

```matlab
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear regression model using the Poisson distribution. Specify the starting model as a model that contains only a constant (intercept) term. Also, specify a model with an intercept and linear term for each predictor as the largest model to consider as the fit by using the 'Upper' name-value pair argument.

```matlab
mdl = stepwiseglm(X,y,'constant','Upper','linear','Distribution','poisson')
```

```
1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094
```

`stepwiseglm` finds the three correct predictors: `x5`, `x10`, and `x15`.

More About

Canonical Link Function

The default link function for a generalized linear model is the canonical link function. You can specify a link function when you fit a model with `fitglm` or `stepwiseglm` by using the 'Link' name-value pair argument.
### Distribution

### Cook’s Distance

The Cook’s distance \( D_i \) of observation \( i \) is

\[
D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1 - h_{ii})^2},
\]

where

- \( \hat{\phi} \) is the dispersion parameter (estimated or theoretical).
- \( e_i \) is the linear predictor residual, \( g(y_i) - x_i\hat{\beta} \), where
  - \( g \) is the link function.
  - \( y_i \) is the observed response.
  - \( x_i \) is the observation.
  - \( \hat{\beta} \) is the estimated coefficient vector.
- \( p \) is the number of coefficients in the regression model.
- \( h_{ii} \) is the \( i \)th diagonal element of the Hat Matrix on page 32-2366 \( H \).

### Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation \( i \) is the value of the \( i \)th diagonal term \( h_{ii} \) of the hat matrix \( H \). Because the sum of the leverage values is \( p \) (the number of coefficients in the regression model), an observation \( i \) can be considered an outlier if its leverage substantially exceeds \( p/n \), where \( n \) is the number of observations.

### Hat Matrix

The hat matrix \( H \) is defined in terms of the data matrix \( X \) and a diagonal weight matrix \( W \):

\[
H = X(X^T W X)^{-1} X^T W^T. 
\]

\( W \) has diagonal elements \( w_i \):

\[
w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}}, 
\]
where

- $g$ is the link function mapping $y_i$ to $x_i b$.
- $g'$ is the derivative of the link function $g$.
- $V$ is the variance function.
- $\mu_i$ is the $i$th mean.

The diagonal elements $H_{ii}$ satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^{n} h_{ii} = p,$$

where $n$ is the number of observations (rows of $X$), and $p$ is the number of coefficients in the regression model.

**Deviance**

Deviance of a model $M_1$ is twice the difference between the loglikelihood of the model $M_1$ and the saturated model $M_S$. A saturated model is the model with the maximum number of parameters that you can estimate.

For example, if you have $n$ observations ($y_i$, $i = 1, 2, ..., n$) with potentially different values for $X_i^T \beta$, then you can define a saturated model with $n$ parameters. Let $L(b, y)$ denote the maximum value of the likelihood function for a model with the parameters $b$. Then the deviance of the model $M_1$ is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where $b_1$ and $b_s$ contain the estimated parameters for the model $M_1$ and the saturated model, respectively. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where $n$ is the number of parameters in the saturated model and $p$ is the number of parameters in the model $M_1$.

Assume you have two different generalized linear regression models $M_1$ and $M_2$, and $M_1$ has a subset of the terms in $M_2$. You can assess the fit of the models by comparing the deviances $D_1$ and $D_2$ of the two models. The difference of the deviances is

$$D = D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y))$$
$$= -2(\log L(b_2, y) - \log L(b_1, y)).$$

Asymptotically, the difference $D$ has a chi-square distribution with degrees of freedom $v$ equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can obtain the $p$-value for this test by using $1 - \text{chi2cdf}(D, v)$.

Typically, you examine $D$ using a model $M_2$ with a constant term and no predictors. Therefore, $D$ has a chi-square distribution with $p - 1$ degrees of freedom. If the dispersion is estimated, the difference divided by the estimated dispersion has an $F$ distribution with $p - 1$ numerator degrees of freedom and $n - p$ denominator degrees of freedom.

**Terms Matrix**

A terms matrix $T$ is a $t$-by-($p + 1$) matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable $j$ in term $i$. 

32-2367
For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of T represents one term:

- \([0 \ 0 \ 0 \ 0]\) — Constant term or intercept
- \([0 \ 1 \ 0 \ 0]\) — B; equivalently, \(A^0 \times B^1 \times C^0\)
- \([1 \ 0 \ 1 \ 0]\) — A*C
- \([2 \ 0 \ 0 \ 0]\) — A^2
- \([0 \ 1 \ 2 \ 0]\) — B*(C^2)

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Extended Capabilities

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitglm` or `stepwiseglm`, the following restrictions apply.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the 'CategoricalVars' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
  - The Link, Derivative, and Inverse fields of the 'Link' name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 31-2.

“Generalized Linear Models” on page 12-9

**Introduced in R2012a**
**generateCode**

**Package:** classreg.learning.coder.config.svm

Generate C/C++ code using coder configurer

**Syntax**

generateCode(configurer)
generateCode(configurer, cfg)
genereateCode(___,'OutputPath',outputPath)

**Description**

After training a machine learning model, create a coder configurer for the model by using learnerCoderConfigurer. Modify the properties of the configurer to specify code generation options. Then use generateCode to generate C/C++ code for the predict and update functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use generateCode for the highlighted step.

![Code Generation Workflow](image)

generateCode(configurer) generates a MEX (MATLAB Executable) function for the predict and update functions of a machine learning model by using configurer. The generated MEX function is named outputFileFileName, which is the file name stored in the OutputFileName property of a coder configurer.

To generate a MEX function, generateCode first generates the following MATLAB files required to generate code and stores them in the current folder:

- **predict.m, update.m, and initialize.m** — predict.m and update.m are the entry-point functions for the predict and update functions of the machine learning model, respectively, and these two functions call initialize.m.
- A MAT-file that includes machine learning model information — generateCode uses the saveLearnerForCoder function to save machine learning model information in a MAT-file whose file name is stored in the OutputFileName property of a coder configurer. initialize.m loads the saved MAT-file by using the loadLearnerForCoder function.

After generating the necessary MATLAB files, generateCode creates the MEX function and the code for the MEX function in the codegen\mex\outputFileName folder and copies the MEX function to the current folder.
generateCode(configurer, cfg) generates C/C++ code using the build type specified by cfg.

generateCode(___, 'OutputPath', outputPath) specifies the folder path for the output files in addition to any of the input arguments in previous syntaxes. generateCode generates the MATLAB files in the folder specified by outputPath and generates C/C++ code in the folder outputPath \codegen\type\outputFileName where type is the build type specified by cfg.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the predict and update functions of the model by using a coder configurer.

Load the carsmall data set and train a support vector machine (SVM) regression model.

load carsmall
X = [Horsepower, Weight];
Y = MPG;
Mdl = fitrsvm(X, Y);
Mdl is a RegressionSVM object.

Create a coder configurer for the RegressionSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

configurer = learnerCoderConfigurer(Mdl, X)

configurer = RegressionSVMCoderConfigurer with properties:

Update Inputs:
    Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
    Scale: [1x1 LearnerCoderInput]
    Bias: [1x1 LearnerCoderInput]

Predict Inputs:
    X: [1x1 LearnerCoderInput]

Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'

Properties, Methods

configurer is a RegressionSVMCoderConfigurer object, which is a coder configurer of a RegressionSVM object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use mex -setup to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).
Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```matlab
generateCode(configurer)
```

generateCode creates these files in output folder:
- `'initialize.m'`
- `'predict.m'`
- `'update.m'`
- `'RegressionSVMModel.mat'`

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```matlab
type predict.m

function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
type update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
initialize('update',varargin{:});
end
type initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        % SupportVectors
        % Scale
        % Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
```

32-2371
Specify Build Type

Train a machine learning model and generate code by using the coder configurer of the trained model. When generating code, specify the build type and other configuration options using a code generation configuration object.

Load the ionosphere data set and train a binary support vector machine (SVM) classification model.

```matlab
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```matlab
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Create a code generation configuration object by using `coder.config`. Specify `'dll'` to generate a dynamic library and specify the `GenerateReport` property as `true` to enable the code generation report.

```matlab
cfg = coder.config('dll');
cfg.GenerateReport = true;
```

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` and the configuration object `cfg` to generate code. Also, specify the output folder path.

```matlab
generateCode(configurer,cfg,'OutputPath','testPath')
```

Specified folder does not exist. Folder has been created.

`generateCode` creates these files in output folder:

- `'initialize.m'`
- `'predict.m'`
- `'update.m'`
- `'ClassificationSVMModel.mat'`

Code generation successful: To view the report, open (`'codegen\dll\ClassificationSVMModel\html\report.mldatx'`).

`generateCode` creates the specified folder. The function also generates the MATLAB files required to generate code and stores them in the folder. Then `generateCode` generates C code in the `testPath` folder.
Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

load fisheriris
X = meas;
Y = species;

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

t = templateSVM('KernelFunction','gaussian','Standardize',true);

Train a multiclass ECOC model using the template t.

Mdl = fitcecoc(X,Y,'Learners',t);
Mdl is a ClassificationECOC object.

Create Coder Configurer

Create a coder configurer for the ClassificationECOC model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the predict function, which are the predicted labels and negated average binary losses.

configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)

configurer = ClassificationECOCCoderConfigurer with properties:

  Update Inputs:
  BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
  Prior: [1x1 LearnerCoderInput]
  Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
  X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
  NumOutputs: 2
  OutputFileName: 'ClassificationECOCModel'

Properties, Methods
configurer is a ClassificationECOCCoderConfigurer object, which is a coder configurer of a ClassificationECOC object. The display shows the tunable input arguments of predict and update: X, BinaryLearners, Prior, and Cost.

**Specify Coder Attributes of Parameters**

Specify the coder attributes of predict arguments (predictor data and the name-value pair arguments 'Decoding' and 'BinaryLoss') and update arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of predict and update in the generated code.

First, specify the coder attributes of X so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```matlab
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is Inf and the size is variable, meaning that X can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. X contains 4 predictors, so the second value of the SizeVector attribute must be 4 and the second value of the VariableDimensions attribute must be false.

Next, modify the coder attributes of BinaryLoss and Decoding to use the 'BinaryLoss' and 'Decoding' name-value pair arguments in the generated code. Display the coder attributes of BinaryLoss.

```matlab
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
        Value: 'hinge'
       SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
       Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the Value attribute of BinaryLoss as 'exponential'.

```matlab
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
        Value: 'exponential'
       SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
```
If you modify attribute values when Tunability is false (logical 0), the software sets the Tunability to true (logical 1).

Display the coder attributes of Decoding.

```matlab
configurer.Decoding
ans =
    EnumeratedInput with properties:
         Value: 'lossweighted'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'lossweighted'  'lossbased'}
     IsConstant: 1
     Tunability: 0
```

Specify the IsConstant attribute of Decoding as false so that you can use all available values in BuiltInOptions in the generated code.

```matlab
configurer.Decoding.IsConstant = false;
```

```matlab
configurer.Decoding
ans =
    EnumeratedInput with properties:
         Value: [1x1 LearnerCoderInput]
    SelectedOption: 'NonConstant'
    BuiltInOptions: {'lossweighted'  'lossbased'}
     IsConstant: 0
     Tunability: 1
```

The software changes the Value attribute of Decoding to a LearnerCoderInput object so that you can use both 'lossweighted' and 'lossbased' as the value of 'Decoding'. Also, the software sets the SelectedOption to 'NonConstant' and the Tunability to true.

Finally, modify the coder attributes of SupportVectors in BinaryLearners. Display the coder attributes of SupportVectors.

```matlab
configurer.BinaryLearners.SupportVectors
ans =
    LearnerCoderInput with properties:
          SizeVector: [54 4]
      VariableDimensions: [1 0]
           DataType: 'double'
         Tunability: 1
```

The default value of VariableDimensions is [true false] because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

configurer

c = ClassificationECOCCoderConfigurer with properties:

Update Inputs:
  BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
  Prior: [1x1 LearnerCoderInput]
  Cost: [1x1 LearnerCoderInput]

Predict Inputs:
  X: [1x1 LearnerCoderInput]
  BinaryLoss: [1x1 EnumeratedInput]
  Decoding: [1x1 EnumeratedInput]

Code Generation Parameters:
  NumOutputs: 2
  OutputFileName: 'ClassificationECOCModel'

Properties, Methods

The display now includes BinaryLoss and Decoding as well.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`).

generateCode(configurer)

generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
• Create the code for the MEX function in the codegen\mex\ClassificationECOCModel folder.
• Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the predict function of Mdl and the predict function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified 'Decoding' as a tunable input argument by changing the IsConstant attribute before generating the code, you also need to specify it in the call to the MEX function, even though 'lossweighted' is the default value of 'Decoding'.

\[
\begin{align*}
[label,\text{NegLoss}] &= \text{predict}(Mdl,X,\text{'BinaryLoss','exponential'}); \\
[label\_mex,\text{NegLoss\_mex}] &= \text{ClassificationECOCModel}(\text{'predict'},X,\text{'BinaryLoss','exponential'};\text{'Decoding'}); \\
\end{align*}
\]

Compare label to label\_mex by using isequal.

isequal(label,label\_mex)

ans = logical

1

isequal returns logical 1 (true) if all the inputs are equal. The comparison confirms that the predict function of Mdl and the predict function in the MEX function return the same labels.

NegLoss\_mex might include round-off differences compared to NegLoss. In this case, compare NegLoss\_mex to NegLoss, allowing a small tolerance.

\[
\text{find}(\text{abs(NegLoss-NegLoss\_mex)} > 1e-8)
\]

ans =

0x1 empty double column vector

The comparison confirms that NegLoss and NegLoss\_mex are equal within the tolerance 1e–8.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify 'KernelScale' as 'auto' so that the software selects an appropriate scale factor using a heuristic procedure.

\[
\begin{align*}
t\_\text{new} &= \text{templateSVM}('\text{KernelFunction'},\text{'gaussian','Standardize',true,'KernelScale','auto'}); \\
\text{retrainedMdl} &= \text{fitcecoc}(X,Y,'\text{Learners'},t\_\text{new}); \\
\end{align*}
\]

Extract parameters to update by using validatedUpdateInputs. This function detects the modified model parameters in retrainedMdl and validates whether the modified parameter values satisfy the coder attributes of the parameters.

\[
\text{params} = \text{validatedUpdateInputs}(\text{configurer},\text{retrainedMdl});
\]

Update parameters in the generated code.

\[
\text{ClassificationECOCModel}(\text{'update'},\text{params})
\]
### Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```matlab
[Label, NegLoss] = predict(retrainedMdl, X, 'BinaryLoss', 'exponential', 'Decoding', 'lossbased');
[Label_mex, NegLoss_mex] = ClassificationECOCModel('predict', X, 'BinaryLoss', 'exponential', 'Decoding', 'lossbased');
isequal(Label, Label_mex)
ans = logical
1

find(abs(NegLoss - NegLoss_mex) > 1e-8)
ans =
    0x1 empty double column vector
```

The comparison confirms that `Label` and `Label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

### Input Arguments

- **configurer** — Coder configurer
coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

<table>
<thead>
<tr>
<th>Model</th>
<th>Coder Configurer Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary decision tree for multiclass classification</td>
<td>ClassificationTreeCoderConfigurer</td>
</tr>
<tr>
<td>SVM for one-class and binary classification</td>
<td>ClassificationSVMCoderConfigurer</td>
</tr>
<tr>
<td>Linear model for binary classification</td>
<td>ClassificationLinearCoderConfigurer</td>
</tr>
<tr>
<td>Multiclass model for SVMs and linear models</td>
<td>ClassificationECOCoderConfigurer</td>
</tr>
<tr>
<td>Binary decision tree for regression</td>
<td>RegressionTreeCoderConfigurer</td>
</tr>
<tr>
<td>Support vector machine (SVM) regression</td>
<td>RegressionSVMCoderConfigurer</td>
</tr>
<tr>
<td>Linear regression</td>
<td>RegressionLinearCoderConfigurer</td>
</tr>
</tbody>
</table>

- **cfg** — Build type

  - 'mex' (default) | 'dll' | 'lib' | code generation configuration object

Build type, specified as 'mex', 'dll', 'lib', or a code generation configuration object created by `coder.config`.

`generateCode` generates C/C++ code using one of the following build types.

- 'mex' — Generates a MEX function that has a platform-dependent extension. A MEX function is a C/C++ program that is executable from the Command Window. Before generating a C/C++ library for deployment, generate a MEX function to verify that the generated code provides the correct functionality.
• 'dll' — Generate a dynamic C/C++ library.
• 'lib' — Generate a static C/C++ library.

- Code generation configuration object created by coder.config — Generate C/C++ code using the code generation configuration object to customize code generation options. You can specify the build type and other configuration options using the object. For example, modify the GenerateReport parameter to enable the code generation report, and modify the TargetLang parameter to generate C++ code. The default value of the TargetLang parameter is 'C', generating C code.

```matlab
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.TargetLang = 'C++';
```

For details, see the -config option of codegen, coder.config, and “Configure Build Settings” (MATLAB Coder).

generateCode generates C/C++ code in the folder `outputPath\codegen\type \outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the OutputFileName property of configurer.

**outputPath — Folder path for output files**

*current folder (default) | character vector | string scalar*

Folder path for the output files of `generateCode`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateCode` creates the folder.

generateCode searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then `generateCode` generates the files. Otherwise, `generateCode` does not generate any MATLAB files.

generateCode generates C/C++ code in the folder `outputPath\codegen\type \outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the OutputFileName property of configurer.

Example: 'C:\myfiles'

Data Types: char | string

**Limitations**

- The `generateCode` function uses the `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` functions, so the code generation limitations of these functions also apply to the `generateCode` function. For details, see the function reference pages `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
- For the code generation usage notes and limitations of a machine learning model and its object functions, see the Code Generation sections of the corresponding reference pages.

**Introduced in R2018b**
generateFiles

Package: classreg.learning.coder.config.svm

Generate MATLAB files for code generation using coder configurer

Syntax

generateFiles(configurer)
generateFiles(configurer,'OutputPath',outputPath)

Description

generateFiles(configurer) generates the MATLAB files required to generate C/C++ code by using the coder configurer configurer, and saves the generated files in the current folder.

To customize the code generation workflow, use generateFiles and codegen. If you do not need to customize your workflow, use generateCode.

generateFiles generates the following MATLAB files:

• predict.m, update.m, and initialize.m — predict.m and update.m are the entry-point functions for the predict and update functions of the machine learning model, respectively, and these two functions call initialize.m. You can modify these files according to your code generation workflow. For example, you can modify the predict.m file to include data preprocessing, or you can add these entry-point functions to another code generation project.

• A MAT-file that includes machine learning model information — generateFiles uses the saveLearnerForCoder function to save machine learning model information in a MAT-file whose file name is stored in the OutputFileName property of a coder configurer. initialize.m loads the saved MAT-file by using the loadLearnerForCoder function.

After you generate these files, generate C/C++ code by using codegen and the prepared codegen argument stored in the CodeGenerationArguments property of a coder configurer.

If the folder already includes all four MATLAB files, then generateFiles does not generate any files.

generateFiles(configurer,'OutputPath',outputPath) generates the MATLAB files in the folder specified by outputPath.

Examples

Generate MATLAB® Files for Code Generation

Train a machine learning model and then generate the MATLAB files required to generate C/C++ code for the predict and update functions of the model by using a coder configurer.

Load the ionosphere data set and train a binary support vector machine (SVM) classification model.
load ionosphere
Mdl = fitcsvm(X,Y);

Mdl is a ClassificationSVM object.

Create a coder configurer for the ClassificationSVM object.

configurer = learnerCoderConfigurer(Mdl,X);

configurer is a ClassificationSVMCoderConfigurer object, which is a coder configurer of a
ClassificationSVM object.

Use generateFiles to generate the MATLAB files required to generate C/C++ code for the
predict and update functions of the model.

generateFiles(configurer)

generateFiles generates predict.m, update.m, initialize.m, and
ClassificationSVMModel.mat (a MAT-file that includes machine learning model information).

Display the contents of the predict.m, update.m, and initialize.m files.

type predict.m % Display contents of predict.m
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:50
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m % Display contents of update.m
function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:50
initialize('update',varargin{:});
end

type initialize.m % Display contents of initialize.m
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:53:50
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        % SupportVectors
        % Scale
        % Bias
        % Prior
        % Cost
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
Generate C/C++ code by using codegen and the prepared codegen argument stored in the CodeGenerationArguments property of configurer.

cfArgs = configurer.CodeGenerationArguments;
codegen(cfArgs{:})

**Input Arguments**

- **configurer** — Coder configurer
coder configurer object

  Coder configurer of a machine learning model, specified as a coder configurer object created by using learnerCoderConfigurer.

<table>
<thead>
<tr>

- **outputPath** — Folder path for output files
current folder (default) | character vector | string scalar

  Folder path for the output files of generateFiles, specified as a character vector or string array.

  The specified folder path can be an absolute path or a relative path to the current folder path.

  - The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
  - The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

  If the specified folder does not exist, then generateFiles creates the folder.

  generateFiles searches the specified folder for the four MATLAB files: predict.m, update.m, initialize.m, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then generateFiles generates the files. Otherwise, generateFiles does not generate any MATLAB files.
Example: ‘C:\myfiles’
Data Types: char | string

**Alternative Functionality**

- To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`. In addition to generating the four MATLAB files generated by `generateFiles`, the `generateCode` function also generates the C/C++ code.

**See Also**

`generateCode` | `learnerCoderConfigurer` | `update` | `validatedUpdateInputs`

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-68

**Introduced in R2018b**
generateLearnerDataTypeFcn

Generate function that defines data types for fixed-point code generation

**Syntax**

```
generateLearnerDataTypeFcn(filename,X)
generateLearnerDataTypeFcn(filename,X,Name,Value)
```

**Description**

To generate fixed-point C/C++ code for the `predict` function of a machine learning model, use `generateLearnerDataTypeFcn`, `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.

- After training a machine learning model, save the model using `saveLearnerForCoder`.
- Create a structure that defines fixed-point data types by using the function generated from `generateLearnerDataTypeFcn`.
- Define an entry-point function that loads the model by using both `loadLearnerForCoder` and the structure, and then calls the `predict` function.
- Generate code using `codegen`, and then verify the generated code.

The `generateLearnerDataTypeFcn` function requires Fixed-Point Designer, and generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the `predict` function of a machine learning model. Use `generateLearnerDataTypeFcn` for the highlighted step.

```
Train Model -> Save Model -> Define Fixed-Point Data Types -> Define Entry-Point Function -> (Optional) Optimize Fixed-Point Data Types -> Generate Code -> Verify Generated Code
```

`generateLearnerDataTypeFcn(filename,X)` generates a data type function on page 32-2391 that defines fixed-point data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model. `filename` stores the machine learning model, and `X` contains the predictor data for the `predict` function of the model.

Use the generated function to create a structure that defines fixed-point data types. Then, use the structure as the input argument `T` of `loadLearnerForCoder`.

`generateLearnerDataTypeFcn(filename,X,Name,Value)` specifies additional options by using one or more name-value pair arguments. For example, you can specify 'WordLength', 32 to use 32-bit word length for the fixed-point data types.

**Examples**

**Generate Fixed-Point C/C++ Code for Prediction**

After training a machine learning model, save the model using `saveLearnerForCoder`. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by
using the data type function generated by `generateLearnerDataTypeFcn`. Then, define an entry-point function that loads the model by using both `loadLearnerForCoder` and the specified fixed-point data types, and calls the `predict` function of the model. Use `codegen` to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using `codegen`, you can use `buildInstrumentedMex` and `showInstrumentationResults` to optimize the fixed-point data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

### Train Model

Load the `ionosphere` data set and train a binary SVM classification model.

```matlab
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

### Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```matlab
saveLearnerForCoder(Mdl,'myMdl');
```

### Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```matlab
generateLearnerDataTypeFcn('myMdl',X)
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```matlab
T = myMdl_datatype('Fixed')
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi`. The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```matlab
T.XDataType
```

```matlab
ans =
[]
```
Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.
- Predict labels and scores using the loaded model.

```matlab
type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

**Note:** If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` function.

```matlab
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```matlab
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

codegen generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```matlab
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```matlab
verify_labels = isequal(labels,labels_fx)
```
verify_labels = logical
    1

isequal returns logical 1 (true), which means labels and labels_fx are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

\[
\text{sum}(\text{strcmp}(\text{labels}_\text{fx}, \text{labels}) == 0)/\text{numel}(\text{labels}_\text{fx}) \times 100
\]

ans = 0

Find the maximum of the relative differences between the score outputs.

\[
\text{relDiff_scores} = \max(\text{abs}(\text{scores}_\text{fx}.\text{double}(\cdot,1)-\text{scores}(\cdot,1))/\text{scores}(\cdot,1))
\]

relDiff_scores = 0.0055

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see “Tips” on page 32-2392 in generateLearnerDataTypeFcn, “Data Type Function” on page 32-2391, and “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

Input Arguments

filename — Name of MAT-file that contains structure array representing model object
character vector | string scalar

Name of the MATLAB formatted binary file (MAT-file) that contains the structure array representing a model object, specified as a character vector or string scalar.

You must create the filename file using saveLearnerForCoder, and the model in filename can be one of the following:

- Classification model
  - Decision tree (CompactClassificationTree)
  - Ensemble of decision trees (CompactClassificationEnsemble, ClassificationBaggedEnsemble)
  - SVM (support vector machine) (CompactClassificationSVM)
- Regression model
  - Decision tree (CompactRegressionTree)
  - Ensemble of decision trees (CompactRegressionEnsemble, RegressionBaggedEnsemble)
  - SVM (CompactRegressionSVM)

The extension of the filename file must be .mat. If filename has no extension, then generateLearnerDataTypeFcn appends .mat.

If filename does not include a full path, then generateLearnerDataTypeFcn loads the file from the current folder.

Example: 'myMdl'

Data Types: char | string
**X — Predictor data**
numeric matrix

Predictor data for the `predict` function of the model stored in `filename`, specified as an \( n \)-by-\( p \) numeric matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables.

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:
```matlab
generateLearnerDataTypeFcn(filename,X,'OutputFunctionName','myDataTypeFcn','WordLength',32)
```
generates a data type function named `myDataTypeFcn` that uses 32 bits for the word length when defining the fixed-point data type for each variable.

**OutputFunctionName — Name of generated function**

`filename` plus `_datatype` (default) | character vector | string scalar

Name of the generated function, specified as the comma-separated pair consisting of `'OutputFunctionName'` and a character vector or string scalar. The `'OutputFunctionName'` value must be a valid MATLAB function name.

The default function name is the file name in `filename` followed by `_datatype`. For example, if `filename` is `myMdl`, then the default function name is `myMdl_datatype`.

Example: `'OutputFunctionName','myDataTypeFcn'`

Data Types: `char` | `string`

**WordLength — Word length in bits**

16 (default) | numeric scalar

Word length in bits, specified as the comma-separated pair consisting of `'WordLength'` and a numeric scalar.

The generated data type function on page 32-2391 defines a fixed-point object for each variable using the specified `'WordLength'` value. If a variable requires a longer word length than the specified value, the software doubles the word length for the variable.

The optimal word length depends on your target hardware properties. When the specified word length is longer than the longest word size of your target hardware, the generated code contains multiword operations.

For details, see “Fixed-Point Data Types” (Fixed-Point Designer).

Example: `'WordLength',32`

Data Types: `single` | `double`

**OutputRange — Range of predict output**

range simulated using `X` (default) | numeric vector of two elements
Range of the output argument of the `predict` function, specified as the comma-separated pair consisting of 'OutputRange' and a numeric vector of two elements (minimum and maximum values of the output).

The 'OutputRange' value specifies the range of predicted class scores for a classification model and the range of predicted responses for a regression model. The following tables list the output arguments for which you can specify the range by using the 'OutputRange' name-value pair argument.

### Classification Model

<table>
<thead>
<tr>
<th>Model</th>
<th><code>predict</code> Function of Model</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decision tree</td>
<td><code>predict</code></td>
<td><code>score</code></td>
</tr>
<tr>
<td>Ensemble of decision trees</td>
<td><code>predict</code></td>
<td><code>score</code></td>
</tr>
<tr>
<td>SVM</td>
<td><code>predict</code></td>
<td><code>score</code></td>
</tr>
</tbody>
</table>

### Regression Model

<table>
<thead>
<tr>
<th>Model</th>
<th><code>predict</code> Function of Model</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decision tree</td>
<td><code>predict</code></td>
<td><code>Yfit</code></td>
</tr>
<tr>
<td>Ensemble of decision trees</td>
<td><code>predict</code></td>
<td><code>Yfit</code></td>
</tr>
<tr>
<td>SVM</td>
<td><code>predict</code></td>
<td><code>yfit</code></td>
</tr>
</tbody>
</table>

When `X` contains a large number of observations and the range for the output argument is known, specify the 'OutputRange' value to reduce the amount of computation.

If you do not specify the 'OutputRange' value, then the software simulates the output range using the predictor data `X` and the `predict` function.

The software determines the span of numbers that the fixed-point data can represent by using the 'OutputRange' value and the 'PercentSafetyMargin' value.

Example: 'OutputRange',[0,1]
Data Types: `single` | `double`

### PercentSafetyMargin — Safety margin percentage

10 (default) | numeric scalar

Safety margin percentage, specified as the comma-separated pair consisting of 'PercentSafetyMargin' and a numeric scalar.

For each variable, the software simulates the range of the variable and adds the specified safety margin to determine the span of numbers that the fixed-point data can represent. Then, the software proposes the maximum fraction length that does not cause overflows.

Use caution when you specify the 'PercentSafetyMargin' value. If a variable range is large, then increasing the safety margin can cause underflow, because the software decreases fraction length to represent a larger range using a given word length.

Example: 'PercentSafetyMargin',15
Data Types: `single` | `double`
More About

Data Type Function

Use the data type function generated by `generateLearnerDataTypeFcn` to create a structure that defines fixed-point data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model. Use the output structure of the data type function as the input argument `T` of `loadLearnerForCoder`.

If `filename` is 'myMdl', then `generateLearnerDataTypeFcn` generates a data type function named `myMdl_datatype`. The `myMdl_datatype` function supports this syntax:

```matlab
T = myMdl_datatype(dt)
```

`T = myMdl_datatype(dt)` returns a data type structure that defines data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model.

Each field of `T` contains a fixed-point object returned by `fi`. The input argument `dt` specifies the `DataType` property of the fixed-point object.

- Specify `dt` as 'Fixed' (default) for fixed-point code generation.
- Specify `dt` as 'Double' to simulate floating-point behavior of the fixed-point code.

Use the output structure `T` as the second input argument of `loadLearnerForCoder`.

The structure `T` contains the fields in the following table. These fields define the data types for the variables that directly influence the precision of the model. These variables, along with other named and internal variables, are required to run the `predict` function of the model.

<table>
<thead>
<tr>
<th>Description</th>
<th>Fields</th>
</tr>
</thead>
</table>
| Common fields for classification | • XDataType (input)  
• ScoreDataType (output or internal variable) and TransformedScoreDataType (output) |
<p>|                              | • If you train a model using the default 'ScoreTransform' value of 'none' or 'identity' (that is, you do not transform predicted scores), then the ScoreDataType field influences the precision of the output scores. |
|                              | • If you train a model using a value of 'ScoreTransform' other than 'none' or 'identity' (that is, you do transform predicted scores), then the ScoreDataType field influences the precision of the internal untransformed scores. The TransformedScoreDataType field influences the precision of the transformed output scores. |
| Common fields for regression  | • XDataType (input) |
|                              | • YFitDataType (output) |</p>
<table>
<thead>
<tr>
<th>Description</th>
<th>Fields</th>
</tr>
</thead>
</table>
| Additional fields for an ensemble of decision trees | • WeakLearnerOutputDataType (internal variable) — Data type for outputs from weak learners.  
• AggregatedLearnerWeightsDataType (internal variable) — Data type for a weighted aggregate of the outputs from weak learners, applicable only if you train a model using bagging ('Method','bag'). The software computes predicted scores (ScoreDataType) by dividing the aggregate by the sum of learner weights. |
| Additional fields for SVM | • XnormDataType (internal variable), applicable only if you train a model using 'Standardize' or 'KernelScale'  
• InnerProductDataType (internal variable) |

The software proposes the maximum fraction length that does not cause overflows, based on the default word length (16) and safety margin (10%) for each variable.

The following code shows the data type function `myMdl_datatype`, generated by `generateLearnerDataTypeFcn` when `filename` is 'myMdl' and the model in the `filename` file is an SVM classifier:

```matlab
function T = myMdl_datatype(dt)
if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...  
    'OverflowAction','Wrap', ...  
    'ProductMode','FullPrecision', ...  
    'MaxProductWordLength',128, ...  
    'SumMode','FullPrecision', ...  
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,16,14,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,16,14,fm,'DataType',dt);

% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist),  
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,16,6,fm,'DataType',dt);
end
```

**Tips**

- To improve the precision of the generated fixed-point code, you can tune the fixed-point data types. Modify the fixed-point data types by updating the data type function on page 32-2391 (`myMdl_datatype`) and creating a new structure, and then regenerate the code using the new structure. You can update the `myMdl_datatype` function in one of two ways:
• Regenerate the `myMdl_datatype` function by using `generateLearnerDataTypeFcn` and its name-value pair arguments.
  - Increase the word length by using the `WordLength` name-value pair argument.
  - Decrease the safety margin by using the `PercentSafetyMargin` name-value pair argument.

If you increase the word length or decrease the safety margin, the software can propose a longer fraction length, and therefore, improve the precision of the generated code based on the given data set.

• Manually modify the fixed-point data types in the function file (`myMdl_datatype.m`). For each variable, you can tune the word length and fraction length and specify fixed-point math settings using a `fimath` object.

• In the generated fixed-point code, a large number of operations or a large variable range can result in loss of precision, compared to the precision of the corresponding floating-point code. When training an SVM model, keep the following tips in mind to avoid loss of precision in the generated fixed-point code:
  - Data standardization (`'Standardize'`) — To avoid overflows in the model property values of support vectors in an SVM model, you can standardize the predictor data. Instead of using the `'Standardize'` name-value pair argument when training the model, standardize the predictor data before passing the data to the fitting function and the `predict` function so that the fixed-point code does not include the operations for the standardization.
  - Kernel function (`'KernelFunction'`) — Using the Gaussian kernel or linear kernel is preferable to using a polynomial kernel. A polynomial kernel requires higher computational complexity than the other kernels, and the output of a polynomial kernel function is unbounded.
  - Kernel scale (`'KernelScale'`) — Using a kernel scale requires additional operations if the value of `'KernelScale'` is not 1.
  - The prediction of a one-class classification problem might have loss of precision if the predicted class score values have a large range.

**Compatibility Considerations**

**Specify precision of transformed scores before and after their transformation**

Behavior changed in R2020a

In R2019b, you could train an SVM classifier for fixed-point code generation with some nondefault score transforms ('isman', 'sign', 'symmetric', or 'symmetricisman'). The `generateLearnerDataTypeFcn` function generated a data type function whose output structure contained only one field related to the scores, `ScoreDataType`. This field influenced the precision of the output scores both before and after their transformation.

Starting in R2020a, when you train an SVM classifier with a score transform other than `'none'` or `'identity'`, the `generateLearnerDataTypeFcn` function generates a data type function whose output structure `T` contains two fields related to the scores: `ScoreDataType` and `TransformedScoreDataType`. Use these fields to influence the precision of the output scores before and after their transformation, respectively. For more details, see “Data Type Function” on page 32-2391.

To update your code, rerun the `generateLearnerDataTypeFcn` function and then regenerate the output structure `T`.

Introduced in R2019b
geocdf

Geometric cumulative distribution function

Syntax

\[ y = \text{geocdf}(x,p) \]
\[ y = \text{geocdf}(x,p,'upper') \]

Description

\[ y = \text{geocdf}(x,p) \] returns the cumulative distribution function (cdf) of the geometric distribution at each value in \( x \) using the corresponding probabilities in \( p \). \( x \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( p \) must lie on the interval \([0,1]\). 

\[ y = \text{geocdf}(x,p,'upper') \] returns the complement of the geometric distribution cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at \( x \) equal to 3. The probability of success (tossing a heads) \( p \) in any given trial is 0.5.

\[
x = 3; 
p = 0.5; 
y = \text{geocdf}(x,p) 
\]

\[ y = 0.9375 \]

The returned value of \( y \) indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

More About

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

\[ y = F(x|p) = 1 - (1 - p)^{x+1}; \quad x = 0, 1, 2, ... , \]

where \( p \) is the probability of success, and \( x \) is the number of failures before the first success. The result \( y \) is the probability of observing up to \( x \) trials before a success, when the probability of success in any given trial is \( p \).

Topics
“Geometric Distribution” on page B-63

Introduced before R2006a
**geoinv**

Geometric inverse cumulative distribution function

**Syntax**

```matlab
x = geoinv(y,p)
```

**Description**

```matlab
x = geoinv(y,p) returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in y using the corresponding probabilities in p. geoinv returns the smallest positive integer x such that the geometric cdf evaluated at x is equal to or exceeds y. You can think of y as the probability of observing x successes in a row in independent trials, where p is the probability of success in each trial.
```

```matlab
y and p can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for p or y is expanded to a constant array with the same dimensions as the other input. The values in p and y must lie on the interval [0, 1].
```

**Examples**

**Compute Geometric Distribution icdf**

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a “success” means the car does not start, while a “failure” means the car does start. The probability of success for each trial p equals 0.03, while the probability of observing x failures in a row before observing a success y equals 0.1.

```matlab
y = 0.1;
p = 0.03;
x = geoinv(y,p)
```

`x = 3`

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```matlab
y2 = geocdf(2,p) % cdf for x = 2
```

`y2 = 0.0873`
y3 = geocdf(3,p)  % cdf for x = 3
y3 = 0.1147

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

“Geometric Distribution” on page B-63

**Introduced before R2006a**
geomean

Geometric mean

Syntax

m = geomean(X)
m = geomean(X,'all')
m = geomean(X,dim)
m = geomean(X,vecdim)
m = geomean(___,nanflag)

Description

m = geomean(X) returns the geometric mean on page 32-2404 of X.

• If X is a vector, then geomean(X) is the geometric mean of the elements in X.
• If X is a matrix, then geomean(X) is a row vector containing the geometric mean of each column of X.
• If X is a multidimensional array, then geomean operates along the first nonsingleton dimension of X.

m = geomean(X,'all') returns the geometric mean of all the elements in X.

m = geomean(X,dim) returns the geometric mean along the operating dimension dim of X.

m = geomean(X,vecdim) returns the geometric mean over the dimensions specified in the vector vecdim. For example, if X is a 2-by-3-by-4 array, then geomean(X,[1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the geometric mean of the elements on the corresponding page of X.

m = geomean(___,nanflag) specifies whether to exclude NaN values from the calculation, using any of the input argument combinations in previous syntaxes. By default, geomean includes NaN values in the calculation (nanflag has the value 'includenan'). To exclude NaN values, set the value of nanflag to 'omitnan'.

Examples

Compare Geometric and Arithmetic Mean

Set the random seed for reproducibility of the results.

rng('default')

Create a matrix of exponential random numbers with 5 rows and 4 columns.

X = exprnd(1,5,4)
X = 5×4
Compute the geometric and arithmetic means of the columns of X.

\[
\text{geometric} = \text{geomean}(X)
\]

```
geometric = 1×4
0.2805    0.3083    0.2079    0.2698
```

\[
\text{arithmetic} = \text{mean}(X)
\]

```
arithmetic = 1×4
0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than the geometric mean for all the columns of X.

**Geometric Mean of All Elements**

Find the geometric mean over multiple dimensions by using the 'all' input argument.

Create a 2-by-5-by-4 array X.

\[
X = \text{reshape}(1:40,\{[2 5 4]\})
\]

```
X =

X(:,:,1) =
1     3     5     7     9
2     4     6     8    10

X(:,:,2) =
11    13    15    17    19
12    14    16    18    20

X(:,:,3) =
21    23    25    27    29
22    24    26    28    30

X(:,:,4) =
31    33    35    37    39
32    34    36    38    40
```
Find the geometric mean of all the elements of \( X \).
\[
m = \text{geomean}(X, 'all')
\]
\[
m = 15.7685
\]
m is the geometric mean of the entire array \( X \).

**Geometric Mean Along Specified Dimensions**

Find the geometric mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array \( X \).
\[
X = \text{reshape}(1:30, [3 5 2])
\]

\[
X = \\
X(:,:,1) = \\
1 4 7 10 13  \\
2 5 8 11 14  \\
3 6 9 12 15 \\
X(:,:,2) = \\
16 19 22 25 28  \\
17 20 23 26 29  \\
18 21 24 27 30
\]

Find the geometric mean of \( X \) along the default dimension.
\[
gmean1 = \text{geomean}(X)
\]
\[
gmean1 = \\
gmean1(:,:,1) = \\
1.8171 4.9324 7.9581 10.9696 13.9761 \\
gmean1(:,:,2) = \\
16.9804 19.9833 22.9855 25.9872 28.9885
\]

By default, \text{geomean} operates along the first dimension of \( X \) whose size does not equal 1. In this case, this dimension is the first dimension of \( X \). Therefore, \( gmean1 \) is a 1-by-5-by-2 array.

Find the geometric mean of \( X \) along the second dimension.
\[
gmean2 = \text{geomean}(X, 2)
\]
\[
gmean2 = \\
gmean2(:,:,1) = \\
1.8171 4.9324 7.9581 10.9696 13.9761 \\
gmean2(:,:,2) = \\
16.9804 19.9833 22.9855 25.9872 28.9885
\]
gmean2 is a 3-by-1-by-2 array.

Find the geometric mean of X along the third dimension.

gmean3 = geomean(X, 3)

gmean3 = 3×5

4.0000  8.7178  12.4097  15.8114  19.0788
5.8310 10.0000  13.5647  16.9115  20.1494
7.3485 11.2250  14.6969  18.0000  21.2132

gmean3 is a 3-by-5 array.

Find the geometric mean of each page of X by specifying the first and second dimensions using the vecdim input argument.

mpage = geomean(X, [1 2])

mpage =

mpage(:,:,1) =

6.4234

mpage(:,:,2) =

22.5845

For example, mpage(1, 1, 2) is the geometric mean of the elements in X(:, :, 2).

Find the geometric mean of the elements in each X(i, :, :) slice by specifying the second and third dimensions.

mrow = geomean(X, [2 3])

mrow = 3×1

10.5475
12.1932
13.5862
For example, \( \text{mean}(3) \) is the geometric mean of the elements in \( X(3,:,:,:) \), and is equivalent to specifying \( \text{geomean}(X(3,:,:,:) \text{,}'all') \).

**Geometric Mean Excluding NaN**

Create a vector and compute its geomean, excluding NaN values.

```matlab
x = 1:10;
x(3) = nan; % Replace the third element of x with a NaN value
n = geomean(x,'omitnan')
n = 4.7408
```

If you do not specify 'omitnan', then \( \text{geomean}(x) \) returns NaN.

**Input Arguments**

- **X** — Input data
  
  nonnegative vector | nonnegative matrix | nonnegative multidimensional array
  
  Input data that represents a sample from a population, specified as a nonnegative vector, matrix, or multidimensional array.
  
  - If \( X \) is a vector, then \( \text{geomean}(X) \) is the geometric mean of the elements in \( X \).
  - If \( X \) is a matrix, then \( \text{geomean}(X) \) is a row vector containing the geometric mean of each column of \( X \).
  - If \( X \) is a multidimensional array, then \( \text{geomean} \) operates along the first nonsingleton dimension of \( X \).
  
  To specify the operating dimension when \( X \) is a matrix or an array, use the \( \text{dim} \) input argument.

  Data Types: \( \text{single} \) | \( \text{double} \)

- **dim** — Dimension
  
  positive integer scalar
  
  Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of \( X \) whose size does not equal 1.

  Consider a two-dimensional array \( X \):
  
  - If \( \text{dim} \) is equal to 1, then \( \text{geomean}(X,1) \) returns a row vector containing the geometric mean for each column in \( X \).
  - If \( \text{dim} \) is equal to 2, then \( \text{geomean}(X,2) \) returns a column vector containing the geometric mean for each row in \( X \).

  If \( \text{dim} \) is greater than \( \text{ndims}(X) \) or if \( \text{size}(X,\text{dim}) \) is 1, then \( \text{geomean} \) returns \( X \).

  Data Types: \( \text{single} \) | \( \text{double} \)

- **vecdim** — Vector of dimensions
  
  positive integer vector
Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `geomean(X,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the geometric mean of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

`nanflag` — NaN condition

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — Include NaN values when computing the `geomean`. This returns NaN.
- `'omitnan'` — Ignore NaN values in the input.

Data Types: `char` | `string`

**Output Arguments**

`m` — Geometric mean

scalar | vector | matrix | multidimensional array

Geometric mean, returned as a scalar, vector, matrix, or multidimensional array.

**More About**

**Geometric Mean**

The geometric mean of a sample `X` is

\[ m = \left( \prod_{i=1}^{n} x_i \right)^{1/n} \]

where `n` is the number of values in `X`. 

32-2404

Topics
“Geometric Distribution” on page B-63

Introduced before R2006a
geopdf

Geometric probability density function

Syntax

\[ y = \text{geopdf}(x,p) \]

Description

\[ y = \text{geopdf}(x,p) \] returns the probability density function (pdf) of the geometric distribution at each value in \( x \) using the corresponding probabilities in \( p \). \( x \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( p \) must lie on the interval \([0, 1]\).

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distribution at \( x \) equal to 3. The probability of success (tossing a heads) \( p \) in any given trial is 0.5.

\[
\begin{align*}
 x &= 3; \\
p &= 0.5; \\
y &= \text{geopdf}(x,p) \\
y &= 0.0625
\end{align*}
\]

The returned value of \( y \) indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

More About

Geometric Distribution pdf

The probability density function (pdf) of the geometric distribution is

\[
y = f(x|p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \ldots,
\]

where \( p \) is the probability of success, and \( x \) is the number of failures before the first success. The result \( y \) is the probability of observing exactly \( x \) trials before a success, when the probability of success in any given trial is \( p \). For discrete distributions, the pdf is also known as the probability mass function (pmf).
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics
“Geometric Distribution” on page B-63

Introduced before R2006a
geornd

Geometric random numbers

Syntax

\[ r = \text{geornd}(p) \]
\[ r = \text{geornd}(p,m,n,...) \]
\[ r = \text{geornd}(p,[m,n,...]) \]

Description

\( r = \text{geornd}(p) \) generates random numbers from a geometric distribution with probability parameter \( p \). \( p \) can be a vector, a matrix, or a multidimensional array. The size of \( r \) is equal to the size of \( p \). The parameters in \( p \) must lie in the interval \([0, 1]\).

\( r = \text{geornd}(p,m,n,...) \) or \( r = \text{geornd}(p,[m,n,...]) \) generates a multidimensional \( m \)-by-\( n \)-by-\( ... \) array containing random numbers from the geometric distribution with probability parameter \( p \). \( p \) can be a scalar or an array of the same size as \( r \).

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant \( p \).

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter \( p \) equal to 0.01.

\[
\text{rng default} \quad \% \text{ For reproducibility} \\
p = 0.01; \\
r1 = \text{geornd}(0.01)
\]

\( r1 = 20 \)

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success \( p \) equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter \( p \) equal to 0.01.

\[
r2 = \text{geornd}(p,1,5) \\
r2 = 1 \times 5 \\
\]

\[
\begin{array}{cccc}
9 & 205 & 9 & 45 & 231 \\
\end{array}
\]
Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success \( p \) equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities \( p \).

\[
p = [0.01 \ 0.1 \ 0.5];
\]

\[
r3 = 
\begin{bmatrix}
127 & 5 & 0
\end{bmatrix}
\]

Each element of the returned 1-by-3 array \( r3 \) contains one random number generated from the geometric distribution described by the corresponding parameter in \( P \). For example, the first element in \( r3 \) represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success \( p \) equal to 0.01. The second element in \( r3 \) represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success \( p \) equal to 0.1. The third element in \( r3 \) represents an experiment in which zero failures were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success \( p \) equal to 0.5.

Extended Capabilities

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**See Also**

**Topics**
“Geometric Distribution” on page B-63
Introduced before R2006a
**geostat**

Geometric mean and variance

**Syntax**

\[ [m,v] = \text{geostat}(p) \]

**Description**

\[ [m,v] = \text{geostat}(p) \]

returns the mean \( m \) and variance \( v \) of a geometric distribution with corresponding probability parameters in \( p \). \( p \) can be a vector, a matrix, or a multidimensional array. The parameters in \( p \) must lie in the interval \([0,1]\).

**Examples**

**Compute Mean and Variance of Geometric Distribution**

Define a probability vector that contains six different parameter values.

\[ p = 1./(1:6) \]

\[ p = \begin{bmatrix} 1.0000 & 0.5000 & 0.3333 & 0.2500 & 0.2000 & 0.1667 \end{bmatrix} \]

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

\[ [m,v] = \text{geostat}(1./(1:6)) \]

\[ m = \begin{bmatrix} 0 & 1.0000 & 2.0000 & 3.0000 & 4.0000 & 5.0000 \end{bmatrix} \]

\[ v = \begin{bmatrix} 0 & 2.0000 & 6.0000 & 12.0000 & 20.0000 & 30.0000 \end{bmatrix} \]

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter \( p \) equal to \( 1/3 \) is 2, and its variance is 6.
More About

Geometric Distribution Mean and Variance

The mean of the geometric distribution is mean = \( \frac{1-p}{p} \), and the variance of the geometric distribution is var = \( \frac{1-p}{p^2} \), where \( p \) is the probability of success.

Extended Capabilities

Topics
“Geometric Distribution” on page B-63

Introduced before R2006a
**GapEvaluation**

**Package:** clustering.evaluation  
**Superclasses:** clustering.evaluation.ClusterCriterion  

Gap criterion clustering evaluation object

**Description**

GapEvaluation is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using evalclusters.

**Construction**

`eva = evalclusters(x,clust,'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Gap',Name,Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

**Input Arguments**

- **x** — Input data  
  matrix  
  Input data, specified as an \(N\)-by-\(P\) matrix. \(N\) is the number of observations, and \(P\) is the number of variables.  
  Data Types: single | double

- **clust** — Clustering algorithm  
  'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle  
  Clustering algorithm, specified as one of the following.

  - 'kmeans'  
    Cluster the data in \(x\) using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.

  - 'linkage'  
    Cluster the data in \(x\) using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.

  - 'gmdistribution'  
    Cluster the data in \(x\) using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form \(C = \text{clustfun}(\text{DATA},K)\), where \(\text{DATA}\) is the data to be clustered, and \(K\) is the number of clusters. The output of \(\text{clustfun}\) must be one of the following:

- A vector of integers representing the cluster index for each observation in \(\text{DATA}\). There must be \(K\) unique values in this vector.
A numeric $n$-by-$K$ matrix of score for $n$ observations and $K$ classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify clust as a $n$-by-$K$ matrix containing the proposed clustering solutions. $n$ is the number of observations in the sample data, and $K$ is the number of proposed clustering solutions. Column $j$ contains the cluster indices for each of the $N$ points in the $j$th clustering solution.

Data Types: single | double | char | string | function_handle

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,..., NameN, ValueN.

Example: 'KList',[1:5], 'Distance', 'cityblock' specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

B — Number of reference data sets
100 (default) | positive integer value

Number of reference data sets generated from the reference distribution ReferenceDistribution, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B',150

Data Types: single | double

Distance — Distance metric
'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean' Squared Euclidean distance
'Euclidean' Euclidean distance
'cityblock' Sum of absolute differences
'cosine' One minus the cosine of the included angle between points (treated as vectors)
'correlation' One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see pdist.

You can also specify a function for the distance metric by using a function handle (MATLAB). The distance function must be of the form
d2 = distfun(XI,XJ),

where XI is a 1-by-$n$ vector corresponding to a single row of the input matrix $X$, and XJ is an $m_2$-by-$n$ matrix corresponding to multiple rows of $X$. distfun must return an $m_2$-by-1 vector of distances $d2$, whose $k$th element is the distance between $XI$ and $XJ(k,:)$. Distance only accepts a function handle if the clustering algorithm clust accepts a function handle as the distance metric. For example, the kmeans clustering algorithm does not accept a function
handle as the distance metric. Therefore, if you use the kmeans algorithm and then specify a function handle for Distance, the software errors.

- When clust is 'kmeans' or 'gmdistribution', evalclusters uses the distance metric specified for Distance to cluster the data.
- If clust is 'linkage', and Distance is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.
- If clust is 'linkage' and Distance is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for Distance must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance','Euclidean'

Data Types: single | double | char | string | function_handle

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when clust is a clustering algorithm name or a function handle. When criterion is 'gap', clust must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]

Data Types: single | double

ReferenceDistribution — Reference data generation method

‘PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

- 'PCA' Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x.
- 'uniform' Generate reference data uniformly over the range of each feature in the data matrix x.

Example: 'ReferenceDistribution','uniform'

SearchMethod — Method for selecting optimal number of clusters

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.
'globalMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(	ext{GAPMAX}), \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, \( \text{GAPMAX} \) is the largest gap value, and \( \text{SE}(	ext{GAPMAX}) \) is the standard error corresponding to the largest gap value.

'firstMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1), \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, and \( \text{SE}(K + 1) \) is the standard error of the clustering solution with \( K + 1 \) clusters.

Example: 'SearchMethod','globalMaxSE'

**Properties**

**B**

Number of data sets generated from the reference distribution, stored as a positive integer value.

**ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

**CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

**CriterionValues**

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

**Distance**

Distance metric used for clustering data, stored as a valid distance metric name.

**ExpectedLogW**

Expectation of the natural logarithm of \( W \) based on the generated reference data, stored as a vector of scalar values. \( W \) is the within-cluster dispersion computed using the distance metric Distance.

**InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.
**LogW**

Natural logarithm of $W$ based on the input data, stored as a vector of scalar values. $W$ is the within-cluster dispersion computed using the distance metric $\text{Distance}$.

**Missing**

Logical flag for excluded data, stored as a column vector of logical values. If $\text{Missing}$ equals $\text{true}$, then the corresponding value in the data matrix $x$ is not used in the clustering solution.

**NumObservations**

Number of observations in the data matrix $X$, minus the number of missing ($\text{NaN}$) values in $X$, stored as a positive integer value.

**OptimalK**

Optimal number of clusters, stored as a positive integer value.

**OptimalY**

Optimal clustering solution corresponding to $\text{OptimalK}$, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, $\text{OptimalY}$ is empty.

**ReferenceDistribution**

Reference data generation method, stored as a valid reference distribution name.

**SE**

Standard error of the natural logarithm of $W$ with respect to the reference data for each number of clusters in $\text{InspectedK}$, stored as a vector of scalar values. $W$ is the within-cluster dispersion computed using the distance metric $\text{Distance}$.

**SearchMethod**

Method for determining the optimal number of clusters, stored as a valid search method name.

**StdLogW**

Standard deviation of the natural logarithm of $W$ with respect to the reference data for each number of clusters in $\text{InspectedK}$. $W$ is the within-cluster dispersion computed using the distance metric $\text{Distance}$.

**X**

Data used for clustering, stored as a matrix of numerical values.

**Methods**

- increaseB: Increase reference data sets
**Inherited Methods**

- **addK** Evaluate additional numbers of clusters
- **plot** Plot clustering evaluation object criterion values
- **compact** Compact clustering evaluation object

**Examples**

**Evaluate Clustering Solution Using Gap Criterion**

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```matlab
load fisheriris
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```matlab
rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```matlab
eva =
GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
    OptimalK: 5
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is five.

Plot the gap criterion values for each number of clusters tested.

```matlab
plot(eva)
```
Based on the plot, the maximum value of the gap criterion occurs at six clusters. However, the value at five clusters is within one standard error of the maximum, so the suggested optimal number of clusters is five.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```matlab
figure
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgkc','xod^*');
```
The plot shows cluster 4 in the lower-left corner, completely separated from the other four clusters. Cluster 4 contains flowers with the smallest petal widths and lengths. Cluster 2 is in the upper-right corner and contains flowers with the largest petal widths and lengths. Cluster 5 is next to cluster 2 and contains flowers with similar petal widths as the flowers in cluster 2, but smaller petal lengths than the flowers in cluster 2. Clusters 1 and 3 are near the center of the plot and contain flowers with measurements between the extremes.

More About

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

\[ Gap_n(k) = E_n^k \{ \log(W_k) \} - \log(W_k), \]

where \( n \) is the sample size, \( k \) is the number of clusters being evaluated, and \( W_k \) is the pooled within-cluster dispersion measurement.
\[ W_k = \sum_{r=1}^{k} \frac{1}{2n_r} D_r, \]

where \( n_r \) is the number of data points in cluster \( r \), and \( D_r \) is the sum of the pairwise distances for all points in cluster \( r \).

The expected value \( E_n^\star \{ \log(W_k) \} \) is determined by Monte Carlo sampling from a reference distribution, and \( \log(W_k) \) is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

**Topics**

- Class Attributes (MATLAB)
- Property Attributes (MATLAB)
Class: dataset

(Not Recommended) Access dataset array properties

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

```matlab
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

**Description**

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

**Examples**

Create a dataset array from Fisher's iris data and access the information.

```matlab
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs),'%-d'));
iris = dataset({nominal(species),'species'},
                 {meas,'SL','SW','PL','PW'},
                 'ObsNames',NameObs);
get(iris)
```

```
Description: ''
Units: {}
DimNames: {'Observations' 'Variables'}
UserData: []
ObsNames: {150x1 cell}
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

```
ON = get(iris,'ObsNames');
ON(1:3)
ans =
    'Obs1'
    'Obs2'
    'Obs3'
```

getlabels

(Not Recommended) Access nominal or ordinal array labels

**Note** The nominal and ordinal array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

```matlab
labels = getlabels(A)
```

**Description**

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of character vectors, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

**Input Arguments**

`A` — Nominal or ordinal array
nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with `nominal` or `ordinal`.

**See Also**

`getlevels` | `nominal` | `ordinal`

gevcdf

Generalized extreme value cumulative distribution function

Syntax

\[ p = \text{gevcdf}(x,k,sigma,mu) \]
\[ p = \text{gevcdf}(x,k,sigma,mu, \text{\textquoteleft}upper\textquoteleft) \]

Description

\[ p = \text{gevcdf}(x,k,sigma,mu) \] returns the cdf of the generalized extreme value (GEV) distribution with shape parameter \( k \), scale parameter \( sigma \), and location parameter, \( mu \), evaluated at the values in \( x \). The size of \( p \) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

\[ p = \text{gevcdf}(x,k,sigma,mu, \text{\textquoteleft}upper\textquoteleft) \] returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for \( k \), \( sigma \), and \( mu \) are 0, 1, and 0, respectively.

When \( k < 0 \), the GEV is the type III extreme value distribution. When \( k > 0 \), the GEV distribution is the type II, or Frechet, extreme value distribution. If \( w \) has a Weibull distribution as computed by the \text{wblcdf} function, then \(-w\) has a type III extreme value distribution and \( 1/w \) has a type II extreme value distribution. In the limit as \( k \) approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the \text{evcdf} function.

The mean of the GEV distribution is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). The GEV distribution has positive density only for values of \( X \) such that \( k*(X-mu)/sigma > -1 \).

Topics
“Generalized Extreme Value Distribution” on page B-55
Introduced before R2006a
**gevfit**

Generalized extreme value parameter estimates

**Syntax**

parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)

**Description**

parmhat = gevfit(X) returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. parmhat(1) is the shape parameter, k, parmhat(2) is the scale parameter, sigma, and parmhat(3) is the location parameter, mu.

[parmhat,parmci] = gevfit(X) returns 95% confidence intervals for the parameter estimates.

[parmhat,parmci] = gevfit(X,alpha) returns 100(1-alpha)% confidence intervals for the parameter estimates.

[...] = gevfit(X,alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gevfit') for parameter names and default values. Pass in [] for alpha to use the default values.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblfit function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evfit function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution is defined for k*(X-mu)/sigma > -1.

“Generalized Extreme Value Distribution” on page B-55
Introduced before R2006a
geinv

Generalized extreme value inverse cumulative distribution function

Syntax

X = geinv(P,k,sigma,mu)

Description

X = geinv(P,k,sigma,mu) returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter mu, evaluated at the values in P. The size of X is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k, sigma, and mu are 0, 1, and 0, respectively.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblinv function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evinv function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution has positive density only for values of X such that k*(X-mu)/sigma > -1.

Topics
“Generalized Extreme Value Distribution” on page B-55

Introduced before R2006a
**gevlike**

Generalized extreme value negative log-likelihood

**Syntax**

\[
\text{nlogL} = \text{gevlike}(\text{params, data}) \\
[\text{nlogL}, \text{ACOV}] = \text{gevlike}(\text{params, data})
\]

**Description**

\[ \text{nlogL} = \text{gevlike}(\text{params, data}) \] returns the negative of the log-likelihood \( nlogL \) for the generalized extreme value (GEV) distribution, evaluated at parameters \( \text{params} \). \( \text{params}(1) \) is the shape parameter, \( k \), \( \text{params}(2) \) is the scale parameter, \( \sigma \), and \( \text{params}(3) \) is the location parameter, \( \mu \).

\[ [\text{nlogL}, \text{ACOV}] = \text{gevlike}(\text{params, data}) \] returns the inverse of Fisher's information matrix, \( \text{ACOV} \). If the input parameter values in \( \text{params} \) are the maximum likelihood estimates, the diagonal elements of \( \text{ACOV} \) are their asymptotic variances. \( \text{ACOV} \) is based on the observed Fisher's information, not the expected information.

When \( k < 0 \), the GEV is the type III extreme value distribution. When \( k > 0 \), the GEV distribution is the type II, or Frechet, extreme value distribution. If \( w \) has a Weibull distribution as computed by the \text{wbllike} function, then \(-w\) has a type III extreme value distribution and \( 1/w \) has a type II extreme value distribution. In the limit as \( k \) approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the \text{evlike} function.

The mean of the GEV distribution is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). The GEV distribution has positive density only for values of \( X \) such that \( k*(X-\mu)/\sigma > -1 \).

gevrnd

Generalized extreme value random numbers

Syntax

R = gevrnd(k,sigma,mu)
R = gevrnd(k,sigma,mu,m,n,...)
R = gevrnd(k,sigma,mu,[m,n,...])

Description

R = gevrnd(k,sigma,mu) returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu. The size of R is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of R is the size of the other parameters.

R = gevrnd(k,sigma,mu,m,n,...) or R = gevrnd(k,sigma,mu,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the GEV distribution with parameters k, sigma, and mu. The k, sigma, mu parameters can each be scalars or arrays of the same size as R.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblrnd function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evrnd function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution has positive density only for values of X such that k*(X-mu)/sigma > -1.

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

32-2433
• The output is nonscalar.
• An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**
“Generalized Extreme Value Distribution” on page B-55

**Introduced before R2006a**
**gevstat**

Generalized extreme value mean and variance

**Syntax**

\[ [M,V] = \text{gevstat}(k,\sigma,\mu) \]

**Description**

\[ [M,V] = \text{gevstat}(k,\sigma,\mu) \]

returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter \( k \), scale parameter \( \sigma \), and location parameter, \( \mu \).

The sizes of \( M \) and \( V \) are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for \( k \), \( \sigma \), and \( \mu \) are 0, 1, and 0, respectively.

When \( k < 0 \), the GEV is the type III extreme value distribution. When \( k > 0 \), the GEV distribution is the type II, or Frechet, extreme value distribution. If \( w \) has a Weibull distribution as computed by the \text{wblstat} function, then \( -w \) has a type III extreme value distribution and \( 1/w \) has a type II extreme value distribution. In the limit as \( k \) approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the \text{evstat} function.

The mean of the GEV distribution is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). The GEV distribution has positive density only for values of \( X \) such that \( k*(X-\mu)/\sigma > -1 \).

**gline**

Interactively add line to plot

**Syntax**

\[ \text{gline}(h) \]
\[ \text{gline} \]
\[ hline = \text{gline}(...) \]

**Description**

\( \text{gline}(h) \) allows you to draw a line segment in the figure with handle \( h \) by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

\( \text{gline} \) with no input arguments defaults to \( h = \text{gcf} \) and draws in the current figure.

\( hline = \text{gline}(...) \) returns the handle \( hline \) to the line.

**Examples**

Use \( \text{gline} \) to connect two points in a plot:

\[ x = 1:10; \]
\[ y = x + \text{randn}(1,10); \]
\[ \text{scatter}(x,y,25,'b','*') \]
\[ \text{lsline} \]
\[ \mu = \text{mean}(y); \]
\[ \text{hold on} \]
\[ \text{plot}([1 10],[\mu \mu],'ro') \]

\( hline = \text{gline}; \% \text{Connect circles} \)
\[ \text{set}(hline,'Color','r') \]

Introduced before R2006a
glmfit

Generalized linear model regression

Syntax

b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)

Description

b = glmfit(X,y,distr) returns a (p + 1)-by-1 vector b of coefficient estimates for a generalized linear regression of the responses in y on the predictors in X, using the distribution distr. X is an n-by-p matrix of p predictors at each of n observations. distr can be any of the following: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, y is an n-by-1 vector of observed responses. For the binomial distribution, y can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note By default, glmfit adds a first column of 1s to X, corresponding to a constant term in the model. Do not enter a column of 1s directly into X. You can change the default behavior of glmfit using the 'constant' parameter, below.

glmfit treats NaNs in either X or y as missing values, and ignores them.

b = glmfit(X,y,distr,param1,val1,param2,val2,...) additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'link'</td>
<td>'identity', default for the distribution 'normal'</td>
<td>( \mu = Xb )</td>
</tr>
<tr>
<td></td>
<td>'log', default for the distribution 'poisson'</td>
<td>( \log(\mu) = Xb )</td>
</tr>
<tr>
<td></td>
<td>'logit', default for the distribution 'binomial'</td>
<td>( \log(\mu/(1 - \mu)) = Xb )</td>
</tr>
<tr>
<td></td>
<td>'probit'</td>
<td>( \text{norminv}(\mu) = Xb )</td>
</tr>
<tr>
<td></td>
<td>'comploglog'</td>
<td>( \log(-\log(1 - \mu)) = Xb )</td>
</tr>
<tr>
<td></td>
<td>'reciprocal', default for the distribution 'gamma'</td>
<td>( 1/\mu = Xb )</td>
</tr>
<tr>
<td></td>
<td>'loglog'</td>
<td>( \log(-\log(\mu)) = Xb )</td>
</tr>
</tbody>
</table>
### Parameter | Value | Description
--- | --- | ---
p (a number), default for the distribution 'inverse gaussian' (with p = -2) | $\mu^p = Xb$ | 

- cell array of the form `{FL FD FI}`, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).
- structure array having these fields:
  - 'Link' — Link function
  - 'Derivative' — Derivative of the link function
  - 'Inverse' — Inverse of the link function

The value of each field is a character vector corresponding to a function that is on the path or a function handle (created using @).

- Custom-defined link function. You must provide
  - FL(mu)
  - FD = dFL(mu)/dmu
  - FI = FL^(-1)

- Custom-defined link function, its derivative, and its inverse.

- 'estdisp' | 'on' | glmfit estimates a dispersion parameter for the binomial or Poisson distribution.

- 'off' (Default for binomial or Poisson distribution) | glmfit uses the theoretical value of 1.0 for those distributions.

- 'offset' | Vector | glmfit uses offset as an additional predictor variable, but with a coefficient value fixed at 1.0.

- 'weights' | Vector of prior weights, such as the inverses of the relative variance of each observation

- 'constant' | 'on' (default) | glmfit includes a constant term in the model and returns a $(p + 1)$-by-1 vector of coefficient estimates b. The coefficient of the constant term is the first element of b.

- 'off' | glmfit omits the constant term and returns a p-by-1 vector of coefficient estimates b.

---

[b,dev] = glmfit(...) returns dev, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.
[b,dev,stats] = glmfit(...) returns dev and stats.

stats is a structure with the following fields:

- **beta** — Coefficient estimates b
- **dfe** — Degrees of freedom for error
- **sfit** — Estimated dispersion parameter
- **s** — Theoretical or estimated dispersion parameter
- **estdisp** — 0 when the 'estdisp' name-value pair argument value is 'off' and 1 when the 'estdisp' name-value pair argument value is 'on'.
- **covb** — Estimated covariance matrix for B
- **se** — Vector of standard errors of the coefficient estimates b
- **coeffcorr** — Correlation matrix for b
- **t** — t statistics for b
- **p** — p-values for b
- **resid** — Vector of residuals
- **residp** — Vector of Pearson residuals
- **residd** — Vector of deviance residuals
- **resida** — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then stats.s is set equal to stats.sfit. Also, the elements of stats.se differ by the factor stats.s from their theoretical values.

**Examples**

**Fit Generalized Linear Model with Probit Link**

Enter the sample data.

```matlab
x = [2100 2300 2500 2700 2900 3100 ...
    3300 3500 3700 3900 4100 4300];
```
```matlab
n = [48 42 31 34 31 21 23 23 21 16 17 21];
```
```matlab
y = [1 2 0 3 8 8 14 17 19 15 17 21];
```

Each y value is the number of successes in the corresponding number of trials in n, and x contains the predictor variable values.

Fit a probit regression model for y on x.

```matlab
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes. Plot the percent observed and estimated percent success versus the x values.

```matlab
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n,'o',x,yfit./n,'-',LineWidth,2)
```
Use Custom-Defined Link Function

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```matlab
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a logit link function. Store them in a cell array.

```matlab
link = @(mu) log(mu ./ (1-mu));
derlink = @(mu) 1 ./ (mu .* (1-mu));
invlink = @(resp) 1 ./ (1 + exp(-resp));
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function that you defined.
Fit a generalized linear model by using the logit link function and compare the results.

```matlab
b = glmfit(X,y, 'binomial', 'link', 'logit')
```

Introduced before R2006a
glmval

Generalized linear model values

Syntax

yhat = glmval(b,X,link)  
[yhat,dylo,dyhi] = glmval(b,X,link,stats)  
[...] = glmval(...,param1,val1,param2,val2,...)

Description

yhat = glmval(b,X,link) computes predicted values for the generalized linear model with link function link and predictors X. Distinct predictor variables should appear in different columns of X. b is a vector of coefficient estimates as returned by the glmfit function. link can be any of the character vectors, string scalars, or custom-defined link functions used as values for the 'link' name-value pair argument in the glmfit function.

Note By default, glmval adds a first column of 1s to X, corresponding to a constant term in the model. Do not enter a column of 1s directly into X. You can change the default behavior of glmval using the 'constant' parameter.

[yhat,dylo,dyhi] = glmval(b,X,link,stats) also computes 95% confidence bounds for the predicted values. When the stats structure output of the glmfit function is specified, dylo and dyhi are also returned. dylo and dyhi define a lower confidence bound of yhat-dylo, and an upper confidence bound of yhat+dyhi. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

[...] = glmval(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are listed in this table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'confidence'</td>
<td>the confidence level for the confidence bounds</td>
</tr>
<tr>
<td></td>
<td>A scalar between 0 and 1</td>
</tr>
<tr>
<td>'size'</td>
<td>the size parameter (N) for a binomial model</td>
</tr>
<tr>
<td></td>
<td>A scalar, or a vector with one value for each row of X</td>
</tr>
<tr>
<td>'offset'</td>
<td>used as an additional predictor variable, but with a coefficient value fixed at 1.0</td>
</tr>
<tr>
<td></td>
<td>A vector</td>
</tr>
<tr>
<td>'constant'</td>
<td>'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b.</td>
</tr>
<tr>
<td></td>
<td>'off' — Omit the constant term</td>
</tr>
<tr>
<td>'simultaneous'</td>
<td>Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)</td>
</tr>
<tr>
<td></td>
<td>true or false</td>
</tr>
</tbody>
</table>
Examples

Fit Generalized Linear Model with Probit Link

Enter the sample data.

\[ x = [2100, 2300, 2500, 2700, 2900, \ldots, 3300, 3500, 3700, 3900, 4100, 4300]' \];
\[ n = [48, 42, 31, 34, 31, 21, 23, 21, 16, 17, 21]' \);
\[ y = [1, 2, 0, 3, 8, 8, 14, 17, 19, 15, 17, 21]' \];

Each \( y \) value is the number of successes in the corresponding number of trials in \( n \), and \( x \) contains the predictor variable values.

Fit a probit regression model for \( y \) on \( x \).

\[ b = \text{glmfit}(x,[y \ n],'\text{binomial}', '\text{link}', '\text{probit}'); \]

Compute the estimated number of successes. Plot the percent observed and estimated percent success versus the \( x \) values.

\[ y\text{fit} = \text{glmval}(b,x,'\text{probit}', '\text{size}', n); \]
\[ \text{plot}(x, y./n, 'o', x,y\text{fit}./n,'-', 'LineWidth',2) \]
Use Custom-Defined Link Function

Enter sample data.

\[
x = [2100 2300 2500 2700 2900 3100 3300 3500 3700 3900 4100 4300]';
\]
\[
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
\]
\[
y = [1 2 6 3 8 8 14 17 19 15 17 21]';
\]

Each y value is the number of successes in corresponding number of trials in n, and x contains the predictor variable values.

Define three function handles, created by using @, that define the link, the derivative of the link, and the inverse link for a probit link function. Store the handles in a cell array.

\[
\text{link} = @(\text{mu}) \text{norminv}(	ext{mu});
\]
\[
\text{derlink} = @(\text{mu}) 1 ./ \text{normpdf}(	ext{norminv}(	ext{mu}));
\]
\[
\text{invlink} = @(\text{resp}) \text{normcdf}(	ext{resp});
\]
\[
\text{F} = \{\text{link}, \text{derlink}, \text{invlink}\};
\]

Fit a generalized linear model for y on x by using the link function that you defined.

\[
\text{b} = \text{glmfit}(x, [y\ n], '\text{binomial}', '\text{link}', \text{F});
\]

Compute the estimated number of successes. Plot the observed and estimated percent success versus the x values.

\[
\text{yfit} = \text{glmval}(\text{b}, x, \text{F}, '\text{size}', n);
\]
\[
\text{plot}(x, y./n, 'o', x, yfit./n, '-','\text{LineWidth}',2)
\]
Generate Code from Function That Predicts Responses Given New Data

Train a generalized linear model, and then generate code from a function that classifies new observations based on the model. This example is based on the “Use Custom-Defined Link Function” on page 32-2444 example.

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
    3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Suppose that the inverse normal pdf is an appropriate link function for the problem.

Define a function named `myInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the standard normal cdf.

```
function in = myInvNorm(mu) %#codegen
    %myInvNorm Inverse of standard normal cdf for code generation
    %myInvNorm is a GLM link function that accepts a numeric vector mu, and
    %returns in, which is a numeric vector of corresponding values of the
    %inverse of the standard normal cdf.
    in = norminv(mu);
end
```

Define another function named `myDInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the derivative of the link function.

```
function din = myDInvNorm(mu) %#codegen
    %myDInvNorm Derivative of inverse of standard normal cdf for code generation
    %myDInvNorm corresponds to the derivative of the GLM link function
    %myInvNorm. myDInvNorm accepts a numeric vector mu, and returns din,
    %which is a numeric vector of corresponding derivatives of the inverse
    %of the standard normal cdf.
    din = 1./normpdf(norminv(mu));
end
```

Define another function named `myInvInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the link function.

```
function iin = myInvInvNorm(mu) %#codegen
    %myInvInvNorm Standard normal cdf for code generation
    %myInvInvNorm is the inverse of the GLM link function myInvNorm.
end
```

32-2446
Create a structure array that specifies each of the link functions. Specifically, the structure array contains fields named 'Link', 'Derivative', and 'Inverse'. The corresponding values are the names of the functions.

```matlab
link = struct('Link','myInvNorm','Derivative','myDInvNorm','Inverse','myInvInvNorm')
```

Fit a GLM for $y$ on $x$ using the link function $link$. Return the structure array of statistics.

```matlab
[b,~,stats] = glmfit(x,[y n],'binomial','link',link);
```

$b$ is a 2-by-1 vector of regression coefficients.

In your current working folder, define a function called `classifyGLM.m` that:

- Accepts measurements with columns corresponding to those in $x$, regression coefficients whose dimensions correspond to $b$, a link function, the structure of GLM statistics, and any valid `glmval` name-value pair argument
- Returns predictions and confidence interval margins of error

```matlab
function [yhat,lo,hi] = classifyGLM(b,x,link,varargin) %#codegen
%CLASSIFYGLM Classify measurements using GLM model
% CLASSIFYGLM classifies the n observations in the n-by-1 vector x using
% the GLM model with regression coefficients b and link function link,
% and then returns the n-by-1 vector of predicted values in yhat.
% CLASSIFYGLM also returns margins of error for the predictions using
% additional information in the GLM statistics structure stats.
narginchk(3,Inf);
if(isstruct(varargin{1}))
    stats = varargin{1};
    [yhat,lo,hi] = glmval(b,x,link,stats,varargin{2:end});
else
    yhat = glmval(b,x,link,varargin{:});
end
end
```
Generate a MEX function from classifyGLM.m. Because C uses static typing, codegen must determine the properties of all variables in MATLAB® files at compile time. To ensure that the MEX function can use the same inputs, use the -args argument to specify the following in the order given:

- Regression coefficients b as a compile-time constant
- In-sample observations x
- Link function as a compile-time constant
- Resulting GLM statistics as a compile-time constant
- Name 'Confidence' as a compile-time constant
- Confidence level 0.9

To designate arguments as compile-time constants, use coder.Constant.

codegen -config:mex classifyGLM -args {coder.Constant(b),x,coder.Constant(link),coder.Constant(stats),coder.Constant('Confidence'),coder.Constant(0.9)}

codegen generates the MEX file classifyGLM_mex.mexw64 in your current folder. The file extension depends on your system platform.

Compare predictions by using glmval and classifyGLM_mex. Specify name-value pair arguments in the same order as in the -args argument in the call to codegen.

```matlab
[yhat1,melo1,mehi1] = glmval(b,x,link,stats,'Confidence',0.9);
[yhat2,melo2,mehi2] = classifyGLM_mex(b,x,link,stats,'Confidence',0.9);

comp1 = (yhat1 - yhat2)'*(yhat1 - yhat2);
agree1 = comp1 < eps
comp2 = (melo1 - melo2)'*(melo1 - melo2);
agree2 = comp2 < eps
comp3 = (mehi1 - mehi2)'*(mehi1 - mehi2);
agree3 = comp3 < eps
```

agree1 = logical
1

agree2 = logical
1

agree3 = logical
1
The generated MEX function produces the same predictions as `predict`.

**Topics**

“Introduction to Code Generation” on page 31-2

**Introduced before R2006a**
**glyphplot**

Glyph plot

**Syntax**

```matlab
glyphplot(X)
glyphplot(X,'glyph','face')
glyphplot(X,'glyph','face','features',f)
glyphplot(X,...,'grid',[rows,cols])
glyphplot(X,...,'grid',[rows,cols],'page',p)
glyphplot(X,...,'centers',C)
glyphplot(X,...,'centers',C,'radius',r)
glyphplot(X,...,'obslabels',labels)
glyphplot(X,...,'standardize',method)
h = glyphplot(X,...)
```

**Description**

`glyphplot(X)` creates a star plot from the multivariate data in the $n$-by-$p$ matrix $X$. Rows of $X$ correspond to observations, columns to variables. A star plot represents each observation as a “star” whose $i$th spoke is proportional in length to the $i$th coordinate of that observation. `glyphplot` standardizes $X$ by shifting and scaling each column separately onto the interval $[0,1]$ before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in $X$ as missing values, and does not plot the corresponding rows of $X$.

`glyphplot(X,'glyph','face')` creates a face plot from $X$. A face plot represents each observation as a “face,” whose $i$th facial feature is drawn with a characteristic proportional to the $i$th coordinate of that observation. The features are described in “Face Features” on page 32-2451.

`glyphplot(X,'glyph','face','features',f)` creates a face plot where the $i$th element of the index vector $f$ defines which facial feature will represent the $i$th column of $X$. $f$ must contain integers from 0 to 17, where 0 indicate that the corresponding column of $X$ should not be plotted. See “Face Features” on page 32-2451 for more information.

`glyphplot(X,...,'grid',[rows,cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X,...,'grid',[rows,cols],'page',p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page $p$. If $p$ is a vector, `glyphplot` displays multiple pages in succession. If $p$ is 'all', `glyphplot` displays all pages. If $p$ is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X,...,'centers',C)` creates a plot with each glyph centered at the locations in the $n$-by-2 matrix $C$.

`glyphplot(X,...,'centers',C,'radius',r)` creates a plot with glyphs positioned using $C$, and scale the glyphs so the largest has radius $r$. 

32-2450
glyphplot(X,...,'obslabels',labels) labels each glyph with the text in labels. By default, the glyphs are labelled 1:N. Use ' ' for blank labels.

glyphplot(X,...,'standardize',method) standardizes X before making the plot. Choices for method are
- 'column' — Maps each column of X separately onto the interval [0,1]. This is the default.
- 'matrix' — Maps the entire matrix X onto the interval [0,1].
- 'PCA' — Transforms X to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval [0,1].
- 'off' — No standardization. Negative values in X may make a star plot uninterpretable.

glyphplot(X,...,prop1,val1,...) sets properties to the specified property values for all line graphics objects created by glyphplot.

h = glyphplot(X,...) returns a matrix of handles to the graphics objects created by glyphplot. For a star plot, h(:,1) and h(:,2) contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, h(:,1) and h(:,2) contain object handles to the lines making up each face and to the pupils, respectively. h(:,3) contains handles to the text objects for the labels, if present.

**Face Features**

The following table describes the correspondence between the columns of the vector f, the value of the 'Features' input parameter, and the facial features of the glyph plot. If X has fewer than 17 columns, unused features are displayed at their default value.

<table>

Introduced before R2006a
gmdistribution

Create Gaussian mixture model

Description

A gmdistribution object stores a Gaussian mixture distribution, also called a Gaussian mixture model (GMM), which is a multivariate distribution that consists of multivariate Gaussian distribution components. Each component is defined by its mean and covariance. The mixture is defined by a vector of mixing proportions, where each mixing proportion represents the fraction of the population described by a corresponding component.

Creation

You can create a gmdistribution model object in two ways.

- Use the gmdistribution function (described here) to create a gmdistribution model object by specifying the distribution parameters.
- Use the fitgmdist function to fit a gmdistribution model object to data given a fixed number of components.

Syntax

gm = gmdistribution(mu,sigma)

gm = gmdistribution(mu,sigma,p)

Description

gm = gmdistribution(mu,sigma) creates a gmdistribution model object using the specified means mu and covariances sigma with equal mixing proportions.

gm = gmdistribution(mu,sigma,p) specifies the mixing proportions of multivariate Gaussian distribution components.

Input Arguments

mu — Means
k-by-m numeric matrix

Means of multivariate Gaussian distribution components, specified as a k-by-m numeric matrix, where k is the number of components and m is the number of variables in each component. mu(i,:) is the mean of component i.

Data Types: single | double

sigma — Covariances
numeic vector | numeric matrix | numeric array

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.
Given that \( k \) is the number of components and \( m \) is the number of variables in each component, \( \sigma \) is one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( m )-by-( m )-by-( k ) array</td>
<td>( \sigma(:,:,i) ) is the covariance matrix of component ( i ).</td>
</tr>
<tr>
<td>( 1 )-by-( m )-by-( k ) array</td>
<td>Covariance matrices are diagonal. ( \sigma(1,:,i) ) contains the diagonal elements of the covariance matrix of component ( i ).</td>
</tr>
<tr>
<td>( m )-by-( m ) matrix</td>
<td>Covariance matrices are the same across components.</td>
</tr>
<tr>
<td>( 1 )-by-( m ) vector</td>
<td>Covariance matrices are diagonal and the same across components.</td>
</tr>
</tbody>
</table>

Data Types: single | double

**\( p \) — Mixing proportions of mixture components**

*numeric vector of length \( k \)*

Mixing proportions of mixture components, specified as a numeric vector of length \( k \), where \( k \) is the number of components. The default is a row vector of \((1/k)\)s, which sets equal proportions. If \( p \) does not sum to \( 1 \), \text{gmdistribution} normalizes it.

Data Types: single | double

**Properties**

**Distribution Parameters**

**\( \mu \) — Means**

*\( k \)-by-\( m \) numeric matrix*

This property is read-only.

Means of multivariate Gaussian distribution components, specified as a \( k \)-by-\( m \) numeric matrix, where \( k \) is the number of components and \( m \) is the number of variables in each component. \( \mu(i,:) \) is the mean of component \( i \).

- If you create a \text{gmdistribution} object by using the \text{gmdistribution} function, then the \text{mu} input argument of \text{gmdistribution} sets this property.
- If you fit a \text{gmdistribution} object to data by using the \text{fitgmdist} function, then \text{fitgmdist} estimates this property.

Data Types: single | double

**\( \Sigma \) — Covariances**

*numeric vector | numeric matrix | numeric array*

This property is read-only.

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that \( k \) is the number of components and \( m \) is the number of variables in each component, \( \Sigma \) is one of the values in this table.
### Value Description

</tbody>
</table>

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

### ComponentProportion — Mixing proportions of mixture components

1-by-$k$ numeric vector

This property is read-only.

Mixing proportions of mixture components, specified as a 1-by-$k$ numeric vector.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `p` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

### Distribution Characteristics

### CovarianceType — Type of covariance matrices

'`diagonal'` | `'full'`

This property is read-only.

Type of covariance matrices, specified as either 'diagonal' or 'full'.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the 'CovarianceType' name-value pair argument of `fitgmdist` sets this property.

### DistributionName — Distribution name

'`gaussian mixture distribution'` (default)

This property is read-only.

Distribution name, specified as 'gaussian mixture distribution'.

### NumComponents — Number of mixture components

Positive integer

This property is read-only.
Number of mixture components, $k$, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the $k$ input argument of `fitgmdist` sets this property.

Data Types: `single` | `double`

**NumVariables — Number of variables**

positive integer

This property is read-only.

Number of variables in the multivariate Gaussian distribution components, $m$, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the input data `X` of `fitgmdist` sets this property.

Data Types: `double`

**SharedCovariance — Flag indicating shared covariance**

true | false

This property is read-only.

Flag indicating whether a covariance matrix is shared across mixture components, specified as `true` or `false`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the `'SharedCovariance'` name-value pair argument of `fitgmdist` sets this property.

Data Types: `logical`

**Properties for Fitted Object**

The following properties apply only to a fitted object you create by using `fitgmdist`. The values of these properties are empty if you create a `gmdistribution` object by using the `gmdistribution` function.

**AIC — Akaike Information Criterion**

scalar

This property is read-only.

Akaike information criterion (AIC), specified as a scalar: $\text{AIC} = 2*\text{NlogL} + 2*p$, where $\text{NlogL}$ is the negative loglikelihood (the `NegativeLogLikelihood` property) and $p$ is the number of estimated parameters.
AIC is a model selection tool you can use to compare multiple models fit to the same data. AIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with a smaller value of AIC is better.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

**BIC — Bayes Information Criterion**

Scalar

This property is read-only.

Bayes information criterion (BIC), specified as a scalar: $BIC = 2\times N\log L + p\times \log(n)$, where $N\log L$ is the negative loglikelihood (the `NegativeLogLikelihood` property), $n$ is the number of observations, and $p$ is the number of estimated parameters.

BIC is a model selection tool you can use to compare multiple models fit to the same data. BIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with the lowest BIC value is the best fitting model.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

**Converged — Flag indicating convergence**

Flag indicating whether the Expectation-Maximization (EM) algorithm is converged when fitting a Gaussian mixture model, specified as `true` or `false`.

You can change the optimization options by using the `'Options'` name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `logical`

**NegativeLogLikelihood — Negative loglikelihood**

Scalar

This property is read-only.

Negative loglikelihood of the fitted Gaussian mixture model given the input data $X$ of `fitgmdist`, specified as a scalar.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`
**NumIterations — Number of iterations**
positive integer

This property is read-only.

Number of iterations in the Expectation-Maximization (EM) algorithm, specified as a positive integer.

You can change the optimization options, including the maximum number of iterations allowed, by using the 'Options' name-value pair argument of fitgmdist.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: double

**ProbabilityTolerance — Tolerance for posterior probabilities**
nonnegative scalar value in range \([0,1e-6]\)

This property is read-only.

Tolerance for posterior probabilities, specified as a nonnegative scalar value in the range \([0,1e-6]\).

The 'ProbabilityTolerance' name-value pair argument of fitgmdist sets this property.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: single | double

**RegularizationValue — Regularization parameter value**
nonnegative scalar

This property is read-only.

Regularization parameter value, specified as a nonnegative scalar.

The 'RegularizationValue' name-value pair argument of fitgmdist sets this property.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: single | double

**Object Functions**
cdf      Cumulative distribution function for Gaussian mixture distribution
cluster  Construct clusters from Gaussian mixture distribution
mahal    Mahalanobis distance to Gaussian mixture component
pdf      Probability density function for Gaussian mixture distribution
posterior Posterior probability of Gaussian mixture component
random   Random variate from Gaussian mixture distribution

**Examples**
Create Gaussian Mixture Distribution Using gmdistribution

Create a two-component bivariate Gaussian mixture distribution by using the gmdistribution function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

\[
\begin{align*}
\mu &= \begin{bmatrix} 1 & 2 \\ -3 & -5 \end{bmatrix}; \\
\sigma &= \text{cat}(3, [2.5, 1 1]) \quad \text{1-by-2-by-2 array}
\end{align*}
\]

\[
\begin{align*}
\sigma( :, :, 1) &= \\
&= \begin{bmatrix} 2.0000 & 0.5000 \\
&\end{bmatrix} \\
\sigma( :, :, 2) &= \\
&= \begin{bmatrix} 1 & 1 \\
&\end{bmatrix}
\end{align*}
\]

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. \(\sigma(1,:,:i)\) contains the diagonal elements of the covariance matrix of component \(i\).

Create a `gmdistribution` object. By default, the `gmdistribution` function creates an equal proportion mixture.

\[
\begin{align*}
gm &= \text{gmdistribution}(\mu, \sigma) \\
gm &= \text{Gaussian mixture distribution with 2 components in 2 dimensions}
\end{align*}
\]

\[
\begin{align*}
\text{Component 1:} \\
\text{Mixing proportion: } 0.500000 \\
\text{Mean:} & \begin{bmatrix} 1 & 2 \end{bmatrix} \\
\text{Component 2:} \\
\text{Mixing proportion: } 0.500000 \\
\text{Mean:} & \begin{bmatrix} -3 & -5 \end{bmatrix}
\end{align*}
\]

List the properties of the `gm` object.

\[
\begin{align*}
\text{properties}(gm)
\end{align*}
\]

Properties for class gmdistribution:
You can access these properties by using dot notation. For example, access the `ComponentProportion` property, which represents the mixing proportions of mixture components.

```plaintext
gm.ComponentProportion
ans = 1×2
    0.5000    0.5000
```

A `gmdistribution` object has properties that apply only to a fitted object. The fitted object properties are `AIC`, `BIC`, `Converged`, `NegativeLogLikelihood`, `NumIterations`, `ProbabilityTolerance`, and `RegularizationValue`. The values of the fitted object properties are empty if you create an object by using the `gmdistribution` function and specifying distribution parameters. For example, access the `NegativeLogLikelihood` property by using dot notation.

```plaintext
gm.NegativeLogLikelihood
ans =
    []
```

After you create a `gmdistribution` object, you can use the object functions. Use `cdf` and `pdf` to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use `random` to generate random vectors. Use `cluster`, `mahal`, and `posterior` for cluster analysis.

Visualize the object by using `pdf` and `fsurf`.

```plaintext
fsurf(@(x,y)reshape(pdf(gm,[x(:) y(:)]),size(x)),[-10 10])
```
Fit Gaussian Mixture Model to Data Using `fitgmdist`

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```matlab
mu1 = [1 2];          % Mean of the 1st component
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5];        % Mean of the 2nd component
sigma2 = [1 0; 0 1];  % Covariance of the 2nd component

r1 = mvnrnd(mu1,sigma1,1000); % Generate random variates from each component
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2]; % Combine the two sets of random variates
```

The combined data set `X` contains random variates following a mixture of two bivariate Gaussian distributions.
Fit a two-component GMM to $X$.

gm = fitgmdist(X,2)

gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:   -2.9617   -4.9727

Component 2:
Mixing proportion: 0.500000
Mean:    0.9539    2.0261

List the properties of the gm object.

properties(gm)

Properties for class gmdistribution:

- NumVariables

Topics

“Simulate Data from Gaussian Mixture Model” on page 5-116
“Cluster Using Gaussian Mixture Model” on page 16-39

Introduced in R2007b
**gname**

Add case names to plot

**Syntax**

```matlab
gname(cases)
gname
h = gname(cases,line_handle)
```

**Description**

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array, string array, or cell array of character vectors, in which each row of the character array or each element of the string array or cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a string array, cell array of character vectors, or character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

```
h = gname(cases,line_handle)
```
returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

**Examples**

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```matlab
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```
Click the point at the top of the graph to display its label, “New York.”

*Introduced before R2006a*
gpcdf

Generalized Pareto cumulative distribution function

Syntax

p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')

Description

p = gpcdf(x,k,sigma,theta) returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter k, scale parameter sigma, and threshold (location) parameter, theta, evaluated at the values in x. The size of p is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

p = gpcdf(x,k,sigma,theta,'upper') returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for k, sigma, and theta are 0, 1, and 0, respectively.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for

x > theta, or, when

k < 0, 0 ≤ \frac{x - \theta}{\sigma} ≤ - \frac{1}{k}.

Introduced before R2006a
gpfit

Generalized Pareto parameter estimates

Syntax

parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)

Description

parmhat = gpfit(x) returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in x. parmhat(1) is the tail index (shape) parameter, k and parmhat(2) is the scale parameter, sigma. gpfit does not fit a threshold (location) parameter.

[parmhat,parmci] = gpfit(x) returns 95% confidence intervals for the parameter estimates.

[parmhat,parmci] = gpfit(x,alpha) returns 100(1-alpha)% confidence intervals for the parameter estimates.

[...] = gpfit(x,alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gpfit') for parameter names and default values.

Other functions for the generalized Pareto, such as gpcdf allow a threshold parameter, theta. However, gpfit does not estimate theta. It is assumed to be known, and subtracted from x before calling gpfit.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for

k > theta, or, when k < 0, for

0 ≤ \frac{x - \theta}{\sigma} ≤ - \frac{1}{k}

Introduced before R2006a
gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

\[ x = \text{gpinv}(p,k,sigma,theta) \]

Description

\[ x = \text{gpinv}(p,k,sigma,theta) \]
returns the inverse cdf for a generalized Pareto (GP) distribution
with tail index (shape) parameter \( k \), scale parameter \( sigma \), and threshold (location) parameter \( theta \), evaluated at the values in \( p \). The size of \( x \) is the common size of the input arguments. A scalar
input functions as a constant matrix of the same size as the other inputs.

Default values for \( k \), \( sigma \), and \( theta \) are 0, 1, and 0, respectively.

When \( k = 0 \) and \( theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and
\( theta = sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to
\( sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the
variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for
\[ x > theta, \text{ or, when} \]
\[ k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}. \]

Introduced before R2006a
gplike

Generalized Pareto negative loglikelihood

Syntax

nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)

Description

nlogL = gplike(params,data) returns the negative of the loglikelihood nlogL for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters params. params(1) is the tail index (shape) parameter, k, and params(2) is the scale parameter. gplike does not allow a threshold (location) parameter.

[nlogL,acov] = gplike(params,data) returns the inverse of Fisher's information matrix, acov. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of acov are their asymptotic variances. acov is based on the observed Fisher's information, not the expected information.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for

x > theta, or, when

k < 0, 0 ≤ x - \theta / \sigma ≤ -1/k.

Generalized Pareto probability density function

Syntax

p = gppdf(x,k,sigma,theta)

Description

p = gppdf(x,k,sigma,theta) returns the pdf of the generalized Pareto (GP) distribution with the
tail index (shape) parameter k, scale parameter sigma, and threshold (location) parameter, theta,
evaluated at the values in x. The size of p is the common size of the input arguments. A scalar input
functions as a constant matrix of the same size as the other inputs.

Default values for k, sigma, and theta are 0, 1, and 0, respectively.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and
theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to
sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the
variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for

x > theta, or, when

k < 0, 0 ≤ (x - theta)/sigma ≤ -1/k.

gplotmatrix

Matrix of scatter plots by group

Syntax

gplotmatrix(X,[],group)
gplotmatrix(X,Y,group)
gplotmatrix(X,Y,group,clr,sym,siz)
gplotmatrix(X,Y,group,clr,sym,siz,doleg)
gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt)
gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt,xnam)
gplotmatrix(X,Y,group,clr,sym,siz,doleg,[],xnam,ynam)

gplotmatrix(parent, ___ )

[h,ax,bigax] = gplotmatrix( ___ )

Description

gplotmatrix(X,[],group) creates a matrix of scatter plots and histograms of the data in X, grouped by the grouping variable in group. Each off-diagonal plot in the resulting figure is a scatter plot of a column of X against another column of X. The software also plots the outlines of the grouped histograms in the diagonal plots of the plot matrix. X and group must have the same number of rows.

gplotmatrix(X,Y,group) creates a matrix of scatter plots. Each plot in the resulting figure is a scatter plot of a column of X against a column of Y. For example, if X has p columns and Y has q columns, then the figure contains a q-by-p matrix of scatter plots. All plots are grouped by the grouping variable group. The input arguments X, Y, and group must all have the same number of rows.

gplotmatrix(X,Y,group,clr,sym,siz) specifies the marker color clr, symbol sym, and size siz for each group.

gplotmatrix(X,Y,group,clr,sym,siz,doleg) controls whether a legend is displayed in the figure. gplotmatrix creates a legend by default.

gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt) controls the display options for the diagonal plots in the plot matrix of X.

gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt,xnam) labels the x-axes and y-axes of the scatter plots using the column names specified in xnam. The input argument xnam must contain one name for each column of X. Set dispopt to 'variable' to display the variable names along the diagonal of the scatter plot matrix.

gplotmatrix(X,Y,group,clr,sym,siz,doleg,[],xnam,ynam) labels the x-axes and y-axes of the scatter plots using the column names specified in xnam and ynam. The input arguments xnam and ynam must contain one name for each column of X and Y, respectively.

gplotmatrix(parent, ___ ) creates the scatter plot matrix in the figure or panel specified by parent. Specify parent as the first input argument followed by any of the input argument combinations in the previous syntaxes.
[h,ax,bigax] = gplotmatrix( ___ ) returns graphics handles to the individual plots and the entire scatter plot matrix.

You can pass in [] for clr, sym, siz, doleg, and dispopt to use their default values.

Examples

**Scatter Plots with Grouped Data**

Create a matrix of scatter plots for each combination of variables in a data set. Group the data according to a separate variable.

Load the `fisheriris` data set, which contains flower data. The four columns of `meas` are the sepal length, sepal width, petal length, and petal width of the flowers. `species` contains the flower species names: setosa, versicolor, and virginica. Visually compare the flower measurements across flower species.

```matlab
load fisheriris
gplotmatrix(meas,[],species)
```

In the matrix of scatter plots, the x-axis of the leftmost column of scatter plots corresponds to sepal length, the first column in `meas`. Similarly, the y-axis of the bottom row of scatter plots corresponds to petal width, the last column in `meas`. Therefore, the scatter plot in the bottom left of the matrix compares sepal length values (along the x-axis) to petal width values (along the y-axis). The color of each point depends on the species of the flower.
The diagonal plots are histograms rather than scatter plots. For example, the plot in the top left of the matrix shows the distribution of sepal length values for each species of flower.

Create Scatter Plot Matrix with Subset of Variables

Create scatter plots comparing a subset of the variables in a data set to another subset of variables. Group the data according to a separate variable.

Load the `discrim` data set.

```matlab
load discrim
```

The `ratings` array contains rating values of 329 US cities for the nine categories listed in the `categories` array. The `group` array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with the fourth and seventh categories, `crime` and `arts`. Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```matlab
X = ratings(:,1:2);
Y = ratings(:,[4 7]);
gplotmatrix(X,Y,group)
```
The matrix of scatter plots shows the specified comparisons, with each city size group represented by a different color.

Adjust the appearance of the plots by specifying marker colors and symbols, and labeling the axes with the rating categories.

\[
xnames = \text{categories}(1:2,:);
ynames = \text{categories}([4 7],:);
gplotmatrix(X,Y,group,'br','.o',[],'on',[],xnames,ynames)
\]

---

**Scatter Plot Matrix with Multiple Grouping Variables**

Create a matrix of scatter plots comparing data variables by using two grouping variables.

Load the `patients` data set. Compare patient diastolic and systolic blood pressure values. Group the patients according to their gender and smoker status. Convert `Smoker` to a categorical variable to have more descriptive labels in the legend. Display grouped histograms along the diagonal of the plot matrix by using the `'grpbars'` display option, and label the axes.

```matlab
load patients
X = [Diastolic Systolic];
labeledSmoker = categorical(Smoker,[true false],{'Smoker','Nonsmoker'});
group = {Gender,labeledSmoker};
color = lines(4)
```
xnames = {'Diastolic','Systolic'};
gplotmatrix(X,[],group,color,[],[],[],'grpbars',xnames)

For example, the scatter plot in the bottom left of the matrix shows that smokers (blue and yellow markers) tend to have higher diastolic and systolic blood pressure values, regardless of gender.

**Modify Scatter Plot Matrix Appearance**

Create a matrix of scatter plots that display grouped data. Modify the appearance of one of the scatter plots.

Load the carsmall data set. Create a scatter plot matrix using different car measurements. Group the cars by the number of cylinders. Specify the group colors, and display the car variable names along the diagonal of the plot matrix. Add a title to the plot matrix.
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
color = lines(3)
color = 3x3

0 0.4470 0.7410
0.8500 0.3250 0.0980
0.9290 0.6940 0.1250

xnames = {'Acceleration', 'Displacement', 'Horsepower', 'MPG', 'Weight'};
[h,ax] = gplotmatrix(X,[],Cylinders,color,[],[],[],'variable',xnames);
title('Car Data')

Change the appearance of the scatter plot in the bottom left of the matrix by using h and ax. First, change the colors of the data points in the scatter plot. Then, add grid lines to the scatter plot.

bottomleftPlot = h(5,1,:);
bottomleftPlot(1).Color = 'blue';
bottomleftPlot(2).Color = 'red';
bottomleftPlot(3).Color = 'yellow';

bottomleftAxes = ax(5,1);
bottomleftAxes.XGrid = 'on';
bottomleftAxes.YGrid = 'on';
**Input Arguments**

**X — Input data**  
numeric matrix | datetime array | duration array

Input data, specified as an n-by-p numeric matrix, datetime array, or duration array. `gplotmatrix` creates a matrix of plots using the columns of X. If you do not specify an additional input matrix Y, then `gplotmatrix` creates a p-by-p matrix of plots. The off-diagonal plots are scatter plots, and the diagonal plots depend on the value of `dispopt`. In each scatter plot, `gplotmatrix` plots one column of X against another column of X. The points in the scatter plots are grouped according to `group`.

If you specify Y, then `gplotmatrix` creates a q-by-p matrix of scatter plots using the p columns of X and the q columns of Y.

Data Types: single | double | datetime | duration

**Y — Input data**  
numeric matrix | datetime array | duration array

Input data, specified as an n-by-q numeric matrix, datetime array, or duration array. `gplotmatrix` creates a q-by-p matrix of scatter plots using the p columns of X and the q columns of Y. For each column of the plot matrix, the x-axis values of the scatter plots are the same as the values in the corresponding column of X. Similarly, for each row of the plot matrix, the y-axis values of the scatter plots are the same as the values in the corresponding column of Y. The points in the scatter plots are grouped according to `group`. 
X and Y must have the same number of rows.

Data Types: single | double | datetime | duration

group — Grouping variable
categorical vector | numeric vector | logical vector | character array | string array | cell array

Grouping variable, specified as a categorical vector, numeric vector, logical vector, character array, string array, or cell array of character vectors. Alternatively, group can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. In any case, group must have the same number of rows as X. Points in the same group appear on the graph with the same marker color, symbol, and size.

Example:
categorical({'blue','red','yellow','blue','yellow','red','red','yellow','blue','red'})

Example: `{Smoker,Gender}` where Smoker and Gender are grouping variables

Data Types: categorical | single | double | logical | char | string | cell

clr — Marker colors
character vector | string scalar | string array | cell array of character vectors | matrix of RGB values

Marker colors, specified as one of the following:

- Character vector or string scalar of color short names.
- String array or cell array of character vectors designating color names or short names.
- Three-column matrix of RGB values in the range [0,1]. The three columns represent the R (red) value, G (green) value, and B (blue) value.

You can choose among these predefined colors and their equivalent RGB triplets.

<table>
<thead>
<tr>
<th>Color Name</th>
<th>Short Name</th>
<th>RGB Triplet</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>'red'</td>
<td>'r'</td>
<td>[1 0 0]</td>
<td></td>
</tr>
<tr>
<td>'green'</td>
<td>'g'</td>
<td>[0 1 0]</td>
<td></td>
</tr>
<tr>
<td>'blue'</td>
<td>'b'</td>
<td>[0 0 1]</td>
<td></td>
</tr>
<tr>
<td>'cyan'</td>
<td>'c'</td>
<td>[0 1 1]</td>
<td></td>
</tr>
<tr>
<td>'magenta'</td>
<td>'m'</td>
<td>[1 0 1]</td>
<td></td>
</tr>
<tr>
<td>'yellow'</td>
<td>'y'</td>
<td>[1 1 0]</td>
<td></td>
</tr>
<tr>
<td>'black'</td>
<td>'k'</td>
<td>[0 0 0]</td>
<td></td>
</tr>
<tr>
<td>'white'</td>
<td>'w'</td>
<td>[1 1 1]</td>
<td></td>
</tr>
</tbody>
</table>

When the total number of groups exceeds the number of specified colors, gplotmatrix cycles through the specified colors.

Example: `{‘blue’,’black’,’green’}`

Example: `[0 0 1; 0 0.5 0.5; 0.5 0.5 0.5]`

Data Types: char | string | cell | single | double
**sym — Marker symbols**

'. ' (default) | character vector | string scalar

Marker symbols, specified as a character vector or string scalar.

You can choose among these marker options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'o'</td>
<td>Circle</td>
</tr>
<tr>
<td>'+'</td>
<td>Plus sign</td>
</tr>
<tr>
<td>'*'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'.'</td>
<td>Point</td>
</tr>
<tr>
<td>'x'</td>
<td>Cross</td>
</tr>
<tr>
<td>'s'</td>
<td>Square</td>
</tr>
<tr>
<td>'d'</td>
<td>Diamond</td>
</tr>
<tr>
<td>'^'</td>
<td>Upward-pointing triangle</td>
</tr>
<tr>
<td>'v'</td>
<td>Downward-pointing triangle</td>
</tr>
<tr>
<td>'&gt;'</td>
<td>Right-pointing triangle</td>
</tr>
<tr>
<td>'&lt;'</td>
<td>Left-pointing triangle</td>
</tr>
<tr>
<td>'p'</td>
<td>Five-pointed star (pentagram)</td>
</tr>
<tr>
<td>'h'</td>
<td>Six-pointed star (hexagram)</td>
</tr>
<tr>
<td>'none'</td>
<td>No markers</td>
</tr>
</tbody>
</table>

By default, `gplotmatrix` assigns '.' as the marker symbol for each group. When the total number of groups exceeds the number of specified symbols, `gplotmatrix` cycles through the specified symbols.

Example: 'x'
Example: 'xo+'

Data Types: char | string

**siz — Marker sizes**

positive numeric vector

Marker sizes, specified as a positive numeric vector. The default value is determined by the number of observations. When the total number of groups exceeds the number of specified sizes, `gplotmatrix` cycles through the specified sizes.

Example: [6 12]

Data Types: single | double

**doleg — Option to include legend**

'on' (default) | 'off'

Option to include a legend, specified as either 'on' or 'off'. By default, the legend is displayed in the figure.
**dispopt — Display options for diagonal plots**

'stairs' (default) | 'hist' | 'grpbars' | 'none' | 'variable'

Display options for the diagonal plots in the plot matrix, specified as 'stairs', 'hist', 'grpbars', 'none', or 'variable'. This table describes the different display options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'stairs'</td>
<td>Plot the outlines of grouped histograms.</td>
</tr>
<tr>
<td>'hist'</td>
<td>Plot histograms.</td>
</tr>
<tr>
<td>'grpbars'</td>
<td>Plot grouped histograms.</td>
</tr>
<tr>
<td>'none'</td>
<td>Display blank plots.</td>
</tr>
<tr>
<td>'variable'</td>
<td>Display variable names. To use this display option, you must specify xnam.</td>
</tr>
</tbody>
</table>

The default is 'stairs' when group contains more than one group. Otherwise, gplotmatrix displays a single histogram in each diagonal plot.

To generate the histograms, gplotmatrix uses the 'pdf' type of normalization for numeric data and the 'count' type of normalization for datetime and duration data. (See the 'Normalization' name-value pair argument of histogram.) Note that the y-axis tick mark labels do not apply to the histograms. Use data tips to see the correct histogram values.

**xnam — X column names**

character array | string array | cell array of character vectors

X column names, specified as a character array, string array, or cell array of character vectors. xnam must contain one name for each column of X.

Example: {'Sepal Length','Sepal Width','Petal Length','Petal Width'}

Data Types: char | string | cell

**ynam — Y column names**

character array | string array | cell array of character vectors

Y column names, specified as a character array, string array, or cell array of character vectors. ynam must contain one name for each column of Y.

Example: {'Diastolic','Systolic'}

Data Types: char | string | cell

**parent — Parent container**

Figure object | Panel object

Parent container, specified as a Figure or Panel object.

**Output Arguments**

**h — Line handles to individual plots**

array of Line and Histogram objects

Line handles to individual plots, returned as a one of these arrays:
• \( p \)-by-\( p \)-by-\( k \) array of Line and Histogram objects if you do not specify \( Y \)
• \( q \)-by-\( p \)-by-\( k \) array of Line objects if you specify both \( X \) and \( Y \)

\( p \) is the number of columns in \( X \), \( q \) is the number of columns in \( Y \), and \( k \) is the number of unique groups in \( \text{group} \).

Each scatter plot has \( k \) corresponding Line objects in \( h \), and each histogram has \( k \) corresponding Histogram objects in \( h \).

\textbf{ax} — Axes handles to individual plots

matrix of Axes objects

Axes handles to individual plots, returned as a matrix of Axes objects. If \texttt{dispopt} is ‘hist’, ‘stairs’, or ‘grpbars’, then \texttt{ax} contains one extra row of handles to invisible axes where the histograms are plotted.

\textbf{bigax} — Axes handle to entire plot matrix

Axes object

Axes handle to the entire plot matrix, returned as an Axes object. \texttt{bigax} points to the current axes, so a subsequent \texttt{title}, \texttt{xlabel}, or \texttt{ylabel} command produces labels that are centered with respect to the entire plot matrix.

\textbf{See Also}

\texttt{grpstats} \texttt{| gscatter} \texttt{| plotmatrix}

\textbf{Topics}

“Create Scatter Plots Using Grouped Data” on page 4-2
“MANOVA” on page 9-49
“Grouping Variables” on page 2-45

\textbf{Introduced before R2006a}
**gprnd**

Generalized Pareto random numbers

**Syntax**

\[ r = \text{gprnd}(k, \sigma, \theta) \]
\[ r = \text{gprnd}(k, \sigma, \theta, m, n, \ldots) \]
\[ R = \text{gprnd}(K, \sigma, \theta, [m, n, \ldots]) \]

**Description**

\( r = \text{gprnd}(k, \sigma, \theta) \) returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter \( k \), scale parameter \( \sigma \), and threshold (location) parameter, \( \theta \). The size of \( r \) is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of \( r \) is the size of the other parameters.

\( r = \text{gprnd}(k, \sigma, \theta, m, n, \ldots) \) or \( R = \text{gprnd}(K, \sigma, \theta, [m, n, \ldots]) \) generates an \( m \)-by-\( n \)-by-... array. The \( k, \sigma, \theta \) parameters can each be scalars or arrays of the same size as \( r \).

When \( k = 0 \) and \( \theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and \( \theta = \sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to \( \sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for

\[ x > \theta, \text{ or, when} \]
\[ 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k} \]

**References**

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:
• The output is nonscalar.
• An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

gpstat

Generalized Pareto mean and variance

Syntax

[m,v] = gpstat(k,sigma,theta)

Description

[m,v] = gpstat(k,sigma,theta) returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter k, scale parameter sigma, and threshold (location) parameter, theta.

The default value for theta is 0.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for x > theta, or when k < 0, 0 ≤ (x–theta)/sigma ≤ -1/k.

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)

Description

B = growTrees(B,ntrees) grows ntrees new trees and appends them to those trees already stored in the ensemble B.

B = growTrees(B,ntrees,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'NumPrint' Specifies that a diagnostic message showing training progress should display after every value training cycles (grown trees). Default is no diagnostic messages.

'Options' A struct that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to statset. You can retrieve values of the individual fields with a call to statget. Applicable statset parameters are:

• 'UseParallel' — If true and if a parpool of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.

• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.

• Streams — A RandStream object or cell array of such objects. If you do not specify Streams, growTrees uses the default stream or streams. If you choose to specify Streams, use a single object except in the case

• UseParallel is true
• UseSubstreams is false

In that case, use a cell array the same size as the Parallel pool.
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

TreeBagger | TreeBagger | fitctree | fitrtree | statget | statset
grp2idx

Create index vector from grouping variable

Syntax

\[
[g,gN] = \text{grp2idx}(s)
\]

\[
[g,gN,gL] = \text{grp2idx}(s)
\]

Description

\[ [g,gN] = \text{grp2idx}(s) \]
creates an index vector \( g \) from the grouping variable \( s \). The output \( g \) is a vector of integer values from 1 up to the number \( K \) of distinct groups. \( gN \) is a cell array of character vectors representing the list of group names.

\[ [g,gN,gL] = \text{grp2idx}(s) \]
also returns a column vector \( gL \) representing the list of the group levels with the same data type as \( s \).

Examples

Create Index Vector from Categorical Vector

Create a categorical vector by using discretize and convert it to an index vector by using grp2idx.

Load the hospital data set and convert the ages in hospital.Ages to categorical values representing the ages by decade.

\[
\text{load hospital}
\]
\[
\text{edges} = 0:10:100; \quad % \text{Bin edges}
\]
\[
\text{labels} = \text{strcat}((0:10:90)','s'); \quad % \text{Labels for the bins}
\]
\[
\text{s} = \text{discretize(hospital.Age,edges,'Categorical',labels)};
\]

Display the ages and the groups of ages for the first five samples.

\[
\text{ages} = \text{hospital.Age}(1:5)
\]

\[
\begin{align*}
38 \\
43 \\
38 \\
40 \\
49
\end{align*}
\]

\[
\text{groups} = \text{s}(1:5)
\]

\[
\begin{align*}
30s \\
40s \\
30s
\end{align*}
\]
Create an index vector from the categorical vector `s`.

```matlab
[g,gN,gL] = grp2idx(s);
```

Display the index values corresponding to the first five samples.

```matlab
g(1:5)
ans = 5x1
4
5
4
5
5
```

Reproduce the input argument `s` using the output `gL`.

```matlab
gL(g(1:5))
ans = 5x1 categorical
30s
40s
30s
40s
40s
```

Use `gN(g)` to reproduce the input argument `s` as a cell array of character vectors.

```matlab
gN(g(1:5))
ans = 5x1 cell
{30s}    ...
{30s}    ...
{30s}    ...
```

**Input Arguments**

`s` — Grouping variable

categorical vector | numeric vector | logical vector | datetime vector | duration vector | string array | cell array of character vectors | character array

Grouping variable, specified as a categorical, numeric, logical, datetime, or duration vector, a string array, a cell array of character vectors, or a character array with each row representing a group label.

`grp2idx` treats `NaNs` (numeric, duration, or logical), `' ' (empty character arrays or cell arrays of character vectors), `" "` (empty strings), `<missing>` values (string), `<undefined>` values.
(categorical), and NaTs (datetime) in s as missing values and returns NaNs in the corresponding rows of g. The outputs gN and gL do not include entries for missing values.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | string | cell | categorical | datetime | duration

**Output Arguments**

**g** — Group index  
positive integer vector

Group index, returned as a positive integer vector with values from 1 up to the number K of distinct groups in s.

**gN** — List of group names  
cell array of character vectors

List of group names, returned as a cell array of character vectors.

The order of gN depends on the data type of the grouping variable s.

- For numeric and logical vectors, the order is the sorted order of s.
- For categorical vectors, the order is the order of categories(s).
- For other data types, the order is the order of first appearance in s.

gN(g) reproduces the contents of s in a cell array.

**gL** — List of group levels  
categorical vector | numeric vector | logical vector | datetime vector | duration vector | cell array of character vectors | character array

List of group levels, returned as the same data type as s: a categorical, numeric, logical, datetime, or duration vector, a cell array of character vectors, or a character array with each row representing a group label. (The software treats string arrays as cell arrays of character vectors.)

The set of groups and their order in gL are the same as those in gN, but gL has the same data type as s.

If s is a character matrix, then gL(g,:) reproduces s; otherwise, gL(g) reproduces s.

**Extended Capabilities**

**C/C++ Code Generation**  
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument s can be a numeric, logical, or character vector or a cell array of character vectors. Code generation does not support a categorical, datetime, or duration vector or a string array for the input argument.
- In the generated code, the second and third outputs, gN and gL, are identical. gN and gL have the same data type as the input argument s.
For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Topics
“Grouping Variables” on page 2-45

Introduced before R2006a
**grpstats**

Summary statistics organized by group

**Syntax**

```matlab
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)
```

```matlab
means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)
```

**Description**

**statarray = grpstats(tbl,groupvar)** returns a table or dataset array with the means for the data groups specified in tbl determined by the values of the grouping variable or variables specified in groupvar.

- If there is a single grouping variable, then there is a row in statarray for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a string array or cell array of character vectors containing multiple grouping variable names, or a vector of column numbers, then there is a row in statarray for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in tbl (other than those specified in groupvar) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

**statarray = grpstats(tbl,groupvar,whichstats)** returns the group values for the summary statistics types specified in whichstats.

**statarray = grpstats(tbl,groupvar,whichstats,Name,Value)** uses additional options specified by one or more `Name,Value` pair arguments.

**means = grpstats(X,group)** returns a column vector or matrix with the means of the groups of the data in the matrix or vector X determined by the values of the grouping variable or variables, group. The rows of means correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in means for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a string array or cell array of grouping variables, then there is a row in means for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
• If X is a matrix, then means is a matrix with the same number of columns as X. Each column of means has the group means for the corresponding column of X.

\[
[\text{stats1}, \ldots, \text{statsN}] = \text{grpstats}(\text{X}, \text{group}, \text{whichstats})
\]
returns column vectors or arrays with group values for the summary statistic types specified in whichstats.

\[
[\text{stats1}, \ldots, \text{statsN}] = \text{grpstats}(\text{X}, \text{group}, \text{whichstats}, '\text{Alpha}', \alpha)
\]
specifies the significance level for confidence and prediction intervals.

\text{grpstats}(\text{X}, \text{group}, \alpha)
plots the means of the groups of data in the vector or matrix X determined by the values of the grouping variable, group. The grouping variable values are on the horizontal plot axis. Each group mean has \(100 \times (1 - \alpha)\)% confidence intervals.

• If X is a matrix, then \text{grpstats} plots the means and confidence intervals for each column of X.

• If group is a cell array of grouping variables, then \text{grpstats} plots the means and confidence intervals for the groups of data in X determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

load('hospital')

The dataset array hospital has 100 observations and 7 variables.

Create a dataset array with only the variables Sex, Age, Weight, and Smoker.

dsa = hospital(:,{'Sex','Age','Weight','Smoker'});

Sex is a nominal array, with levels Male and Female. The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean for the numeric and logical arrays, Age, Weight, and Smoker, grouped by the levels in Sex.

\text{statarray} = \text{grpstats}(\text{dsa}, '\text{Sex}')

\text{statarray} =

\begin{array}{cccc}
\text{Sex} & \text{GroupCount} & \text{mean}_\text{Age} & \text{mean}_\text{Weight} & \text{mean}_\text{Smoker} \\
\text{Female} & \text{Female} & 53 & 37.717 & 130.47 & 0.24528 \\
\text{Male} & \text{Male} & 47 & 38.915 & 180.53 & 0.44681 \\
\end{array}

\text{statarray} is a dataset array with two rows, corresponding to the levels in Sex. GroupCount is the number of observations in each group. The means of Age, Weight, and Smoker, grouped by Sex, are given in mean_Age, mean_Weight, and mean_Smoker.

Compute the mean for Age and Weight, grouped by the values in Smoker.

\text{statarray} = \text{grpstats}(\text{dsa}, '\text{Smoker}', '\text{mean}', '\text{DataVars}',\{'\text{Age}', '\text{Weight}'\})
In this case, not all variables in dsa (excluding the grouping variable, Smoker) are numeric or logical arrays; the variable Sex is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using DataVars.

Compute the minimum and maximum weight, grouped by the combinations of values in Sex and Smoker.

```matlab
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
                   'DataVars','Weight')
```

There are two unique values in Smoker and two levels in Sex, for a total of four possible combinations of values: Female Nonsmoker (Female_0), Female Smoker (Female_1), Male Nonsmoker (Male_0), and Male Smoker (Male_1).

Specify the names for the columns in the output.

```matlab
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
                   'DataVars','Weight','VarNames',{'Gender','Smoker',...
                                               'GroupCount','LowestWeight','HighestWeight'})
```

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```matlab
load('hospital')
```

The dataset array hospital has 100 observations and 7 variables.

Create a dataset array with only the variables Age, Weight, and Smoker.

```matlab
dsa = hospital(:,{'Age','Weight','Smoker'});
```

The variables Age and Weight have numeric values, and Smoker has logical values.
Compute the mean, minimum, and maximum for the numeric and logical arrays, Age, Weight, and Smoker, with no grouping.

\[
\text{statarray} = \text{grpstats}(\text{dsa},[],\{'\text{mean}', '\text{min}', '\text{max}'\})
\]

\[
\begin{array}{cccccc}
\text{GroupCount} & \text{mean\_Age} & \text{min\_Age} & \text{max\_Age} & \text{mean\_Weight} \\
\text{All} & 100 & 38.28 & 25 & 50 & 154 \\
\text{All} & 111 & 202 & 0.34 & \text{false} & \text{true} \\
\end{array}
\]

The observation name All indicates that all observations in dsa were used to compute the summary statistics.

**Group Means for a Matrix Using One or More Grouping Variables**

Load the sample data.

load('carsmall')

All variables are measured for 100 cars. Origin is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). Cylinders has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

\[
\text{means} = \text{grpstats}(\text{Acceleration}, \text{Origin})
\]

\[
\text{means} = \begin{bmatrix} 14.4377 \\ 18.0500 \\ 15.8867 \\ 16.3778 \\ 16.6000 \\ 15.5000 \end{bmatrix}
\]

\text{means} is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

\[
\text{means} = \text{grpstats}(\text{Acceleration}, \{\text{Origin}, \text{Cylinders}\})
\]

\[
\text{means} = \begin{bmatrix} 17.0818 \\ 16.5267 \\ 11.6406 \\ 18.0500 \\ 15.9143 \\ 15.5000 \\ 16.3375 \end{bmatrix}
\]
There are 18 possible combinations of grouping variable values because Origin has 6 unique values and Cylinders has 3 unique values. Only 10 of the possible combinations appear in the data, so means is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```matlab
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},{'mean','gname'})
```

The output grps shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

**Multiple Summary Statistics for a Matrix Organized by Group**

Load the sample data.

```matlab
load carsmall
```

The variable Acceleration was measured for 100 cars. The variable Origin is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum and maximum acceleration grouped by country of origin.

```matlab
[grpMin,grpMax,grp] = grpstats(Acceleration,Origin,{'min','max','gname'})
```
The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

**Plot Prediction Intervals for a New Observation in Each Group**

Load the sample data.

```matlab
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```matlab
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```matlab
ngrps = length(grp); % Number of groups
errorbar((1:ngrps)',means,pred(:,2)-means)
xlim([0.5 3.5])
set(gca,'xtick',1:ngrps,'xticklabel',grp)
title('90% Prediction Intervals for Weight by Year')
```
Plot Group Means and Confidence Intervals

Load the sample data.

```matlab
load('carsmall')
```

The variables Acceleration and Weight are the acceleration and weight values measured for 100 cars. The variable Cylinders is the number of cylinders in each car. The variable Model_Year has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by Cylinders, with 95% confidence intervals.

```matlab
grpstats(Acceleration,Cylinders,0.05)
```
The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and 95% confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.

```matlab
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```
The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model_Year. Specify 95% confidence intervals.

\[ \text{grpstats(Acceleration,\{Cylinders,Model\_Year\},0.05)} \]
There are nine possible combinations of grouping variable values because there are three unique values in Cylinders and three unique values in Model_Year. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

**Input Arguments**

- **tbl** — Input data
  
  table | dataset array

  Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.
Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in tbl (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument DataVars to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

**groupvar — Identifiers for the grouping variables**
character vector | string array | cell array of character vectors | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, tbl, specified as one of the following:

- Character vector, string array, or cell array: Names of the grouping variables
- Positive integer or vector of positive integers: Variable numbers of the grouping variables
- Vector of logical values with number of elements equal to the number of variables in tbl: Logical indicator with value true for grouping variables and false otherwise
- []: No groups (returns summary statistics for all data)

Any variable that is identified by groupvar as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors.

For example, consider an input table, tbl, with six variables. The fourth variable is named Gender. To be a valid grouping variable, the data type of Gender might be a string array, a cell array of character vectors, or a nominal array, with the unique values Male and Female. To specify the variable Gender as the grouping variable, you can use any of these syntaxes:

- statarray = grpstats(tbl,'Gender')
- statarray = grpstats(tbl,4)
- statarray = grpstats(tbl,logical([0 0 0 1 0 0]))

Data Types: double | logical | char | string | cell

**whichstats — Types of summary statistics**
character vector | string scalar | function handle | string array | cell array of character vectors and function handles

Types of summary statistics to compute, specified as a character vector, a string scalar, a function handle, a string array, or a cell array of character vectors and function handles. Use a cell array to specify multiple types of summary statistics.

Values include:

- 'mean': Mean
- 'sem': Standard error of the mean
- 'numel': Count, or number, of non-NaN elements
- 'gname': Group name
- 'std': Standard deviation
- 'var': Variance
'min'    Minimum
'max'    Maximum
'range'  Range
'meanCI' 95% confidence interval for the mean
'predCI' 95% prediction interval for a new observation

Example: [stat1,stat2] = grpstats(X,group,{'mean','sem'})

You can specify different significance levels for the 'meanCI' and 'predCI' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time grpstats calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an nvals-by-1 column vector for descriptive statistics of length nvals (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-ncols row vector, or an nvals-by-ncols matrix, where ncols is the number of columns in the input data matrix.

Example: [stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

Example: stat1 = grpstats(X,group,@(x)sum(x,1))

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanCI' or 'predCI' in whichstats, you can use alpha to specify the significance level for the confidence or prediction intervals. If you specify alpha, then grpstats returns 100×(1−alpha)% confidence or prediction intervals. If you do not specify alpha, then grpstats returns 95% intervals (alpha = 0.05).
- Use alpha with the syntax on page 32-2497 to plot group means and corresponding 100×(1−alpha)% confidence intervals.

Data Types: double

X — Input data

vector | matrix

Input data, specified as a vector or a matrix. If X is a matrix, then grpstats returns summary statistics for each column of X.

Data Types: double | single

group — Grouping variable

categorical array | logical or numeric vector | datetime or duration vector | string array | cell array of character vectors | []
Grouping variable, specified as a categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group. *grpstats* groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data \( X \). Observations (rows) with the same value of the grouping variable are in the same group. Use \([\ ]\) to compute summary statistics for all data, without using groups.

For example, if \( \text{Gender} \) is a string array or cell array of character vectors with values 'Male' and 'Female', you can use \( \text{Gender} \) as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if \( \text{Smoker} \) is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array \( \{\text{Gender},\text{Smoker}\} \) divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. *grpstats* returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'DataVars',[1,3,4],'Alpha',0.01 specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

When you include 'meanci' or 'predci' in *whichstats*, you can use Alpha to specify the significance level for confidence or prediction intervals. If you specify the value \( \alpha \), then *grpstats* returns \( 100 \times (1 - \alpha)\)% confidence or prediction intervals.

If you do not specify a value for Alpha, then *grpstats* returns 95% intervals (\( \alpha = 0.05 \)).

Example: 'Alpha',0.1

Data Types: double

**DataVars — Variable names or columns**

string array | cell array of character vectors | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data tbl you want to compute summary statistics for, specified as the comma-separated pair consisting of 'DataVars' and a string array, cell array of character vectors, vector of positive integers, or logical vector. Use a character vector or string scalar to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (true if you want to compute summary statistics, false otherwise).
You must specify **DataVars** if there are any variables in **tbl** (other than the grouping variables specified in **groupvar**) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars',{'Height','Weight'}`

Data Types: `double` | `string` | `cell` | `char`

**VarNames** — Variable names for output

string array | cell array of character vectors

Variable names for the output **statarray**, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors. By default, **grpstats** constructs output variable names by appending a prefix to the variable names from the input data **tbl**. This prefix corresponds to the summary statistic name.

Example: `'VarNames',{'Gender','GroupCount','MaleMean','FemaleMean'}`

Data Types: `string` | `cell`

**Output Arguments**

**statarray** — Group summary statistics
table | dataset array

Group summary statistics, returned as a table or a dataset array. If **tbl** is a table, **grpstats** returns **statarray** as a table. If **tbl** is a dataset array, **grpstats** returns **statarray** as a dataset array.

**statarray** contains summary statistic values for the groups of data in **tbl** determined by the levels of the grouping variables specified by **groupvar**. There is a row in **statarray** for each observed value or combination of values in the variables specified by **groupvar**. The output **statarray** contains:

- All grouping variables specified by **groupvar**.
- The variable **GroupCount**, containing the number of observations in each group.
- Group summary statistic values for all variables in **tbl** (other than those specified by **groupvar**), or for only the variables specified using **DataVars**.

The total number of variables in **statarray** is \( ngroupvars + 1 + ndatavars\times nstats \), where **ngroupvars** is the number of variables in **groupvar**, **ndatavars** is the number of variables for which summary statistics are computed, and **nstats** is the number of summary statistic types specified in **whichstats**.

**grpstats** assigns default names to the variables in **statarray**, unless you specify variable names using the name-value pair argument **VarNames**.

**means** — Group means

column vector | array

Group means for the groups of data in the vector or matrix **X** determined by the levels of **group**, returned as an \( ngroups\times ncols \) array. Here, **ngroups** is the number of unique values in the grouping variable, and **ncols** is the number of columns in **X**. If **X** is a vector, then **means** is a column vector.

**stats1,...,statsN** — Group summary statistics

column vectors | arrays
Group summary statistics for the groups of data in the vector or matrix $X$ determined by the levels of group, returned as $ngroups$-by-$ncols$ arrays. Here, $ngroups$ is the number of unique values in the grouping variable, and $ncols$ is the number of columns in $X$. You must specify an output argument for each type of summary statistic specified in $whichstats$.

If a summary statistic type in $whichstats$ returns a value of length $nvals$ (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an $ngroups$-by-$ncols$-by-$nvals$ array.

**Algorithms**

- $grpstats$ treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- $grpstats$ ignores empty group names.

**Alternative Functionality**

MATLAB includes the function `groupsummary`, which also returns group summaries and is recommended when you are working with a table.

**Extended Capabilities**

### Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.
- The $whichstats$ option cannot be specified as a function handle. In addition to the current built-in options, $whichstats$ can also be:
  - `'Count'` — Number of non-NaNs.
  - `'NNZ'` — Number of nonzeros and non-NaNs.
  - `'Kurtosis'` — Compute kurtosis.
  - `'Skewness'` — Compute skewness.
  - `'all-stats'` — Compute all summary statistics.
- Group order is not guaranteed to be the same as the in-memory $grpstats$ computation. Specify `'gname'` as the $whichstats$ option to return the order of rows of the summary statistics. For example $[\text{means}, \text{grpname}] = \text{grpstats}(x, bins, \{'\text{mean}', 'gname'\})$ returns the means of groups in $x$ in the same order that the groups appear in $grpname$.
- Summary statistics for nonnumeric variables return NaNs.
- $grpstats$ always operates on the first dimension.
- If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable $GroupLabel$ that contains the same information.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Introduced before R2006a
 grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

\[
\text{statstbl} = \text{grpstats}(\text{rm},g) \\
\text{statstbl} = \text{grpstats}(\text{rm},g,\text{stats})
\]

Description

\[
\text{statstbl} = \text{grpstats}(\text{rm},g)
\]
returns the count, mean, and variance for the data used to fit the repeated measures model \(\text{rm}\), grouped by the factors, \(g\).

\[
\text{statstbl} = \text{grpstats}(\text{rm},g,\text{stats})
\]
returns the statistics specified by \(\text{stats}\) for the data used to fit the repeated measures model \(\text{rm}\), grouped by the factors, \(g\).

Input Arguments

\(\text{rm} - \text{Repeated measures model}\)
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

\(g - \text{Name of grouping factor or factors}\)
character vector | string array | cell array of character vectors

Name of grouping factor or factors, specified as a character vector, string array, or cell array of character vectors.

Example: 'Drug'
Example: {'Drug','Sex'}
Data Types: char | string | cell

\(\text{stats} - \text{Statistics to compute}\)
character vector | string scalar | function handle | string array | cell array of multiple character vectors and function handles

Statistics to compute, specified as one of the following:

- Character vector or string scalar specifying the name of the statistics to compute. Names can be one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mean'</td>
<td>Mean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>'sem'</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>'numel'</td>
<td>Count or number of elements</td>
</tr>
<tr>
<td>'gname'</td>
<td>Group name</td>
</tr>
<tr>
<td>'std'</td>
<td>Standard deviation</td>
</tr>
<tr>
<td>'var'</td>
<td>Variance</td>
</tr>
<tr>
<td>'min'</td>
<td>Minimum</td>
</tr>
<tr>
<td>'max'</td>
<td>Maximum</td>
</tr>
<tr>
<td>'range'</td>
<td>Maximum minus minimum</td>
</tr>
<tr>
<td>'meanci'</td>
<td>95% confidence interval for the mean</td>
</tr>
<tr>
<td>'predci'</td>
<td>95% prediction interval for a new observation</td>
</tr>
</tbody>
</table>

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.

- A string array or cell array of character vectors and function handles.

Example: `@median`
Example: `@skewness`
Example: `'gname'`
Example: `{'gname','range','predci'}`

### Output Arguments

`statstbl` — Statistics values for each group

Statistics values for each group, returned as a table.

### Examples

#### Compute Group Statistics

Load the sample data.

```matlab
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```matlab
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4],'VarNames',{'Measurements'});
```
Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```matlab
grpstats(rm,'species')
```

```
ans=3×4 table
species    GroupCount     mean     std
____________    __________    _______    ______
{'setosa'     }       200        2.5355    1.8483
{'versicolor'}       200         3.573    1.7624
{'virginica' }       200         4.285    1.9154
```

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```matlab
grpstats(rm,'species',{'gname','range','predci'})
```

```
ans=3×5 table
species      gname      GroupCount    range    predci
______________    ______________    __________    _____    ____________________
{'setosa'     }    {'setosa'     }       200         5.7      -1.1185      6.1895
{'versicolor'}    {'versicolor'}       200           6     0.088976       7.057
{'virginica' }    {'virginica' }       200         6.5       0.4985      8.0715
```

**Statistics for Data Grouped by Two Factors**

Load the sample data.

```matlab
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```matlab
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors Group and Gender.

```matlab
GS = grpstats(rm,{'Group','Gender'},{'mean','std',@skewness,@kurtosis})
```

```
GS=6×7 table
Group    Gender    GroupCount     mean     std    skewness    kurtosis
_______    _______    __________    _______    _______    _______    _______
```
Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

See Also

`fitrm` | `plot`
gscatter

Scatter plot by group

Syntax

\[
gscatter(x,y,g) \\
gscatter(x,y,g,clr,sym,siz) \\
gscatter(x,y,g,clr,sym,siz,doleg) \\
gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam) \\
gscatter(ax,___) \\
h = gscatter(___)
\]

Description

\(gscatter(x,y,g)\) creates a scatter plot of \(x\) and \(y\), grouped by \(g\). The inputs \(x\) and \(y\) are vectors of the same size.

\(gscatter(x,y,g,clr,sym,siz)\) specifies the marker color \(clr\), symbol \(sym\), and size \(siz\) for each group.

\(gscatter(x,y,g,clr,sym,siz,doleg)\) controls whether a legend is displayed on the graph. \(gscatter\) creates a legend by default.

\(gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)\) specifies the names to use for the x-axis and y-axis labels. If you do not provide \(xnam\) and \(ynam\), and the \(x\) and \(y\) inputs are variables with names, then \(gscatter\) labels the axes with the variable names.

\(gscatter(ax,___)\) uses the plot axes specified by the axes object \(ax\). Specify \(ax\) as the first input argument followed by any of the input argument combinations in the previous syntaxes.

\(h = gscatter(___}\) returns graphics handles corresponding to the groups in \(g\).

You can pass in [] for \(clr\), \(sym\), \(siz\), and \(doleg\) to use their default values.

Examples

Scatter Plot with Default Settings

Load the carsmall data set.

\[load carsmall\]

Plot the Displacement values on the x-axis and the Horsepower values on the y-axis. \(gscatter\) uses the variable names as the default labels for the axes. Group the data points by Model_Year.

\[gscatter(Displacement,Horsepower,Model_Year)\]
Scatter Plot with One Grouping Variable

Load the `discrim` data set.

```matlab
load discrim
```

The data set contains ratings of cities according to nine factors such as climate, housing, education, and health. The matrix `ratings` contains the ratings information.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```matlab
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')
xlabel('climate')
ylabel('housing')
```
Scatter Plot with Multiple Grouping Variables

Load the hospital data set.

```matlab
load hospital
```

Plot the ages and weights of the hospital patients. Group the patients according to their gender and smoker status. Use the o symbol to represent nonsmokers and the * symbol to represent smokers.

```matlab
x = hospital.Age;
y = hospital.Weight;
g = {hospital.Sex,hospital.Smoker};
gscatter(x,y,g,'rkgb','o*',8,'on','Age','Weight')
legend('Location','northeastoutside')
```
Specify Axes for Scatter Plot

Load the carsmall data set. Create a figure with two subplots and return the axes objects as ax1 and ax2. Create a scatter plot in each set of axes by referring to the corresponding Axes object. In the left subplot, group the data using the Model_Year variable. In the right subplot, group the data using the Cylinders variable. Add a title to each plot by passing the corresponding Axes object to the title function.

```matlab
load carsmall
color = lines(6); % Generate color values

ax1 = subplot(1,2,1); % Left subplot
gscatter(ax1,Acceleration,MPG,Model_Year,color(1:3,:))
title(ax1,'Left Subplot (Model Year)')

ax2 = subplot(1,2,2); % Right subplot
gscatter(ax2,Acceleration,MPG,Cylinders,color(4:6,:))
title(ax2,'Right Subplot (Cylinders)')
```
Create and Modify Scatter Plot

Load the carbig data set.

```matlab
carbig
```

Create a scatter plot comparing Acceleration to MPG. Group data points based on Origin.

```matlab
h = gscatter(Acceleration,MPG,Origin)
```

Display the Line object corresponding to the group labeled (Japan).

```matlab
jgroup = h(3)
```
jgroup =
Line (Japan) with properties:

    Color: [0.2857 1 0]
    LineStyle: 'none'
    LineWidth: 0.5000
    Marker: '.'
    MarkerSize: 15
    MarkerFaceColor: 'none'
    XData: [1x79 double]
    YData: [1x79 double]
    ZData: [1x0 double]

Show all properties

Change the marker color for the Japan group to black.

jgroup.Color = 'k';

**Input Arguments**

\( x \) — \( x \)-axis values

numeric vector

\( x \)-axis values, specified as a numeric vector. \( x \) must have the same size as \( y \).
Data Types: single | double

**y** — y-axis values
numeric vector

y-axis values, specified as a numeric vector. `y` must have the same size as `x`.

Data Types: single | double

**g** — Grouping variable
categorical vector | logical vector | numeric vector | character array | string array | cell array of character vectors | cell array

Grouping variable, specified as a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors. Alternatively, `g` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group appear on the scatter plot with the same marker color, symbol, and size.

The number of rows in `g` must be equal to the length of `x`.

Example: `species`
Example: `{Cylinders,Origin}`

Data Types: categorical | logical | single | double | char | string | cell

**clr** — Marker colors
color vector or string scalar of colors | matrix of RGB triplet values

Marker colors, specified as either a character vector or string scalar of colors recognized by the `plot` function or a matrix of RGB triplet values. Each RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range [0,1].

This table lists the available color characters and their equivalent RGB triplet values.

<table>
<thead>
<tr>
<th>Long Name</th>
<th>Short Name</th>
<th>RGB Triplet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow</td>
<td>'y'</td>
<td>[1 1 0]</td>
</tr>
<tr>
<td>Magenta</td>
<td>'m'</td>
<td>[1 0 1]</td>
</tr>
<tr>
<td>Cyan</td>
<td>'c'</td>
<td>[0 1 1]</td>
</tr>
<tr>
<td>Red</td>
<td>'r'</td>
<td>[1 0 0]</td>
</tr>
<tr>
<td>Green</td>
<td>'g'</td>
<td>[0 1 0]</td>
</tr>
<tr>
<td>Blue</td>
<td>'b'</td>
<td>[0 0 1]</td>
</tr>
<tr>
<td>White</td>
<td>'w'</td>
<td>[1 1 1]</td>
</tr>
<tr>
<td>Black</td>
<td>'k'</td>
<td>[0 0 0]</td>
</tr>
</tbody>
</table>

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: `'rgb'`
Example: `[0 0 1; 0 0 0]`
Data Types: char | string | single | double

**sym — Marker symbols**

A character vector or string scalar of symbols.

Marker symbols, specified as a character vector or string scalar of symbols recognized by the `plot` function. This table lists the available marker symbols.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'o'</td>
<td>Circle</td>
</tr>
<tr>
<td>'+'</td>
<td>Plus sign</td>
</tr>
<tr>
<td>'*'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'.'</td>
<td>Point</td>
</tr>
<tr>
<td>'x'</td>
<td>Cross</td>
</tr>
<tr>
<td>'s'</td>
<td>Square</td>
</tr>
<tr>
<td>'d'</td>
<td>Diamond</td>
</tr>
<tr>
<td>'^'</td>
<td>Upward-pointing triangle</td>
</tr>
<tr>
<td>'v'</td>
<td>Downward-pointing triangle</td>
</tr>
<tr>
<td>'&gt;'</td>
<td>Right-pointing triangle</td>
</tr>
<tr>
<td>'&lt;'</td>
<td>Left-pointing triangle</td>
</tr>
<tr>
<td>'p'</td>
<td>Five-pointed star (pentagram)</td>
</tr>
<tr>
<td>'h'</td>
<td>Six-pointed star (hexagram)</td>
</tr>
<tr>
<td>'none'</td>
<td>No markers</td>
</tr>
</tbody>
</table>

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: 'o+*v'

Data Types: char | string

**siz — Marker sizes**

A positive numeric vector.

Marker sizes, specified as a positive numeric vector in points. The default value is determined by the number of observations. If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: [6 12]

Data Types: single | double

**doleg — Option to include legend**

'off' (default) | 'on'

Option to include a legend, specified as either 'on' or 'off'. By default, the legend is displayed on the graph.

**xnam — x-axis label**

A character vector or string scalar.

x variable name (default) | character vector | string scalar
x-axis label, specified as a character vector or string scalar.

Data Types: char | string

ynam — y-axis label
y variable name (default) | character vector | string scalar

y-axis label, specified as a character vector or string scalar.

Data Types: char | string

ax — Axes for plot
Axes object | UIAxes object

Axes for the plot, specified as an Axes or UIAxes object. If you do not specify ax, then gscatter creates the plot using the current axes. For more information on creating an axes object, see axes and uiaxes.

Output Arguments

h — Graphics handles
array of Line objects

Graphics handles, returned as an array of Line objects. Each Line object corresponds to one of the groups in g. You can use dot notation to query and set properties of the line objects. For a list of Line object properties, see Chart Line.

Topics
“Create Scatter Plots Using Grouped Data” on page 4-2
“MANOVA” on page 9-49
“Grouping Variables” on page 2-45

Introduced before R2006a
gt

Class: qrandstream

Greater than relation for handles

Syntax

\[
\text{h1} > \text{h2}
\]

Description

\( \text{h1} > \text{h2} \) performs element-wise comparisons between handle arrays \( \text{h1} \) and \( \text{h2} \). \( \text{h1} \) and \( \text{h2} \) must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise \( > \) result.

If one of \( \text{h1} \) or \( \text{h2} \) is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

\[
\text{tf} = \text{gt(} \text{h1}, \text{h2} \text{)}
\]

stores the result in a logical array of the same dimensions.

eq | ge | le | lt | ne | qrandstream

32-2526
haltonset

Halton quasirandom point set

Description

haltonset is a quasirandom point set object that produces points from the Halton sequence. The Halton sequence uses different prime bases in each dimension to fill space in a highly uniform manner.

Creation

Syntax

\[
p = \text{haltonset}(d)
\]
\[
p = \text{haltonset}(d,\text{Name},\text{Value})
\]

Description

\[
p = \text{haltonset}(d)
\]

constructs a \(d\)-dimensional point set \(p\), which is a haltonset object with default property settings. The input argument \(d\) corresponds to the Dimensions property of \(p\).

\[
p = \text{haltonset}(d,\text{Name},\text{Value})
\]

sets properties on page 32-2527 of \(p\) using one or more name-value pair arguments. Enclose each property name in quotes. For example,

\[
\text{haltonset}(5, '\text{Leap}', 2)
\]

creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object \(p\) encapsulates properties of a Halton quasirandom sequence. The point set is finite, with a length determined by the Skip and Leap properties and by limits on the size of the point set indices (maximum value of \(2^{53}\)). Values of the point set are generated whenever you access \(p\) using net or parenthesis indexing. Values are not stored within \(p\).

Properties

Dimensions — Number of dimensions

positive integer scalar

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar. For example, each point in the point set \(p\) with \(p.\text{Dimensions} = 5\) has five values.

Use the \(d\) input argument to specify the number of dimensions when you create a point set using the haltonset function.

Leap — Interval between points

\(0\) (default) | positive integer scalar
Interval between points in the sequence, specified as a positive integer scalar. In other words, the Leap property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default Leap value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the Leap values with care. Many Leap values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [1].

One rule for choosing Leap values for Halton sets is to set the value to \((n–1)\), where \(n\) is a prime number that has not been used to generate one of the dimensions. For example, for a d-dimensional point set, specify the \((d+1)\)th or greater prime number for \(n\).

Example: \(p = \text{haltonset}(2,'Leap',4);\) (where \(d = 2\) and \(n = 5\))
Example: \(p.Leap = 100;\)

**ScrambleMethod** — Settings that control scrambling

| 0x0 structure (default) | structure with Type and Options fields |
---|---|

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- **Type** — A character vector containing the name of the scramble
- **Options** — A cell array of parameter values for the scramble

Use the scramble object function to set scrambles. For a list of valid scramble types, see the type input argument of scramble. An error occurs if you set an invalid scramble type for a given point set.

The ScrambleMethod property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a 0x0 structure.

**Skip** — Number of initial points in sequence to omit

| 0 (default) | positive integer scalar |
---|---|

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often \((0,0,0,...)\), which can cause the sequence to be unbalanced because the counterpart of the point, \((1,1,1,...)\), never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

Example: \(p = \text{haltonset}(_,\'Skip',2e3);\)
Example: \(p.Skip = 1e3;\)

**Type** — Sequence type

- 'Halton' (default)

This property is read-only.

Sequence type on which the quasirandom point set \(p\) is based, specified as 'Halton'.

---

32-2528
Object Functions
net  Generate quasirandom point set
scramble  Scramble quasirandom point set

You can also use the following MATLAB functions with a haltonset object. The software treats the point set object like a matrix of multidimensional points.
length  Length of largest array dimension
size  Array size

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```matlab
p = haltonset(3,'Skip',1e3,'Leap',1e2)
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : none
```

Apply reverse-radix scrambling by using scramble.

```matlab
p = scramble(p,'RR2')
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : RR2
```

Generate the first four points by using net.

```matlab
X0 = net(p,4)
```

```
X0 = 4×3
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```matlab
X = p(1:3:11,:)```
Tips

• The Skip and Leap properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across \( N \) different workers by using the function labindex. On each \( n \)th worker, set the Skip property of the point set to \( n - 1 \) and the Leap property to \( N - 1 \). The following code shows how to partition a sequence across three workers.

```matlab
Nworkers = 3;
p = haltonset(10,'Leap',Nworkers-1);
spmd(Nworkers)
p.Skip = labindex - 1;

  % Compute something using points 1,4,7...
  % or points 2,5,8... or points 3,6,9...
end
```

Algorithms

Halton Sequence Generation

Consider a default haltonset object \( p \) that contains \( d \)-dimensional points. Each \( p(i,:) \) is a point in a Halton sequence. The \( j \)th coordinate of the point, \( p(i,j) \), is equal to

\[
\sum_{k=0}^{a_{ij}(k)} b_j^{k-1}.
\]

• \( b_j \) is the \( j \)th prime.
• The \( a_{ij}(k) \) coefficients are nonnegative integers less than \( b_j \) such that \( i - 1 = \sum_{k=0}^{a_{ij}(k)} b_j^{k} \).

In other words, the \( a_{ij}(k) \) values are the base \( b_j \) digits of the integer \( i - 1 \).

For more information, see [1].

Topics
"Generating Quasi-Random Numbers" on page 7-13

Introduced in R2008a
harmmean

Harmonic mean

Syntax

m = harmmean(X)
m = harmmean(X,'all')
m = harmmean(X,dim)
m = harmmean(X,vecdim)
m = harmmean(___,nanflag)

Description

m = harmmean(X) calculates the harmonic mean on page 32-2536 of a sample. For vectors, harmmean(X) is the harmonic mean of the elements in X. For matrices, harmmean(X) is a row vector containing the harmonic means of each column. For N-dimensional arrays, harmmean operates along the first nonsingleton dimension of X.

m = harmmean(X,'all') returns the harmonic mean of all elements of X.

m = harmmean(X,dim) takes the harmonic mean along the operating dimension dim of X.

m = harmmean(X,vecdim) returns the harmonic mean over the dimensions specified in the vector vecdim. Each element of vecdim represents a dimension of the input array X. The output m has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and m. For example, if X is a 2-by-3-by-4 array, then harmmean(X,[1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the harmonic mean of the elements on the corresponding page of X.

m = harmmean(___,nanflag) specifies whether to exclude NaN values from the calculation, using any of the input argument combinations in previous syntaxes. By default, harmmean includes NaN values in the calculation (nanflag has the value 'includenan'). To exclude NaN values, set the value of nanflag to 'omitnan'.

Examples

Compare Harmonic and Arithmetic Mean

Set the random seed for reproducibility of the results.

rng('default')

Create a matrix of exponential random numbers with 5 rows and 4 columns.

X = exprnd(1,5,4)

X = 5x4
    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
    2.0637    0.6035    0.0438    0.0880
Compute the harmonic and arithmetic means of the columns of $X$.

\[
\text{harmonic} = \text{harmmean}(X)
\]

\[
\text{harmonic} = \begin{bmatrix}
0.1743 & 0.0928 & 0.0797 & 0.1205
\end{bmatrix}
\]

\[
\text{arithmetic} = \text{mean}(X)
\]

\[
\text{arithmetic} = \begin{bmatrix}
0.5833 & 0.8577 & 0.5734 & 0.6357
\end{bmatrix}
\]

The arithmetic mean is greater than the harmonic mean for all the columns of $X$.

**Harmonic Mean of All Values**

Find the harmonic mean of all the values in an array.

Create a 3-by-5-by-2 array $X$.

\[
X = \text{reshape}(1:30, [3 5 2])
\]

\[
X =
\begin{array}{cccccc}
1 & 4 & 7 & 10 & 13 \\
2 & 5 & 8 & 11 & 14 \\
3 & 6 & 9 & 12 & 15 \\
\end{array}
\]

\[
X(:,:,2) =
\begin{array}{cccccc}
16 & 19 & 22 & 25 & 28 \\
17 & 20 & 23 & 26 & 29 \\
18 & 21 & 24 & 27 & 30 \\
\end{array}
\]

Find the harmonic mean of the elements of $X$.

\[
m = \text{harmmean}(X, 'all')
\]

\[
m = 7.5094
\]
**Harmonic Mean Along Specified Dimensions**

Find the harmonic mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array X.

\[
X = \text{reshape}(1:30, [3 5 2])
\]

\[
X = \\
X(:,:,1) = \\
\begin{bmatrix}
1 & 4 & 7 & 10 & 13 \\
2 & 5 & 8 & 11 & 14 \\
3 & 6 & 9 & 12 & 15 \\
\end{bmatrix}
\]

\[
X(:,:,2) = \\
\begin{bmatrix}
16 & 19 & 22 & 25 & 28 \\
17 & 20 & 23 & 26 & 29 \\
18 & 21 & 24 & 27 & 30 \\
\end{bmatrix}
\]

Find the harmonic mean of \(X\) along the default dimension.

\[
hmean1 = \text{harmmean}(X)
\]

\[
hmean1 = \\
hmean1(:,:,1) = \\
\begin{bmatrix}
1.6364 & 4.8649 & 7.9162 & 10.9392 & 13.9523 \\
\end{bmatrix}
\]

\[
hmean1(:,:,2) = \\
\begin{bmatrix}
\end{bmatrix}
\]

By default, \(\text{harmmean}\) operates along the first dimension of \(X\) whose size does not equal 1. In this case, this dimension is the first dimension of \(X\). Therefore, \(hmean1\) is a 1-by-5-by-2 array.

Find the harmonic mean of \(X\) along the second dimension.

\[
hmean2 = \text{harmmean}(X, 2)
\]

\[
hmean2 = \\
hmean2(:,:,1) = \\
\begin{bmatrix}
3.1852 \\
5.0641 \\
6.5693 \\
\end{bmatrix}
\]

\[
hmean2(:,:,2) = \\
\begin{bmatrix}
21.1595 \\
22.1979 \\
\end{bmatrix}
\]
hmean2 is a 3-by-1-by-2 array.

Find the harmonic mean of $X$ along the third dimension.

$hmean3 = \text{harmmean}(X,3)$

$hmean3 = 3\times5$

\[
\begin{array}{cccccc}
1.8824 & 6.6087 & 10.6207 & 14.2857 & 17.7561 \\
3.5789 & 8.0000 & 11.8710 & 15.4595 & 18.8837 \\
\end{array}
\]

$hmean3$ is a 3-by-5 array.

Find the harmonic mean of each page of $X$ by specifying the first and second dimensions using the `vecdim` input argument.

$mpage = \text{harmmean}(X,[1\ 2])$

$mpage =$

$mpage(:,:,1) =$

\[
4.5205
\]

$mpage(:,:,2) =$

\[
22.1645
\]

For example, $mpage(1,1,2)$ is the harmonic mean of the elements in $X(:,:,2)$.

Find the harmonic mean of the elements in each $X(i,:,:)$ slice by specifying the second and third dimensions.

$mrow = \text{harmmean}(X,[2\ 3])$

$mrow = 3\times1$

\[
\begin{array}{c}
5.5369 \\
8.2469 \\
10.2425 \\
\end{array}
\]

For example, $mrow(3)$ is the harmonic mean of the elements in $X(3,:,:)$ and is equivalent to specifying $\text{harmmean}(X(3,:,:),'all')$.

**Harmonic Mean Excluding NaN**

Create a vector and compute its `harmmean`, excluding NaN values.
x = 1:10;
x(3) = nan; % Replace the third element of x with a NaN value
n = harmmean(x,'omitnan')
n = 3.4674

If you do not specify 'omitnan', then harmmean(x) returns NaN.

More About

Harmonic Mean

The harmonic mean of a sample X is

\[ m = \frac{n}{\sum_{i=1}^{n} \frac{1}{x_i}} \]

where n is the number of values in X.

Tips

• When harmmean computes the harmonic mean of an array containing 0, the returned value is 0.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• These input arguments are not supported: 'all', vecdim, and nanflag.
• The dim input argument must be a compile-time constant.
• If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

• The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

geomean | mean | median | trimmean

Introduced before R2006a
hist3
Bivariate histogram plot

Syntax

hist3(X)
hist3(X,'Nbins',nbins)
hist3(X,'Ctrs',ctrs)
hist3(X,'Edges',edges)
hist3(___,Name,Value)
hist3(ax,___)

N = hist3(___)
[N,c] = hist3(___)

Description

hist3(X) creates a bivariate histogram plot of X(:,1) and X(:,2) using 10-by-10 equally spaced bins. The hist3 function displays the bins as 3-D rectangular bars, and the height of each bar indicates the number of elements in the bin.

hist3(X,'Nbins',nbins) specifies the number of bins in each dimension of the histogram. This syntax is equivalent to hist3(X,nbins).

hist3(X,'Ctrs',ctrs) specifies the centers of the bins in each dimension of the histogram. This syntax is equivalent to hist3(X,ctrs).

hist3(X,'Edges',edges) specifies the edges of the bins in each dimension.

hist3(___,Name,Value) specifies graphical properties using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, 'FaceAlpha',0.5 creates a semitransparent histogram. For a list of properties, see Surface Properties.

hist3(ax,___) plots into the axes specified by ax instead of the current axes (gca). The option ax can precede any of the input argument combinations in the previous syntaxes.

N = hist3(___) returns the number of elements in X that fall in each bin. This syntax does not create a histogram.

[N,c] = hist3(___) also returns the bin centers. This syntax does not create a histogram.

Examples

Histogram of Vectors

Load the sample data.

load carbig
Create a bivariate histogram with the default settings.

```matlab
X = [MPG,Weight];
hist3(X)
xlabel('MPG')
ylabel('Weight')
```

Specify Centers of Histogram Bins

Create a bivariate histogram on the bins specified by the bin centers, and count the number of elements in each bin.

Load the sample data.

```matlab
load carbig
```

Create a bivariate histogram. Specify the centers of the histogram bins using a two-element cell array.

```matlab
X = [MPG,Weight];
hist3(X,'Ctrs',{0:10:50 2000:500:5000})
xlabel('MPG')
ylabel('Weight')
```
Count the number of elements in each bin.

\[ N = \text{hist3}(X,'Ctrs',
\{0:10:50 2000:500:5000\}) \]

\[
N = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & 3 & 16 & 26 & 6 \\
6 & 34 & 50 & 49 & 27 & 10 & 0 \\
70 & 49 & 11 & 3 & 0 & 0 & 0 \\
29 & 4 & 2 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

---

**Color Histogram Bars by Height**

Load the sample data.

```matlab
load carbig
```

Create a bivariate histogram. Specify graphical properties to color the histogram bars by height representing the frequency of the observations.

```matlab
X = [MPG,Weight];
hist3(X,'CDataMode','auto','FaceColor','interp')
```
Tiled Histogram View

Load the sample data.

load carbig

Create a bivariate tiled histogram. Specify graphical properties to color the top surface of the histogram bars by the frequency of the observations. Change the view to two-dimensional.

X = [MPG,Weight];
hist3(X,'CdataMode','auto')
xlabel('MPG')
ylabel('Weight')
colorbar
view(2)
Adjust Graphical Properties

Create a bivariate histogram and adjust its graphical properties by using the handle of the histogram surface object.

Load the sample data.

load carbig

Create a bivariate histogram with 7 bins in each dimension.

X = [MPG,Weight];
hist3(X,'Nbins',[7 7])
xlabel('MPG')
ylabel('Weight')
The `hist3` function creates a bivariate histogram, which is a type of surface plot. Find the handle of the surface object and adjust the face transparency.

```matlab
s = findobj(gca,'Type','Surface');
s.FaceAlpha = 0.65;
```
Plot Histogram with Intensity Map

Create a bivariate histogram and add the 2-D projected view of intensities to the histogram.

Load the seamount data set (a seamount is an underwater mountain). The data set consists of a set of longitude (x) and latitude (y) locations, and the corresponding seamount elevations (z) measured at those coordinates. This example uses x and y to draw a bivariate histogram.

load seamount

Draw a bivariate histogram.

hist3([x,y])
xlabel('Longitude')
ylabel('Latitude')
hold on
Count the number of elements in each bin.

\[ N = \text{hist3}([x,y]); \]

Generate a grid to draw the 2-D projected view of intensities by using \texttt{pcolor}.

\[ N_{\text{pcolor}} = N'; \]
\[ N_{\text{pcolor}}(\text{size}(N_{\text{pcolor}},1)+1,\text{size}(N_{\text{pcolor}},2)+1) = 0; \]
\[ x_l = \text{linspace}(\text{min}(x),\text{max}(x),\text{size}(N_{\text{pcolor}},2)); \quad \% \text{Columns of } N_{\text{pcolor}} \]
\[ y_l = \text{linspace}(\text{min}(y),\text{max}(y),\text{size}(N_{\text{pcolor}},1)); \quad \% \text{Rows of } N_{\text{pcolor}} \]

Draw the intensity map by using \texttt{pcolor}. Set the \( z \)-level of the intensity map to view the histogram and the intensity map together.

\[ h = \text{pcolor}(x_l,y_l,N_{\text{pcolor}}); \]
\[ \text{colormap}(\text{'hot'}) \quad \% \text{Change color scheme} \]
\[ \text{colorbar} \quad \% \text{Display colorbar} \]
\[ h.ZData = -\text{max}(N_{\text{pcolor}}(:))*\text{ones(size}(N_{\text{pcolor}})); \]
\[ \text{ax} = \text{gca}; \]
\[ \text{ax.ZTick(ax.ZTick < 0)} = []; \]
\[ \text{title('Seamount Location Histogram and Intensity Map')}; \]
Input Arguments

**X — Data to distribute among bins**

*m*-by-2 numeric matrix

Data to distribute among the bins, specified as an *m*-by-2 numeric matrix, where *m* is the number of data points. Corresponding elements in \(X(:,1)\) and \(X(:,2)\) specify the x and y coordinates of 2-D data points.

\texttt{hist3} ignores all \texttt{NaN} values. Similarly, \texttt{hist3} ignores \texttt{Inf} and \texttt{–Inf} values unless you explicitly specify \texttt{Inf} or \texttt{–Inf} as a bin edge by using the \texttt{edges} input argument.

Data Types: \texttt{single} | \texttt{double}

**nbins — Number of bins**

[10 10] (default) | two-element vector of positive integers

Number of bins in each dimension, specified as a two-element vector of positive integers. \texttt{nbins(1)} specifies the number of bins in the first dimension, and \texttt{nbins(2)} specifies the number of bins in the second dimension.

Example: [10 20]

Data Types: \texttt{single} | \texttt{double}
**ctrs — Bin centers**
two-element cell array of numeric vectors

Bin centers in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `ctrs{1}` and `ctrs{2}` are the positions of the bin centers in the first and second dimensions, respectively.

`hist3` assigns rows of `X` falling outside the range of the grid to the bins along the outer edges of the grid.

Example: `{0:10:100 0:50:500}`

Data Types: `cell`

**edges — Bin edges**
two-element cell array of numeric vectors

Bin edges in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `edges{1}` and `edges{2}` are the positions of the bin edges in the first and second dimensions, respectively.

The value `X(k,:)` is in the `(i,j)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`.

The last bins in each dimension also include the last (outer) edge. For example, `X(k,:)` falls into the `(I,j)`th bin if `edges{1}(I–1) ≤ X(k,1) ≤ edges{1}(I)` and `edges{2}(J) ≤ X(k,2) < edges{2}(J+1)`, where `I` is the length of `edges{1}`. Also, `X(k,:)` falls into the `(i,J)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(J–1) ≤ X(k,2) ≤ edges{2}(J)`, where `J` is the length of `edges{2}`.

`hist3` does not count rows of `X` falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-`NaN` values.

Example: `{0:10:100 0:50:500}`

Data Types: `cell`

**ax — Target axes**
current axes (`gca`) (default) | Axes object

Target axes, specified as an axes object. If you do not specify an Axes object, then the `hist3` function uses the current axes (`gca`). For details, see Axes Properties.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `hist3(X,'FaceColor','interp','CDataMode','auto')` colors the histogram bars according to the height of the bars.

The graphical properties listed here are only a subset. For a full list, see Surface Properties.

**CDataMode — Selection mode for vertex colors**

`'manual'` (default) | `'auto'`
Selection mode for CData (vertex colors), specified as the comma-separated pair consisting of 'CDataMode' and one of these values:

- 'manual' — Use manually specified values in the CData property. The default color in CData is light steel blue corresponding to an RGB triple value of \([0.75 \ 0.85 \ 0.95]\).
- 'auto' — Use the ZData values to set the colors. ZData contains the z-coordinate data for the eight corners of each bar.

Example: 'CDataMode','auto'

**EdgeColor — Edge line color**

\([0 \ 0 \ 0]\) (default) | 'none' | 'flat' | 'interp' | RGB triplet | hexadecimal color code | color name | short name

Edge line color, specified as the comma-separated pair consisting of 'EdgeColor' and one of these values:

- 'none' — Do not draw the edges.
- 'flat' — Use a different color for each edge based on the values in the CData property.
- 'interp' — Use interpolated coloring for each edge based on the values in the CData property.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the edges. These values do not use the color values in the CData property.

The default color of \([0 \ 0 \ 0]\) corresponds to black edges.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range \([0,1]\); for example, \([0.4 \ 0.6 \ 0.7]\).
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

<table>
<thead>
<tr>
<th>Color Name</th>
<th>Short Name</th>
<th>RGB Triplet</th>
<th>Hexadecimal Color Code</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>'red'</td>
<td>'r'</td>
<td>[1 0 0]</td>
<td>'#FF0000'</td>
<td></td>
</tr>

<td>'#000000'</td>
<td></td>
</tr>
<tr>
<td>'white'</td>
<td>'w'</td>
<td>[1 1 1]</td>
<td>'#FFFFFF'</td>
<td></td>
</tr>
</tbody>
</table>

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.
Example: 'FaceAlpha', 0.5

FaceColor — Face color

'flat' (default) | 'interp' | 'none' | 'texturemap' | RGB triplet | hexadecimal color code | color name | short name

Face color, specified as the comma-separated pair consisting of 'FaceColor' and one of these values:

- 'flat' — Use a different color for each face based on the values in the CData property.
- 'interp' — Use interpolated coloring for each face based on the values in the CData property.
- 'none' — Do not draw the faces.
- 'texturemap' — Transform the color data in CData so that it conforms to the surface.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the faces. These values do not use the color values in the CData property.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.
• An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range \([0, 1]\); for example, \([0.4 \ 0.6 \ 0.7]\).

• A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

</tr>
<tr>
<td>'none'</td>
<td>No line</td>
<td>No line</td>
</tr>
</tbody>
</table>

Example: 'LineStyle',':'

**LineWidth — Line width**

0.5 (default) | positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points.

Example: 'LineWidth',0.75

Data Types: single | double

**Output Arguments**

**N — Number of elements in each bin**

numeric matrix

Number of elements in X that fall in each bin, returned as a numeric matrix.

**c — Bin centers**

two-element cell array of numeric vectors

Bin centers in each dimension, returned as a two-element cell array of numeric vectors. c{1} and c{2} are the positions of the bin centers in the first and second dimensions, respectively.

**Tips**

The `hist3` function creates a bivariate histogram, which is a type of surface plot. You can specify surface properties using one or more name-value pair arguments. Also, you can change the appearance of the histogram by changing the surface property values after you create a histogram. Get the handle of the surface object by using `s = findobj(gca,'Type','Surface')`, and then use `s` to modify the surface properties. For an example, see “Adjust Graphical Properties” on page 32-2542. For a list of properties, see Surface Properties.

**Alternative Functionality**

The `histogram2` function enables you to create a bivariate histogram using a `Histogram2` object. You can use the name-value pair arguments of `histogram2` to use normalization (‘Normalization’), adjust the width of the bins in each dimension (‘BinWidth’), and display the histogram as a rectangular array of tiles instead of 3-D bars (‘DisplayStyle’).

**See Also**

`accumarray` | `bar3` | `binScatterPlot` | `histcounts2` | `histogram2`
Introduced before R2006a
**histfit**

Histogram with a distribution fit

**Syntax**

```matlab
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)
histfit(ax,___)
h = histfit(___)
```

**Description**

*histfit(data)* plots a histogram of values in *data* using the number of bins equal to the square root of the number of elements in *data* and fits a normal density function.

*histfit(data,nbins)* plots a histogram using *nbins* bins and fits a normal density function.

*histfit(data,nbins,dist)* plots a histogram with *nbins* bins and fits a density function from the distribution specified by *dist*.

*histfit(ax,___)* uses the plot axes specified by the Axes object *ax*. Specify *ax* as the first input argument followed by any of the input argument combinations in the previous syntaxes.

*h = histfit(___)* returns a vector of handles *h*, where *h(1)* is the handle to the histogram and *h(2)* is the handle to the density curve.

**Examples**

**Histogram with a Normal Distribution Fit**

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```matlab
histfit(r)
```
histfit uses fitdist to fit a distribution to data. Use fitdist to obtain parameters used in fitting.

```matlab
pd = fitdist(r,'Normal')
pd =
    NormalDistribution

Normal distribution
    mu = 10.1231   [9.89244, 10.3537]
    sigma = 1.1624   [1.02059, 1.35033]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

**Histogram for a Given Number of Bins**

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.
Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```matlab
rng default;  % For reproducibility
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```matlab
histfit(b,10,'beta')
```
Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```matlab
rng default;  % For reproducibility
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```matlab
histfit(b,10,'kernel')
```
Specify Axes for Histogram with Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 3 and variance 1.

```matlab
rng('default') % For reproducibility
r = normrnd(3,1,100,1);
```

Create a figure with two subplots and return the Axes objects as ax1 and ax2. Create a histogram with a normal distribution fit in each set of axes by referring to the corresponding Axes object. In the left subplot, plot a histogram with 10 bins. In the right subplot, plot a histogram with 5 bins. Add a title to each plot by passing the corresponding Axes object to the title function.

```matlab
ax1 = subplot(1,2,1); % Left subplot
histfit(ax1,r,10,'normal')
title(ax1,'Left Subplot')

ax2 = subplot(1,2,2); % Right subplot
histfit(ax2,r,5,'normal')
title(ax2,'Right Subplot')
```
Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default % for reproducibility
r = normrnd(10,1,100,1);

Construct a histogram with a normal distribution fit.

h = histfit(r,10,'normal')
```
h = 2x1 graphics array:

Bar
Line

Change the bar colors of the histogram.

h(1).FaceColor = [.8 .8 1];
Change the color of the density curve.

\[ h(2).\text{Color} = [.2 \ .2 \ .2]; \]
**Input Arguments**

**data — Input data**

vector

Input data, specified as a vector.

- Example: `data = [1.5 2.5 4.6 1.2 3.4]`
- Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

**nbins — Number of bins**

positive integer | `[]`

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use `[]` for the default number of bins when fitting a distribution.

- Example: `y = histfit(x,8)`
- Example: `y = histfit(x,10,'gamma')`
- Example: `y = histfit(x,[ ],'weibull')`

Data Types: `double` | `single`
dist — Distribution to fit
'normal' (default) | character vector | string scalar

Distribution to fit to the histogram, specified as a character vector or string scalar. The following table shows the supported distributions.

<table>
<thead>
<tr>
<th>dist</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'beta'</td>
<td>Beta</td>

ax — Axes for plot
Axes object

Axes for the plot, specified as an Axes object. If you do not specify ax, then histfit creates the plot using the current axes. For more information on creating an Axes object, see axes.

Output Arguments

h — Handles for the plot
plot handle
Handles for the plot, returned as a vector, where h(1) is the handle to the histogram, and h(2) is the handle to the density curve. `histfit` normalizes the density to match the total area under the curve with that of the histogram.

**Algorithms**

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

**See Also**

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)

Description

PSTATES = hmmdecode(seq,TRANS,EMIS) calculates the posterior state probabilities, PSTATES, of the sequence seq from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i, given the observed sequence of symbols, sym. You specify the model by a transition probability matrix, TRANS, and an emissions probability matrix, EMIS. TRANS(i,j) is the probability of transition from state i to state j. EMIS(k,seq) is the probability that symbol seq is emitted from state k.

PSTATES is an array with the same length as seq and one row for each state in the model. The (i,j)th element of PSTATES gives the probability that the model is in state i at the jth step, given the sequence seq.

Note  The function hmmdecode begins with the model in state 1 at step 0, prior to the first emission. hmmdecode computes the probabilities in PSTATES based on the fact that the model begins in state 1.

[PSTATES,logpseq] = hmmdecode(...) returns logpseq, the logarithm of the probability of sequence seq, given transition matrix TRANS and emission matrix EMIS.

[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...) returns the forward and backward probabilities of the sequence scaled by S.

hmmdecode(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

Examples

trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6; 1/10 1/10 1/10 1/10 1/10 1/2];
[seq,states] = hmmgenerate(100,trans,emis);
pStates = hmmdecode(seq,trans,emis);
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{one','two','three','four','five','six'})
pStates = hmmdecode(seq,trans,emis,...
    'Symbols',{one','two','three','four','five','six});

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)

Description

[TRANS,EMIS] = hmmestimate(seq,states) calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.

hmmestimate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmestimate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

hmmestimate(...,'Pseudoemissions',PSEUDOE) specifies pseudocount emission values in the matrix PSEUDOE. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the i → k emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

hmmestimate(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size m-by-m, where m is the number of states in the hidden Markov model. If the i → j transition does not occur in states, you can set PSEUDOTR(i,j) to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence states, or the emission might never occur in the sequence seq. In either case, the algorithm returns a probability of 0 for the given transition or emission in TRANS or EMIS. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of PSEUDOE or PSEUDOTR to 1. For example, if the transition i → j does not occur in states, set PSEUDOTR(i,j) = 1. This forces TRANS(i,j) to be positive. If you have an estimate for the expected number of transitions i → j in a sequence of the same length as states, and the actual
number of transitions \(i \rightarrow j\) that occur in \(\text{seq}\) is substantially less than what you expect, you can set \(\text{PSEUDOTR}(i,j)\) to the expected number. This increases the value of \(\text{TRANS}(i,j)\). For transitions that do occur in states with the frequency you expect, set the corresponding entry of \(\text{PSEUDOTR}\) to 0, which does not increase the corresponding entry of \(\text{TRANS}\).

If you do not know the sequence of states, use \text{hmmtrain} to estimate the model parameters.

**Examples**

```matlab
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

**References**

**See Also**

**Introduced before R2006a**
hmmgenerate

Hidden Markov model states and emissions

Syntax

[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)

Description

[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence seq of emission symbols
- A random sequence states of states

The length of both seq and states is len. TRANS(i,j) is the probability of transition from state i to state j. EMIS(k,l) is the probability that symbol l is emitted from state k.

Note  The function hmmgenerate begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1 with probability T_{1i_1}, and generates an emission a_{k_1} with probability E_{i_1k_1}. hmmgenerate returns i_1 as the first entry of states, and a_{k_1} as the first entry of seq.

hmmgenerate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be specified as a numeric array, a string array, or a cell array of character vectors. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmgenerate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be specified as a numeric array, a string array, or a cell array of character vectors. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output states is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
   'Symbols',
   '{one','two','three','four','five','six'},...
   'Statenames',
   {'fair';'loaded'})

hmmdecode | hmmestimate | hmmtrain | hmmviterbi

Introduced before R2006a
hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)

Description

[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS) estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. seq can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. TRGUESS and EMITGUESS are initial estimates of the transition and emission probability matrices. TRGUESS(i,j) is the estimated probability of transition from state i to state j. EMITGUESS(i,k) is the estimated probability that symbol k is emitted from state i.

hmmtrain(...,'Algorithm',algorithm) specifies the training algorithm. algorithm can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

hmmtrain(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmtrain(...,'Tolerance',tol) specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is 1e-4.

hmmtrain(...,'Maxiterations',maxiter) specifies the maximum number of iterations for the estimation process. The default maximum is 100.

hmmtrain(...,'Verbose',true) returns the status of the algorithm at each iteration.

hmmtrain(...,'Pseudoemissions',PSEUDOE) specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the i→k emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

hmmtrain(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size m-by-m, where m is the number of states in the hidden Markov model. If the i→j transition has not occurred in seq, you can set PSEUDOTR(i,j) to be a positive number representing an estimate of the expected number of such transitions in the sequence seq.
transition does not occur in states, you can set $PSEUDOTR(i,j)$ to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

**Tolerance**

The input argument 'tolerance' controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for tolerance:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of 'tolerance' is $1e^{-6}$. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

**maxiterations**

The maximum number of iterations, 'maxiterations', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

**Examples**

```matlab
trans = [0.95, 0.05;
        0.10, 0.90];
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];
seq1 = hmmgenerate(100,trans,emis);
seq2 = hmmgenerate(200,trans,emis);
seqs = {seq1,seq2};
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)

Description

STATES = hmmviterbi(seq,TRANS,EMIS) given a sequence, seq, calculates the most likely path through the hidden Markov model specified by transition probability matrix, TRANS, and emission probability matrix EMIS. TRANS(i,j) is the probability of transition from state i to state j. EMIS(i,k) is the probability that symbol k is emitted from state i.

Note The function hmmviterbi begins with the model in state 1 at step 0, prior to the first emission. hmmviterbi computes the most likely path based on the fact that the model begins in state 1.

hmmviterbi(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmviterbi(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

Examples

trans = [0.95,0.05;
        0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];
[seq,states] = hmmgenerate(100,trans,emis);
estimatedStates = hmmviterbi(seq,trans,emis);

[seq,states] = ...
    hmmgenerate(100,trans,emis,...
        'Statenames',{‘fair’;'loaded'});
estimatesStates = ...
    hmmviterbi(seq,trans,emis,...
        'Statenames',{‘fair’;'loaded'});

Introduced before R2006a
horzcat

Class: dataset

(Not Recommended) Horizontal concatenation for dataset arrays

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

ds = horzcat(ds1, ds2, ...)

Description

ds = horzcat(ds1, ds2, ...) horizontally concatenates the dataset arrays ds1, ds2, ... . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and horzcat includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. horzcat concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also
cat | vertcat
**hougen**

Hougen-Watson model

**Syntax**

```matlab
yhat = hougen(beta,x)
```

**Description**

`yhat = hougen(beta,x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

\[
\hat{y} = \frac{\beta_1 x_2 - x_3/\beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}
\]

**References**

`rsmdemo`

**Introduced before R2006a**
**hygecdf**

Hypergeometric cumulative distribution function

**Syntax**

```plaintext
hygecdf(x,M,K,N)
hygecdf(x,M,K,N,'upper')
```

**Description**

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

\[
p = F(x | M, K, N) = \sum_{i=0}^{x} \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}
\]

The result, `p`, is the probability of drawing up to `x` of a possible `K` items in `N` drawings without replacement from a group of `M` objects.

**Examples**

**Compute Hypergeometric Distribution CDF**

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```plaintext
p = hygecdf(2,100,20,10)
p = 0.6812
```

**Extended Capabilities**

cdf | hygeinv | hygepdf | hygernd | hygestat

Introduced before R2006a
**hygeinv**

Hypergeometric inverse cumulative distribution function

**Syntax**

`hygeinv(P,M,K,N)`

**Description**

`hygeinv(P,M,K,N)` returns the smallest integer `X` such that the hypergeometric cdf evaluated at `X` equals or exceeds `P`. You can think of `P` as the probability of observing `X` defective items in `N` drawings without replacement from a group of `M` items where `K` are defective.

**Examples**

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```matlab
x = hygeinv(0.99,1000,10,50)
x = 3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```matlab
x = hygeinv(0.50,1000,10,50)
x = 0
```

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

`hygecdf` | `hygepdf` | `hygernd` | `hygestat` | `icdf`

Introduced before R2006a
**hygepdf**

Hypergeometric probability density function

**Syntax**

\[ Y = \text{hygepdf}(X, M, K, N) \]

**Description**

\[ Y = \text{hygepdf}(X, M, K, N) \] computes the hypergeometric pdf at each of the values in \( X \) using the corresponding size of the population, \( M \), number of items with the desired characteristic in the population, \( K \), and number of samples drawn, \( N \). \( X, M, K, \) and \( N \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in \( M, K, \) and \( N \) must all be positive integers, with \( N \leq M \). The values in \( X \) must be less than or equal to all the parameter values.

The hypergeometric pdf is

\[ y = f(x) = \binom{K}{x} \binom{M - K}{N - x} \binom{M}{N} \]

The result, \( y \), is the probability of drawing exactly \( x \) of a possible \( K \) items in \( n \) drawings without replacement from a group of \( M \) objects.

**Examples**

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

\[ p = \text{hygepdf}(0:5, 100, 20, 10) \]

\[ p = \\begin{array}{cccc}
0.0951 & 0.2679 & 0.3182 & 0.2092 & 0.0841 & 0.0215 \\
\end{array} \]

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

hygecdf | hygeinv | hygernd | hygestat | pdf

Introduced before R2006a
**hygernd**

Hypergeometric random numbers

**Syntax**

\[
R = \text{hygernd}(M,K,N) \\
R = \text{hygernd}(M,K,N,m,n,\ldots) \\
R = \text{hygernd}(M,K,N,[m,n,\ldots])
\]

**Description**

\( R = \text{hygernd}(M,K,N) \) generates random numbers from the hypergeometric distribution with corresponding size of the population, \( M \), number of items with the desired characteristic in the population, \( K \), and number of samples drawn, \( N \). \( M \), \( K \), and \( N \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( R \). A scalar input for \( M \), \( K \), or \( N \) is expanded to a constant array with the same dimensions as the other inputs.

\( R = \text{hygernd}(M,K,N,m,n,\ldots) \) or \( R = \text{hygernd}(M,K,N,[m,n,\ldots]) \) generates an \( m \)-by-\( n \)-by-... array. The \( M \), \( K \), \( N \) parameters can each be scalars or arrays of the same size as \( R \).

**Examples**

\[
\text{numbers} = \text{hygernd}(1000,40,50)
\]

\[
\text{numbers} = \\
\quad 1
\]

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

hygecdf | hygeinv | hygepdf | hygestat | random

Introduced before R2006a
hygestat

Hypergeometric mean and variance

Syntax

[MN, V] = hygestat(M, K, N)

Description

[MN, V] = hygestat(M, K, N) returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. Vector or matrix inputs for M, K, and N must have the same size, which is also the size of MN and V. A scalar input for M, K, or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M, K, and N is NK/M, and the variance is NK(M-K)(M-N)/[M^2(M-1)].

Examples

The hypergeometric distribution approaches the binomial distribution, where p = K/M, as M goes to infinity.

[m, v] = hygestat(10.(1:4), 10.(0:3), 9)

m =
0.9000 0.9000 0.9000 0.9000
v =
0.0900 0.7445 0.8035 0.8094

[m, v] = binostat(9, 0.1)

m =
0.9000
v =
0.8100

hyperparameters

Variable descriptions for optimizing a fit function

Syntax

VariableDescriptions = hyperparameters(FitFcnName,predictors,response)
VariableDescriptions = hyperparameters(FitFcnName,predictors,response, LearnerType)

Description

VariableDescriptions = hyperparameters(FitFcnName,predictors,response) returns the default variables for the given fit function. These are the variables that apply when you set the OptimizeHyperparameters name-value pair to 'auto'.

VariableDescriptions = hyperparameters(FitFcnName,predictors,response, LearnerType) returns the variables for an ensemble fit with specified learner type. This syntax applies when FitFcnName is 'fitcecoc', 'fitcensemble', or 'fitrensemble'.

Examples

Obtain Default Hyperparameters

Obtain the default hyperparameters for the fitcsvm classifier.

Load the ionosphere data.

load ionosphere

Obtain the hyperparameters.

VariableDescriptions = hyperparameters('fitcsvm',X,Y);

Examine all the hyperparameters.

for ii = 1:length(VariableDescriptions) 
    disp(ii),disp(VariableDescriptions(ii))
end

1

optimizableVariable with properties:

    Name: 'BoxConstraint'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1

2
optimizableVariable with properties:

Name: 'KernelScale'
Range: [1.0000e-03 1000]
Type: 'real'
Transform: 'log'
Optimize: 1

3

optimizableVariable with properties:

Name: 'KernelFunction'
Range: {'gaussian' 'linear' 'polynomial'}
Type: 'categorical'
Transform: 'none'
Optimize: 0

4

optimizableVariable with properties:

Name: 'PolynomialOrder'
Range: [2 4]
Type: 'integer'
Transform: 'none'
Optimize: 0

5

optimizableVariable with properties:

Name: 'Standardize'
Range: {'true' 'false'}
Type: 'categorical'
Transform: 'none'
Optimize: 0

Change the PolynomialOrder hyperparameter to have a wider range and to be used in an optimization.

VariableDescriptions(4).Range = [2,5];
VariableDescriptions(4).Optimize = true;
disp(VariableDescriptions(4))

optimizableVariable with properties:

Name: 'PolynomialOrder'
Range: [2 5]
Type: 'integer'
Transform: 'none'
Optimize: 1

Obtain Ensemble Hyperparameters

Obtain the default hyperparameters for the fitrensemble ensemble regression function.
Load the `carsmall` data.

```matlab
load carsmall
```

Use Horsepower and Weight as predictor variables, and MPG as the response variable.

```matlab
X = [Horsepower Weight];
Y = MPG;
```

Obtain the default hyperparameters for a Tree learner.

```matlab
VariableDescriptions = hyperparameters('fitrensemble',X,Y,'Tree');
```

Examine all the hyperparameters.

```matlab
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

1

```
optimizableVariable with properties:
    Name: 'Method'
    Range: {'Bag'  'LSBoost'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 1
```

2

```
optimizableVariable with properties:
    Name: 'NumLearningCycles'
    Range: [10 500]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```

3

```
optimizableVariable with properties:
    Name: 'LearnRate'
    Range: [1.0000e-03 1]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

4

```
optimizableVariable with properties:
    Name: 'MinLeafSize'
    Range: [1 50]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```
optimizableVariable with properties:
    Name: 'MaxNumSplits'
    Range: [1 99]
    Type: 'integer'
    Transform: 'log'
    Optimize: 0

optimizableVariable with properties:
    Name: 'NumVariablesToSample'
    Range: [1 2]
    Type: 'integer'
    Transform: 'none'
    Optimize: 0

Change the MaxNumSplits hyperparameter to have a wider range and to be used in an optimization.

VariableDescriptions(5).Range = [1,200];
VariableDescriptions(5).Optimize = true;
disp(VariableDescriptions(5))

optimizableVariable with properties:
    Name: 'MaxNumSplits'
    Range: [1 200]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1

Input Arguments

FitFcnName — Name of fitting function
    'fitcdiscr'| 'fitcecoc' | 'fitcensemble' | 'fitckernel' | 'fitcknn' | 'fitclinear' | 'fitcnb' | 'fitcsvm' | 'fitctree' | 'fitrensemble' | 'fitrgp' | 'fitrkernel' | 'fitrlinear' | 'fitrsvm' | 'fitrtree'

Name of fitting function, specified as one of the listed classification or regression fit function names.

If FitFcnName is 'fitcecoc', 'fitcensemble', or 'fitrensemble', then also specify the learner type in the LearnerType argument.

Example: 'fitctree'

predictors — Predictor data
data matrix with D predictor columns | table with D predictor columns

Predictor data, specified as a matrix with D predictor columns or as a table with D predictor columns, where D is the number of predictors.

Example: X

Data Types: double | logical | char | string | table | cell | categorical | datetime
response — Class labels or numeric response
grouping variable | scalar

Class labels or numeric response, specified as a grouping variable (see “Grouping Variables” on page 2-45) or as a scalar.

Example: Y

Data Types: single | double | logical | char | string | cell

LearnerType — Learner type for ensemble fit
'Discriminant' | 'Kernel' | 'KNN' | 'Linear' | 'SVM' | 'Tree' | template of a listed learner

Learner type for ensemble fit, specified as 'Discriminant', 'Kernel', 'KNN', 'Linear', 'SVM', 'Tree', or a template of a listed learner. Use this argument when FitFcnName is 'fitcecoc', 'fitcensemble', or 'fitrensemble'.

For 'fitcensemble' you can use only 'Discriminant', 'KNN', 'Tree', or an associated template.

For 'fitrensemble', you can use only 'Tree' or templateTree.

Example: 'Tree'

Output Arguments

VariableDescriptions — Variable descriptions
vector of optimizableVariable objects

Variable descriptions, returned as a vector of optimizableVariable objects. The variables have their default parameters set, such as range and variable type. All eligible variables exist in the descriptions, but the variables unused in the 'auto' setting have their Optimize property set to false. You can update the variables by using dot notation, as shown in “Examples” on page 32-0.

Introduced in R2016b
icdf

Package: prob

Inverse cumulative distribution function

Syntax

\[
x = \text{icdf}('\text{name}', p, A) \\
x = \text{icdf}('\text{name}', p, A, B) \\
x = \text{icdf}('\text{name}', p, A, B, C) \\
x = \text{icdf}('\text{name}', p, A, B, C, D) \\
x = \text{icdf}(\text{pd}, p)
\]

Description

\(x = \text{icdf}('\text{name}', p, A)\) returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the probability values in p.

\(x = \text{icdf}('\text{name}', p, A, B)\) returns the icdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the probability values in p.

\(x = \text{icdf}('\text{name}', p, A, B, C)\) returns the icdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the probability values in p.

\(x = \text{icdf}('\text{name}', p, A, B, C, D)\) returns the icdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the probability values in p.

\(x = \text{icdf}(\text{pd}, p)\) returns the icdf function of the probability distribution object pd, evaluated at the probability values in p.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, \(\mu\), equal to 0 and the standard deviation, \(\sigma\), equal to 1.

\[
\mu = 0; \\
\text{sigma} = 1; \\
\text{pd} = \text{makedist('Normal','mu',mu,'sigma',sigma)};
\]

Define the input vector p to contain the probability values at which to calculate the icdf.

\[
p = [0.1,0.25,0.5,0.75,0.9];
\]

Compute the icdf values for the standard normal distribution at the values in p.

\[
x = \text{icdf(pd,p)}
\]
Each value in \( x \) corresponds to a value in the input vector \( p \). For example, at the value \( p \) equal to 0.9, the corresponding icdf value \( x \) is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the \texttt{icdf} function and specify a standard normal distribution using the same parameter values for \( \mu \) and \( \sigma \).

\[ x_2 = \text{icdf('Normal',}p,\mu,\sigma) \]
\[ x_2 = 1 \times 5 \]
\[ -1.2816 \quad -0.6745 \quad 0 \quad 0.6745 \quad 1.2816 \]

The icdf values are the same as those computed using the probability distribution object.

**Compute the Poisson Distribution icdf**

Create a Poisson distribution object with the rate parameter, \( \lambda \), equal to 2.

\[
\text{lambda} = 2; \\
\text{pd} = \text{makedist('Poisson',}'\text{lambda}',\text{lambda});
\]

Define the input vector \( p \) to contain the probability values at which to calculate the icdf.

\[ p = [0.1,0.25,0.5,0.75,0.9]; \]

Compute the icdf values for the Poisson distribution at the values in \( p \).

\[ x = \text{icdf(pd,}p) \]
\[ x = 1 \times 5 \]
\[ 0 \quad 1 \quad 2 \quad 3 \quad 4 \]

Each value in \( x \) corresponds to a value in the input vector \( p \). For example, at the value \( p \) equal to 0.9, the corresponding icdf value \( x \) is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the \texttt{icdf} function and specify a Poisson distribution using the same value for the rate parameter \( \lambda \).

\[ x_2 = \text{icdf('Poisson',}p,\text{lambda}) \]
\[ x_2 = 1 \times 5 \]
\[ 0 \quad 1 \quad 2 \quad 3 \quad 4 \]

The icdf values are the same as those computed using the probability distribution object.
Compute Standard Normal Critical Values

Create a standard normal distribution object.

```matlab
pd = makedist('Normal')
pd = NormalDistribution
    Normal distribution
    mu = 0
    sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

```matlab
x = icdf(pd,[.025,.975])
x = 1x2
    -1.9600   1.9600
```

Plot the cdf and shade the critical regions.

```matlab
p = normspec(x,0,1,'outside')
```
p = 0.0500

Example: 'Normal'

**p — Probability values at which to evaluate icdf**

scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values in the range [0,1].
If one or more of the input arguments \( p, A, B, C, \) and \( D \) are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `name` for the definitions of \( A, B, C, \) and \( D \) for each distribution.

Example: \([0.1, 0.25, 0.5, 0.75, 0.9]\)

Data Types: `single` | `double`

**A — First probability distribution parameter**

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments \( p, A, B, C, \) and \( D \) are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `name` for the definitions of \( A, B, C, \) and \( D \) for each distribution.

Data Types: `single` | `double`

**B — Second probability distribution parameter**

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments \( p, A, B, C, \) and \( D \) are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `name` for the definitions of \( A, B, C, \) and \( D \) for each distribution.

Data Types: `single` | `double`

**C — Third probability distribution parameter**

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments \( p, A, B, C, \) and \( D \) are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `name` for the definitions of \( A, B, C, \) and \( D \) for each distribution.

Data Types: `single` | `double`

**D — Fourth probability distribution parameter**

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments \( p, A, B, C, \) and \( D \) are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `name` for the definitions of \( A, B, C, \) and \( D \) for each distribution.

Data Types: `single` | `double`

**pd — Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.
<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td>Distribution Fitter</td>
<td>Fit a probability distribution to sample data using the interactive</td>
</tr>
<tr>
<td></td>
<td>Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
<tr>
<td>paretotails</td>
<td>Create a piecewise distribution object that has generalized Pareto</td>
</tr>
<tr>
<td></td>
<td>distributions in the tails.</td>
</tr>
</tbody>
</table>

**Output Arguments**

\[ x \rightarrow \text{icdf values} \]

_scalar value | array of scalar values_

\( x \) is the icdf value of the distribution, specified by the corresponding elements in the distribution parameters \((A, B, C, \text{and } D)\) or specified by the probability distribution object \((pd)\), evaluated at the corresponding element in \(p\).

**Alternative Functionality**

\texttt{icdf} is a generic function that accepts either a distribution by its name 'name' or a probability distribution object \(pd\). It is faster to use a distribution-specific function, such as \texttt{norminv} for the normal distribution and \texttt{binoinv} for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-13.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include \texttt{coder.Constant('Normal')} in the -args value of codegen.
- The input argument \(pd\) can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create \(pd\) by fitting a probability distribution to sample data from the \texttt{fitdist} function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

“Supported Distributions” on page 5-13
Introduced before R2006a
inconsistent

Inconsistency coefficient

Syntax

Y = inconsistent(Z)
Y = inconsistent(Z,d)

Description

Y = inconsistent(Z) returns the inconsistency coefficient for each link of the hierarchical cluster tree Z generated by the linkage function. inconsistent calculates the inconsistency coefficient for each link by comparing its height with the average height of other links at the same level of the hierarchy. The larger the coefficient, the greater the difference between the objects connected by the link. For more information, see “Algorithms” on page 32-2601.

Y = inconsistent(Z,d) returns the inconsistency coefficient for each link in the tree Z by searching to a depth d below each link.

Examples

Inconsistency Coefficient Calculation

Examine an inconsistency coefficient calculation for a hierarchical cluster tree.

Load the examgrades data set.

load examgrades

Create a hierarchical cluster tree.

Z = linkage(grades);

Create a matrix of inconsistency coefficient information using inconsistent. Examine the information for the 84th link.

Y = inconsistent(Z);
Y(84,:)

ans = 1x4
    7.2741  0.3624  3.0000  0.5774

The fourth column of Y contains the inconsistency coefficient, which is computed using the mean in the first column of Y and the standard deviation in the second column of Y.

Because the rows of Y correspond to the rows of Z, examine the 84th link in Z.

Z(84,:)
ans = 1×3
    190.0000  203.0000    7.4833

The 84th link connects the 190th and 203rd clusters in the tree and has a height of 7.4833. The 190th cluster corresponds to the link of index 190 – 120 = 70, where 120 is the number of observations. The 203rd cluster corresponds to the 83rd link.

By default, inconsistent uses two levels of the tree to compute Y. Therefore, it uses only the 70th, 83rd, and 84th links to compute the inconsistency coefficient for the 84th link. Compare the values in Y(84,:) with the corresponding computations by using the link heights in Z.

mean84 = mean([Z(70,3) Z(83,3) Z(84,3)])
mean84 = 7.2741
std84 = std([Z(70,3) Z(83,3) Z(84,3)])
std84 = 0.3624
inconsistent84 = (Z(84,3)-mean84)/std84
inconsistent84 = 0.5774

**Compute Inconsistency Coefficient**

Create the sample data.

X = gallery('uniforndata',[10 2],12);
Y = pdist(X);

Generate the hierarchical cluster tree.

Z = linkage(Y,'single');

Generate a dendrogram plot of the hierarchical cluster tree.

dendrogram(Z)
Compute the inconsistency coefficient for each link in the cluster tree \( Z \) to depth 3.

\[ W = \text{inconsistent}(Z,3) \]

\[ W = 9 \times 4 \]

\[
\begin{array}{cccc}
0.1313 & 0 & 1.0000 & 0 \\
0.1386 & 0 & 1.0000 & 0 \\
0.1463 & 0.0109 & 2.0000 & 0.7071 \\
0.2391 & 0 & 1.0000 & 0 \\
0.1951 & 0.0568 & 4.0000 & 0.9425 \\
0.2308 & 0.0543 & 4.0000 & 0.9320 \\
0.2395 & 0.0748 & 4.0000 & 0.7636 \\
0.2654 & 0.0945 & 4.0000 & 0.9203 \\
0.3769 & 0.0950 & 3.0000 & 1.1040 \\
\end{array}
\]

**Input Arguments**

\( Z \) — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree, specified as a numeric matrix returned by \texttt{linkage}. \( Z \) is an \((m - 1)\)-by-3 matrix, where \( m \) is the number of observations. Columns 1 and 2 of \( Z \) contain cluster
indices linked in pairs to form a binary tree. \( Z(I, 3) \) contains the linkage distances between the two clusters merged in row \( Z(I,:) \).

Data Types: single | double

\[ \text{d — Depth} \]

2 (default) | positive integer scalar

Depth, specified as a positive integer scalar. For each link \( k \), inconsistent calculates the corresponding inconsistency coefficient using all the links in the tree within \( d \) levels below \( k \).

Data Types: single | double

**Output Arguments**

\[ \text{Y — Inconsistency coefficient information} \]

numeric matrix

Inconsistency coefficient information, returned as an \((m - 1)\)-by-4 matrix, where the \((m - 1)\) rows correspond to the rows of \( Z \). This table describes the columns of \( Y \).

<tr>
<td>2</td>
<td>Standard deviation of the heights of all the links included in the calculation</td>
</tr>
<tr>
<td>3</td>
<td>Number of links included in the calculation</td>
</tr>
<tr>
<td>4</td>
<td>Inconsistency coefficient</td>
</tr>
</tbody>
</table>

Data Types: double

**Algorithms**

For each link \( k \), the inconsistency coefficient is calculated as

\[ Y(k, 4) = (Z(k, 3) - Y(k, 1))/Y(k, 2), \]

where \( Y \) is the inconsistency coefficient information for links in the hierarchical cluster tree \( Z \).

For links that have no further links below them, the inconsistency coefficient is set to 0.

“Hierarchical Clustering” on page 16-6
Introduced before R2006a
`increaseB`  

**Class:** clustering.evaluation.GapEvaluation  
**Package:** clustering.evaluation

Increase reference data sets

**Syntax**

```matlab
eva_out = increaseB(eva,nref)
```

**Description**

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

**Input Arguments**

- **eva** — Clustering evaluation data  
  clustering evaluation object  
  Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

- **nref** — Number of additional reference data sets  
  positive integer value  
  Number of additional reference data sets, specified as a positive integer value.

**Output Arguments**

- **eva_out** — Updated clustering evaluation data  
  clustering evaluation object  
  Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

**Examples**
Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using evalclusters, then use increaseB to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

load fisheriris

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using kmeans, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

rng('default') % For reproducibility
eva = evalclusters(meas,'kmeans','gap','klist',1:5,'B',50)

eva =
  GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0870 0.5822 0.8766 1.0007 1.0465]
    OptimalK: 4

The clustering evaluation object eva contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is four.

The value of the B property of eva shows 50 reference data sets.

eva.B

ans = 50

Increase the number of reference data sets by 100, for a total of 150 sets.

eva = increaseB(eva,100)

eva =
  GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0794 0.5850 0.8738 1.0034 1.0508]
    OptimalK: 5

The returned results now indicate that the optimal number of clusters is five.

The value of the B property of eva now shows 150 reference data sets.

eva.B

ans = 150

evalclusters
interactionplot

Interaction plot for grouped data

Syntax

interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)

Description

interactionplot(Y,GROUP) displays the two-factor interaction plot for the group means of matrix Y with groups defined by entries in GROUP, which can be a cell array or a matrix. Y is a numeric matrix or vector. If Y is a matrix, the rows represent different observations and the columns represent replications of each observation. If Y is a vector, the rows give the means of each entry in GROUP. If GROUP is a cell array, then each cell of GROUP must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If GROUP is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as Y. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (i,j) is the interaction of the two variables whose names are given at row diagonal (i,i) and column diagonal (j,j), respectively.

interactionplot(Y,GROUP,'varnames',VARNAMES) displays the interaction plot with user-specified grouping variable names VARNAMES. VARNAMES is a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ...

[h,AX,bigax] = interactionplot(...) returns a handle h to the figure window, a matrix AX of handles to the subplot axes, and a handle bigax to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable y.

rng default; % For reproducibility
y = randn(1000,1);

Randomly generate data for four three-level factors.

group = ceil(3*rand(1000,4));

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

interactionplot(y,group,'varnames',{'A','B','C','D'})

maineffectsplot | multivarichart

Introduced in R2006b
**intersect**

**Class:** dataset

(Not Recommended) Set intersection for dataset array observations

---

**Syntax**

```matlab
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

---

**Description**

*C = intersect(A,B)* for dataset arrays *A* and *B* returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array *C* are in sorted order.

*C = intersect(A,B,vars)* returns the set of common observations from the two arrays, considering only the variables specified in *vars*, with repetitions removed. The observations in the dataset array *C* are sorted by those variables.

The values for variables not specified in *vars* for each observation in *C* are taken from the corresponding observations in *A*. If there are multiple observations in *A* that correspond to an observation in *C*, then those values are taken from the first occurrence.

*C = intersect(A,B,vars,setOrder)* returns the observations in *C* in the order specified by *setOrder*.

*[C,iA,iB] = intersect( ___ )* also returns index vectors *iA* and *iB* such that *C = A(iA,:)* and *C = B(iB,:)*. If there are repeated observations in *A* or *B*, then *intersect* returns the index of the first occurrence. You can use any of the previous input arguments.

---

**Input Arguments**

* **A,B**
  
  Input dataset arrays.

* **vars**
  
  String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. *vars* indicates the variables in *A* and *B* that *intersect* considers.

  Specify *vars* as [] to use its default value of all variables.
**setOrder**

Flag indicating the sorting order for the observations in C. The possible values of setOrder are:

- 'sorted' Observations in C are in sorted order (default).
- 'stable' Observations in C are in the same order that they appear in A.

**Output Arguments**

**C**

Dataset array with the common set of observations in A and B, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

**iA**

Index vector, indicating the observations in A that are common to B. The vector iA contains the index to the first occurrence of any repeated observations in A.

**iB**

Index vector, indicating the observations in B that are common to A. The vector iB contains the index to the first occurrence of any repeated observations in B.

**Examples**

**Intersection of Two Dataset Arrays**

Load sample data.

```
A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'));
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'),'Sheet',2);

[C,iA,iB] = intersect(A,B);
```

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

```
   id     name  sex age  wgt smoke
  ---- ---- ---- --- ---- ----
 TRW-072 WHITE m    39 202    1
```

```
B(iB,:)
```

```
   id     name  sex age  wgt smoke
  ---- ---- ---- --- ---- ----
 TRW-072 WHITE m    39 202    1
```
ans =

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>sex</th>
<th>age</th>
<th>wgt</th>
<th>smoke</th>
</tr>
</thead>
<tbody>
<tr>
<td>'TRW-072'</td>
<td>'WHITE'</td>
<td>'m'</td>
<td>39</td>
<td>202</td>
<td>1</td>
</tr>
</tbody>
</table>

Topics
"Merge Dataset Arrays" on page 2-85
"Dataset Arrays" on page 2-112
invpred

Inverse prediction

Syntax

\[X_0 = \text{invpred}(X,Y,Y_0)\]
\[[X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0)\]
\[[X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0,\text{name1,val1,\text{name2,val2,\ldots}})\]

Description

\(X_0 = \text{invpred}(X,Y,Y_0)\) accepts vectors \(X\) and \(Y\) of the same length, fits a simple regression, and returns the estimated value \(X_0\) for which the height of the line is equal to \(Y_0\). The output, \(X_0\), has the same size as \(Y_0\), and \(Y_0\) can be an array of any size.

\[[X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0)\] also computes 95% inverse prediction intervals. \(DXLO\) and \(DXUP\) define intervals with lower bound \(X_0–DXLO\) and upper bound \(X_0+DXUP\). Both \(DXLO\) and \(DXUP\) have the same size as \(Y_0\).

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to \(-\text{Inf}\) or \(+\text{Inf}\), and some may extend over the entire real line.

\[[X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0,\text{name1,val1,\text{name2,val2,\ldots}})\] specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'alpha'</td>
<td>A value between 0 and 1 specifying a confidence level of (100% \times (1-\alpha)). Default is (\alpha=0.05) for 95% confidence.</td>
</tr>
<tr>
<td>'predopt'</td>
<td>Either 'observation', the default value to compute the intervals for (X_0) at which a new observation could equal (Y_0), or 'curve' to compute intervals for the (X_0) value at which the curve is equal to (Y_0).</td>
</tr>
</tbody>
</table>

Examples

Inverse Prediction

Generate sample data.

\[x = 4*\text{rand}(25,1);\]
\[y = 10 + 5*x + \text{randn}(\text{size}(x));\]

Make a scatterplot of the data.

\text{scatter}(x,y)
Predict the $x$ value for a given $y$ value of 20.

$x_0 = \text{invpred}(x,y,20)$

$x_0 = 1.9967$

**See Also**

polyconf | polyfit | polytool | polyval

*Introduced before R2006a*
**iqr**

**Package:** prob

Interquartile range

**Syntax**

\[ r = \text{iqr}(x) \]
\[ r = \text{iqr}(x, \text{dim}) \]
\[ r = \text{iqr}(x, \text{vecdim}) \]
\[ r = \text{iqr}(\text{pd}) \]

**Description**

\[ r = \text{iqr}(x) \] returns the interquartile range of the values in \( x \).

- If \( x \) is a vector, then \( r \) is the difference between the 75th and the 25th percentiles of the data contained in \( x \).
- If \( x \) is a matrix, then \( r \) is a row vector containing the difference between the 75th and the 25th percentiles of the sample data in each column of \( x \).
- If \( x \) is a multidimensional array, then \text{iqr} operates along the first nonsingleton dimension of \( x \). The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

\[ r = \text{iqr}(x, \text{all}') \] returns the interquartile range of all the values in \( x \).

\[ r = \text{iqr}(x, \text{dim}) \] returns the interquartile range along the dimension of \( x \) specified by \( \text{dim} \).

\[ r = \text{iqr}(x, \text{vecdim}) \] returns the interquartile range over the dimensions specified by \( \text{vecdim} \). For example, if \( x \) is a matrix, then \( \text{iqr}(x, [1 2]) \) is the interquartile range of all the elements of \( x \) because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

\[ r = \text{iqr}(\text{pd}) \] returns the interquartile range of the probability distribution \( \text{pd} \).

**Examples**

**Compute the Interquartile Range**

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values \( \mu \) equal to 10 and \( \sigma \) equal to 1.

```matlab
rng default  % For reproducibility
x = normrnd(10,1,4)
x = 4x4
```

\[ 10.5377 \quad 10.3188 \quad 13.5784 \quad 10.7254 \]
\[ 11.8339 \quad 8.6923 \quad 12.7694 \quad 9.9369 \]
Compute the interquartile range for each column of data.
\[
r = \text{iqr}(x)
\]
\[
r = 1 \times 4
\]
\[
2.2086 \quad 1.2013 \quad 2.5969 \quad 0.8541
\]

Compute the interquartile range for each row of data.
\[
r2 = \text{iqr}(x,2)
\]
\[
r2 = 4 \times 1
\]
\[
1.7237 \\
2.9870 \\
1.9449 \\
1.8797
\]

**Compute Interquartile Range of Multidimensional Array**

Compute the interquartile range of a multidimensional array over multiple dimensions by specifying the 'all' and vecdim input arguments.

Create a 3-by-4-by-2 array \( X \).
\[
X = \text{reshape}(1:24, [3 4 2])
\]
\[
X = 
X(:,:,1) =
1 \quad 4 \quad 7 \quad 10
2 \quad 5 \quad 8 \quad 11
3 \quad 6 \quad 9 \quad 12
\]
\[
X(:,:,2) =
13 \quad 16 \quad 19 \quad 22
14 \quad 17 \quad 20 \quad 23
15 \quad 18 \quad 21 \quad 24
\]

Compute the interquartile range of all the values in \( X \).
\[
rall = \text{iqr}(X, 'all')
\]
\[
rall = 12
\]

Compute the interquartile range of each page of \( X \). Specify the first and second dimensions as the operating dimensions along which the interquartile range is calculated.
rpage = iqr(X,[1 2])

rpage =
rpage(:,:,1) =
   6

rpage(:,:,2) =
   6

For example, rpage(1,1,1) is the interquartile range of all the elements in X(:,:,1).

Compute the interquartile range of the elements in each X(i,:,:) slice by specifying the second and third dimensions as the operating dimensions.

rrow = iqr(X,[2 3])

rrow = 3x1
   12
   12
   12

For example, rrow(3) is the interquartile range of all the elements in X(3,:,:).

**Compute the Normal Distribution Interquartile Range**

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

pd = makedist('Normal','mu',0,'sigma',1);

Compute the interquartile range of the standard normal distribution.

r = iqr(pd)

r = 1.3490

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities y equal to 0.75 and 0.25.

r2 = icdf(pd,0.75) - icdf(pd,0.25)

r2 = 1.3490

**Interquartile Range of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students’ exam grade data.

load examgrades;
x = grades(:,1);
Create a normal distribution object by fitting it to the data.

```matlab
pd = fitdist(x,'Normal')
pd =
   NormalDistribution
   Normal distribution
   mu = 75.0083   [73.4321, 76.5846]  
sigma =  8.7202   [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```matlab
r = iqr(pd)
r = 11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```matlab
y = icdf(pd,[0.25,0.75])
y = 1×2
   69.1266   80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```matlab
y(2)-y(1)
an = 11.7634
```

Use `boxplot` to visualize the interquartile range.

```matlab
boxplot(x)
```
The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

**Input Arguments**

**x — Input array**

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: single | double

**dim — Dimension**

positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix x, when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of x. When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of x. For n-dimensional arrays, `iqr` operates along the first nonsingleton dimension of x.

Data Types: single | double

**vecdim — Vector of dimensions**

positive integer vector
Vector of dimensions, specified as a positive integer vector. Each element of vecdim represents a dimension of the input array x. The output r has length 1 in the specified operating dimensions. The other dimension lengths are the same for x and r.

For example, if x is a 2-by-3-by-3 array, then iqr(x, [1 2]) returns a 1-by-1-by-3 array. Each element of the output array is the interquartile range of the elements on the corresponding page of x.

Data Types: single | double

pd — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td>Distribution Fitter</td>
<td>Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
</tbody>
</table>

Output Arguments

r — Interquartile range values
scalar | vector | matrix | multidimensional array

Interquartile range values, returned as a scalar, vector, matrix, or multidimensional array.

- If you input an array x, then the dimensions of r depend on whether the 'all', dim, or vecdim input arguments are specified. Each interquartile range value in r is the difference between the 75th and the 25th percentiles of the specified data contained in x.
- If you input a probability distribution pd, then the scalar value of r is the difference between the values of the 75th and 25th percentiles of the probability distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• These input arguments are not supported: 'all' and vecdim.
• The dim input argument must be a compile-time constant.
• If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
• The input argument pd can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create pd by fitting a probability distribution to sample data from the fitdist function. For an example, see “Code Generation for Probability Distribution Objects” on page 31-70.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• These input arguments are not supported: 'all', vecdim, and pd.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
isempty

Class: dataset

(Not Recommended) True for empty dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

tf = isempty(A)

Description

tf = isempty(A) returns true (1) if A is an empty dataset and false (0) otherwise. An empty array has no elements, that is prod(size(A))==0.

See Also
size

32-2620
islevel

(Not Recommended) Determine if levels are in nominal or ordinal array

**Note** The nominal and ordinal array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

```
tf = islevel(levels,A)
```

**Description**

```tf = islevel(levels,A)``` returns a logical array indicating which of the levels in ```levels``` correspond to a level in the nominal or ordinal array ```A```.

**Input Arguments**

- **A** — Nominal or ordinal array
  - ```nominal array | ordinal array```:
    - Nominal or ordinal array, specified as a ```nominal``` or ```ordinal``` array object created with ```nominal``` or ```ordinal```

- **levels** — Levels to test
  - ```character vector | string array | cell array of character vectors | 2-D character matrix```:
    - Levels to test, specified as a character vector, string array, cell array of character vectors, or 2-D character matrix.

**Output Arguments**

- **tf** — Level indicator
  - ```logical array```:
    - Level indicator, returned as a logical array of the same size as ```levels```. ```tf``` has the value `1` (true) when the corresponding element of ```levels``` is the label of a level in the nominal or ordinal array ```A```, even if the level contains no elements. Otherwise, ```tf``` has the value `0` (false).

**See Also**

- ```isequal | ismember | nominal | ordinal```
ismember

Class: dataset

(Not Recommended) Dataset array elements that are members of set

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember(____)

Description

LiA = ismember(A,B) for dataset arrays A and B returns a vector of logical values the same length as A. The output vector, LiA, has value 1 (true) in the elements that correspond to observations in A that are also present in B, and 0 (false) otherwise.

LiA = ismember(A,B,vars) returns a vector of logical values the same length as A. The output vector, LiA, has value 1 (true) in the elements that correspond to observations in A that are also present in B for the variables specified in vars only, and 0 (false) otherwise.

[LiA,LocB] = ismember(____) also returns a vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, or 0 if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in vars, the corresponding element of LiA is 1.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. vars indicates which variables to match observations on in A and B.
Output Arguments

LiA

Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in A is present in B. Otherwise, LiA has value 0 (false).

If you specify vars, LiA has value 1 when the corresponding observation in A is present in B for the variables in vars only.

LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in vars.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```matlab
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```matlab
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

A =

Check which observations in A are present in B.

```matlab
LiA = ismember(A,B)
```

LiA = 10x1 logical array

0
1
0
0
Display the observations in A that are present in B.

\[
A(LiA,:) = \begin{bmatrix}
\text{LastName} & \text{Sex} & \text{Age} & \text{Weight} & \text{Smoker} \\
LQW-768 & \{\text{TAYLOR}\} & \text{Female} & 31 & 132 & \text{false} \\
PUE-347 & \{\text{YOUNG}\} & \text{Female} & 25 & 114 & \text{false} \\
XUE-826 & \{\text{JACKSON}\} & \text{Male} & 25 & 174 & \text{false}
\end{bmatrix}
\]

Find the location of the observations in B.

\[
[-,\text{LocB}] = \text{ismember}(A,B)
\]

\[
\text{LocB} = \begin{bmatrix}10 & 1 & 0 & 0 & 0 & 0 & 28 & 0 & 13\end{bmatrix}
\]

Display the observations in B that match observations in A.

\[
B(\text{LocB}(\text{LocB}>0),:) = \begin{bmatrix}
\text{LastName} & \text{Sex} & \text{Age} & \text{Weight} & \text{Smoker} \\
LQW-768 & \{\text{TAYLOR}\} & \text{Female} & 31 & 132 & \text{false} \\
PUE-347 & \{\text{YOUNG}\} & \text{Female} & 25 & 114 & \text{false} \\
XUE-826 & \{\text{JACKSON}\} & \text{Male} & 25 & 174 & \text{false}
\end{bmatrix}
\]

“Dataset Arrays” on page 2-112
ismissing

Class: dataset

(Not Recommended) Find dataset array elements with missing values

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB table data type instead. See MATLAB table documentation for more information.

**Syntax**

\[ I = \text{ismissing}(ds) \]
\[ I = \text{ismissing}(ds,\text{Name},\text{Value}) \]

**Description**

\[ I = \text{ismissing}(ds) \] returns a logical array that indicates which elements in the dataset array, \( ds \), contain a missing value. By default, ismissing recognizes NaN as a missing value in numeric variables, '' as a missing value in character variables, and <undefined> as a missing value in categorical arrays.

- \( ds2 = ds(\neg\text{any}(I,2),:) \) creates a new dataset array containing only the complete observations in \( ds \).
- \( ds2 = ds(:,\neg\text{any}(I,1)) \) creates a new dataset array containing only the variables from \( ds \) with no missing values.

\[ I = \text{ismissing}(ds,\text{Name},\text{Value}) \] returns missing value indices with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

\( ds \)

- dataset array

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**NumericTreatAsMissing**

Vector of numeric values to treat as missing value indicators in floating point \( ds \) variables. ismissing always treats a NaN value as a missing value.

**Default:**
**StringTreatAsMissing**
Character vector, string array, or cell array of character vectors to treat as missing value indicators in character ds variables. `ismissing` always treats '' as a missing value.

**Output Arguments**

I
Logical array indicating which elements in ds contain a missing value. I is the same size as ds, with value 1 for elements that contain a missing value.

**See Also**
dataset | isempty | isnan | isundefined | replaceWithMissing

**Topics**
“Clean Messy and Missing Data” on page 2-97
“Dataset Arrays” on page 2-112
**isValid**

**Class:** qrandstream

Test handle validity

**Syntax**

tf = isValid(h)

**Description**

tf = isValid(h) performs an element-wise check for validity on the handle elements of h. The result is a logical array of the same dimensions as h, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

**See Also**
delete | qrandstream
iwishrnd

Inverse Wishart random numbers

Syntax

W = iwishrnd(Tau,df)
W = iwishrnd(Tau,df,DI)
[W,DI] = iwishrnd(Tau,df)

Description

W = iwishrnd(Tau,df) generates a random matrix W from the inverse Wishart distribution with parameters Tau and df. The inverse of W has the Wishart distribution with covariance matrix Sigma = inv(Tau) and with df degrees of freedom. Tau is a symmetric and positive definite matrix.

W = iwishrnd(Tau,df,DI) expects DI to be the transpose of the inverse of the Cholesky factor of Tau, so that DI'*DI = inv(Tau), where inv is the MATLAB inverse function. DI is lower-triangular and the same size as Tau. If you call iwishrnd multiple times using the same value of Tau, it is more efficient to supply DI instead of computing it each time.

[W,DI] = iwishrnd(Tau,df) returns DI so you can use it as an input in future calls to iwishrnd.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter tau so that the mean of the output matrix is Tau/(df-d-1) where d is the dimension of Tau.

**jackknife**

Jackknife sampling

**Syntax**

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

**Description**

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the n-by-p data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are n data samples. Each of the n rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with @. Row i of `jackstat` contains the results for the sample consisting of `X` with the i'th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set 'Options' as a structure you create with `statset`. `jackknife` uses the following field in the structure:

```
'UseParallel'  If true, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is false, meaning serial computation.
```

**Examples**

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var,y,1);
n = length(y);
```
bias = -\sigma^2/n \ % \ known \ bias \ formula
jbias = (n-1)*(\text{mean}(m)-\text{var}(y,1)) \ % \ jackknife \ bias \ estimate

bias =
   -0.2500

jbias =
   -0.3378

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2006a
jbtest

Jarque-Bera test

Syntax

h = jbtest(x)
h = jbtest(x, alpha)
h = jbtest(x, alpha, mctol)
[h, p] = jbtest( ___ )
[h, p, jbstat, critval] = jbtest( ___ )

Description

h = jbtest(x) returns a test decision for the null hypothesis that the data in vector x comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

h = jbtest(x, alpha) returns a test decision for the null hypothesis at the significance level specified by alpha.

h = jbtest(x, alpha, mctol) returns a test decision based on a p-value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to mctol.

[h, p] = jbtest( ___ ) also returns the p-value p of the hypothesis test, using any of the input arguments from the previous syntaxes.

[h, p, jbstat, critval] = jbtest( ___ ) also returns the test statistic jbstat and the critical value critval for the test.

Examples

Test for a Normal Distribution

Load the data set.

load carbig

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

h = jbtest(MPG)

h = 1

The returned value of h = 1 indicates that jbtest rejects the null hypothesis at the default 5% significance level.
Test the Hypothesis at a Different Significance Level

Load the data set.

load carbig

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

[h,p] = jbtest(MPG,0.01)

h = 1
p = 0.0022

The returned value of $h = 1$, and the returned $p$-value less than $\alpha = 0.01$ indicate that $\text{jbtest}$ rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

load carbig

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact $p$-value.

[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)

h = 1
p = 0.0022
jbstat = 18.2275
critval = 5.8461

The returned value of $h = 1$ indicates that $\text{jbtest}$ rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, $\text{jbstat}$, is larger than the critical value, $\text{critval}$, which indicates rejection of the null hypothesis.

Input Arguments

$x$ — Sample data
vector

Sample data for the hypothesis test, specified as a vector. $\text{jbtest}$ treats NaN values in $x$ as missing values and ignores them.

Data Types: single | double

$\alpha$ — Significance level
$0.05$ (default) | scalar value in the range (0,1)
Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If alpha is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, jbtest looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use mctol.

Example: 0.01
Data Types: single | double

**mctol — Maximum Monte Carlo standard error**

nonnegative scalar value

Maximum Monte Carlo standard error on page 32-2634 for the p-value, p, specified as a nonnegative scalar value. If you specify a value for mctol, jbtest computes a Monte Carlo approximation for p directly, rather than interpolating into a table of precomputed values. jbtest chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for p less than mctol.

If you specify a value for mctol, you must also specify a value for alpha. You can specify alpha as [] to use the default value of 0.05.

Example: 0.0001
Data Types: single | double

**Output Arguments**

**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as 1 or 0.

- If h = 1, this indicates the rejection of the null hypothesis at the alpha significance level.
- If h = 0, this indicates a failure to reject the null hypothesis at the alpha significance level.

**p — p-value**

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

jbtest warns when p is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use mctol to compute a more accurate p-value.

**jbstat — Test statistic**
	nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

**critval — Critical value**

nonnegative scalar value

Critical value for the Jarque-Bera test at the alpha significance level, returned as a nonnegative scalar value. If alpha is in the range [0.001,0.50], and if the sample size is less than or equal to 2000,
jbtest looks up the critical value for the test in a table of precomputed values. If you use mctol, jbtest determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when jbstat > critval.

More About

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

\[ JB = \frac{n}{6} \left( s^2 + \frac{(k - 3)^2}{4} \right), \]

where \( n \) is the sample size, \( s \) is the sample skewness, and \( k \) is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p-value.

The Monte Carlo standard error is calculated as

\[ SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{mcreps}}, \]

where \( \hat{p} \) is the estimated p-value of the hypothesis test, and \( mcreps \) is the number of Monte Carlo replications performed. jbtest chooses the number of Monte Carlo replications, \( mcreps \), large enough to make the Monte Carlo standard error for \( \hat{p} \) less than the value specified for mctol.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see lillietest) for small samples. jbtest, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

Introduced before R2006a
johnsrnd

Johnson system random numbers

Syntax

\[ r = \text{johnsrnd}(\text{quantiles}, m, n) \]
\[ r = \text{johnsrnd}(\text{quantiles}) \]
\[ [r, \text{type}] = \text{johnsrnd}(...) \]
\[ [r, \text{type}, \text{coefs}] = \text{johnsrnd}(...) \]

Description

\[ r = \text{johnsrnd}(\text{quantiles}, m, n) \] returns an \( m \)-by-\( n \) matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by \( \text{quantiles} \).

\( \text{quantiles} \) is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles \([-1.5 -0.5 0.5 1.5]\). In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities \([0.067 0.309 0.691 0.933]\). \( \text{quantiles} \) may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

\textbf{Note} Because \( r \) is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

\[ r = \text{johnsrnd}(\text{quantiles}) \] returns a scalar value.

\[ r = \text{johnsrnd}(\text{quantiles}, m, n, ...) \] or \( r = \text{johnsrnd}(\text{quantiles}, [m, n, ...]) \) returns an \( m \)-by-\( n \)-by-\( ... \) array.

\[ [r, \text{type}] = \text{johnsrnd}(...) \] returns the type of the specified distribution within the Johnson system. \( \text{type} \) is \'SN\', \'SL\', \'SB\', or \'SU\'. Set \( m \) and \( n \) to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- \'SN\' — Identity transformation (normal distribution on page B-119)
- \'SL\' — Exponential transformation (lognormal distribution on page B-88)
- \'SB\' — Logistic transformation (bounded)
- \'SU\' — Hyperbolic sine transformation (unbounded)

\[ [r, \text{type}, \text{coefs}] = \text{johnsrnd}(...) \] returns coefficients \( \text{coefs} \) of the transformation that defines the distribution. \( \text{coefs} \) is \([\text{gamma, eta, epsilon, lambda}]\). If \( z \) is a standard normal random variable and \( h \) is one of the transformations defined above, \( r = \text{lambda} \times h((z-\text{gamma})/\text{eta}) + \text{epsilon} \) is a random variate from the distribution type corresponding to \( h \).
Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```matlab
rng default; % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

![QQ Plot of Sample Data versus Standard Normal](image)

Generate random values skewed to the right.

```matlab
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```
Generate random values that match some sample data well in the right-hand tail.

load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]

ans = 2×4

16.7000   18.2086   19.5376   21.7263
16.6986   18.2220   19.9078   22.0918

Determine the distribution type and the coefficients.

[r,type,coefs] = johnsrnd([qnorm;q],0)

r =

[]
type =
'SU'
coefs = 1×4

Introduced in R2006a
join

Class: dataset

(Not Recommended) Merge observations

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)

Description

C = join(A,B) creates a dataset array C by merging observations from the two dataset arrays A and B. join performs the merge by first finding key variables, that is, pairs of dataset variables, one in A and one in B, that share the same name. Each observation in B must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from A. join then uses these key variables to define a many-to-one correspondence between observations in A and those in B. join uses this correspondence to replicate the observations in B and combine them with the observations in A to create C.

C = join(A,B,keys) performs the merge using the variables specified by keys as the key variables in both A and B. keys is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

C contains one observation for each observation in A. Variables in C include all of the variables from A, as well as one variable corresponding to each variable in B (except for the keys from B). If A and B contain variables with identical names, join adds the suffix '_left' and '_right' to the corresponding variables in C.

C = join(A,B,param1,val1,param2,val2,...) specifies optional parameter name/value pairs to control how the dataset variables in A and B are used in the merge. Parameters are:

• 'Keys' — Specifies the variables to use as keys in both A and B.
• 'LeftKeys' — Specifies the variables to use as keys in A.
• 'RightKeys' — Specifies the variables to use as keys in B.

You may provide either the 'Keys' parameter, or both the 'LeftKeys' and 'RightKeys' parameters. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. 'LeftKeys' or 'RightKeys' must both specify the same number of key variables, and join pairs the left and right keys in the order specified.
• 'LeftVars' — Specifies which variables from A to include in C. By default, join includes all variables from A.
• 'RightVars' — Specifies which variables from B to include in C. By default, join includes all variables from B except the key variables.

You can use 'LeftVars' or 'RightVars' to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

[C,IB] = join(...) returns an index vector IB, where join constructs C by horizontally concatenating A(:,LeftVars) and B(IB,RightVars). join can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

C = join(A,B,'Type',TYPE,...) performs the join operation specified by TYPE. TYPE is one of 'inner', 'leftouter', 'rightouter', 'fullouter', or 'outer' (which is a synonym for 'fullouter'). For an inner join, C only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, C also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains variables corresponding to the key variables from both A and B, and join sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. join sorts the observations in the result C by the key values.

C = join(A,B,'Type',TYPE,'MergeKeys',true,...) includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, join creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to true overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to false is equivalent to not passing in the 'MergeKeys' parameter.

[C,IA,IB] = join(A,B,'Type',TYPE,...) returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, join constructs C by horizontally concatenating A(IA,LeftVars) and B(IB,RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs),'%-d')));
iris = dataset({nominal(species),'species'},...
    {meas,'SL','SW','PL','PW'},...
    'ObsNames',NameObs);

Create a separate dataset array with the diploid chromosome counts for each species of iris:
snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},[[38;108;70],'cc'])
CC =

<table>
<thead>
<tr>
<th>species</th>
<th>cc</th>
</tr>
</thead>
<tbody>
<tr>
<td>setosa</td>
<td>38</td>
</tr>
<tr>
<td>versicolor</td>
<td>108</td>
</tr>
<tr>
<td>virginica</td>
<td>70</td>
</tr>
</tbody>
</table>

Broadcast the data in CC to the rows of iris using the key variable species in each dataset:

iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =

<table>
<thead>
<tr>
<th>species</th>
<th>SL</th>
<th>SW</th>
<th>PL</th>
<th>PW</th>
<th>cc</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obs1</td>
<td>setosa</td>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
</tr>
<tr>
<td>Obs2</td>
<td>setosa</td>
<td>4.9</td>
<td>3</td>
<td>1.4</td>
<td>0.2</td>
</tr>
<tr>
<td>Obs51</td>
<td>versicolor</td>
<td>7</td>
<td>3.2</td>
<td>4.7</td>
<td>1.4</td>
</tr>
<tr>
<td>Obs52</td>
<td>versicolor</td>
<td>6.4</td>
<td>3.2</td>
<td>4.5</td>
<td>1.5</td>
</tr>
<tr>
<td>Obs101</td>
<td>virginica</td>
<td>6.3</td>
<td>3.3</td>
<td>6</td>
<td>2.5</td>
</tr>
<tr>
<td>Obs102</td>
<td>virginica</td>
<td>5.8</td>
<td>2.7</td>
<td>5.1</td>
<td>1.9</td>
</tr>
</tbody>
</table>

Create two datasets and join them using the 'MergeKeys' flag:

% Create two data sets that both contain the key variable % 'Key1'. The two arrays contain observations with common % values of Key1, but each array also contains observations % with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17],...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7],...
    'VarNames',{'Key1' 'Var2'})
% Combine a and b with an outer join, which matches up % observations with common key values, but also retains % observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')
% Join a and b, merging the key values as a single variable % in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)
% Join a and b, retaining only observations whose key % values match.
cinner = join(a,b,'key','Key1','Type','inner',...
    'MergeKeys',true)
a =

<table>
<thead>
<tr>
<th>Key1</th>
<th>Var1</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
</tr>
<tr>
<td>'c'</td>
<td>3</td>
</tr>
<tr>
<td>'e'</td>
<td>11</td>
</tr>
<tr>

KDTreeSearcher

Create Kd-tree nearest neighbor searcher

Description

KDTreeSearcher model objects store the results of a nearest neighbor search that uses the Kd-tree algorithm. Results include the training data, distance metric and its parameters, and maximum number of data points in each leaf node (that is, the bucket size). The Kd-tree algorithm partitions an n-by-K data set by recursively splitting n points in K-dimensional space into a binary tree.

Once you create a KDTreeSearcher model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbor search using knnsearch or a radius search using rangesearch. The Kd-tree algorithm is more efficient than the exhaustive search algorithm when K is small (that is, K ≤ 10), the training and query sets are not sparse, and the training and query sets have many observations.

Creation

Use either the createns function or the KDTreeSearcher function (described here) to create a KDTreeSearcher model object. Both functions use the same syntax except that the createns function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The createns function also creates an ExhaustiveSearcher object. Specify 'NSMethod','kdtree' to create a KDTreeSearcher object. The default is 'kdtree' if K ≤ 10, the training data is not sparse, and the distance metric is Euclidean, city block, Chebychev, or Minkowski.

Syntax

Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)

Description

Mdl = KDTreeSearcher(X) grows a default Kd-tree (Mdl) using the n-by-K numeric matrix of training data (X).

Mdl = KDTreeSearcher(X,Name,Value) specifies additional options using one or more name-value pair arguments. You can specify the maximum number of data points in each leaf node (that is, the bucket size) and the distance metric, and set the distance metric parameter (DistParameter) property. For example, KDTreeSearcher(X,'Distance','minkowski','BucketSize',10) specifies to use the Minkowski distance when searching for nearest neighbors and to use 10 for the bucket size. To specify DistParameter, use the P name-value pair argument.

Input Arguments

X — Training data
numeric matrix
Training data that grows the Kd-tree, specified as a numeric matrix. \( X \) has \( n \) rows, each corresponding to an observation (that is, an instance or example), and \( K \) columns, each corresponding to a predictor (that is, a feature).

Data Types: single \| double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \textit{Name}, \textit{Value} arguments. \textit{Name} is the argument name and \textit{Value} is the corresponding value. \textit{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

**Distance — Distance metric**

\texttt{'euclidean'} (default) \| \texttt{'chebychev'} \| \texttt{'cityblock'} \| \texttt{'minkowski'}

Distance metric used when you call \texttt{knnsearch} or \texttt{rangesearch} to find nearest neighbors for future query points, specified as the comma-separated pair consisting of ‘Distance’ and one of these values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{'chebychev'}</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>\texttt{'cityblock'}</td>
<td>City block distance.</td>
</tr>
<tr>
<td>\texttt{'euclidean'}</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>\texttt{'minkowski'}</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the \texttt{'P'} name-value pair argument.</td>
</tr>
</tbody>
</table>

For more details, see “Distance Metrics” on page 18-11.

The software does not use the distance metric for creating a \texttt{KDTreeSearcher} model object, so you can alter the distance metric by using dot notation after creating the object.

Example: ‘Distance’, ‘minkowski’

**P — Exponent for Minkowski distance metric**

2 (default) \| positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of \texttt{‘P’} and a positive scalar. This argument is valid only if ‘Distance’ is ‘minkowski’.

Example: ‘P’, 3

Data Types: single \| double

**BucketSize — Maximum number of data points in each leaf node**

50 (default) \| positive integer

Maximum number of data points in each leaf node of the Kd-tree, specified as the comma-separated pair consisting of ‘BucketSize’ and a positive integer.

Example: ‘BucketSize’, 10

Data Types: single \| double
Properties

**X — Training data**
numeric matrix

This property is read-only.

Training data that grows the Kd-tree, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

The input argument X of createns or KDTreeSearcher sets this property.

Data Types: single | double

**Distance — Distance metric**
'chebychev' | 'cityblock' | 'minkowski'

Distance metric used when you call knnsearch or rangesearch to find nearest neighbors for future query points, specified as 'chebychev', 'cityblock', 'euclidean', or 'minkowski'.

The 'Distance' name-value pair argument of createns or KDTreeSearcher sets this property.

The software does not use the distance metric for creating a KDTreeSearcher model object, so you can alter it by using dot notation.

**DistParameter — Distance metric parameter values**
[] | positive scalar

Distance metric parameter values, specified as empty ([]) or a positive scalar.

If Distance is 'minkowski', then DistParameter is the exponent in the Minkowski distance formula. Otherwise, DistParameter is [], indicating that the specified distance metric formula has no parameters.

The 'P' name-value pair argument of createns or KDTreeSearcher sets this property.

You can alter DistParameter by using dot notation, for example, Mdl.DistParameter = PNew, where PNew is a positive scalar.

Data Types: single | double

**BucketSize — Maximum number of data points in each leaf node**
positive integer

This property is read-only.

Maximum number of data points in each leaf node of the Kd-tree, specified as a positive integer.

The 'BucketSize' name-value pair argument of createns or KDTreeSearcher sets this property.

Data Types: single | double

Object Functions

knnsearch Find k-nearest neighbors using searcher object
rangesearch  Find all neighbors within specified distance using searcher object

Examples

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
k = 4
```

X has 150 observations and 4 predictors.

Grow a four-dimensional Kd-tree using the entire data set as training data.

```
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 = 
    KDTreeSearcher with properties:
        BucketSize: 50
        Distance: 'euclidean'
        DistParameter: []
        X: [150x4 double]
```

Mdl1 is a KDTreeSearcher model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional Kd-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a Kd-tree by using createns.

```
Mdl2 = createns(X)
```

```
Mdl2 = 
    KDTreeSearcher with properties:
        BucketSize: 50
        Distance: 'euclidean'
        DistParameter: []
        X: [150x4 double]
```

Mdl2 is also a KDTreeSearcher model object, and it is equivalent to Mdl1. Because X has four columns and the default distance metric is Euclidean, createns creates a KDTreeSearcher model by default.

To find the nearest neighbors in X to a batch of query data, pass the KDTreeSearcher model object and the query data to knnsearch or rangesearch.
Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:,[3 4]);  % Predictors
```

Grow a two-dimensional Kd-tree using createns and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X,'Distance','Minkowski')
```

```
Mdl = 
    KDTreeSearcher with properties:
        BucketSize: 50
        Distance: 'minkowski'
        DistParameter: 2
        X: [150x2 double]
```

Because `X` has two columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default.

Access properties of `Mdl` by using dot notation. For example, use `Mdl.DistParameter` to access the Minkowski distance exponent.

```
Mdl.DistParameter
ans = 2
```

You can pass query data and `Mdl` to:
- `knnsearch` to find indices and distances of nearest neighbors
- `rangesearch` to find indices of all nearest neighbors within a distance that you specify

Alter Properties of KDTreeSearcher Model

Create a `KDTreeSearcher` model object and alter the `Distance` property by using dot notation.

```
load fisheriris
X = meas;
```

Grow a default four-dimensional Kd-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
Mdl = 
    KDTreeSearcher with properties:
```
Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Minkowski distance.

### Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a Kd-tree nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find k-nearest neighbors.

Load Fisher’s iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                     % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','minkowski')
```

```
Mdl =
     KDTreesearcher with properties:
        BucketSize: 50
          Distance: 'minkowski'
      DistParameter: 2
             X: [145x4 double]
```
Because \( X \) has four columns and the distance metric is Minkowski, \texttt{createns} creates a KDTreeSearcher model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (\( \text{Mdl}.X \)) that are the two nearest neighbors of each point in the query data (\( Q \)).

\[
\text{IdxNN} = \text{knnsearch(Mdl,Q,'K',2)}
\]

\[
\text{IdxNN} = \begin{array}{ll}
17 & 4 \\
6 & 2 \\
1 & 12 \\
89 & 66 \\
124 & 100
\end{array}
\]

Each row of \( \text{IdxNN} \) corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of \( Q(3,:) \) is \( X(12,:) \).

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The \texttt{knnsearch} and \texttt{rangesearch} functions support code generation.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-13.

“Distance Metrics” on page 18-11

**Introduced in R2010a**
**kfoldEdge**

**Package:** classreg.learning.partition

Classification edge for cross-validated ECOC model

**Syntax**

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-2656 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC` `CVMdl`). For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```matlab
t = templateSVM(‘Standardize’,1);
CVMdl = fitcecoc(X,Y,’CrossVal’,’on’,’Learners’,t,’ClassNames’,classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the edges.

```matlab
edge = kfoldEdge(CVMdl)
edge = 0.4825
```
Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Display Individual Edges for Each Cross-Validation Fold**

The classification edge is a relative measure of classifier quality. To determine which folds perform poorly, display the edges for each fold.

Load Fisher's iris data set. Specify the predictor data $X$, the response data $Y$, and the order of the classes in $Y$.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```matlab
edges = kfoldEdge(CVMdl,'Mode','individual')
```

```matlab
edges = 8×1
    0.4791
    0.4872
    0.4260
    0.5302
    0.5064
    0.4575
    0.4860
    0.4687
```

The edges have similar magnitudes across folds. Folds that perform poorly have small edges relative to the other folds.

To return the average classification edge across the folds that perform well, specify the 'Folds' name-value pair argument.

**Select ECOC Model Features by Comparing Cross-Validation Edges**

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.
Load Fisher's iris data set. Specify the predictor data \(X\), the response data \(Y\), and the order of the classes in \(Y\).

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define the following two data sets.
- \(\text{fullX}\) contains all the predictors.
- \(\text{partX}\) contains the petal dimensions.

```matlab
fullX = X;
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

\(\text{CVMdl}\) and \(\text{PCVMdl}\) are \text{ClassificationPartitionedECOC} models. By default, the software implements 10-fold cross-validation.

Estimate the edge for each classifier.

```matlab
fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.4825
partEdge = kfoldEdge(PCVMdl)
partEdge = 0.4951
```

The two models have comparable edges.

### Input Arguments

**CVMdl** — Cross-validated ECOC model
\text{ClassificationPartitionedECOC} model

Cross-validated ECOC model, specified as a \text{ClassificationPartitionedECOC} model. You can create a \text{ClassificationPartitionedECOC} model in two ways:

- Pass a trained ECOC model (\text{ClassificationECOC}) to \text{crossval}.
- Train an ECOC model using \text{fitcecoc} and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

32-2653
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'BinaryLoss','hinge')` specifies `'hinge'` as the binary learner loss function.

**BinaryLoss — Binary learner loss function**

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle
--- | --- | --- | --- | --- | --- | --- | ---

Binary learner loss function, specified as the comma-separated pair consisting of `BinaryLoss` and a built-in loss function name or function handle.

- This table describes the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log(1 + \exp(-2y_js_j))/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log(1 + \exp(-y_js_j))/[2\log(2)]$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `BinaryLoss`,@customFunction.

`customFunction` has this form:

```matlab
bLoss = customFunction(M,s)
```

where:

- $M$ is the $K$-by-$L$ coding matrix stored in `Mdl.CodingMatrix`.
- $s$ is the 1-by-$L$ row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$ is the number of classes.
- $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.
The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel classification models of SVM learners.</td>
<td>'hinge'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code>.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by <code>LogitBoost</code>.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior',true</code> in <code>fitcecoc</code>.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line. Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `lossweighted` or `lossbased`. For more information, see “Binary Loss” on page 32-2824. Example: `'Decoding','lossbased'`

**Folds — Fold indices for prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMdl.KFold`. The software uses only the folds specified in `Folds` for prediction. Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

**Mode — Aggregation level for output**

`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`. This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'average'</code></td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length $k$ containing one value per fold, where $k$ is the number of folds.</td>
</tr>
</tbody>
</table>

Example: `Mode','individual'`

**Options — Estimation options**

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', true)`.

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `Verbose',1`

Data Types: `single` | `double`

**Output Arguments**

**edge — Classification edge**

numeric scalar | numeric column vector

Classification edge on page 32-2656, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `edge` is the average classification edge over all folds. Otherwise, `edge` is a $k$-by-$1$ numeric column vector containing the classification edge for each fold, where $k$ is the number of folds.

**More About**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same
scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j, s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>( \log[1 + \exp(-2y_j s_j)] / [2 \log(2)] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>

</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.
Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldEdge

Classification edge for observations not used for training

Syntax

E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)

Description

E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification ensemble obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

ens

Object of class ClassificationPartitionedEnsemble. Create ens with fitcensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create ens from a classification ensemble with crossval.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

folds

Indices of folds ranging from 1 to ens.KFold. Use only these folds for predictions.

Default: 1:ens.KFold

mode

Character vector or string scalar representing the meaning of the output edge:

- 'average' — edge is a scalar value, the average over all folds.
- 'individual' — edge is a vector of length ens.KFold with one element per fold.
- 'cumulative' — edge is a vector of length min(ens.NTrainedPerFold) in which element J is obtained by averaging values across all folds for weak learners 1:J in each fold.

Default: 'average'
Output Arguments

E

The average classification margin. E is a scalar or vector, depending on the setting of the mode name-value pair.

Examples

Compute K-Fold Edge of Held-Out Observations

Compute the k-fold edge for an ensemble trained on the Fisher iris data.

Load the sample data set.

load fisheriris

Train an ensemble of 100 boosted classification trees.

\[ t = \text{templateTree}('\text{MaxNumSplits}',1); \]
\[ \text{ens} = \text{fitcensemble}(\text{meas},\text{species},'\text{Learners}',t); \]

Create a cross-validated ensemble from \text{ens} and find the classification edge.

\[ \text{rng}(10,\text{'twister'}) \quad \text{For reproducibility} \]
\[ \text{cvens} = \text{crossval}(\text{ens}); \]
\[ E = \text{kfoldEdge}(\text{cvens}) \]

\[ E = 3.2052 \]

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in obj.Prior.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix obj.X.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from 0 to 1.

**kfoldEdge**

**Package:** classreg.learning.partition

Classification edge for cross-validated kernel classification model

**Syntax**

```matlab
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-2665 obtained by the cross-validated, binary kernel model (ClassificationPartitionedKernel) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds or the aggregation level.

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```matlab
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```matlab
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```matlab
CVMdl = classreg.learning.partition.ClassificationPartitionedKernel
CrossValidatedModel: 'Kernel'
ResponseName: 'Y'
NumObservations: 351
KFold: 10
Partition: [1x1 cvpartition]
ClassNames: {'b'  'g'}
ScoreTransform: 'none'
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`. 
Estimate the cross-validated classification edge.

e = \text{kfoldEdge}(\text{CVMdl})

e = 1.5585

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in \text{kfoldEdge}.

\textbf{Feature Selection Using k-Fold Edges}

Perform feature selection by comparing k-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load the \text{ionosphere} data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

\text{load ionosphere}

Randomly choose half of the predictor variables.

\text{rng(1); \% For reproducibility}
\text{p = size(X,2); \% Number of predictors}
\text{idxPart = randsample(p,ceil(0.5*p));}

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

\text{CVMdl = fitckernel(X,Y,'CrossVal','on');}
\text{PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');}

\text{CVMdl} and \text{PCVMdl} are \text{ClassificationPartitionedKernel} models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold edge for each classifier.

\text{fullEdge = kfoldEdge(CVMdl)}
\text{fullEdge = 1.5142}
\text{partEdge = kfoldEdge(PCVMdl)}
\text{partEdge = 1.8910}

Based on the k-fold edges, the classifier that uses half of the predictors is the better model.

\textbf{Input Arguments}

\textbf{CVMdl} — Cross-validated, binary kernel classification model
\text{ClassificationPartitionedKernel} model object

Cross-validated, binary kernel classification model, specified as a \text{ClassificationPartitionedKernel} model object. You can create a
ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldEdge applies the same data used to cross-validate the kernel classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldEdge(CVMdl,'Mode','individual') returns the classification edge for each fold.

Folds — Fold indices for prediction
1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]
Data Types: single | double

Mode — Aggregation level for output
'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length k containing one value per fold, where k is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

Output Arguments

edge — Classification edge
numeric scalar | numeric column vector

Classification edge on page 32-2665, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k-by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.
More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by

\[ f(x) = T(x)\beta + b. \]

• \( T(\cdot) \) is a transformation of an observation for feature expansion.
• \( \beta \) is the estimated column vector of coefficients.
• \( b \) is the estimated scalar bias.

The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**kfoldEdge**

**Package:** classreg.learning.partition

Classification edge for cross-validated kernel ECOC model

**Syntax**

```matlab
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-2670 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```matlab
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods
CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification edges.

deedge = kfoldEdge(CVMdl)
deedge = 0.4145

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Feature Selection Using k-Fold Edges**

Perform feature selection by comparing k-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

load fisheriris
X = meas;
Y = species;

Randomly choose half of the predictor variables.

rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');

CVMdl and PCVMdl are ClassificationPartitionedKernelECOC models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold edge for each classifier.

fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.4092

partEdge = kfoldEdge(PCVMdl)
partEdge = 0.4161

Based on the k-fold edges, the two classifiers are comparable.
Input Arguments

CVMdl — Cross-validated kernel ECOC model
ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:
- 'Learners'— Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldEdge(CVMdl,'BinaryLoss','hinge') specifies 'hinge' as the binary learner loss function.

BinaryLoss — Binary learner loss function
'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set\{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j,s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty,\infty))</td>
<td>(\log(1 + \exp(-2yjs_j))/(2\log(2)))</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty,\infty))</td>
<td>(\exp(-yjs_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty,\infty))</td>
<td>(1 - \text{sign}(yjs_j)/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty,\infty))</td>
<td>(\max(0,1 - yjs_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty,\infty))</td>
<td>(1 - yjs_j/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty,\infty))</td>
<td>(\log(1 + \exp(-yjs_j))/(2\log(2)))</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>((1 - y(2s_j - 1))^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss',@customFunction.

  customFunction has this form:

  \[ bLoss = \text{customFunction}(M,s) \]
where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \texttt{Mdl.CodingMatrix}.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \texttt{bLoss} is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then \texttt{BinaryLoss} is 'hinge'. If all binary learners are kernel classification models using logistic regression, then \texttt{BinaryLoss} is 'quadratic'.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

\textbf{Decoding — Decoding scheme}

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2670.

Example: 'Decoding','lossbased'

\textbf{Folds — Fold indices for prediction}

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to \texttt{CVMdl.KFold}.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

\textbf{Mode — Aggregation level for output}

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length ( k ) containing one value per fold, where ( k ) is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'
Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options'.statset('UseParallel',true).

Verbose — Verbosity level
0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

edge — Classification edge
numeric scalar | numeric column vector

Classification edge on page 32-2670, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k-by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.
Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j, s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>( \log[1 + \exp(-2y_j s_j)] / [2\log(2)] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty, \infty))</td>
<td>( \exp(-y_j s_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty, \infty))</td>
<td>( [1 - \text{sign}(y_j s_j)]/2 )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty, \infty))</td>
<td>( \max(0,1 - y_j s_j)/2 )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty, \infty))</td>
<td>( (1 - y_j s_j)/2 )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty, \infty))</td>
<td>( \log[1 + \exp(-y_j s_j)] / [2\log(2)] )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j(2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b
**kfoldEdge**

Classification edge for observations not used for training

**Syntax**

```matlab
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges on page 32-2678 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the edge calculation.

**Input Arguments**

- **CVMdl** — Cross-validated, binary, linear classification model
  
  Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

  To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the linear classification model (X and Y).

- **Name-Value Pair Arguments**
  
  Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

  - **Folds** — Fold indices to use for classification-score prediction
    
    Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

    Example: 'Folds',[1 4 10]

    Data Types: `single` | `double`
**Mode — Edge aggregation level**

`'average'` (default) | `'individual'`

Edge aggregation level, specified as the comma-separated pair consisting of `Mode` and `'average'` or `'individual'`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'average'</code></td>
<td>Returns classification edges averaged over all folds</td>
</tr>
<tr>
<td><code>'individual'</code></td>
<td>Returns classification edges for each fold</td>
</tr>
</tbody>
</table>

Example: `Mode', 'individual'

**Output Arguments**

**e — Cross-validated classification edges**

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-2678, returned as a numeric scalar, vector, or matrix.

Let $L$ be the number of regularization strengths in the cross-validated models (that is, $L$ is `numel(CVMdl.Trained{1}.Lambda)`) and $F$ be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then $e$ is a 1-by-$L$ vector. $e(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength $j$.
- Otherwise, $e$ is an $F$-by-$L$ matrix. $e(i,j)$ is the classification edge for fold $i$ of the cross-validated model that uses regularization strength $j$.

To estimate $e$, `kfoldEdge` uses the data that created `CVMdl` (see $X$ and $Y$).

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load the NLP data set.

```matlab
load nlpdata
```

$X$ is a sparse matrix of predictor data, and $Y$ is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```matlab
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```
CVMdl is a ClassificationPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

e = kfoldEdge(CVMdl)

e = 8.1243

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Feature Selection Using k-fold Edges**

One way to perform feature selection is to compare k-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in "Estimate k-Fold Cross-Validation Edge" on page 32-2674.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

* fullX contains all predictors.
* partX contains 1/2 of the predictors chosen at random.

```matlab
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```matlab
CVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',... 'ObservationsIn','columns');
PCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',... 'ObservationsIn','columns');
```

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Estimate the k-fold edge for each classifier.

```matlab
fullEdge = kfoldEdge(CVMdl)
fullEdge = 16.5629
```

```matlab
partEdge = kfoldEdge(PCVMdl)
partEdge = 13.9030
```
Based on the $k$-fold edges, the classifier that uses all of the predictors is the better model.

**Find Good Lasso Penalty Using $k$-fold Edge**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare $k$-fold edges.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 32-2674.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^{1}$.

```matlab
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e^{-8}$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

The `CVMdl` object is a `ClassificationPartitionedLinear` model object. Because `fitclinear` implements 5-fold cross-validation, `CVMdl` contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

```matlab
eFolds = kfoldEdge(CVMdl,'Mode','individual')
eFolds = 5×11
```

```matlab
0.9958 0.9958 0.9958 0.9958 0.9958 0.9925 0.9766 0.9131 0.8468 0.8127 0.8127
0.9991 0.9991 0.9991 0.9991 0.9991 0.9991 0.9780 0.9141 0.8267 0.8128 0.8128
0.9992 0.9992 0.9992 0.9992 0.9992 0.9992 0.9782 0.9149 0.8253 0.8128 0.8128
0.9974 0.9974 0.9974 0.9974 0.9974 0.9974 0.9931 0.9773 0.9171 0.8442 0.8128
```
eFolds is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in \( \Lambda \). You can use eFolds to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

\[
e = \text{kfoldEdge}(CVMdl)
\]

\[
e = 1\times11
\]

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

\[
\text{figure; plot(log10}(\Lambda), \text{log10}(e), 'o')\]

\[
[-, \text{maxEIdx}] = \text{max}(e); \text{maxLambda} = \Lambda(\text{maxEIdx}); \text{hold on}\]

\[
\text{plot(log10}(\text{maxLambda}), \text{log10}(e(\text{maxEIdx})), 'ro'); \text{ylabel('log}_{10} 5\text{-fold edge}')}\]

\[
\text{xlabel('log}_{10} \Lambda') \text{legend('Edge', 'Max edge')}\]

\text{hold off}
Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

LambdaFinal = Lambda(5);

Train a linear classification model using the entire data set and specify the regularization strength LambdaFinal.

MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...  'Learner','logistic','Solver','sparsa','Regularization','lasso',...  'Lambda',LambdaFinal);

To estimate labels for new observations, pass MdlFinal and the new data to predict.

**More About**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.
**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as $m = 2yf(x)$.

$x$ is an observation. If the true label of $x$ is the positive class, then $y$ is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation $x$. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

For linear classification models, the raw classification score for classifying the observation $x$, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$  

For the model with regularization strength $j$, $\beta_j$ is the estimated column vector of coefficients (the model property Beta(:,j)) and $b_j$ is the estimated, scalar bias (the model property Bias(j)).

The raw classification score for classifying $x$ into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**Introduced in R2016a**
kfoldEdge

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

Description

e = kfoldEdge(CVMdl) returns the cross-validated classification edges on page 32-2688 obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models CVMdl. That is, for every fold, kfoldEdge estimates the classification edge for observations that it holds out when it trains using all other observations.

e contains a classification edge for each regularization strength in the linear classification models that comprise CVMdl.

e = kfoldEdge(CVMdl,Name,Value) uses additional options specified by one or more Name,Value pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

Input Arguments

**CVMdl — Cross-validated, ECOC model composed of linear classification models**

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model object using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, kfoldEdge applies the same data used to cross-validate the ECOC model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**BinaryLoss — Binary learner loss function**

`'hamming' 'linear' 'logit' 'exponential' 'binodeviance' 'hinge' 'quadratic' 'function handle'`

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.
• This table contains names and descriptions of the built-in functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j, s_j)\) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j, s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>(\frac{\log[1 + \exp(-2y_js_j)]}{2\log(2)})</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty, \infty))</td>
<td>(\exp(-y_js_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty, \infty))</td>
<td>(\frac{1 - \text{sign}(y_js_j)}{2})</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty, \infty))</td>
<td>(\frac{\max(0,1 - y_js_j)}{2})</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty, \infty))</td>
<td>(\frac{1 - y_js_j}{2})</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty, \infty))</td>
<td>(\frac{\log[1 + \exp(-y_js_j)]}{2\log(2)})</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>(\frac{[1 - y(2s_j - 1)]^2}{2})</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when \(y_j = 0\). Also, the software calculates the mean binary loss for each class.

• For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss',@customFunction.

`customFunction` should have this form

\[
\text{bLoss} = \text{customFunction}(M, s)
\]

where:

• \(M\) is the \(K\)-by-\(L\) coding matrix stored in `Mdl.CodingMatrix`.
• \(s\) is the 1-by-\(L\) row vector of classification scores.
• \(\text{bLoss}\) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
• \(K\) is the number of classes.
• \(L\) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

By default, if all binary learners are linear classification models using:

• SVM, then `BinaryLoss` is 'hinge'
• Logistic regression, then `BinaryLoss` is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding** — Decoding scheme

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

Example: 'Decoding','lossbased'

Folds — Fold indices to use for classification-score prediction

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

Mode — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns classification edges averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns classification edges for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

Options — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options',statset('UseParallel',true).

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double
Output Arguments

**e — Cross-validated classification edges**
numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-2688, returned as a numeric scalar, vector, or matrix.

Let $L$ be the number of regularization strengths in the cross-validated models (that is, $L$ is `numel(CVMdl.Trained{1}.BinaryLearners{1}.Lambda)`) and $F$ be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then $e$ is a 1-by-$L$ vector. $e(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength $j$.
- Otherwise, $e$ is a $F$-by-$L$ matrix. $e(i,j)$ is the classification edge for fold $i$ of the cross-validated model that uses regularization strength $j$.

Examples

**Estimate k-Fold Cross-Validation Edge**

Load the NLP data set.

```matlab
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in `Y` that are not 'simulink', 'dsp', or 'comm'.

```matlab
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

*CVMdl* is a *ClassificationPartitionedLinearECOC* model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```matlab
e = kfoldEdge(CVMdl)
e = 0.7232
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.
Feature Selection Using k-fold Edges

One way to perform feature selection is to compare k-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 32-2683, and orient the predictor data so that observations correspond to columns.

```matlab
load nlpdata
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:
- fullX contains all predictors.
- partX contains a 1/2 of the predictors chosen at random.

```matlab
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to optimize the objective function using SpaRSA.

```matlab
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```matlab
CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on','ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on','ObservationsIn','columns');
```

CVMdl and PCVMdl are ClassificationPartitionedLinearECOC models.

Estimate the k-fold edge for each classifier.

```matlab
fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.3090
partEdge = kfoldEdge(PCVMdl)
partEdge = 0.2617
```

Based on the k-fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k-fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k-fold edges.
Load the NLP data set. Preprocess the data as in “Feature Selection Using k-fold Edges” on page 32-2683.

```matlab
load nlpdata
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 8 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^1$.

```matlab
Lambda = logspace(-8,1,8);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, optimize the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to $1e-8$.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```matlab
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinearECOC
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
```

CVMdl is a `ClassificationPartitionedLinearECOC` model.

Estimate the edges for each fold and regularization strength.

```matlab
eFolds = kfoldEdge(CVMdl,'Mode','individual')
eFolds = 5×8
```

```matlab
0.5511    0.5520    0.5525    0.5514    0.4869    0.2933    0.1025    0.0857
0.5257    0.5270    0.5270    0.5277    0.4801    0.2944    0.1049    0.0866
0.5256    0.5265    0.5276    0.5276    0.4724    0.2884    0.1034    0.0866
0.5386    0.5394    0.5405    0.5373    0.4824    0.2903    0.1009    0.0854
0.5497    0.5551    0.5582    0.5575    0.4944    0.2939    0.1030    0.0849
```

eFolds is a 5-by-8 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in Lambda. You can use eFolds to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.
e = kfoldEdge(CVMdl)
e = 1x8
    0.5382  0.5400  0.5411  0.5403  0.4832  0.2921  0.1029  0.0858

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

figure;
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
hold on
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge','Max edge')
hold off

Several values of Lambda yield similarly high edges. Greater regularization strength values lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

LambdaFinal = Lambda(4);
Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength \( \text{LambdaFinal} \).

\[
t = \text{templateLinear}('\text{Learner}', '\text{logistic}', '\text{Solver}', '\text{sparsa}', ...
  '\text{Regularization}', '\text{lasso}', '\text{Lambda}', \text{LambdaFinal}, '\text{GradientTolerance}', 1e-8);
\]
\[
\text{MdlFinal} = \text{fitcecoc}(X, Y, '\text{Learners}', t, '\text{ObservationsIn}', '\text{columns}');
\]

To estimate labels for new observations, pass \( \text{MdlFinal} \) and the new data to \text{predict}.

### More About

#### Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \text{argmin}_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \text{argmin}_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j, s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>( \log[1 + \exp(-2y_j s_j)]/[2\log(2)] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty, \infty))</td>
<td>( \exp(-y_j s_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty, \infty))</td>
<td>([1 - \text{sign}(y_j s_j)]/2 )</td>
</tr>
</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**References**

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel', true)
For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldEdge

Classification edge for observations not used for training

Syntax

E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)

Description

E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification model obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

obj

Object of class ClassificationPartitionedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

folds

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.

Default: 1:obj.KFold

mode

Character vector or string scalar representing the meaning of the output edge:

• 'average' — edge is a scalar value, the average over all folds.
• 'individual' — edge is a vector of length obj.KFold with one element per fold.

Default: 'average'
Output Arguments

\[ E \]

The average classification margin. \( E \) is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

**Estimate the k-fold Edge of a Classifier**

Compute the k-fold edge for a model trained on Fisher’s iris data.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Train a classification tree classifier.

```matlab
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```matlab
cvtree = crossval(tree);
```

Compute the k-fold edge.

```matlab
t = kfoldEdge(cvtree);
t = 0.8578
```

More About

**Edge**

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix \( X \). A high value of margin indicates a more reliable prediction than a low value.

**Score**

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.
For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor \( X \) as true when \( X < 0.15 \) or \( X > 0.95 \), and \( X \) is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```matlab
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
[-,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3
0.9059    0.0941    0.8147
0.9059    0.0941    0.9058
0         1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
0         1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
```
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range (.95, 1) instead of the expected 5 observations.

**kfoldfun**

**Package:** classreg.learning.partition

Cross-validate function using cross-validated ECOC model

**Syntax**

vals = kfoldfun(CVMdl,fun)

**Description**

vals = kfoldfun(CVMdl,fun) cross-validates the function fun by applying fun to the data stored in the cross-validated ECOC model CVMdl. You must pass fun as a function handle.

**Examples**

**Estimate Classification Error Using Custom Loss Function**

Train a multiclass ECOC classifier, and then cross-validate the model using a custom k-fold loss function.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation.

Compute the classification error (proportion of misclassified observations) for the validation-fold observations.

```matlab
L = kfoldLoss(CVMdl)
L = 0.0400
```

Examine the result when the cost of misclassifying a flower as versicolor is 10 and the cost of any other error is 1. Write a function named noversicolor that assigns a cost of 1 for general misclassification and a cost of 10 for misclassifying a flower as versicolor.
If you use the live script file for this example, the `noversicolor` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB path.

Compute the mean misclassification error with the `noversicolor` cost.

```matlab
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)
```
```
ans = 0.0667
```

This code creates the function `noversicolor`.

```matlab
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
% noversicolor: Example custom cross-validation function that assigns a cost of
% 10 for misclassifying versicolor irises and a cost of 1 for misclassifying
% the other irises. This example function requires the fisheriris data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
      9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = single(cost/numel(Ytest)); % Average error
end
```

**Input Arguments**

- **CVMdl** — Cross-validated ECOC model
  - `ClassificationPartitionedECOC` model

  Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model.

- **fun** — Cross-validated function
  - function handle

  Cross-validated function, specified as a function handle. `fun` has this syntax:
  ```matlab
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```
  - CMP is a compact model stored in one element of the `CVMdl.Trained` property.
  - Xtrain is the training matrix of predictor values.
  - Ytrain is the training array of response values.
  - Wtrain is the set of training weights for observations.
  - Xtest and Ytest are the validation data, with associated weights Wtest.
  - The returned value `testvals` must have the same size across all folds.

**Output Arguments**

- **vals** — Cross-validation results
  - numeric matrix
Cross-validation results, returned as a numeric matrix. `vals` corresponds to the arrays of the `testvals` output, concatenated vertically over all the folds. For example, if `testvals` from every fold is a numeric vector of length `n`, `kfoldfun` returns a `Kfold-by-n` numeric matrix with one row per fold.

**Introduced in R2014b**
**kfoldfun**

Cross validate function

**Syntax**

vals = kfoldfun(CVMdl,fun)

**Description**

vals = kfoldfun(CVMdl,fun) cross validates the function fun by applying fun to the data stored in the cross-validated model CVMdl. You must pass fun as a function handle.

**Input Arguments**

- **CVMdl** — Cross-validated model
  - ClassificationPartitionedECOC model
  - ClassificationPartitionedEnsemble model
  - ClassificationPartitionedModel model

  Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

- **fun** — Cross-validated function
  - function handle

  Cross-validated function, specified as a function handle. fun has the syntax

  testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

  - CMP is a compact model stored in one element of the CVMdl.Trained property.
  - Xtrain is the training matrix of predictor values.
  - Ytrain is the training array of response values.
  - Wtrain are the training weights for observations.
  - Xtest and Ytest are the test data, with associated weights Wtest.
  - The returned value testvals needs the same size across all folds.

  Data Types: function_handle

**Output Arguments**

- **vals** — Cross-validation results
  - numeric matrix

  Cross-validation results, returned as an numeric matrix. vals is the arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

  Data Types: double
Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom k-fold loss function.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Train a classification tree classifier.

```matlab
Mdl = fitctree(meas,species);
```

Mdl is a ClassificationTree model.

Cross validate Mdl using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```matlab
rng(1); % For reproducibility
CVMdl = crossval(Mdl);
L = kfoldLoss(CVMdl)
```

```matlab
L =
0.0467
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called noversicolor.m that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as versicolor, and save it on your MATLAB path.

```matlab
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
% Attributes a cost of 10 for misclassifying versicolor irises, and 1 for the other irises. This example function requires the |fisheriris| data set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the noversicolor cost.

```matlab
mean(kfoldfun(CVMdl,@noversicolor))
```
ans =

0.2267

**kfoldfun**

Cross validate function

**Syntax**

vals = kfoldfun(obj,fun)

**Description**

vals = kfoldfun(obj,fun) cross validates the function fun by applying fun to the data stored in the cross-validated model obj. You must pass fun as a function handle.

**Input Arguments**

obj

Object of class RegressionPartitionedModel or RegressionPartitionedEnsemble. Create obj with fitrtree or fitrensemble along with one of the cross-validation options: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Alternatively, create obj from a regression tree or regression ensemble with crossval.

fun

A function handle for a cross-validation function. fun has the syntax

testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

- CMP is a compact model stored in one element of the obj.Trained property.
- Xtrain is the training matrix of predictor values.
- Ytrain is the training array of response values.
- Wtrain are the training weights for observations.
- Xtest and Ytest are the test data, with associated weights Wtest.
- The returned value testvals must have the same size across all folds.

**Output Arguments**

vals

The arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

**Examples**

Cross validate a regression tree, and obtain the mean squared error (see kfoldLoss):

load imports-85

t = fitrtree(X(:,[4 5]),X(:,16),...
predictornames', {'length', 'width'}, ...
'reponsename', 'price');
cv = crossval(t);
L = kfoldLoss(cv)

L =
  1.5489e+007

Examine the result of simple averaging of responses instead of using predictions:

f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...  
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))

ans =
  6.3497e+007

**kfoldLoss**

**Package:** classreg.learning.partition

Classification loss for cross-validated ECOC model

**Syntax**

loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)

**Description**

loss = kfoldLoss(CVMdl) returns the classification loss obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) CVMdl. For every fold, kfoldLoss computes the classification loss for validation-fold observations using a model trained on training-fold observations. CVMdl.X contains both sets of observations.

loss = kfoldLoss(CVMdl,Name,Value) returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

**Examples**

**Determine k-Fold Cross-Validation Loss**

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the average classification error.

```matlab
L = kfoldLoss(CVMdl)
L = 0.0400
```

The average classification error for the folds is 4%.
Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in kfoldLoss.

**Display Individual Losses for Each Cross-Validation Fold**

The classification loss is a measure of classifier quality. To determine which folds perform poorly, display the losses for each fold.

Load Fisher's iris data set. Specify the predictor data \( X \), the response data \( Y \), and the order of the classes in \( Y \).

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across all folds and the losses for each fold.

```matlab
loss = kfoldLoss(CVMdl)
loss = 0.0333
losses = kfoldLoss(CVMdl,'Mode','individual')
losses = 8×1
0.0556
0.0526
0.1579
0
0
0
0

The third fold misclassifies a much higher percentage of observations than any other fold.

Return the average classification loss for the folds that perform well by specifying the 'Folds' name-value pair argument.

```matlab
newloss = kfoldLoss(CVMdl,'Folds',[1:2 4:8])
newloss = 0.0153
```

The total classification loss decreases by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.
Determine ECOC Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to kfoldLoss.

Load Fisher's iris data set. Specify the predictor data $X$, the response data $Y$, and the order of the classes in $Y$.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y)  % Class order
```

```matlab
classOrder = 3x1 categorical
    setosa
    versicolor
    virginica
```

rng(1) % For reproducibility

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. $S$ corresponds to the NegLoss output of kfoldPredict.

```matlab
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the cross-validated custom loss.

```matlab
kfoldLoss(CVMdl,'LossFun',lossfun)
an = 0.0101
```

The average minimal binary loss for the validation-fold observations is $0.0101$.

**Input Arguments**

- **CVMdl** — Cross-validated ECOC model
  ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model in two ways:
• Pass a trained ECOC model (ClassificationECOC) to crossval.
• Train an ECOC model using fitcecoc and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

**BinaryLoss — Binary learner loss function**

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle
--- | --- | --- | --- | --- | --- | --- | ---
Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set {–1,1,0}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```matlab
bLoss = customFunction(M,s)
```

where:

- `M` is the $K$-by-$L$ coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by-$L$ row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
• $K$ is the number of classes.
• $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel classification models of SVM learners.</td>
<td>'hinge'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by AdaboostM1 or GentleBoost.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by LogitBoost.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior',true in fitcecoc.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `BinaryLoss', 'binodeviance`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

Example: 'Decoding', 'lossbased'

**Folds — Fold indices for prediction**

1:CVmdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVmdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: 'Folds', [1 4 10]

Data Types: `single` | `double`

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.
• Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-2709.
• Or, specify your own function using function handle notation.

Assume that \( n \) is the number of observations in the training data (CVMdl.NumObservations) and \( K \) is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost),
\]

where:

• The output argument lossvalue is a scalar.
• You specify the function name (lossfun).
• \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames. Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set every element of row \( p \) to 0.
• \( S \) is an \( n \)-by-\( K \) numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMdl.ClassNames. The input \( S \) resembles the output argument NegLoss of kfoldPredict.
• \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes its elements to sum to 1.
• Cost is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

Data Types: char | string | function_handle

Mode — Aggregation level for output
'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length ( k ) containing one value per fold, where ( k ) is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode', 'individual'

Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:
• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel', true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**loss — Classification loss**

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k-by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

**More About**

**Classification Error**

The classification error is a binary classification error measure that has the form

\[ L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j}, \]

where:

• \( w_j \) is the weight for observation \( j \). The software renormalizes the weights to sum to 1.
• \( e_j = 1 \) if the predicted class of observation \( j \) differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

• \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
• $s_j$ is the score of binary learner $j$ for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{k,j}|g(m_{k,j}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{k,j}|g(m_{k,j}, s_j)}{\sum_{j=1}^{L} |m_{k,j}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>

<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

References

**Extended Capabilities**

**Automatic Parallel Support**

 Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

“Concepts of Parallel Computing in Statistics and Machine Learning Toolbox” on page 30-8

**Introduced in R2014b**
**kfoldLoss**

Classification loss for observations not used for training

**Syntax**

L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)

**Description**

L = kfoldLoss(ens) returns loss obtained by cross-validated classification model ens. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

L = kfoldLoss(ens,Name,Value) calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Input Arguments**

ens

Object of class ClassificationPartitionedEnsemble. Create ens with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create ens from a classification ensemble with crossval.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

folds

Indices of folds ranging from 1 to ens.KFold. Use only these folds for predictions.

Default: 1:ens.KFold

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
'exponential' | Exponential
'hinge' | Hinge
'logit' | Logistic
'mincost' | Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic' | Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering
  
  \[
  \text{ens.ScoreTransform} = \text{'doublelogit'};
  \]
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that \(n\) be the number of observations in \(X\) and \(K\) be the number of distinct classes (numel(ens.ClassNames), ens is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

where:

- The output argument \(\text{lossvalue}\) is a scalar.
- You choose the function name (\textit{lossfun}).
- \(C\) is an \(n\)-by-\(K\) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \textit{ens.ClassNames}.
  
  Construct \(C\) by setting \(C(p,q) = 1\) if observation \(p\) is in class \(q\), for each row. Set all other elements of row \(p\) to 0.
- \(S\) is an \(n\)-by-\(K\) numeric matrix of classification scores. The column order corresponds to the class order in \textit{ens.ClassNames}. \(S\) is a matrix of classification scores, similar to the output of \textit{predict}.
- \(W\) is an \(n\)-by-1 numeric vector of observation weights. If you pass \(W\), the software normalizes them to sum to 1.
- \(Cost\) is a \(K\)-by-\(K\) numeric matrix of misclassification costs. For example, \(Cost = \text{ones}(K) - \text{eye}(K)\) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using \textit{'LossFun'},{@lossfun}.

For more details on loss functions, see “Classification Loss” on page 32-2714.

**Default:** 'classiferror'
mode
A character vector or string scalar for determining the output of kfoldLoss:
• 'average' — L is a scalar, the loss averaged over all folds.
• 'individual' — L is a vector of length ens.KFold, where each entry is the loss for a fold.
• 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'average'

Output Arguments
L
Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.
load ionosphere

Train a classification ensemble of 100 decision trees using AdaBoostM1. Specify tree stumps as the weak learners.

t = templateTree('MaxNumSplits',1);
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);

Cross-validate the ensemble using 10-fold cross-validation.
cvens = crossval(ens);

Estimate the cross-validated classification error.
L = kfoldLoss(cvens)
L = 0.0655

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

• L is the weighted average classification loss.
• $n$ is the sample size.
• For binary classification:
  • $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  • $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
• For algorithms that support multiclass classification (that is, $K \geq 3$):
  • $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \\ 0 \\ 1 \\ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  • $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  • $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,
\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the `LossFun` name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>$L = \sum_{j=1}^{n} w_j \log{1 + \exp[-2m_j]}$.</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>$L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}$.</td>
</tr>
</tbody>
</table>

It is the weighted fraction of misclassified observations where $\hat{y}_j$ is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.
<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>

kfoldLoss

Package: classreg.learning.partition

Classification loss for cross-validated kernel classification model

Syntax

loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)

Description

loss = kfoldLoss(CVMdl) returns the classification loss on page 32-2722 obtained by the cross-valuated, binary kernel model (ClassificationPartitionedKernel) CVMdl. For every fold, kfoldLoss computes the classification loss for validation-fold observations using a model trained on training-fold observations.

By default, kfoldLoss returns the classification error.

loss = kfoldLoss(CVMdl,Name,Value) returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, or aggregation level.

Examples

Estimate k-Fold Cross-Validation Classification Error

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (’b’) or good (’g’).

load ionosphere

Cross-validate a binary kernel classification model using the data.

CVMdl = fitckernel(X,Y,'Crossval','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'

Properties, Methods
CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

loss = kfoldLoss(CVMdl)

loss = 0.0940

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Specify Custom Classification Loss

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

load ionosphere

Cross-validate a binary kernel classification model using the data.

CVMdl = fitckernel(X,Y,'Crossval','on')

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Create an anonymous function that measures linear loss, that is,

\[ L = \frac{\sum_j - w_j y_j f_j}{\sum_j w_j} \]

\(w_j\) is the weight for observation \(j\), \(y_j\) is the response \(j\) (-1 for the negative class and 1 otherwise), and \(f_j\) is the raw classification score of observation \(j\).

linearloss = @(C,S,W,Cost)sum((-W.*sum(S.*C,2))/sum(W));

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.
Estimate the cross-validated classification loss using the linear loss function.

\[
\text{loss} = \text{kfoldLoss(CVMdl,'LossFun','linearloss')}
\]

\[
\text{loss} = -0.7792
\]

**Input Arguments**

**CVMdl — Cross-validated, binary kernel classification model**

*ClassificationPartitionedKernel* model object

Cross-validated, binary kernel classification model, specified as a *ClassificationPartitionedKernel* model object. You can create a *ClassificationPartitionedKernel* model object by using *fitckernel* and specifying any one of the cross-validation `Name-Value` pair arguments.

To obtain estimates, \(\text{kfoldLoss}\) applies the same data used to cross-validate the kernel classification model \((X\text{ and }Y)\).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

**Folds — Fold indices for prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

**LossFun — Loss function**

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see kfoldPredict).

- Specify your own function by using function handle notation.

Assume that \( n \) is the number of observations in \( X \), and \( K \) is the number of distinct classes \( \text{numel(CVMdl.ClassNames)} \), where CVMdl is the input model. Your function must have this signature:

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

- The output argument lossvalue is a scalar.
- You specify the function name (lossfun).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames. Construct \( C \) by setting \( C(p,q) = 1 \), if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.
- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in CVMdl.ClassNames. \( S \) is a matrix of classification scores, similar to the output of kfoldPredict.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes the weights to sum to 1.
- \( Cost \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( Cost = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun',@lossfun

Data Types: char | string | function_handle

**Mode — Aggregation level for output**

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length $k$ containing one value per fold, where $k$ is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

Output Arguments

**loss — Classification loss**  
numeric scalar | numeric column vector

Classification loss on page 32-2722, returned as a numeric scalar or numeric column vector.

If **Mode** is 'average', then **loss** is the average classification loss over all folds. Otherwise, **loss** is a $k$-by-1 numeric column vector containing the classification loss for each fold, where $k$ is the number of folds.

More About

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- $y_j$ is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for the transformed observation (row) $j$ of the predictor data $X$ using feature expansion.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute to the average loss.
- The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

This table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>

**See Also**
ClassificationPartitionedKernel | fitckernel

**Introduced in R2018b**
**kfoldLoss**

**Package:** classreg.learning.partition

Classification loss for cross-validated kernel ECOC model

**Syntax**

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

**Description**

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `kfoldLoss` applies the same data used to create `CVMdl` (see `fitcecoc`).

By default, `kfoldLoss` returns the classification error on page 32-2730.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Classification Error**

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```matlab
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods
CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

```matlab
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0333
```

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair 'Mode','individual' in kfoldLoss.

**Determine Model Quality Using Custom Cross-Validation Loss**

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to kfoldLoss.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```matlab
rng(1) % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    Num Observations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. S corresponds to the NegLoss output of kfoldPredict.

```matlab
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```
Compute the cross-validated custom loss.

\[ \text{kfoldLoss(CVMdl,'LossFun',lossfun)} \]

\[ \text{ans} = 0.0199 \]

The average minimal binary loss for the validation-fold observations is about 0.02.

**Input Arguments**

CVMdl — Cross-validated kernel ECOC model
`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'`– Set the value to `kernel`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

**BinaryLoss — Binary learner loss function**

- `'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>

</tr>
</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

\[
\text{bLoss} = \text{customFunction}(\text{M},s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-2730.

Example: `'Decoding','lossbased'`

**Folds — Fold indices for prediction**

1:CVMd1.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMd1.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

**LossFun — Loss function**

`'classiferror'` (default) | `function handle`

32-2728
Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-2730.
- Or, specify your own function using function handle notation.

Assume that n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature

definition

2. The output argument lossvalue is a scalar.
3. You specify the function name (lossfun).
4. C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set every element of row p to 0.
5. S is an n-by-K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMdl.ClassNames. The input S resembles the output argument NegLoss of kfoldPredict.
6. W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes its elements to sum to 1.
7. Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

Data Types: char | string | function_handle

Mode — Aggregation level for output

'default' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length k containing one value per fold, where k is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode', 'individual'

Options — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:
You need a Parallel Computing Toolbox license.

Specify 'Options', statset('UseParallel', true).

**Verbose — Verosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `Verbose`, 1

Data Types: `single` | `double`

**Output Arguments**

**loss — Classification loss**

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If `Mode` is 'average', then `loss` is the average classification loss over all folds. Otherwise, `loss` is a `k`-by-1 numeric column vector containing the classification loss for each fold, where `k` is the number of folds.

**More About**

**Classification Error**

The classification error is a binary classification error measure that has the form

\[
L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},
\]

where:

- `w_j` is the weight for observation `j`. The software renormalizes the weights to sum to 1.
- `e_j = 1` if the predicted class of observation `j` differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- `m_{kj}` is element `(k,j)` of the coding design matrix `M` (that is, the code corresponding to class `k` of binary learner `j`).
• $s_j$ is the score of binary learner $j$ for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$
\hat{k} = \arg\min_k \sum_{j=1}^L m_{k,j} g(m_{k,j}, s_j).
$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L m_{k,j} g(m_{k,j}, s_j)}{\sum_{j=1}^L m_{k,j}}.
$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j, s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty, \infty)$</td>
<td>$\frac{\log[1 + \exp(-2y_j s_j)]}{2\log(2)}$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty, \infty)$</td>
<td>$\frac{1 - \text{sign}(y_j s_j)}{2}$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>$\frac{1 - y_j s_j}{2}$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>$\frac{\log[1 + \exp(-y_j s_j)]}{2\log(2)}$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$\frac{(1 - y_j (2s_j - 1))^2}{2}$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Introduced in R2018b**
**kfoldLoss**

Classification loss for observations not used in training

**Syntax**

```matlab
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

**Description**

`L = kfoldLoss(CVMdl)` returns the cross-validated classification losses on page 32-2739 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification loss for observations that it holds out when it trains using all other observations.

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

**Input Arguments**

- **CVMdl** — Cross-validated, binary, linear classification model
  `ClassificationPartitionedLinear` model object

  Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

  To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the linear classification model (`X` and `Y`).

- **Name-Value Pair Arguments**

  Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

- **Folds** — Fold indices to use for classification-score prediction
  Numeric vector of positive integers

  Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

  Example: `'Folds',[1 4 10]`

  Data Types: `single` | `double`
**LossFun — Loss function**

'`classiferror'` (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'Mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function using function handle notation.

Let \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel(Mdl.ClassNames)} \), \( Mdl \) is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. \( S \) is a matrix of classification scores, similar to the output of `predict`.

- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, `\text{Cost} = \text{ones(K)} - \text{eye(K)}` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.
Data Types: char | string | function_handle

Mode — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns losses averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns losses for each fold</td>
</tr>
</tbody>
</table>

Example: ‘Mode’, 'individual'

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-2739, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LossFun.

Let R be the number of regularizations strengths is the cross-validated models (stored in numel(CVMdl.Trained{1}.Lambda)) and F be the number of folds (stored in CVMdl.KFold).

- If Mode is 'average', then L is a 1-by-R vector. L(j) is the average classification loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, L is an F-by-R matrix. L(i,j) is the classification loss for fold i of the cross-validated model that uses regularization strength j.

To estimate L, kfoldLoss uses the data that created CVMdl (see X and Y).

Examples

Estimate k-Fold Cross-Validation Classification Error

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');

CVMdl is a ClassificationPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

ce = kfoldLoss(CVMdl)

ce = 7.6017e-04

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Classification Error” on page 32-2735, and transpose the predictor data.

load nlpdata
Ystats = Y == 'stats';
X = X';

Cross-validate a binary, linear classification model using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','KFold',5,...
    'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 5-by-1 cell array holding a ClassificationLinear models that the software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

\[ L = \frac{\sum_{j} - w_j y_j f_j}{\sum_{j} w_j}. \]

\( w_j \) is the weight for observation \( j \), \( y_j \) is response \( j \) (-1 for the negative class, and 1 otherwise), and \( f_j \) is the raw classification score of observation \( j \). Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the LossFun name-value pair argument.

Because the function does not use classification cost, use ~ to have kfoldLoss ignore its position.

linearloss = @(C,S,W,~)sum(-W.*sum(S.*C,2))/sum(W);

Estimate the average cross-validated classification loss using the linear loss function. Also, obtain the loss for each fold.

ce = kfoldLoss(CVMdl,'LossFun',linearloss)

ce = -8.0982
Find Good Lasso Penalty Using k-fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-2736.

load nlpdata
Ystats = Y == 'stats';
X = X';

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{0.5}$.

Lambda = logspace(-6,-0.5,11);

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e^{-8}$.

rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',... 'KFold',5,'Learner','logistic','Solver','sparsa',... 'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =  
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Extract a trained linear classification model.

Mdl1 = CVMdl.Trained{1}

Mdl1 =  
    ClassificationLinear
Mdl1 is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

\[
\text{ce} = \text{kfoldLoss(CVMdl)};
\]

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validate the models. Determine the number of nonzero coefficients per model.

\[
\text{Mdl} = \text{fitclinear}(X,Ystats,'ObservationsIn','columns','Learner','logistic','Solver','sparsa','Regularization','lasso',\Lambda,\text{Grad}\text{eantTolerance},1e^{-8});
\]

\[
\text{numNZCoeff} = \text{sum(Mdl.Beta} \neq 0\text{);}
\]

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

\[
\text{figure; [h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),log10(Lambda),log10(numNZCoeff));}
\]

\[
\text{hL1.Marker = 'o'; hL2.Marker = 'o';}
\]

\[
\text{ylabel(h(1),'} \log_{10} \text{ classification error'});
\]

\[
\text{ylabel(h(2),'} \log_{10} \text{ nonzero-coefficient frequency'});
\]

\[
\text{xlabel('log_{10} Lambda')}}
\]

\[
\text{title('Test-Sample Statistics')}
\]

\[
\text{hold off}
\]
Choose the indexes of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

**More About**

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
• \(y_j\) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.

• \(f(X_j)\) is the raw classification score for observation (row) \(j\) of the predictor data \(X\).

• \(m_j = y_j f(X_j)\) is the classification score for classifying observation \(j\) into the class corresponding to \(y_j\). Positive values of \(m_j\) indicate correct classification and do not contribute much to the average loss. Negative values of \(m_j\) indicate incorrect classification and contribute significantly to the average loss.

• For algorithms that support multiclass classification (that is, \(K \geq 3\)):

  • \(y_j^*\) is a vector of \(K - 1\) zeros, with 1 in the position corresponding to the true, observed class \(y_j\). For example, if the true class of the second observation is the third class and \(K = 4\), then \(y_j^* = [0 \ 0 \ 1 \ 0]'\). The order of the classes corresponds to the order in the ClassNames property of the input model.

  • \(f(X_j)\) is the length \(K\) vector of class scores for observation \(j\) of the predictor data \(X\). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.

  • \(m_j = y_j^* f(X_j)\). Therefore, \(m_j\) is the scalar classification score that the model predicts for the true, observed class.

• The weight for observation \(j\) is \(w_j\). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>(L = \sum_{j=1}^{n} w_j \log {1 + \exp[-2m_j]}).</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>(L = \sum_{j=1}^{n} w_j \exp(-m_j)).</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>(L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}).</td>
</tr>
</tbody>
</table>
  
  It is the weighted fraction of misclassified observations where \(\hat{y}_j\) is the class label corresponding to the class with the maximal posterior probability. \(I\{x\}\) is the indicator function.

| Hinge loss            | 'hinge'          | \(L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}\). |

32-2740
<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.</td>
</tr>
</tbody>
</table>
| Minimal cost      | 'mincost'        | Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1,\ldots,n$.  
1. Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:  
   $$y_j = f(X_j)C.$$  
   $f(X)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the Cost property.  
2. For observation $j$, predict the class label corresponding to the minimum expected classification cost:  
   $$\hat{y}_j = \min_{j=1,\ldots,K} (y_j).$$  
3. Using $C$, identify the cost incurred ($c_j$) for making the prediction.  
The weighted, average, minimum cost loss is  
   $$L = \sum_{j=1}^{n} w_j c_j.$$ |
| Quadratic loss    | 'quadratic'      | $L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.       |

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through [0,1].

ClassificationLinear | ClassificationPartitionedLinear | kfoldPredict | loss

Introduced in R2016a
**kfoldLoss**

Classification loss for observations not used in training

**Syntax**

```matlab
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

**Description**

$L = \text{kfoldLoss}(\text{CVMdl})$ returns the cross-validated classification error on page 32-2752 rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models $\text{CVMdl}$. That is, for every fold, $\text{kfoldLoss}$ estimates the classification error rate for observations that it holds out when it trains using all other observations. $\text{kfoldLoss}$ applies the same data used create $\text{CVMdl}$ (see fitcecoc).

$L$ contains a classification loss for each regularization strength in the linear classification models that compose $\text{CVMdl}$.

$L = \text{kfoldLoss}(\text{CVMdl},\text{Name},\text{Value})$ uses additional options specified by one or more Name,Value pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

**Input Arguments**

- **CVMdl** — Cross-validated, ECOC model composed of linear classification models
  - `ClassificationPartitionedLinearECOC` model object

  Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model object using `fitcecoc` and by:

  1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
  2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

  To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the ECOC model ($X$ and $Y$).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

- **BinaryLoss** — Binary learner loss function
  - `'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

32-2743
Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set {-1,1,0}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>[0,1] or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_js_j)/2$</td>
</tr>
<tr>

<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>[0,1]</td>
<td>$(1 - y(2s - 1))^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction should have this form:

```matlab
bLoss = customFunction(M,s)
```

where:

- M is the $K$-by-$L$ coding matrix stored in Mdl.CodingMatrix.
- s is the 1-by-$L$ row vector of classification scores.
- bLoss is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$ is the number of classes.
- $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

By default, if all binary learners are linear classification models using:

- SVM, then BinaryLoss is 'hinge'
- Logistic regression, then BinaryLoss is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see "Binary Loss" on page 32-2824.

Example: 'Decoding','lossbased'

**Folds — Fold indices to use for classification-score prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or 'classiferror'.

You can:

- Specify the built-in function 'classiferror', then the loss function is the classification error on page 32-2752.
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature lossvalue = lossfun(C,S,W,Cost), where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames. Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set every element of row p to 0.
- S is an n-by-K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMdl.ClassNames. S resembles the output argument NegLoss of kfoldPredict.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes its elements to sum to 1.
- Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) - eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

Data Types: function_handle | char | string

**Mode — Loss aggregation level**

'average' (default) | 'individual'
Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns losses averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns losses for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode', 'individual'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbosity controls the number of diagnostic messages that the software displays in the Command Window.

If 'Verbose' is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**L — Cross-validated classification losses**

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-2752, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LossFun.

Let R be the number of regularizations strengths is the cross-validated models (CVMdl.Trained{1}.BinaryLearners{1}.Lambda) and F be the number of folds (stored in CVMdl.KFold).

- If Mode is 'average', then L is a 1-by-R vector. L(j) is the average classification loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, L is a F-by-R matrix. L(i,j) is the classification loss for fold i of the cross-validated model that uses regularization strength j.

**Examples**
Estimate k-Fold Cross-Validation Classification Error

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.

ce = kfoldLoss(CVMdl)

ce = 0.0958

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

load nlpdata
X = X';

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

t = templateLinear('Solver','sparsa');

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}

CMdl1 =
classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]
CVMdl is a ClassificationPartitionedLinearECOC model. It contains the property Trained, which is a 5-by-1 cell array holding a CompactClassificationECOC models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (C), observation weights (W), and classification cost (Cost), use ~ to have kfoldLoss ignore its their positions.

\[
\text{lossfun} = @(~,S,~,~)\text{mean}(\text{min}(-S,[],2));
\]

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

\[
\text{ce} = \text{kfoldLoss(CVMdl,'LossFun',lossfun)}
\]

\[
\text{ce} = 0.0243
\]

\[
\text{ceFold} = \text{kfoldLoss(CVMdl,'LossFun',lossfun,'Mode','individual')}
\]

\[
\text{ceFold} = 5\times1
\]

\[
\begin{array}{c}
0.0244 \\
0.0255 \\
0.0248 \\
0.0240 \\
0.0226
\end{array}
\]

**Find Good Lasso Penalty Using Cross-Validation**

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

\[
\text{load nlpdata}
\]

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

\[
\text{Y} \left( \text{ismember}(Y,\{'\text{simulink}', '\text{dsp}', '\text{comm}'\}) \right) = '\text{others'};
\]

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2}.

\[
\text{Lambda} = \text{logspace}(-7,-2,11);
\]
Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in Lambda, train using SpaRSA, and lower the tolerance on the gradient of the objective function to $1e^{-8}$.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```matlab
X = X';
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a `ClassificationPartitionedLinearECOC` model.

Dissect CVMdl, and each model within it.

```matlab
numECOCModels = numel(CVMdl.Trained)
numECOCModels = 5

ECOCMdl1 = CVMdl.Trained{1}
```

```matlab
ECOCMdl1 =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'
    BinaryLearners: {6×1 cell}
    CodingMatrix: [4×6 double]
```

Properties, Methods

```matlab
numCLModels = numel(ECOCMdl1.BinaryLearners)
numCLModels = 6

CLMdl1 = ECOCMdl1.BinaryLearners{1}
```

```matlab
CLMdl1 =
    ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [-1 1]
    ScoreTransform: 'logit'
    Beta: [34023×11 double]
    Bias: [-0.3125 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.1593 -0.0737 -0.1759 -0.3452 -0.5174]
    Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04 3.1623e-04 1.0000e-03 0.0032 0.0100]
    Learner: 'logistic'
```

Properties, Methods

Because `fitcecoc` implements 5-fold cross-validation, CVMdl contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear`
models. The number of ClassificationLinear models within each compact ECOC model depends on the number of distinct labels and coding design. Because Lambda is a sequence of regularization strengths, you can think of CLMdl1 as 11 models, one for each regularization strength in Lambda.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```matlab
c = kfoldLoss(CVMdl);
figure;
plot(log10(Lambda),log10(c))
[-,minCEIdx] = min(c);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(c(minCEIdx)),'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE','Min classification error')
hold off
```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',
    'Regularization','lasso',Lambda,minLambda,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass MdlFinal and the new data to predict.
More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}g(m_{kj},s_j)|.
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}g(m_{kj},s_j)|}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).

<table>
<thead>
<tr>

<td>( [1 - yj(2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.
Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the \texttt{loss} and \texttt{predict} object functions), which measures how well an ECOC classifier performs as a whole.

\textbf{Classification Error}

The classification error is a binary classification error measure that has the form

\[ L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j}, \]

where:

- $w_j$ is the weight for observation $j$. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation $j$ differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

\textbf{Extended Capabilities}

\textbf{Automatic Parallel Support}

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the \texttt{UseParallel} option to \texttt{true}.

Set the \texttt{UseParallel} field of the options structure to \texttt{true} using \texttt{statset} and specify the \texttt{Options} name-value pair argument in the call to this function.

For example: \texttt{Options},\texttt{statset('UseParallel',true)}

For more information, see the \texttt{Options} name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a
**kfoldLoss**

Classification loss for observations not used for training

**Syntax**

\[
L = \text{kfoldLoss}(\text{obj})
\]

\[
L = \text{kfoldLoss}(\text{obj},\text{Name},\text{Value})
\]

**Description**

\[
L = \text{kfoldLoss}(\text{obj}) \text{ returns loss obtained by cross-validated classification model } \text{obj}. \text{ For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.}
\]

\[
L = \text{kfoldLoss}(\text{obj},\text{Name},\text{Value}) \text{ calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,\ldots,NameN,ValueN.}
\]

**Input Arguments**

\text{obj}

Object of class ClassificationPartitionedModel.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments.

Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

\text{folds}

Indices of folds ranging from 1 to \text{obj.KFold}. Use only these folds for predictions.

**Default:** 1:obj.KFold

\text{lossfun}

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. All models use posterior probabilities as classification scores by default except SVM models. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior',true when you cross-validate the model using fitcsvm.

- Specify your own function using function handle notation.

Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (numel(obj.ClassNames), obj is the input model). Your function must have this signature:

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in obj.ClassNames.

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.
- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in obj.ClassNames. \( S \) is a matrix of classification scores, similar to the output of predict.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.
- \( Cost \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( Cost = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

For more details on loss functions, see “Classification Loss” on page 32-2756.

**Default**: 'classiferror'

**mode**

A character vector or string scalar for determining the output of kfoldLoss:

- 'average' — \( L \) is a scalar, the loss averaged over all folds.
- 'individual' — \( L \) is a vector of length obj.KFold, where each entry is the loss for a fold.

**Default**: 'average'
Output Arguments

**L**

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

**Estimate Cross-Validated Classification Error**

Load the ionosphere data set.

```matlab
load ionosphere
```

Grow a classification tree.

```matlab
tree = fitctree(X,Y);
```

Cross-validate the classification tree using 10-fold cross-validation.

```matlab
cvtree = crossval(tree);
```

Estimate the cross-validated classification error.

```matlab
L = kfoldLoss(cvtree)
```

L = 0.1111

More About

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- **L** is the weighted average classification loss.
- **n** is the sample size.
- For binary classification:
  - **y**<sub>j</sub> is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - **f(X)<sub>j</sub>** is the raw classification score for observation (row) **j** of the predictor data **X**.
  - **m<sub>j</sub>** = **y**<sub>j</sub>**f(X)<sub>j</sub>** is the classification score for classifying observation **j** into the class corresponding to **y**<sub>j</sub>. Positive values of **m<sub>j</sub>** indicate correct classification and do not contribute much to the average loss. Negative values of **m<sub>j</sub>** indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, **K** ≥ 3):
• \(y_j^*\) is a vector of \(K - 1\) zeros, with 1 in the position corresponding to the true, observed class \(y_j\). For example, if the true class of the second observation is the third class and \(K = 4\), then \(y_2^* = [0 \ 0 \ 1 \ 0]'\). The order of the classes corresponds to the order in the `ClassNames` property of the input model.

• \(f(X_j)\) is the length \(K\) vector of class scores for observation \(j\) of the predictor data \(X\). The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.

• \(m_j = y_j^*f(X_j)\). Therefore, \(m_j\) is the scalar classification score that the model predicts for the true, observed class.

• The weight for observation \(j\) is \(w_j\). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>

Topics
“Examine Quality of KNN Classifier” on page 18-27
**kfoldLoss**

Cross-validation loss of partitioned regression ensemble

**Syntax**

\[
L = \text{kfoldLoss}(cvens)
\]

\[
L = \text{kfoldLoss}(cvens, \text{Name, Value})
\]

**Description**

\[
L = \text{kfoldLoss}(cvens)
\]

returns the cross-validation loss of \( cvens \).

\[
L = \text{kfoldLoss}(cvens, \text{Name, Value})
\]

returns cross-validation loss with additional options specified by one or more \( \text{Name, Value} \) pair arguments. You can specify several name-value pair arguments in any order as \( \text{Name1, Value1, ..., NameN, ValueN} \).

**Input Arguments**

- \( cvens \)

Object of class \( \text{RegressionPartitionedEnsemble} \). Create \( obj \) with \( \text{fitrensemble} \) along with one of the cross-validation options: \( '\text{crossval}', 'kfold', '\text{holdout}', 'leaveout', \text{or}'\text{cvpartition}' \). Alternatively, create \( obj \) from a regression ensemble with \( \text{crossval} \).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \( \text{Name, Value} \) arguments. \( \text{Name} \) is the argument name and \( \text{Value} \) is the corresponding value. \( \text{Name} \) must appear inside quotes. You can specify several name and value pair arguments in any order as \( \text{Name1, Value1, ..., NameN, ValueN} \).

- **folds**

Indices of folds ranging from 1 to \( cvens.\text{KFold} \). Use only these folds for predictions.

**Default:** \( 1: cvens.\text{KFold} \)

- **lossfun**

Function handle for loss function, or \( '\text{mse}' \), meaning mean squared error. If you pass a function handle \( \text{fun} \), \( \text{loss} \) calls it as

\[
\text{fun}(Y, Yfit, W)
\]

where \( Y, Yfit, \) and \( W \) are numeric vectors of the same length.

- \( Y \) is the observed response.
- \( Yfit \) is the predicted response.
- \( W \) is the observation weights.

The returned value \( \text{fun}(Y, Yfit, W) \) should be a scalar.
**Default:** 'mse'

**mode**

Method for computing cross-validation loss.

- **'average'** — $L$ is a scalar value, the average loss over all folds.
- **'individual'** — $L$ is a vector with one element per fold.
- **'cumulative'** — $L$ is a vector with a length of minimum number of observations used for training in each fold. Each element in the vector $L$ is obtained by taking the average of loss across all folds.

**Default:** 'average'

**Output Arguments**

$L$

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. $L$ can be a vector, and can mean different things, depending on the name-value pair settings.

**Examples**

**Find Cross-Validation Loss for Regression Ensemble**

Find the cross-validation loss for a regression ensemble of the carsmall data.

Load the carsmall data set and select displacement, horsepower, and vehicle weight as predictors.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```matlab
rens = fitrensemble(X,MPG);
```

Create a cross-validated ensemble from $rens$ and find the k-fold cross-validation loss.

```matlab
rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

$L = 28.7114$

**See Also**

RegressionPartitionedEnsemble | kfoldPredict | loss
**kfoldLoss**

Regression loss for observations not used in training

**Syntax**

L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)

**Description**

L = kfoldLoss(CVMdl) returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model CVMdl. That is, for every fold, kfoldLoss estimates the regression loss for observations that it holds out when it trains using all other observations.

L contains a regression loss for each regularization strength in the linear regression models that compose CVMdl.

L = kfoldLoss(CVMdl,Name,Value) uses additional options specified by one or more Name,Value pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

**Input Arguments**

CVMdl — Cross-validated, linear regression model
RegressionPartitionedLinear model object

Cross-validated, linear regression model, specified as a RegressionPartitionedLinear model object. You can create a RegressionPartitionedLinear model object using fitrlinear and specifying any of the of the cross-validation, name-value pair arguments, for example, CrossVal.

To obtain estimates, kfoldLoss applies the same data used to cross-validate the linear regression model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Folds** — Fold indices to use for response prediction
1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]

Data Types: single|double
LossFun — Loss function
'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, \( f(x) = x\beta + b \).
  - \( \beta \) is a vector of \( p \) coefficients.
  - \( x \) is an observation from \( p \) predictor variables.
  - \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'epsiloninsensitive'</td>
<td>Epsilon-insensitive loss: ( \ell(y,f(x)) = \max(0,</td>
</tr>
<tr>
<td>'mse'</td>
<td>MSE: ( \ell(y,f(x)) = (y - f(x))^2 )</td>
</tr>
</tbody>
</table>

- 'epsiloninsensitive' is appropriate for SVM learners only.
- Specify your own function using function handle notation.

Let \( n \) be the number of observations in \( X \). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(Y,Yhat,W)
\]

where:
- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- \( Y \) is an \( n \)-dimensional vector of observed responses. kfoldLoss passes the input argument \( Y \) in for \( Y \).
- \( Yhat \) is an \( n \)-dimensional vector of predicted responses, which is similar to the output of predict.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights.

Specify your function using 'LossFun',@lossfun.

Data Types: char | string | function_handle

Mode — Loss aggregation level
'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns losses averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns losses for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'
Output Arguments

L — Cross-validated regression losses
numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LossFun.

Let R be the number of regularization strengths is the cross-validated models (stored in numel(CVMdl.Trained{1}.Lambda)) and F be the number of folds (stored in CVMdl.KFold).

- If Mode is 'average', then L is a 1-by-R vector. L(j) is the average regression loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, L is an F-by-R matrix. L(i,j) is the regression loss for fold i of the cross-validated model that uses regularization strength j.

To estimate L, kfoldLoss uses the data that created CVMdl (see X and Y).

Examples

Estimate k-Fold Mean Squared Error

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Cross-validate a linear regression model using SVM learners.

rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');

CVMdl is a RegressionPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the test-sample MSEs.

mse = kfoldLoss(CVMdl)

mse = 0.1735

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair 'Mode','individual' in kfoldLoss.
Specify Custom Regression Loss

Simulate data as in "Estimate k-Fold Mean Squared Error" on page 32-2764.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training

Cross-validate a linear regression model using 10-fold cross-validation. Optimize the objective function using SpaRSA.

CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',... 'Solver','sparsa');

CVMdl is a RegressionPartitionedLinear model. It contains the property Trained, which is a 10-by-1 cell array holding RegressionLinear models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum_{j=1}^{n} w_j} \sum_{j=1}^{n} w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 
0.5\hat{e}_j^2, & |\hat{e}_j| \leq 1 \\
|\hat{e}_j| - 0.5, & |\hat{e}_j| > 1 
\end{cases}$$

$\hat{e}_j$ is the residual for observation $j$. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ... ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5))/sum(W);

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

mseAve = kfoldLoss(CVMdl,'LossFun',huberloss)
mseAve = -0.4447

mseFold = kfoldLoss(CVMdl,'LossFun',huberloss,'Mode','individual')
mseFold = 10x1

-0.4454
-0.4473
-0.4452
-0.4469
-0.4434
Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \( 10^{-5} \) through \( 10^{-1} \).

```matlab
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```matlab
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```matlab
numCLModels = numel(CVMdl.Trained)
numCLModels = 5
```

CVMdl is a RegressionPartitionedLinear model. Because fitrlinear implements 5-fold cross-validation, CVMdl contains 5 RegressionLinear models that the software trains on each fold.

Display the first trained linear regression model.

```matlab
Mdl1 = CVMdl.Trained{1}
```

```matlab
Mdl1 =
    RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x15 double]
Md11 is a `RegressionLinear` model object. `fitrlinear` constructed Md11 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Md11 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

```matlab
mse = kfoldLoss(CVMdl);
```

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```matlab
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```matlab
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```
Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, \( \text{Lambda}(10) \)).

\[ \text{idxFinal} = 10; \]

Examine the model with corresponding to the minimal MSE.

\[ \text{MdlFinal} = \text{selectModels(Mdl,idxFinal)} \]

\[ \text{MdlFinal} = \text{RegressionLinear} \]

\[ \begin{array}{c}
\text{ResponseName: 'Y'} \\
\text{ResponseTransform: 'none'} \\
\text{Beta: [1000x1 double]} \\
\text{Bias: -0.0050} \\
\text{Lambda: 0.0037} \\
\text{Learner: 'leastsquares'}
\end{array} \]

\[ \text{idxNZCoeff = find(MdlFinal.Beta~=0)} \]

\[ \text{idxNZCoeff = 2x1} \]

\[ \begin{array}{c}
100 \\
200
\end{array} \]
EstCoeff = Mdl.Beta(idxNZCoeff)

EstCoeff = 2×1
    1.0051
    1.9965

MdlFinal is a RegressionLinear model with one regularization strength. The nonzero coefficients EstCoeff are close to the coefficients that simulated the data.

RegressionLinear | RegressionPartitionedLinear | kfoldPredict | loss

Introduced in R2016a
kfoldLoss

Cross-validation loss of partitioned regression model

Syntax

L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel,Name,Value)

Description

L = kfoldLoss(cvmodel) returns the cross-validation loss of cvmodel.

L = kfoldLoss(cvmodel,Name,Value) returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

cvmodel

Object of class RegressionPartitionedModel. Create obj with fitrtree along with one of the cross-validation options: 'CrossVal','KFold','Holdout','Leaveout', or 'CVPartition'. Alternatively, create obj from a regression tree with crossval.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

folds

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.

Default: 1:obj.KFold

lossfun

Function handle for loss function or 'mse', meaning mean squared error. If you pass a function handle fun, kfoldLoss calls it as

fun(Y,Yfit,W)

where Y, Yfit, and W are numeric vectors of the same length.

• Y is the observed response.
• Yfit is the predicted response.
• W is the observation weights.

The returned value fun(Y,Yfit,W) should be a scalar.
**Default:** 'mse'

**mode**

One of the following:

- 'average' — L is the average loss over all folds.
- 'individual' — L is a vector of the individual losses of in-fold observations trained on out-of-fold data.

**Default:** 'average'

**Output Arguments**

**L**

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If **mode** is 'individual', L is a vector of the losses. If **mode** is 'average', L is the average loss.

**Examples**

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```matlab
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

L =

- 44.9635
- 11.8525
- 18.2046
- 9.2965
- 29.4329
- 54.8659
- 24.6446
- 8.2085
- 19.7593
- 16.7394

**Alternatives**

You can avoid constructing a cross-validated tree model by calling **cvloss** instead of **kfoldLoss**. The cross-validated tree can save time if you are going to examine it more than once.

**See Also**

fitrtree | kfoldPredict | loss
kfoldMargin

Package: classreg.learning.partition

Classification margins for cross-validated ECOC model

Syntax

margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)

Description

margin = kfoldMargin(CVMdl) returns classification margins on page 32-2777 obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) CVMdl. For every fold, kfoldMargin computes classification margins for validation-fold observations using an ECOC model trained on training-fold observations. CVMdl.X contains both sets of observations.

margin = kfoldMargin(CVMdl,Name,Value) returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Examples

Estimate k-Fold Cross-Validation Margins

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the margins for validation-fold observations. Display the distribution of the margins using a boxplot.

margin = kfoldMargin(CVMdl);

boxplot(margin)
title('Distribution of Margins')
Select ECOC Model Features by Comparing Cross-Validation Margins

One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. Specify the predictor data \( X \), the response data \( Y \), and the order of the classes in \( Y \).

```matlab
load fisheriris
X = meas;
Y = categorical(species); % Class order
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define the following two data sets.

- `fullX` contains all the predictors.
- `partX` contains the petal dimensions.

```matlab
fullX = X;
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
'ClassNames',classOrder);

CVMdl and PCVMdl are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross-validation.

Estimate the margins for each classifier. Use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Distributions of Margins')

The margin distributions are approximately the same.

**Input Arguments**

*CVMdl* — Cross-validated ECOC model
ClassificationPartitionedECOC model
Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model in two ways:

- Pass a trained ECOC model (ClassificationECOC) to crossval.
- Train an ECOC model using fitcecoc and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldMargin(CVMdl,'Verbose',1) specifies to display diagnostic messages in the Command Window.

**BinaryLoss — Binary learner loss function**

`'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle`

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j,s_j)\) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j,s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty,\infty))</td>
<td>(\log[1 + \exp(-2y_js_j)] /[2\log(2)])</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty,\infty))</td>
<td>(\exp(-y_js_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1] \text{ or } (-\infty,\infty))</td>
<td>([1 - \text{sign}(y_js_j)]/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty,\infty))</td>
<td>(\max(0,1 - y_js_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty,\infty))</td>
<td>((1 - y_js_j)/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty,\infty))</td>
<td>(\log[1 + \exp(-y_js_j)] /[2\log(2)])</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>(\left[1 - y_j(2s_j - 1)\right]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses so that the loss is 0.5 when \(y_j = 0\). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

\[
bLoss = customFunction(M,s)\]

where:

- \(M\) is the \(K\)-by-\(L\) coding matrix stored in `Mdl.CodingMatrix`.
- \(s\) is the 1-by-\(L\) row vector of classification scores.
• **bLoss** is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.

• **K** is the number of classes.

• **L** is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default **BinaryLoss** value depends on the score ranges returned by the binary learners. This table describes some default **BinaryLoss** values based on the given assumptions:

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel classification models of SVM learners.</td>
<td>'hinge'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by AdaboostM1 or GentleBoost.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by LogitBoost.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior', true in fitcecoc.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the **BinaryLoss** property of the trained model at the command line.

**Example:** 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

**Example:** 'Decoding','lossbased'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by **statset**.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.

• Specify 'Options', statset('UseParallel',true).

**Verbose — Verbosity level**

0 (default) | 1
Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

**Output Arguments**

**margin — Classification margins**
numeric vector

Classification margins on page 32-2777, returned as a numeric vector. **margin** is an n-by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (size(CVMdl.X,1)).

**More About**

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}|g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,
\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j,s_j)\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j,s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty,\infty))</td>
<td>(\log[1 + \exp(-2y_j s_j)] / [2\log(2)])</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty,\infty))</td>
<td>(\exp(-y_j s_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty,\infty))</td>
<td>([1 - \text{sign}(y_j s_j)]/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty,\infty))</td>
<td>(\max(0,1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty,\infty))</td>
<td>((1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty,\infty))</td>
<td>(\log[1 + \exp(-y_j s_j)] / [2\log(2)])</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>([1 - y_j(2s_j - 1)]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.
Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options', statset('UseParallel', true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2014b**
**kfoldMargin**

**Package:** classreg.learning.partition

Classification margins for cross-validated kernel classification model

**Syntax**

```matlab
margin = kfoldMargin(CVMdl)
```

**Description**

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 32-2783 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled as either bad ('b') or good ('g').

```matlab
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```matlab
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
```

**Estimate the classification margins for validation-fold observations.**

```matlab
m = kfoldMargin(CVMdl);
size(m)
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the classification margins for validation-fold observations.

```matlab
m = kfoldMargin(CVMdl);
size(m)```
ans = 1×2
    351     1

m is a 351-by-1 vector. \( m(j) \) is the classification margin for observation \( j \).

Plot the \( k \)-fold margins using a boxplot.

```matlab
boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
```

![Distribution of Margins](image)

**Feature Selection Using \( k \)-Fold Margins**

Perform feature selection by comparing \( k \)-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```matlab
load ionosphere
```

Randomly choose 10% of the predictor variables.
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses 10% of the predictors.

CVMdl = fitckernel(X,Y,'CrossVal','on');
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');

CVMdl and PCVMdl are ClassificationPartitionedKernel models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold margins for each classifier.

fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

Plot the distribution of the margin sets using box plots.

boxplot([fullMargins partMargins], ...
    'Labels',{'All Predictors','10% of the Predictors'});
title('Distribution of Margins')

The quartiles of the PCVMdl margin distribution are situated higher than the quartiles of the CVMdl margin distribution, indicating that the PCVMdl model is the better classifier.
## Input Arguments

**CVMdl** — Cross-validated, binary kernel classification model

ClassificationPartitionedKernel model object

Cross-validated, binary kernel classification model, specified as a ClassificationPartitionedKernel model object. You can create a ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldMargin applies the same data used to cross-validate the kernel classification model (X and Y).

## Output Arguments

**margin** — Classification margins

numeric vector

Classification margins on page 32-2783, returned as a numeric vector. margin is an n-by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (size(CVMdl.Y,1)).

## More About

### Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation x. The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

### Classification Score

For kernel classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

\[ f(x) = T(x)\beta + b. \]

- \( T(\cdot) \) is a transformation of an observation for feature expansion.
- \( \beta \) is the estimated column vector of coefficients.
- \( b \) is the estimated scalar bias.

The raw classification score for classifying x into the negative class is \(-f(x)\). The software classifies observations into the class that yields a positive score.
If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

kfoldMargin

Package: classreg.learning.partition

Classification margins for cross-validated kernel ECOC model

Syntax

margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)

Description

margin = kfoldMargin(CVMdl) returns the classification margins on page 32-2790 obtained by
the cross-validated kernel ECOC model (ClassificationPartitionedKernelECOC) CVMdl. For
every fold, kfoldMargin computes the classification margins for validation-fold observations using a
model trained on training-fold observations.

margin = kfoldMargin(CVMdl,Name,Value) returns classification margins with additional
options specified by one or more name-value pair arguments. For example, specify the binary learner
loss function, decoding scheme, or verbosity level.

Examples

Estimate k-Fold Cross-Validation Margins

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower
species.

load fisheriris
X = meas;
Y = species;

Cross-validate an ECOC model composed of kernel binary learners.

CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
classreg.learning.partition.ClassificationPartitionedKernelECOC
   CrossValidatedModel: 'KernelECOC'
   ResponseName: 'Y'
   NumObservations: 150
   KFold: 10
   Partition: [1x1 cvpartition]
   ClassNames: {'setosa' 'versicolor' 'virginica'}
   ScoreTransform: 'none'

Properties, Methods
CVMdl is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the classification margins for validation-fold observations.

```matlab
m = kfoldMargin(CVMdl);
size(m)
ans = 1×2
    150     1
```

m is a 150-by-1 vector. m(j) is the classification margin for observation j.

Plot the k-fold margins using a boxplot.

```matlab
boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
```

![Distribution of Margins](image)

**Feature Selection Using k-Fold Margins**

Perform feature selection by comparing k-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.
Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Randomly choose half of the predictor variables.

```matlab
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```matlab
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

CVMdl and PCVMdl are `ClassificationPartitionedKernelECOC` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold margins for each classifier.

```matlab
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);
```

Plot the distribution of the margin sets using box plots.

```matlab
boxplot([fullMargins partMargins], ...
        'Labels',{'All Predictors','Half of the Predictors'});
title('Distribution of Margins')
```
The PCVMdl margin distribution is similar to the CVMdl margin distribution.

**Input Arguments**

*CVMdl* — Cross-validated kernel ECOC model

*ClassificationPartitionedKernelECOC* model

Cross-validated kernel ECOC model, specified as a *ClassificationPartitionedKernelECOC* model. You can create a *ClassificationPartitionedKernelECOC* model by training an ECOC model using *fitcecoc* and specifying these name-value pair arguments:

- `'Learners'`— Set the value to `'kernel'`, a template object returned by *templateKernel*, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name,Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1,Value1,...,NameN,ValueN*.

Example: `kfoldMargin(CVMdl,'Verbose',1)` specifies to display diagnostic messages in the Command Window.
Binary Loss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j,s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((–\infty,\infty))</td>
<td>( \log[1 + \exp(-2y_js_j)]/[2\log(2)] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((–\infty,\infty))</td>
<td>( \exp(-y_js_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((–\infty,\infty))</td>
<td>( [1 - \text{sign}(y_js_j)]/2 )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((–\infty,\infty))</td>
<td>( \max(0,1 - y_js_j)/2 )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((–\infty,\infty))</td>
<td>( (1 - y_js_j)/2 )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((–\infty,\infty))</td>
<td>( \log[1 + \exp(-y Js_j)]/[2\log(2)] )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j(2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction has this form:

\[
bLoss = \text{customFunction}(M,s)\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in Mdl.CodingMatrix.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then BinaryLoss is 'hinge'. If all binary learners are kernel classification models using logistic regression, then BinaryLoss is 'quadratic'.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2790.

Example: 'Decoding','lossbased'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel',true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If 'Verbose' is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

**Output Arguments**

**margin — Classification margins**

numeric vector

Classification margins on page 32-2790, returned as a numeric vector. margin is an n-by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (size(CVMdl.Y,1)).

**More About**

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:
• $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
• $s_j$ is the score of binary learner $j$ for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}|g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}|g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j, s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty, \infty)$</td>
<td>$\log(1 + \exp(-2y_j s_j))/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty, \infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>$\log(1 + \exp(-y_j s_j))/[2\log(2)]$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

ClassificationPartitionedKernelECOC | fitcecoc

Introduced in R2018b
**kfoldMargin**

Classification margins for observations not used in training

**Syntax**

```matlab
m = kfoldMargin(CVMdl)
```

**Description**

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 32-2799 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

**Input Arguments**

- **CVMdl** — Cross-validated, binary, linear classification model
  - `ClassificationPartitionedLinear` model object

  Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

  To obtain estimates, `kfoldMargin` applies the same data used to cross-validate the linear classification model (`X` and `Y`).

**Output Arguments**

- **m** — Cross-validated classification margins
  - `numeric vector` | `numeric matrix`

  Cross-validated classification margins on page 32-2799, returned as a numeric vector or matrix.

  `m` is `n`-by-`L`, where `n` is the number of observations in the data that created `CVMdl` (see `X` and `Y`) and `L` is the number of regularization strengths in `CVMdl` (that is, `numel(CVMdl.Trained{1}.Lambda)`).

  `m(i,j)` is the cross-validated classification margin of observation `i` using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`.

  Data Types: `single` | `double`

**Examples**
Estimate k-Fold Cross-Validation Margins

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');

CVMdl is a ClassificationPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the cross-validated margins.

m = kfoldMargin(CVMdl);
size(m)

ans = 1x2

31572 1

m is a 31572-by-1 vector. m(j) is the average of the out-of-fold margins for observation j.

Plot the k-fold margins using box plots.

figure;
boxplot(m);
h = gca;
h.YLim = [-5 30];
title('Distribution of Cross-Validated Margins')
Feature Selection Using $k$-fold Margins

One way to perform feature selection is to compare $k$-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in "Estimate $k$-Fold Cross-Validation Margins" on page 32-2793.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```matlab
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```
Cross-validate two binary, linear classification models: one that uses all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```matlab
cVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',... 'ObservationsIn','columns');
pCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',... 'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinear` models.

Estimate the $k$-fold margins for each classifier. Plot the distribution of the $k$-fold margins sets using box plots.

```matlab
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',... {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```

The distributions of the margins of the two classifiers are similar.

![Distribution of Cross-Validated Margins](image)
Find Good Lasso Penalty Using k-fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k-fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Margins” on page 32-2793.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^{1}$.

```matlab
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e^{-8}$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5, ... 'Learner','logistic','Solver','sparsa','Regularization','lasso', ... 'Lambda',Lambda,'GradientTolerance',1e-8)
```

```matlab
CVMdl =
    classificationPartitionedLinear
       CrossValidatedModel: 'Linear'
          ResponseName: 'Y'
       NumObservations: 31572
            KFold: 5
          Partition: [1x1 cvpartition]
        ClassNames: [0 1]
     ScoreTransform: 'none'
```

CVMdl is a ClassificationPartitionedLinear model. Because fitclinear implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models that the software trains on each fold.

Estimate the k-fold margins for each regularization strength.

```matlab
m = kfoldMargin(CVMdl);
size(m)
```

```matlab
ans = 1x2
    31572   11
```

m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.
Plot the k-fold margins for each regularization strength. Because logistic regression scores are in [0,1], margins are in [-1,1]. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```matlab
figure
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```

Several values of Lambda yield k-fold margin distributions that are compacted near 10000. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the k-fold margin distributions start decreasing.

```matlab
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```matlab
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns', ...
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass MdlFinal and the new data to predict.
More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by

\[ f_j(x) = x\beta_j + b_j. \]

For the model with regularization strength \( j \), \( \beta_j \) is the estimated column vector of coefficients (the model property \( \text{Beta}(:,j) \)) and \( b_j \) is the estimated, scalar bias (the model property \( \text{Bias}(j) \)).

The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see \text{ScoreTransform}).

Introduced in R2016a
**kfoldMargin**

Classification margins for observations not used in training

**Syntax**

\[
m = \text{kfoldMargin}(\text{CVMdl})
\]

\[
m = \text{kfoldMargin}(\text{CVMdl},\text{Name,Value})
\]

**Description**

\[
m = \text{kfoldMargin}(\text{CVMdl})
\]
returns the cross-validated classification margins on page 32-2809 obtained by \( \text{CVMdl} \), which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, kfoldMargin estimates the classification margins for observations that it holds out when it trains using all other observations.

\( \text{m} \) contains classification margins for each regularization strength in the linear classification models that comprise \( \text{CVMdl} \).

\[
m = \text{kfoldMargin}(\text{CVMdl},\text{Name,Value})
\]
uses additional options specified by one or more \( \text{Name,Value} \) pair arguments. For example, specify a decoding scheme or verbosity level.

**Input Arguments**

\( \text{CVMdl} \) — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model object using fitcecoc and by:

1 Specifying any one of the cross-validation, name-value pair arguments, for example, CrossVal
2 Setting the name-value pair argument Learners to 'linear' or a linear classification model template returned by templateLinear

To obtain estimates, kfoldMargin applies the same data used to cross-validate the ECOC model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**BinaryLoss** — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.
• This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j, s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>(-\infty, \infty)</td>
<td>( \log[1 + \exp(-2y_j s_j)]/2)log(2)</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>(-\infty, \infty)</td>
<td>( \exp(-y_j s_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or (-\infty, \infty)</td>
<td>( [1 - \text{sign}(y_j s_j)]/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>(-\infty, \infty)</td>
<td>( \max(0, 1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>(-\infty, \infty)</td>
<td>( (1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>(-\infty, \infty)</td>
<td>( \log[1 + \exp(-y_j s_j)]/2\log(2))</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j (2s_j - 1)]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

• For a custom binary loss function, e.g., \( \text{customFunction} \), specify its function handle
  `'BinaryLoss','@customFunction'``

  \( \text{customFunction} \) should have this form

  \[
  bLoss = \text{customFunction}(M,s)
  \]

  where:

  • \( M \) is the \( K \)-by-\( L \) coding matrix stored in \( \text{Mdl.CodingMatrix} \).
  • \( s \) is the 1-by-\( L \) row vector of classification scores.
  • \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  • \( K \) is the number of classes.
  • \( L \) is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

By default, if all binary learners are linear classification models using:

• SVM, then \( \text{BinaryLoss} \) is 'hinge'
• Logistic regression, then \( \text{BinaryLoss} \) is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

Example: 'Decoding', 'lossbased'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**m — Cross-validated classification margins**

numeric vector | numeric matrix

Cross-validated classification margins on page 32-2809, returned as a numeric vector or matrix.

m is n-by-L, where n is the number of observations in X and L is the number of regularization strengths in Mdl (that is, numel(Mdl.Lambda)).

m(i,j) is the cross-validated classification margin of observation i using the ECOC model, composed of linear classification models, that has regularization strength Mdl.Lambda(j).

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.
Y(~(ismember(Y,{'simulink','dsp','comm'})))) = 'others';

Cross-validate a multiclass, linear classification model.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the k-fold margins.

m = kfoldMargin(CVMdl);
size(m)
ans = 1x2
   31572    1

m is a 31572-by-1 vector. m(j) is the average of the out-of-fold margins for observation j.

Plot the k-fold margins using box plots.

figure;
boxplot(m);
h = gca;
h.YLim = [-5 5];
title('Distribution of Cross-Validated Margins')
Feature Selection Using $k$-fold Margins

One way to perform feature selection is to compare $k$-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in "Estimate $k$-Fold Cross-Validation Margins" on page 32-2802, and orient the predictor data so that observations correspond to columns.

```matlab
load nlpdata
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```matlab
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.
t = templateLinear('Solver','sparsa');

Cross-validate two ECOC models composed of binary, linear classification models: one that uses all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',... 'ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',... 'ObservationsIn','columns');

CVMdl and PCVMdl are ClassificationPartitionedLinearECOC models.

Estimate the k-fold margins for each classifier. Plot the distribution of the k-fold margins sets using box plots.

fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins], 'Labels',... {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')

The distributions of the k-fold margins of the two classifiers are similar.
Find Good Lasso Penalty Using $k$-fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of $k$-fold margins.

Load the NLP data set. Preprocess the data as in “Feature Selection Using $k$-fold Margins” on page 32-2804.

load nlpdata
Y(~ismember(Y,{'simulink','dsp','comm'})) = 'others';
X = X';

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^{1}$.

Lambda = logspace(-8,1,11);

Create a linear classification model template that specifies using logistic regression with a lasso penalty, using each of the regularization strengths, optimizing the objective function using SpaRSA, and reducing the tolerance on the gradient of the objective function to $1e^{-8}$.

t = templateLinear('Learner','logistic','Solver','sparsa',...    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)

CVMdl = 
    classificationPartitionedLinearECOC
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the $k$-fold margins for each regularization strength. The scores for logistic regression are in [0,1]. Apply the quadratic binary loss.

m = kfoldMargin(CVMdl,'BinaryLoss','quadratic');
size(m)

ans = 1×2

31572 11
m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k-fold margins for each regularization strength.

```matlab
figure;
boxplot(m)
ylabel('Cross-validated margins')
xlabel('Lambda indices')
```

Several values of Lambda yield similarly high margin distribution centers with low spreads. Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

```matlab
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength LambdaFinal.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda(5),'
    'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass MdlFinal and the new data to predict.
More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j)}{\sum_{j=1}^{L} m_{kj}}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).

<table>
<thead>
<tr>

<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j (2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.
Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**References**

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

marginStats=1×3 table
    Min     Mean      Max
-11.312  7.3236    23.517

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- **AdaBoostM1** scores range from $-\infty$ to $\infty$.
- **Bag** scores range from 0 to 1.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
Prune the tree:

```matlab
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from 0.15 to 0.94 as false. However, it incorrectly classifies observations that are greater than 0.94 as false. Therefore, the score for observations that are greater than 0.15 should be about $0.05/0.85 = 0.06$ for true, and about $0.8/0.85 = 0.94$ for false.

Compute the prediction scores for the first 10 rows of $X$:

```matlab
[~, score] = predict(tree1, X(1:10));
```

```
ans = 10×3
     0.9059    0.0941    0.8147
     0.9059    0.0941    0.9058
     0    1.0000    0.1270
     0.9059    0.0941    0.9134
     0.9059    0.0941    0.6324
     0    1.0000    0.0975
     0.9059    0.0941    0.2785
     0.9059    0.0941    0.5469
     0.9059    0.0941    0.9575
```
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range (.95, 1) instead of the expected 5 observations.

ClassificationPartitionedModel | crossval | kfoldEdge | kfoldLoss | kfoldPredict | kfoldfun
**kfoldPredict**

**Package:** classreg.learning.partition

Classify observations in cross-validated ECOC model

**Syntax**

```matlab
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(__)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)
```

**Description**

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for observations that it holds out during training. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

```matlab
[label,NegLoss,PBScore] = kfoldPredict(__)```
additionaly returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

```matlab
[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)```
additionaly returns posterior class probability estimates for validation-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the cross-validated ECOC model using `fitcecoc`. Otherwise, `kfoldPredict` throws an error.

**Examples**

**Predict k-Fold Cross-Validation Labels**

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
```
classOrder = unique(Y);
rng(1); % For reproducibility

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Predict the validation-fold labels. Print a random subset of true and predicted labels.

labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
     'VariableNames',{'TrueLabels','PredictedLabels'})

ans=10×2 table
    TrueLabels    PredictedLabels
    ________    _______________
    setosa          setosa
    versicolor      versicolor
    setosa          setosa
    virginica       virginica
    versicolor      versicolor
    setosa          setosa
    virginica       virginica
    virginica       virginica
    setosa          setosa
    setosa          setosa

CVMdl correctly labels the validation-fold observations with indices idx.

**Predict Cross-Validation Labels Using Custom Binary Loss Function**

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder);  % Number of classes
rng(1); % For reproducibility

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is \((-\infty, \infty)\). Create a custom binary loss function that:

- Maps the coding design matrix \( (M) \) and positive-class classification scores \( (s) \) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Alternatively, you can specify an anonymous binary loss function. In this case, create a function handle (customBL) to an anonymous binary loss function.

```matlab
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 validation-fold observations.

```matlab
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
idx = randsample(numel(label),10);
classOrder
classOrder = 3x1 categorical
    setosa
    versicolor
    virginica
table(Y(idx),label(idx),NegLoss(idx,:),'VariableNames',
      {'TrueLabel','PredictedLabel','NegLoss'})
```

<table>
<thead>
<tr>
<th>TrueLabel</th>
<th>PredictedLabel</th>
<th>NegLoss</th>
</tr>
</thead>
<tbody>
<tr>
<td>setosa</td>
<td>versicolor</td>
<td>0.37141</td>
</tr>
<tr>
<td>versicolor</td>
<td>versicolor</td>
<td>-1.2167</td>
</tr>
<tr>
<td>setosa</td>
<td>versicolor</td>
<td>0.23927</td>
</tr>
<tr>
<td>virginica</td>
<td>virginica</td>
<td>-1.9154</td>
</tr>
<tr>
<td>versicolor</td>
<td>versicolor</td>
<td>-1.3746</td>
</tr>
<tr>

<td>0.19999</td>
</tr>
<tr>
<td>setosa</td>
<td>versicolor</td>
<td>0.16108</td>
</tr>
</tbody>
</table>

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.
Estimate Cross-Validation Posterior Probabilities

Load Fisher's iris data set. Use the petal dimensions as the predictor data X. Specify the response data Y and the order of the classes in Y.

```matlab
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```matlab
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
t
```

The SVM template, `t`, is an SVM template. Most of its properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train and cross-validate an ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (returned by `kfoldPredict`) using the 'FitPosterior' name-value pair argument. Specify the class order.

```matlab
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
                'ClassNames',classOrder);
CVMdl
```

The `CVMdl` object is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities. Use 10 random initial values for the Kullback-Leibler algorithm.

```matlab
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all the binary learners compute posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```matlab
idx = randsample(size(X,1),10);
CVMdl.ClassNames
ans = 3x1 categorical
    setosa  versicolor  virginica

table(Y(idx),label(idx),Posterior(idx,:),...
      'VariableNames',{'TrueLabel','PredLabel','Posterior'});
ans=10×3 table
    TrueLabel     PredLabel                   Posterior
    ________    __________    ______________________________________
     versicolor    versicolor     0.0086394       0.98243     0.0089291
     versicolor    virginica     2.2197e-14       0.12447       0.87553
      setosa        setosa             0.999    0.00022837    0.00076884
     versicolor    versicolor    2.2194e-14       0.98916      0.010839
```

32-2818
The columns of Posterior correspond to the class order of CVMdl.ClassNames.

---

**Estimate Cross-Validation Posterior Probabilities Using Parallel Computing**

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the arrhythmia data set. Examine the response data Y.

```matlab
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

```
Value    Count   Percent
1      245     54.20%
2       44      9.73%
3       15      3.32%
4       15      3.32%
5       13      2.88%
6       25      5.53%
7        3      0.66%
8        2      0.44%
9        9      1.99%
10      50     11.06%
14        4      0.88%
15        5      1.11%
16       22      4.87%
```

```
n = numel(Y);
K = numel(unique(Y));
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```matlab
t = templateEnsemble('GentleBoost',50,'Tree');
t
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Because the response variable contains many classes, specify a sparse random coding design.

```matlab
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train and cross-validate an ECOC model using parallel computing. Fit posterior probabilities (returned by `kfoldPredict`).
pool = parpool;                      % Invokes workers
Starting parallel pool (parpool) using the 'local' profile ... 
connected to 6 workers.

options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'CrossVal','on');
Warning: One or more folds do not contain points from all the groups.

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold
cross-validation. You can specify a different number of folds using the 'KFold' name-value pair
argument.

The pool invokes six workers, although the number of workers might vary among systems. Because
some classes have low relative frequency, one or more folds most likely do not contain observations
from all classes.

Estimate posterior probabilities, and display the posterior probability of being classified as not having
arrhythmia (class 1) given the data for a random set of validation-fold observations.

[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),...
     'VariableNames',{'OOFSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
ans=10×3 table
     OOFSampleIndex    TrueLabel    PosteriorNoArrhythmia
        ______________    _________    _____________________

               72             16               0.9174
                3              10              0.025649
              202             1                 0.8438
              243             1                 0.9435
               18             1                 0.81198
               49              6               0.090154
              234             1                 0.61625
              315             1                 0.97187

Input Arguments

CVMdl — Cross-validated ECOC model
ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can
create a ClassificationPartitionedECOC model in two ways:

• Pass a trained ECOC model (ClassificationECOC) to crossval.
• Train an ECOC model using fitcecoc and specify any one of these cross-validation name-value
Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldPredict(CVMdl,'PosteriorMethod','qp')` specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle
---|---|---|---|---|---|---|---
Binary learner loss function, specified as the comma-separated pair consisting of `BinaryLoss` and a built-in loss function name or function handle.

- This table describes the built-in functions, where `y_j` is a class label for a particular binary learner (in the set `{-1,1,0}`), `s_j` is the score for observation `j`, and `g(y_j,s_j)` is the binary loss formula.

<table>
<thead>
<tr>

<td><code>[0,1]</code></td>
<td><code>[1 – y_j(2s_j – 1)]^2 / 2</code></td>
</tr>
</tbody>
</table>

The software normalizes binary losses so that the loss is 0.5 when `y_j = 0`. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `BinaryLoss','customFunction`.

`customFunction` has this form:

```
customFunction = customFunction(M,s)
```

where:

- `M` is the `K`-by-`L` coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by-`L` row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- `K` is the number of classes.
- `L` is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.
The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel classification models of SVM learners.</td>
<td>'hinge'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by AdaboostM1 or GentleBoost.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by LogitBoost.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior',true in <code>fitcecoc</code>.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

Example: `'Decoding','lossbased'`

**NumKLInitializations — Number of random initial values**

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod','kl' (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2825.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

**Options — Estimation options**

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel',true).

**PosteriorMethod** — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If PosteriorMethod is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2825.
- If PosteriorMethod is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-2826.
- If you do not request the fourth output argument (Posterior), then the software ignores the value of PosteriorMethod.

Example: 'PosteriorMethod','qp'

**Verbose** — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

**Output Arguments**

**label** — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

*label* has the same data type and number of rows as CVMdl.Y.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

**NegLoss** — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. *NegLoss* is an *n*-by-*K* matrix, where *n* is the number of observations (size(CVMdl.X,1)) and *K* is the number of unique classes (size(CVMdl.ClassNames,1)).
PBScore — Positive-class scores
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. PBScore is an n-by-L matrix, where \( n \) is the number of observations (size(CVMdl.X,1)) and \( L \) is the number of binary learners (size(CVMdl.CodingMatrix,2)).

If the coding matrix varies across folds (that is, the coding scheme is sparserandom or denserandom), then PBScore is empty ([[]]).

Posterior — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. Posterior is an n-by-K matrix, where \( n \) is the number of observations (size(CVMdl.X,1)) and \( K \) is the number of unique classes (size(CVMdl.ClassNames,1)).

You must set ‘FitPosterior’,1 when training the cross-validated ECOC model using fitcecoc in order to request Posterior. Otherwise, the software throws an error.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg \min_k \sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg \min_k \frac{\sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j)}{\sum_{j=1}^{L} m_{kj}}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.
This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set \{-1,1,0\}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.

<table>
<thead>
<tr>
<th>Value</th>

<td>$(1 - y_j (2s_j - 1))^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

### Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- $m_{kj}$ is the element $(k,j)$ of the coding design matrix $M$.
- $I$ is the indicator function.
- $\hat{p}_k$ is the class posterior probability estimate for class $k$ of an observation, $k = 1,\ldots,K$.
- $r_j$ is the positive-class posterior probability for binary learner $j$. That is, $r_j$ is the probability that binary learner $j$ classifies an observation into the positive class, given the training data.

#### Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$
\Delta(r, \hat{r}) = \sum_{j=1}^{K} w_j \left[ r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],
$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner $j$.

- $S_j$ is the set of observation indices on which binary learner $j$ is trained.
- $w_i^*$ is the weight of observation $i$. 

32-2825
The software minimizes the divergence iteratively. The first step is to choose initial values \( \hat{p}_k^{(0)}; k = 1, \ldots, K \) for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes \( \Delta \).
  - \( \hat{p}_k^{(0)} = 1/K; k = 1, \ldots, K \).
  - \( \hat{p}_k^{(0)}; k = 1, \ldots, K \) is the solution of the system

\[
M_{01} \hat{p}^{(0)} = r,
\]

where \( M_{01} \) is \( M \) with all \( m_{kj} = -1 \) replaced with 0, and \( r \) is a vector of positive-class posterior probabilities returned by the \( L \) binary learners [Dietterich et al.] on page 18-189. The software uses \texttt{lsqnonneg} to solve the system.

- If you specify 'NumKLIterations', \( c \), where \( c \) is a natural number, then the software does the following to choose the set \( \hat{p}_k^{(0)}; k = 1, \ldots, K \), and selects the set that minimizes \( \Delta \).
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates \( c \) vectors of length \( K \) using \texttt{rand}, and then normalizes each vector to sum to 1.

At iteration \( t \), the software completes these steps:

1. Compute

\[
\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.
\]

2. Estimate the next class posterior probability using

\[
\hat{p}_k^{(t+1)} = \frac{\sum_{j=1}^{L} w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^{L} w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.
\]

3. Normalize \( \hat{p}_k^{(t+1)}; k = 1, \ldots, K \) so that they sum to 1.

4. Check for convergence.

For more details, see [Hastie et al.] on page 18-190 and [Zadrozny] on page 18-191.

**Posterior Estimation Using Quadratic Programming**

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1. Estimate the positive-class posterior probabilities, \( r_j \), for binary learners \( j = 1, \ldots, L \).
Using the relationship between \( r_j \) and \( \hat{p}_k \) [Wu et al.] on page 18-191, minimize

\[
\sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = +1) \right]^2
\]

with respect to \( \hat{p}_k \) and the restrictions

\[
0 \leq \hat{p}_k \leq 1
\]

\[
\sum_{k} \hat{p}_k = 1.
\]

The software performs minimization using quadprog.

Extended Capabilities

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the ‘UseParallel’ option to true.

Set the ‘UseParallel’ field of the options structure to true using statset and specify the ‘Options’ name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the ‘Options’ name-value pair argument.
For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2014b**
**kfoldPredict**

**Package:** classreg.learning.partition

Classify observations in cross-validated kernel classification model

**Syntax**

```matlab
label = kfoldPredict(CVMdl)
[label,score] = kfoldPredict(CVMdl)
```

**Description**

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated, binary kernel model (ClassificationPartitionedKernel) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations.

`[label,score] = kfoldPredict(CVMdl)` also returns classification scores on page 32-2833 for both classes.

**Examples**

**Classify Observations Using Cross-Validation**

Classify observations using a cross-validated, binary kernel classifier, and display the confusion matrix for the resulting classification.

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```matlab
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```matlab
rng(1);  % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
```

**Properties, Methods**
CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Classify the observations that fitckernel does not use in training the folds.

```matlab
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```matlab
C = confusionchart(Y,label);
```

![Confusion Matrix Image]

The CVMdl model misclassifies 32 good ('g') radar returns as being bad ('b') and misclassifies 7 bad radar returns as being good.

**Estimate k-Fold Cross-Validation Posterior Class Probabilities**

Estimate posterior class probabilities using a cross-validated, binary kernel classifier, and determine the quality of the model by plotting a receiver operating characteristic (ROC) curve. Cross-validated kernel classification models return posterior probabilities for logistic regression learners only.

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').
load ionosphere

Cross-validate a binary kernel classification model using the data. Specify the class order, and fit logistic regression learners.

rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on', ... 
    'ClassNames',{'b','g'},'Learner','logistic')

CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Predict the posterior class probabilities for the observations that fitckernel does not use in training the folds.

[~,posterior] = kfoldPredict(CVMdl);

The output posterior is a matrix with two columns and n rows, where n is the number of observations. Column i contains posterior probabilities of CVMdl.ClassNames(i) given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.

[fpr,tpr,~,auc] = perfcurve(Y,posterior(:,2),CVMdl.ClassNames(2));
auc = 0.9441

The AUC is close to 1, which indicates that the model predicts labels well.

Plot an ROC curve.

plot(fpr,tpr)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
Input Arguments

**CVMdl** — Cross-validated, binary kernel classification model
ClassificationPartitionedKernel model object

Cross-validated, binary kernel classification model, specified as a ClassificationPartitionedKernel model object. You can create a ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the kernel classification model (X and Y).

Output Arguments

**label** — Predicted class labels
categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

**label** has `n` rows, where `n` is the number of observations in `X`, and has the same data type as the observed class labels (Y) used to train `CVMdl`. (The software treats string arrays as cell arrays of character vectors.)
kfoldPredict classifies observations into the class yielding the highest score.

**score — Classification scores**
numeric array

Classification scores on page 32-2833, returned as an n-by-2 numeric array, where n is the number of observations in X. score(i,j) is the score for classifying observation i into class j. The order of the classes is stored in CVMdl.ClassNames.

If CVMdl.Trained{1}.Learner is 'logistic', then classification scores are posterior probabilities.

**More About**

**Classification Score**

For kernel classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

\[ f(x) = T(x)\beta + b. \]

- \( T(\cdot) \) is a transformation of an observation for feature expansion.
- \( \beta \) is the estimated column vector of coefficients.
- \( b \) is the estimated scalar bias.

The raw classification score for classifying x into the negative class is \(-f(x)\). The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

ClassificationPartitionedKernel | fitckernel

**Introduced in R2018b**
**kfoldPredict**

**Package:** classreg.learning.partition

Classify observations in cross-validated kernel ECOC model

**Syntax**

```matlab
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(___)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)
```

**Description**

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations. `kfoldPredict` applies the same data used to create `CVMdl` (see `fitcecoc`).

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(__)` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)` additionally returns posterior class probability estimates for validation-fold observations (`Posterior`).

To obtain posterior class probabilities, the kernel classification binary learners must be logistic regression models. Otherwise, `kfoldPredict` throws an error.

**Examples**

**Classify Observations Using Cross-Validation**

Classify observations using a cross-validated, multiclass kernel ECOC classifier, and display the confusion matrix for the resulting classification.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.
load fisheriris
X = meas;
Y = species;

Cross-validate an ECOC model composed of kernel binary learners.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements
10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair
argument instead of 'CrossVal'.

Classify the observations that fitcecoc does not use in training the folds.

label = kfoldPredict(CVMdl);

Construct a confusion matrix to compare the true classes of the observations to their predicted
labels.

C = confusionchart(Y,label);
The CVMdl model misclassifies four 'versicolor' irises as 'virginica' irises and misclassifies one 'virginica' iris as a 'versicolor' iris.

**Predict Cross-Validation Labels Using Custom Binary Loss**

Load Fisher's iris data set. $X$ contains flower measurements, and $Y$ contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model of kernel classification models using 5-fold cross-validation.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','KFold',5)
```

```matlab
CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
  CrossValidatedModel: 'KernelECOC'
  ResponseName: 'Y'
  NumObservations: 150
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: {'setosa' 'versicolor' 'virginica'}
```
CVMdl is a ClassificationPartitionedKernelECOC model. It contains the property Trained, which is a 5-by-1 cell array of CompactClassificationECOC models.

By default, the kernel classification models that compose the CompactClassificationECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is \((- \infty, \infty)\). Create a custom binary loss function that:

- Maps the coding design matrix \((M)\) and positive-class classification scores \((s)\) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (customBL) to an anonymous binary loss function.

\[
customBL = @(M,s)\text{nanmedian}(1 - \text{bsxfun}(@times,M,s),2)/2;
\]

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

\[
[label,NegLoss] = \text{kfoldPredict}(CVMdl,'BinaryLoss',customBL);
\]

\[
\text{idx} = \text{randsample}(\text{numel}(\text{label}),10);
\]

\[
\text{table}(\text{Y(idx)},\text{label(idx)},\text{NegLoss(idx,1)},\text{NegLoss(idx,2)},\text{NegLoss(idx,3)},...\text{,'VariableNames',\{'True'};\{'Predicted'};...\text{,'Unique'}(\text{CVMdl.ClassNames}))}
\]

The cross-validated model correctly predicts the labels for 9 of the 10 random observations.
**Estimate k-Fold Cross-Validation Posterior Class Probabilities**

Estimate posterior class probabilities using a cross-validated, multiclass kernel ECOC classification model. Kernel classification models return posterior probabilities for logistic regression learners only.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Create a kernel template for the binary kernel classification models. Specify to fit logistic regression learners.

```matlab
t = templateKernel('Learner','logistic')
t = 
Fit template for classification Kernel.

   BetaTolerance: [ ]
  BlockSize: [ ]
  BoxConstraint: [ ]
  Epsilon: [ ]
  NumExpansionDimensions: [ ]
  GradientTolerance: [ ]
  HessianHistorySize: [ ]
  IterationLimit: [ ]
  KernelScale: [ ]
  Lambda: [ ]
  Learner: 'logistic'
  LossFunction: [ ]
  Stream: [ ]
  VerbosityLevel: [ ]
  Version: 1
  Method: 'Kernel'
  Type: 'classification'
```

t is a kernel template. Most of its properties are empty. When training an ECOC classifier using the template, the software sets the applicable properties to their default values.

Cross-validate an ECOC model using the kernel template.

```matlab
rng('default'); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on')
```

```matlab
CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```
CVMdl is a ClassificationPartitionedECOC model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities.

[label,~,~,Posterior] = kfoldPredict(CVMdl);

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display the posterior probabilities for 10 randomly selected observations.

idx = randsample(size(X,1),10);
CVMdl.ClassNames
ans = 3x1 cell
{'setosa'    }
{'versicolor'}
{'virginica' }

table(Y(idx),label(idx),Posterior(idx,:),...'
VariableNames',{'TrueLabel','PredLabel','Posterior'})
ans=10×3 table
  TrueLabel      PredLabel             Posterior
    {'setosa'    }    {'setosa'    }     0.68216     0.18546     0.13238
    {'virginica' }    {'virginica' }      0.1581     0.14405     0.69785
    {'virginica' }    {'virginica' }    0.071807    0.093291      0.8349
    {'setosa'    }    {'setosa'    }     0.74918     0.11434     0.13648
    {'versicolor'}    {'versicolor'}     0.09375     0.67149     0.23476
    {'versicolor'}    {'versicolor'}      0.036202     0.85544      0.10836
    {'versicolor'}    {'versicolor'}     0.2252     0.50473     0.27007
    {'virginica' }    {'virginica' }    0.061562     0.11086     0.82758
    {'setosa'    }    {'setosa'    }     0.42448    0.21181     0.36371
    {'virginica' }    {'virginica' }     0.082705     0.1428    0.7745

The columns of Posterior correspond to the class order of CVMdl.ClassNames.

Input Arguments

CVMdl — Cross-validated kernel ECOC model
ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners'- Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
• One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example: kfoldPredict(CVMdl,'PosteriorMethod','qp') specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic'

| function handle |

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j,s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>(-\infty,\infty)</td>
<td>( \frac{\log(1 + \exp(-2y_js_j))}{2\log(2)} )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>(-\infty,\infty)</td>
<td>( \exp(-y_js_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty,\infty))</td>
<td>( \frac{[1 - \text{sign}(y_js_j)]}{2} )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>(-\infty,\infty)</td>
<td>( \frac{\max(0,1 - y_js_j)}{2} )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>(-\infty,\infty)</td>
<td>( \frac{1 - y_js_j}{2} )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>(-\infty,\infty)</td>
<td>( \frac{\log(1 + \exp(-y_js_j))/2\log(2)} )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( \frac{[1 - y_j(2s_j - 1)]^2}{2} )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss', customFunction.

customFunction has this form:

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in Mdl.CodingMatrix.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
• \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then \( \text{BinaryLoss} \) is 'hinge'. If all binary learners are kernel classification models using logistic regression, then \( \text{BinaryLoss} \) is 'quadratic'.

Example: \('\text{BinaryLoss}', 'binodeviance'\)

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2843.

Example: \('\text{Decoding}', 'lossbased'\)

**NumKLInitializations — Number of random initial values**

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2844.

Example: \('\text{NumKLInitializations}', 5\)

Data Types: single | double

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel', true).

**PosteriorMethod — Posterior probability estimation method**

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

• If PosteriorMethod is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2844.
If PosteriorMethod is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-2845.

If you do not request the fourth output argument (Posterior), then the software ignores the value of PosteriorMethod.

Example: 'PosteriorMethod','qp'

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

**Output Arguments**

**label — Predicted class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

label has the same data type and number of rows as CVMdl.Y.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

**NegLoss — Negated average binary losses**

numeric matrix

Negated average binary losses, returned as a numeric matrix. NegLoss is an n-by-K matrix, where n is the number of observations (size(CVMdl.Y,1)) and K is the number of unique classes (size(CVMdl.ClassNames,1)).

**PBScore — Positive-class scores**

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. PBScore is an n-by-L matrix, where n is the number of observations (size(CVMdl.Y,1)) and L is the number of binary learners (size(CVMdl.CodingMatrix,2)).

If the coding matrix varies across folds (that is, the coding scheme is sparserandom or denserandom), then PBScore is empty ([]).

**Posterior — Posterior class probabilities**

numeric matrix
Posterior class probabilities, returned as a numeric matrix. Posterior is an \( n \)-by-\( K \) matrix, where \( n \) is the number of observations (size(CVMdl.Y,1)) and \( K \) is the number of unique classes (size(CVMdl.ClassNames,1)).

To return posterior probabilities, each kernel classification binary learner must have its Learner property set to ‘logistic’. Otherwise, the software throws an error.

**More About**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \text{argmin}_k \sum_{j=1}^{L} |m_{kj}|g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \text{argmin}_k \frac{\sum_{j=1}^{L} |m_{kj}|g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).

</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Algorithms**

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- \(m_{kj}\) is the element \((k,j)\) of the coding design matrix \(M\).
- \(I\) is the indicator function.
- \(\hat{p}_k\) is the class posterior probability estimate for class \(k\) of an observation, \(k = 1,\ldots,K\).
- \(r_j\) is the positive-class posterior probability for binary learner \(j\). That is, \(r_j\) is the probability that binary learner \(j\) classifies an observation into the positive class, given the training data.

**Posterior Estimation Using Kullback-Leibler Divergence**

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

\[
\Delta(r, \hat{r}) = \sum_{j=1}^{L} w_j \left[ r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],
\]

where \(w_j = \sum_{S_j} w_i\) is the weight for binary learner \(j\).

- \(S_j\) is the set of observation indices on which binary learner \(j\) is trained.
- \(w_i\) is the weight of observation \(i\).

The software minimizes the divergence iteratively. The first step is to choose initial values \(\hat{p}_k^{(0)}; k = 1,\ldots,K\) for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes \(\Delta\).
  - \(\hat{p}_k^{(0)} = 1/K; k = 1,\ldots,K\).
  - \(\hat{p}_k^{(0)}; k = 1,\ldots,K\) is the solution of the system.
\[ M_{01} \tilde{p}^{(0)} = r, \]

where \( M_{01} \) is \( M \) with all \( m_{kj} = -1 \) replaced with 0, and \( r \) is a vector of positive-class posterior probabilities returned by the \( L \) binary learners [Dietterich et al.] on page 18-189. The software uses \texttt{lsqnonneg} to solve the system.

- If you specify ‘\texttt{NumKLIterations}', \( c \), where \( c \) is a natural number, then the software does the following to choose the set \( \tilde{p}_k^{(0)}; \ k = 1, \ldots, K \), and selects the set that minimizes \( \Delta \).
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates \( c \) vectors of length \( K \) using \texttt{rand}, and then normalizes each vector to sum to 1.

At iteration \( t \), the software completes these steps:

1. Compute
   \[
   \tilde{r}^{(t)}_j = \frac{\sum_{k=1}^{K} \tilde{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \tilde{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.
   \]

2. Estimate the next class posterior probability using
   \[
   \tilde{p}_k^{(t+1)} = \frac{\tilde{r}_j^{(t)} \sum_{j=1}^{L} w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^{L} w_j [\tilde{r}_j^{(t)} I(m_{kj} = +1) + (1 - \tilde{r}_j^{(t)}) I(m_{kj} = -1)]}.
   \]

3. Normalize \( \tilde{p}_k^{(t+1)}; \ k = 1, \ldots, K \) so that they sum to 1.

4. Check for convergence.

For more details, see [Hastie et al.] on page 18-190 and [Zadrozny] on page 18-191.

**Posterior Estimation Using Quadratic Programming**

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1. Estimate the positive-class posterior probabilities, \( r_j \), for binary learners \( j = 1, \ldots, L \).
2. Using the relationship between \( r_j \) and \( \tilde{p}_k \) [Wu et al.] on page 18-191, minimize
   \[
   \sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \tilde{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \tilde{p}_k I(m_{kj} = +1) \right]^2
   \]
   with respect to \( \tilde{p}_k \) and the restrictions
   \[
   0 \leq \tilde{p}_k \leq 1, \quad \sum_k \tilde{p}_k = 1.
   \]
The software performs minimization using \texttt{quadprog}.

\textit{Introduced in R2018b}
**kfoldPredict**

Predict labels for observations not used for training

**Syntax**

```latex
Label = kfoldPredict(CVMdl)
[Label,Score] = kfoldPredict(CVMdl)
```

**Description**

`Label = kfoldPredict(CVMdl)` returns cross-validated class labels predicted by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations.

`Label` contains predicted class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`[Label,Score] = kfoldPredict(CVMdl)` also returns cross-validated classification scores on page 32-2854 for both classes. `Score` contains classification scores for each regularization strength in `CVMdl`.

**Input Arguments**

- **CVMdl** — Cross-validated, binary, linear classification model
  ClassificationPartitionedLinear model object

  Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model object using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

  To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the linear classification model (X and Y).

**Output Arguments**

- **Label** — Cross-validated, predicted class labels
  categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

  Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

  In most cases, `Label` is an n-by-L array of the same data type as the observed class labels (see Y) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in the predictor data (see X) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. That is, `Label(i,j)` is the predicted class label for observation i using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`. 

---

32-2847
If \( Y \) is a character array and \( L > 1 \), then \( \text{Label} \) is a cell array of class labels.

**Score — Cross-validated classification scores**

numeric array

Cross-validated classification scores on page 32-2854, returned as an \( n \)-by-2-by-\( L \) numeric array. \( n \) is the number of observations in the predictor data that created \( \text{CVMdl} \) (see \( X \)) and \( L \) is the number of regularization strengths in \( \text{CVMdl.Trained{1}.Lambda} \). \( \text{Score}(i,k,j) \) is the score for classifying observation \( i \) into class \( k \) using the linear classification model that has regularization strength \( \text{CVMdl.Trained{1}.Lambda}(j) \). \( \text{CVMdl.ClassNames} \) stores the order of the classes.

If \( \text{CVMdl.Trained{1}.Learner} \) is 'logistic', then classification scores are posterior probabilities.

**Examples**

**Predict k-fold Cross-Validation Labels**

Load the NLP data set.

```matlab
load nlpdata
```

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```matlab
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
Mdl1 = CVMdl.Trained{1}
```

\( \text{Mdl1} \) is a `ClassificationLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.
Predict labels for the observations that fitlinear did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in Mdl1, label is a column vector of predictions containing as many rows as observations in X.

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Ystats,label);
```

The model misclassifies 15 'stats' documentation pages as being outside of the Statistics and Machine Learning Toolbox documentation, and misclassifies nine pages as 'stats' pages.

**Estimate k-fold Cross-Validation Posterior Class Probabilities**

Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict k-fold Cross-Validation Labels” on page 32-2848. Transpose the predictor data matrix.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```
Cross-validate binary, linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to 1e-8.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','GradientTolerance',1e-8);
```

Predict the posterior class probabilities for observations not used to train each fold.

```matlab
 [~,posterior] = kfoldPredict(CVMdl);
 CVMdl.ClassNames
 ans = 2x1 logical array
     0
     1
```

Because there is one regularization strength in `CVMdl`, `posterior` is a matrix with 2 columns and rows equal to the number of observations. Column `i` contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```matlab
[fpr,tpr,~,auc] = perfcurve(Ystats,posterior(:,2),CVMdl.ClassNames(2));
auc
 auc = 0.9990
```

The AUC is 0.9990, which indicates a model that predicts well.

Plot an ROC curve.

```matlab
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```
The ROC curve indicates that the model classifies almost perfectly.

**Find Good Lasso Penalty Using Cross-Validated AUC**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare cross-validated AUC values.

Load the NLP data set. Preprocess the data as in “Estimate k-fold Cross-Validation Posterior Class Probabilities” on page 32-2849.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

There are 9471 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

```matlab
Lambda = logspace(-6,-0.5,11);
```

Cross-validate a binary, linear classification models that use each of the regularization strengths and 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e^{-8}$.
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',
    'KFold',5,'Learner','logistic','Solver','sparsa',
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl = classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Properties, Methods

Mdl1 = CVMdl.Trained{1}

Mdl1 = ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023×11 double]
    Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.0071 0.0251 0.0891 0.3162]
    Learner: 'logistic'

Properties, Methods

Mdl1 is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Predict the cross-validated labels and posterior class probabilities.

[label,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames;
[n,K,L] = size(posterior)

n = 31572
K = 2
L = 11
posterior(3,1,5)
ans = 1.0000

label is a 31572-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. posterior is a 31572-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, posterior(3,1,5) indicates that the posterior probability
that the first class (label 0) is assigned to observation 3 by the model that uses \texttt{Lambda}(5) as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

```matlab
auc = 1:numel(Lambda);  % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(Ystats,posterior(:,2,j),CVMdl.ClassNames(2));
end
```

Higher values of \texttt{Lambda} lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```matlab
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns','
    'Learner','logistic','Solver','sparsa','Regularization','lasso',
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta==0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```matlab
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'
    \text{log}_{10} \text{ AUC}')
ylabel(h(2),'
    \text{log}_{10} \text{ nonzero-coefficient frequency}')
xlabel('\text{log}_{10} \text{ Lambda}')
title('Cross-Validated Statistics')
hold off
```
Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between $10^{-3}$ to $10^{-1}$ should suffice.

```matlab
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```matlab
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

### More About

#### Classification Score

For linear classification models, the raw classification score for classifying the observation $x$, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$ 

For the model with regularization strength $j$, $\beta_j$ is the estimated column vector of coefficients (the model property `Beta(:,j)`), and $b_j$ is the estimated, scalar bias (the model property `Bias(j)`).
The raw classification score for classifying x into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**See Also**

ClassificationLinear | ClassificationPartitionedLinear | confusionchart | perfcurve | predict | testcholdout

*Introduced in R2016a*
**kfoldPredict**

Predict labels for observations not used for training

**Syntax**

Label = kfoldPredict(CVMdl)
Label = kfoldPredict(CVMdl,Name,Value)
[Label,NegLoss,PBScore] = kfoldPredict(____)
[Label,NegLoss,PBScore,Posterior] = kfoldPredict(____)

**Description**

Label = kfoldPredict(CVMdl) returns class labels predicted by the cross-validated ECOC model composed of linear classification models CVMdl. That is, for every fold, kfoldPredict predicts class labels for observations that it holds out when it trains using all other observations. kfoldPredict applies the same data used create CVMdl (see fitcecoc).

Also, Label contains class labels for each regularization strength in the linear classification models that compose CVMdl.

Label = kfoldPredict(CVMdl,Name,Value) returns predicted class labels with additional options specified by one or more Name,Value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

[Label,NegLoss,PBScore] = kfoldPredict(____) additionally returns, for held-out observations and each regularization strength:

- Negated values of the average binary loss per class (NegLoss).
- Positive-class scores (PBScore) for each binary learner.

[Label,NegLoss,PBScore,Posterior] = kfoldPredict(____) additionally returns posterior class probability estimates for held-out observations and for each regularization strength. To return posterior probabilities, the linear classification model learners must be logistic regression models.

**Input Arguments**

**CVMdl — Cross-validated, ECOC model composed of linear classification models**

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model object using fitcecoc and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, CrossVal
2. Setting the name-value pair argument Learners to 'linear' or a linear classification model template returned by templateLinear

To obtain estimates, kfoldPredict applies the same data used to cross-validate the ECOC model (X and Y).
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

BinaryLoss — Binary learner loss function

'StructuralValue' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>

</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction should have this form

\[
bLoss = \text{customFunction}(M,s)\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in Mdl.CodingMatrix.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

By default, if all binary learners are linear classification models using:
• SVM, then BinaryLoss is 'hinge'
• Logistic regression, then BinaryLoss is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-2824.

Example: 'Decoding','lossbased'

**NumKLInitializations — Number of random initial values**

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

To use this option, you must:

• Return the fourth output argument (Posterior).
• The linear classification models that compose the ECOC models must use logistic regression learners (that is, CVMdl.Trained{1}.BinaryLearners{1}.Learner must be 'logistic').
• PosteriorMethod must be 'kl'.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2866.

Example: 'NumKLInitializations',5

Data Types: single | double

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options',statset('UseParallel',true).

**PosteriorMethod — Posterior probability estimation method**

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

• To use this option, you must return the fourth output argument (Posterior) and the linear classification models that compose the ECOC models must use logistic regression learners (that is, CVMdl.Trained{1}.BinaryLearners{1}.Learner must be 'logistic').
• If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-2866.

• If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-2867.

Example: 'PosteriorMethod','qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

Label — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an `n`-by-`L` array of the same data type as the observed class labels (`Y`) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) `n` is the number of observations in the predictor data (`X`) and `L` is the number of regularization strengths in the linear classification models that compose the cross-validated ECOC model. That is, `Label(i,j)` is the predicted class label for observation `i` using the ECOC model of linear classification models that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If `Y` is a character array and `L` > 1, then `Label` is a cell array of class labels.

The software assigns the predicted label corresponding to the class with the largest, negated, average binary loss (`NegLoss`), or, equivalently, the smallest average binary loss.

NegLoss — Cross-validated, negated, average binary losses

numeric array

Cross-validated, negated, average binary losses, returned as an `n`-by-`K`-by-`L` numeric matrix or array. `K` is the number of distinct classes in the training data and columns correspond to the classes in `CVMdl.ClassNames`. For `n` and `L`, see `Label`. `NegLoss(i,k,j)` is the negated, average binary loss for classifying observation `i` into class `k` using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLoss{1}.Lambda(j)`.

PBScore — Cross-validated, positive-class scores

numeric array

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.
Cross-validated, positive-class scores, returned as an \( n \)-by-\( B \)-by-\( L \) numeric array. \( B \) is the number of binary learners in the cross-validated ECOC model and columns correspond to the binary learners in `CVMdl.Trained{1}.BinaryLearners`. For \( n \) and \( L \), see `Label`. \( PBScore(i,b,j) \) is the positive-class score of binary learner \( b \) for classifying observation \( i \) into its positive class, using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (\([]\)).

**Posterior — Cross-validated posterior class probabilities**
numeric array

Cross-validated posterior class probabilities, returned as an \( n \)-by-\( K \)-by-\( L \) numeric array. For dimension definitions, see `NegLoss`. \( Posterior(i,k,j) \) is the posterior probability for classifying observation \( i \) into class \( k \) using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

To return posterior probabilities, `CVMdl.Trained{1}.BinaryLearner{1}.Learner` must be `'logistic'`.

**Examples**

**Predict k-fold Cross-Validation Labels**

Load the NLP data set.

```matlab
load nlpdata
```

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

Predict labels for the observations that `fitcecoc` did not use in training the folds.

```matlab
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `CVMdl`, `label` is a column vector of predictions containing as many rows as observations in `X`.

Construct a confusion matrix.

```matlab
cm = confusionchart(Y,label);
```
Specify Custom Binary Loss

Load the NLP data set. Transpose the predictor data.

```matlab
load nlpdata
X = X';
```

For simplicity, use the label 'others' for all observations in `Y` that are not 'simulink', 'dsp', or 'comm'.

```matlab
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

```matlab
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}
```

```matlab
CMdl1 =
    classreg.learning.classif.CompactClassificationECOC
```

```

Predicted Class
CVMdl is a ClassificationPartitionedLinearECOC model. It contains the property Trained, which is a 5-by-1 cell array holding a CompactClassificationECOC models that the software trained using the training set of each fold.

By default, the linear classification models that compose the ECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$.

Create a custom binary loss function that:

- Maps the coding design matrix ($M$) and positive-class classification scores ($s$) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
```

```
idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
    NegLoss(idx,4),'VariableNames',{[{'True'};{'Predicted'};...
    categories(CVMdl.ClassNames)})
```

```
ans=10×6 table

```

The software predicts the label based on the maximum negated loss.
Estimate Posterior Class Probabilities

ECOC models composed of linear classification models return posterior probabilities for logistic regression learners only. This example requires the Parallel Computing Toolbox™ and the Optimization Toolbox™.

Load the NLP data set and preprocess the data as in “Specify Custom Binary Loss” on page 32-2861.

```matlab
load nlpdata
X = X';
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 5 logarithmically-spaced regularization strengths from $10^{-5}$ through $10^{-0.5}$.

```matlab
Lambda = logspace(-6,-0.5,5);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA and to use logistic regression learners.

```matlab
t = templateLinear('Solver','sparsa','Learner','logistic','Lambda',Lambda);
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns, and to use parallel computing.

```matlab
rng(1); % For reproducibility
Options = statset('UseParallel',true);
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns',...
    'Options',Options);
```

Predict the cross-validated posterior class probabilities. Specify to use parallel computing and to estimate posterior probabilities using quadratic programming.

```matlab
[label,~,~,Posterior] = kfoldPredict(CVMdl,'Options',Options,...
    'PosteriorMethod','qp');
size(label)
label(3,4)
size(Posterior)
Posterior(3,:,4)
```

```matlab
ans =
    31572         5
```

```matlab
ans =
categorical
   others
```

```matlab
ans =
```
Because there are five regularization strengths:

- **label** is a 31572-by-5 categorical array. `label(3,4)` is the predicted, cross-validated label for observation 3 using the model trained with regularization strength `Lambda(4)`.
- **Posterior** is a 31572-by-4-by-5 matrix. `Posterior(3,:,4)` is the vector of all estimated, posterior class probabilities for observation 3 using the model trained with regularization strength `Lambda(4)`. The order of the second dimension corresponds to `CVMdl.ClassNames`. Display a random set of 10 posterior class probabilities.

Display a random sample of cross-validated labels and posterior probabilities for the model trained using `Lambda(4)`.

```matlab
idx = randsample(size(label,1),10);
table(Y(idx),label(idx,4),Posterior(idx,1,4),Posterior(idx,2,4),...
    Posterior(idx,3,4),Posterior(idx,4,4),...
    'VariableNames',{{'True'};'Predicted'};categories(CVMdl.ClassNames))
```

```
ans =

**More About**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
• \( s_j \) is the score of binary learner \( j \) for an observation.
• \( g \) is the binary loss function.
• \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L \left| m_{kj} \right| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L \left| m_{kj} \right| g(m_{kj}, s_j)}{\sum_{j=1}^L \left| m_{kj} \right|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{–1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).

</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Algorithms**

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

---
• $m_{kj}$ is the element $(k,j)$ of the coding design matrix $M$.
• $I$ is the indicator function.
• $\hat{p}_k$ is the class posterior probability estimate for class $k$ of an observation, $k = 1,...,K$.
• $r_j$ is the positive-class posterior probability for binary learner $j$. That is, $r_j$ is the probability that binary learner $j$ classifies an observation into the positive class, given the training data.

**Posterior Estimation Using Kullback-Leibler Divergence**

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \bar{r}) = \sum_{j=1}^{L} w_j \left[ r_j \log \frac{r_j}{\bar{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \bar{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner $j$.

• $S_j$ is the set of observation indices on which binary learner $j$ is trained.
• $w_i^*$ is the weight of observation $i$.

The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, ..., K$ for the class posterior probabilities.

• If you do not specify `NumKLIterations`, then the software tries both sets of deterministic initial values described next, and selects the set that minimizes $\Delta$.
  • $\hat{p}_k^{(0)} = 1/K$; $k = 1, ..., K$.
  • $\hat{p}_k^{(0)}$; $k = 1, ..., K$ is the solution of the system

$$M_{01} \hat{p}_k^{(0)} = r,$$

where $M_{01}$ is $M$ with all $m_{kj} = -1$ replaced with 0, and $r$ is a vector of positive-class posterior probabilities returned by the $L$ binary learners [Dietterich et al.] on page 18-189. The software uses lsqnonneg to solve the system.

• If you specify `NumKLIterations`, $c$, where $c$ is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)}$; $k = 1, ..., K$, and selects the set that minimizes $\Delta$.
  • The software tries both sets of deterministic initial values as described previously.
  • The software randomly generates $c$ vectors of length $K$ using rand, and then normalizes each vector to sum to 1.

At iteration $t$, the software completes these steps:

1. Compute

$$\bar{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1) \cup m_{kj} = -1)},$$

where $I$ is the indicator function.

32-2866
2 Estimate the next class posterior probability using

\[
\hat{p}_k^{(t+1)} = \frac{\sum_{j=1}^{L} w_j[ r_j I(m_k = 1) + (1 - r_j) I(m_k = -1) ]}{\sum_{j=1}^{L} w_j[ \hat{r}_j^{(t)} I(m_k = 1) + (1 - \hat{r}_j^{(t)}) I(m_k = -1) ]}.
\]

3 Normalize \(\hat{p}_k^{(t+1)}; \ k = 1, \ldots, K\) so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-190 and [Zadrozny] on page 18-191.

**Posterior Estimation Using Quadratic Programming**

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1 Estimate the positive-class posterior probabilities, \(r_j\), for binary learners \(j = 1, \ldots, L\).

2 Using the relationship between \(r_j\) and \(\hat{p}_k\) [Wu et al.] on page 18-191, minimize

\[
\sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \hat{p}_k I(m_k = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_k = 1) \right]^2
\]

with respect to \(\hat{p}_k\) and the restrictions

\[
0 \leq \hat{p}_k \leq 1
\]

\[
\sum_k \hat{p}_k = 1.
\]

The software performs minimization using \texttt{quadprog}.

### Extended Capabilities

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

### Introduced in R2016a
**kfoldPredict**

Predict response for observations not used for training

**Syntax**

```matlab
label = kfoldPredict(obj)
[label,score] = kfoldPredict(obj)
[label,score,cost] = kfoldPredict(obj)
```

**Description**

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label,score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label,score,cost] = kfoldPredict(obj)` returns misclassification costs.

**Input Arguments**

`obj`  
Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

**Output Arguments**

`label`  
Vector of class labels of the same type as the response data used in training `obj`. (The software treats string arrays as cell arrays of character vectors.) Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

`score`  
Numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `obj.X`, and `K` is the number of classes (in `obj.ClassNames`). `score(i,j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “More About” on page 32-2871.

`cost`  
Numeric matrix of misclassification costs of size `N`-by-`K`. `cost(i,j)` is the average misclassification cost of predicting that row `i` of `obj.X` is of class `j`.

**Examples**
Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Train an ensemble of classification trees using AdaBoostM2. Specify tree stumps as the weak learners.

```matlab
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Cross validate the trained ensemble using 10-fold cross validation.

```matlab
CVMdl = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```matlab
[elabel,escore] = kfoldPredict(CVMdl);
```

Display the maximum and minimum scores of each class.

```matlab
max(escore)
an = 1x3
    9.3862    8.9871   10.1866

min(escore)
an = 1x3
    0.0017    3.8359    0.8981
```

Create Confusion Matrix Using Cross-Validation Predictions

Create a confusion matrix using the 10-fold cross-validation predictions of a discriminant analysis model.

Load the `fisheriris` data set. X contains flower measurements for 150 different flowers, and y lists the species, or class, for each flower. Create a variable `order` that specifies the order of the classes.

```matlab
load fisheriris
X = meas;
y = species;
order = unique(y)
order = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```
Create a 10-fold cross-validated discriminant analysis model by using the `fitcdiscr` function. By default, `fitcdiscr` ensures that training and test sets have roughly the same proportions of flower species. Specify the order of the flower classes.

cvmdl = fitcdiscr(X,y,'KFold',10,'ClassNames',order);

Predict the species of the test set flowers.
predictedSpecies = kfoldPredict(cvmdl);

Create a confusion matrix that compares the true class values to the predicted class values.
confusionchart(y,predictedSpecies)

More About

Cost (discriminant analysis)

The average misclassification cost is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 20-7.
Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
Prune the tree:

tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3
     0.9059    0.0941    0.8147
     0.9059    0.0941    0.9058
     0    1.0000    0.1270
     0.9059    0.0941    0.9134
     0.9059    0.0941    0.6324
     0    1.0000    0.0975
     0.9059    0.0941    0.2785
     0.9059    0.0941    0.5469
     0.9059    0.0941    0.9575
```
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range $(0.95, 1)$ instead of the expected 5 observations.

**kfoldPredict**

Predict responses for observations not used for training

**Syntax**

\[ \text{YHat} = \text{kfoldPredict}(\text{CVMdl}) \]

**Description**

\[ \text{YHat} = \text{kfoldPredict}(\text{CVMdl}) \]

returns cross-validated predicted responses by the cross-validated linear regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts responses for observations that it holds out when it trains using all other observations.

\[ \text{YHat} \]

contains predicted responses for each regularization strength in the linear regression models that compose `CVMdl`.

**Input Arguments**

**CVMdl** — Cross-validated, linear regression model

`RegressionPartitionedLinear` model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the linear regression model (\(X\) and \(Y\)).

**Output Arguments**

**YHat** — Cross-validated predicted responses

numeric array

Cross-validated predicted responses, returned as an \(n\)-by-\(L\) numeric array. \(n\) is the number of observations in the predictor data that created `CVMdl` (see \(X\)) and \(L\) is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. \(\text{YHat}(i,j)\) is the predicted response for observation \(i\) using the linear regression model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`.

The predicted response using the model with regularization strength \(j\) is \(\hat{y}_j = x\beta_j + b_j\).

- \(x\) is an observation from the predictor data matrix \(X\), and is row vector.
- \(\beta_j\) is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,j)`.
- \(b_j\) is the estimated, scalar bias, which the software stores in `Mdl.Bias(j)`.

**Examples**
Predict Cross-Validated Responses

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10\% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

\[
\begin{align*}
\text{rng}(1) & \quad \text{For reproducibility} \\
n & = 1e4; \\
d & = 1e3; \\
nz & = 0.1; \\
X & = \text{sprandn}(n,d,nz); \\
Y & = X(:,100) + 2X(:,200) + 0.3*\text{randn}(n,1);
\end{align*}
\]

Cross-validate a linear regression model.

\[
\text{CVMdl} = \text{fitrlinear}(X,Y,'CrossVal','on')
\]

\[
\text{CVMdl} = \text{classreg.learning.partition.RegressionPartitionedLinear} \\
\quad \text{CrossValidatedModel: 'Linear'} \\
\quad \text{ResponseName: 'Y'} \\
\quad \text{NumObservations: 10000} \\
\quad \text{KFold: 10} \\
\quad \text{Partition: [1x1 cvpartition]} \\
\quad \text{ResponseTransform: 'none'}
\]

Properties, Methods

\[
\text{Mdl1} = \text{CVMdl.Trained{1}}
\]

\[
\text{Mdl1} = \text{RegressionLinear} \\
\quad \text{ResponseName: 'Y'} \\
\quad \text{ResponseTransform: 'none'} \\
\quad \text{Beta: [1000x1 double]} \\
\quad \text{Bias: 0.0107} \\
\quad \text{Lambda: 1.1111e-04} \\
\quad \text{Learner: 'svm'}
\]

Properties, Methods

By default, \text{fitrlinear} implements 10-fold cross-validation. \text{CVMdl} is a \text{RegressionPartitionedLinear} model. It contains the property \text{Trained}, which is a 10-by-1 cell array holding 10 \text{RegressionLinear} models that the software trained using the training set.

Predict responses for observations that \text{fitrlinear} did not use in training the folds.

\[
\text{yHat} = \text{kfoldPredict(CVMdl)};
\]

Because there is one regularization strength in \text{Mdl}, \text{yHat} is a numeric vector.
Predict for Models Containing Several Regularization Strengths

Simulate 10000 observations as in "Predict Cross-Validated Responses" on page 32-2876.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
.nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Create a set of 15 logarithmically-spaced regularization strengths from $10^{-5}$ through $10^{-1}$.

Lambda = logspace(-5,-1,15);

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Specify using least squares with a lasso penalty and optimizing the objective function using SpaRSA.

X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

CVMdl is a RegressionPartitionedLinear model. Its Trained property contains a 5-by-1 cell array of trained RegressionLinear models, each one holds out a different fold during training. Because fitrlinear trained using 15 regularization strengths, you can think of each RegressionLinear model as 15 models.

Predict cross-validated responses.

YHat = kfoldPredict(CVMdl);
size(YHat)
ans = 1x2
     10000    15

YHat(2,:)
ans = 1x15
  -1.7338  -1.7332  -1.7319  -1.7299  -1.7266  -1.7239  -1.7135  -1.7210  -1.7324  -1.7063  -1.6397  -1.5112  -1.2631  -0.7841  -0.0096

YHat is a 10000-by-15 matrix. YHat(2,:) is the cross-validated response for observation 2 using the model regularized with all 15 regularization values.

RegressionLinear | RegressionPartitionedLinear | fitrlinear | predict

Introduced in R2016a
**kfoldPredict**

Predict response for observations not used for training

**Syntax**

```
yfit = kfoldPredict(obj)
```

**Description**

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

**Input Arguments**

- `obj`:
  
  Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitrensemble` along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

**Output Arguments**

- `yfit`:
  
  A vector of predicted values for the response data based on a model trained on out-of-fold observations.

**Examples**

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:

```matlab
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
L =
    26.5271
yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )
ans =
    26.5271
```
See Also
fitrtree | kfoldLoss
**kmeans**

*k*-means clustering

**Syntax**

idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans(__)
[idx,C,sumd] = kmeans(__)
[idx,C,sumd,D] = kmeans(__)

**Description**

idx = kmeans(X,k) performs *k*-means clustering on page 32-2895 to partition the observations of the *n*-by-*p* data matrix *X* into *k* clusters, and returns an *n*-by-1 vector (idx) containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables.

By default, kmeans uses the squared Euclidean distance metric and the *k*-means++ algorithm on page 32-2895 for cluster center initialization.

idx = kmeans(X,k,Name,Value) returns the cluster indices with additional options specified by one or more Name,Value pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

[idx,C] = kmeans(__) returns the *k* cluster centroid locations in the *k*-by-*p* matrix *C*.

[idx,C,sumd] = kmeans(__) returns the within-cluster sums of point-to-centroid distances in the *k*-by-1 vector *sumd*.

[idx,C,sumd,D] = kmeans(__) returns distances from each point to every centroid in the *n*-by-*k* matrix *D*.

**Examples**

**Train a k-Means Clustering Algorithm**

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

load fisheriris
X = meas(:,3:4);

figure;
pplot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify \( k = 3 \) clusters.

```matlab
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

\( k \text{means} \) uses the \( k \)-means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the 'Replicates' name-value pair argument.

\( iidx \) is a vector of predicted cluster indices corresponding to the observations in \( X \). \( C \) is a 3-by-2 matrix containing the final centroid locations.

Use \( k\text{means} \) to compute the distance from each centroid to points on a grid. To do this, pass the centroids (\( C \)) and points on a grid to \( k\text{means} \), and implement one iteration of the algorithm.

```matlab
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[xG,x2G] = meshgrid(x1,x2);
XGrid = [xG(:),x2G(:)]; % Defines a fine grid on the plot
idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);
```

Warning: Failed to converge in 1 iterations.

% Assigns each node in the grid to the closest centroid
kmeans displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```matlab
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
    [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'.');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','SouthEast');
hold off;
```

**Fisher's Iris Data**

![Fisher's Iris Data plot](image)

**Partition Data into Two Clusters**

Randomly generate the sample data.

```matlab
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2)];
```

```matlab
figure;
```
There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```matlab
opts = statset('Display','final');
[idx,C] = kmeans(X,2,'Distance','cityblock',
    'Replicates',5,'Options',opts);
```

Replicate 1, 3 iterations, total sum of distances = 201.533.
Replicate 2, 5 iterations, total sum of distances = 201.533.
Replicate 3, 3 iterations, total sum of distances = 201.533.
Replicate 4, 3 iterations, total sum of distances = 201.533.
Replicate 5, 2 iterations, total sum of distances = 201.533.

Best total sum of distances = 201.533

By default, the software initializes the replicates separately using k-means++.

Plot the clusters and the cluster centroids.

```matlab
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(C(:,1),C(:,2),'kx',...
You can determine how well separated the clusters are by passing `idx` to Silhouette.

**Cluster Data Using Parallel Computing**

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox™ license and you set the options for parallel computing, then `kmeans` runs each clustering task (or replicate) in parallel. And, if `Replicates` > 1, then parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```matlab
Mu = bsxfun(@times, ones(20,30), (1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
Mdl = gmdistribution(Mu, Sigma); % Define the Gaussian mixture distribution
rng(1); % For reproducibility
X = random(Mdl, 10000);
```
Mdl is a 30-dimensional gmddistribution model with 20 components. X is a 10000-by-30 matrix of data generated from Mdl.

Specify the options for parallel computing.

```matlab
stream = RandStream('mlfg6331_64');  % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);
```

The input argument 'mlfg6331_64' of RandStream specifies to use the multiplicative lagged Fibonacci generator algorithm. options is a structure array with fields that specify options for controlling estimation.

Cluster the data using k-means clustering. Specify that there are k = 20 clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```matlab
tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.
Replicate 5, 72 iterations, total sum of distances = 7.73161e+06.
Replicate 1, 64 iterations, total sum of distances = 7.72988e+06.
Replicate 3, 68 iterations, total sum of distances = 7.72576e+06.
Replicate 4, 84 iterations, total sum of distances = 7.72696e+06.
Replicate 6, 82 iterations, total sum of distances = 7.73006e+06.
Replicate 7, 40 iterations, total sum of distances = 7.73451e+06.
Replicate 2, 194 iterations, total sum of distances = 7.72953e+06.
Replicate 9, 105 iterations, total sum of distances = 7.72064e+06.
Replicate 10, 125 iterations, total sum of distances = 7.72816e+06.
Replicate 8, 70 iterations, total sum of distances = 7.73188e+06.
Best total sum of distances = 7.72064e+06
toc % Terminate stopwatch timer
```

Elapsed time is 61.915955 seconds.

The Command Window indicates that six workers are available. The number of workers might vary on your system. The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

**Assign New Data to Existing Clusters and Generate C/C++ Code**

kmeans performs k-means clustering to partition data into k clusters. When you have a new data set to cluster, you can create new clusters that include the existing data and the new data by using kmeans. The kmeans function supports C/C++ code generation, so you can generate code that accepts training data and returns clustering results, and then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction by using kmeans and pdist2, respectively.

Use kmeans to create clusters in MATLAB® and use pdist2 in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster
centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function.

Generating C/C++ code requires MATLAB® Coder™.

**Perform k-Means Clustering**

Generate a training data set using three distributions.

```matlab
rng('default') % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);  
     randn(100,2)*0.5-ones(100,2);  
     randn(100,2)*0.75];
```

Partition the training data into three clusters by using `kmeans`.

```matlab
[idx,C] = kmeans(X,3);
```

Plot the clusters and the cluster centroids.

```matlab
figure
gscatter(X(:,1),X(:,2),idx,'bgm')
hold on
plot(C(:,1),C(:,2),'kx')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid')
```
Assign New Data to Existing Clusters

Generate a test data set.

\[
X_{\text{test}} = [\text{randn}(10,2)*0.75+\text{ones}(10,2); \text{randn}(10,2)*0.5-\text{ones}(10,2); \text{randn}(10,2)*0.75];
\]

Classify the test data set using the existing clusters. Find the nearest centroid from each test data point by using `pdist2`.

\[
[-,\text{idx}_\text{test}] = \text{pdist2}(C,X_{\text{test}},'\text{euclidean}','\text{Smallest'},1);
\]

Plot the test data and label the test data using `idx_test` by using `gscatter`.

\[
\text{gscatter}(X_{\text{test}}(:,1),X_{\text{test}}(:,2),\text{idx}_\text{test},'\text{bgm}','\text{ooo}')
\]

Generate Code

Generate C code that assigns new data to the existing clusters. Note that generating C/C++ code requires MATLAB® Coder™.

Define an entry-point function named `findNearestCentroid` that accepts centroid positions and new data, and then find the nearest cluster by using `pdist2`. 
Add the `#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```matlab
type findNearestCentroid % Display contents of findNearestCentroid.m
function idx = findNearestCentroid(C,X) %#codegen
    [~,idx] = pdist2(C,X,'euclidean','Smallest',1); % Find the nearest centroid

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and array size of the inputs of `findNearestCentroid`, pass a MATLAB expression that represents the set of values with a certain data type and array size by using the `-args` option. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38.

```matlab
codegen findNearestCentroid -args {C,Xtest}
```

codegen generates the MEX function `findNearestCentroid_mex` with a platform-dependent extension.

Verify the generated code.

```matlab
myIndx = findNearestCentroid(C,Xtest);
myIndex_mex = findNearestCentroid_mex(C,Xtest);
verifyMEX = isequal(idx_test,myIndx,myIndex_mex)
```

isequal returns logical 1 (`true`), which means all the inputs are equal. The comparison confirms that the `pdist2` function, the `findNearestCentroid` function, and the MEX function return the same index.

You can also generate optimized CUDA® code using GPU Coder™.

```matlab
cfg = coder.gpuConfig('mex');
codegen -config cfg findNearestCentroid -args {C,Xtest}
```

For more information on code generation, see “General Code Generation Workflow” on page 31-5. For more information on GPU coder, see “Get Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

**Input Arguments**

- `X` — Data
  numeric matrix

Data, specified as a numeric matrix. The rows of `X` correspond to observations, and the columns correspond to variables.
If \( X \) is a numeric vector, then \textit{kmeans} treats it as an \( n \)-by-1 data matrix, regardless of its orientation.

The software treats NaNs in \( X \) as missing data and removes any row of \( X \) that contains at least one NaN. Removing rows of \( X \) reduces the sample size. The \textit{kmeans} function returns NaN for the corresponding value in the output argument \( \text{idx} \).

**Data Types:** single | double

\[ k \] — Number of clusters
positive integer

Number of clusters in the data, specified as a positive integer.

**Data Types:** single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \textit{Name,Value} arguments. \textit{Name} is the argument name and \textit{Value} is the corresponding value. \textit{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \textit{Name1,Value1,...,NameN,ValueN}.

Example: \textit{'Distance','cosine','Replicates',10,'Options',statset('UseParallel',1)} specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

**Display — Level of output to display**
‘off’ (default) | ‘final’ | ‘iter’

Level of output to display in the Command Window, specified as the comma-separated pair consisting of \textit{Display} and one of the following options:

- ‘final’ — Displays results of the final iteration
- ‘iter’ — Displays results of each iteration
- ‘off’ — Displays nothing

Example: \textit{Display},'final'

**Distance — Distance metric**
‘sqeuclidean’ (default) | ‘cityblock’ | ‘cosine’ | ‘correlation’ | ‘hamming’

Distance metric, in \( p \)-dimensional space, used for minimization, specified as the comma-separated pair consisting of \textit{Distance} and \textit{sqeuclidean}', 'cityblock', 'cosine', 'correlation', or 'hamming'.

\textit{kmeans} computes centroid clusters differently for the supported distance metrics. This table summarizes the available distance metrics. In the formulae, \( x \) is an observation (that is, a row of \( X \)) and \( c \) is a centroid (a row vector).

<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sqeuclidean'</td>
<td>Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.</td>

</tbody>
</table>

Example: 'Distance','cityblock'

**EmptyAction — Action to take if cluster loses all member observations**

'singleton' (default) | 'error' | 'drop' |

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of 'EmptyAction' and one of the following options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'error'</td>
<td>Treat an empty cluster as an error.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'drop'</td>
<td>Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.</td>
</tr>
<tr>
<td>'singleton'</td>
<td>Create a new cluster consisting of the one point furthest from its centroid (default).</td>
</tr>
</tbody>
</table>

Example: 'EmptyAction','error'

**MaxIter — Maximum number of iterations**

100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter',1000

Data Types: double | single

**OnlinePhase — Online update flag**

'off' (default) | 'on'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'off' or 'on'.

If OnlinePhase is on, then kmeans performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase','on'

**Options — Options for controlling iterative algorithm for minimizing fitting criteria**

[] (default) | structure array returned by statset

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. Supported fields of the structure array specify options for controlling the iterative algorithm.

This table summarizes the supported fields. Note that the supported fields require Parallel Computing Toolbox.
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'Streams'      | A RandStream object or cell array of such objects. If you do not specify Streams, kmeans uses the default stream or streams. If you specify Streams, use a single object except when all of the following conditions exist:  
• You have an open parallel pool.  
• UseParallel is true.  
• UseSubstreams is false.  
In this case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then Streams must supply a single random number stream. |
| 'UseParallel'  | • If true and Replicates > 1, then kmeans implements the k-means algorithm on each replicate in parallel.  
• If Parallel Computing Toolbox is not installed, then computation occurs in serial mode. The default is false, indicating serial computation. |
| 'UseSubstreams'| Set to true to compute in parallel in a reproducible fashion. The default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. |

To ensure more predictable results, use parpool and explicitly create a parallel pool before invoking kmeans and setting 'Options', statset('UseParallel',1).

Example: 'Options', statset('UseParallel',1)
Data Types: struct

**Replicates — Number of times to repeat clustering using new initial cluster centroid positions**

1 (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of 'Replicates' and an integer. kmeans returns the solution with the lowest sumd.

You can set 'Replicates' implicitly by supplying a 3-D array as the value for the 'Start' name-value pair argument.

Example: ‘Replicates’,5
Data Types: double | single

**Start — Method for choosing initial cluster centroid positions**

'plus' (default) | 'cluster' | 'sample' | 'uniform' | numeric matrix | numeric array

32-2893
Method for choosing initial cluster centroid positions (or seeds), specified as the comma-separated pair consisting of 'Start' and 'cluster', 'plus', 'sample', 'uniform', a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cluster'</td>
<td>Perform a preliminary clustering phase on a random 10% subsample of X when the number of observations in the subsample is greater than k. This preliminary phase is itself initialized using 'sample'. If the number of observations in the random 10% subsample is less than k, then the software selects k observations from X at random.</td>
</tr>
<tr>
<td>'plus' (default)</td>
<td>Select k seeds by implementing the k-means++ algorithm on page 32-2895 for cluster center initialization.</td>
</tr>
<tr>
<td>'sample'</td>
<td>Select k observations from X at random.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>Select k points uniformly at random from the range of X. Not valid with the Hamming distance.</td>
</tr>
<tr>
<td>numeric matrix</td>
<td>k-by-p matrix of centroid starting locations. The rows of Start correspond to seeds. The software infers k from the first dimension of Start, so you can pass in [] for k.</td>
</tr>
<tr>
<td>numeric array</td>
<td>k-by-p-by-r array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page j contains the set of seeds for replicate j. The software infers the number of replicates (specified by the 'Replicates' name-value pair argument) from the size of the third dimension.</td>
</tr>
</tbody>
</table>

Example: 'Start','sample'

Data Types: char | string | double | single

Output Arguments

idx — Cluster indices
numeric column vector
Cluster indices, returned as a numeric column vector. idx has as many rows as X, and each row indicates the cluster assignment of the corresponding observation.

C — Cluster centroid locations
numeric matrix
Cluster centroid locations, returned as a numeric matrix. C is a k-by-p matrix, where row j is the centroid of cluster j.
sumd — Within-cluster sums of point-to-centroid distances
numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. sumd is a k-by-1 vector, where element j is the sum of point-to-centroid distances within cluster j.

D — Distances from each point to every centroid
numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. D is an n-by-k matrix, where element (j,m) is the distance from observation j to centroid m.

More About

k-Means Clustering

k-means clustering, or Lloyd’s algorithm [2], is an iterative, data-partitioning algorithm that assigns \( n \) observations to exactly one of \( k \) clusters defined by centroids, where \( k \) is chosen before the algorithm starts.

The algorithm proceeds as follows:

1. Choose \( k \) initial cluster centers (centroid). For example, choose \( k \) observations at random (by using 'Start','sample') or use the k-means ++ algorithm on page 32-2895 for cluster center initialization (the default).
2. Compute point-to-cluster-centroid distances of all observations to each centroid.
3. There are two ways to proceed (specified by OnlinePhase):
   - Batch update — Assign each observation to the cluster with the closest centroid.
   - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

For more details, see “Algorithms" on page 32-2896.

4. Compute the average of the observations in each cluster to obtain \( k \) new centroid locations.
5. Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

k-means++ Algorithm

The k-means++ algorithm uses an heuristic to find centroid seeds for k-means clustering. According to Arthur and Vassilvitskii [1], k-means++ improves the running time of Lloyd’s algorithm, and the quality of the final solution.

The k-means++ algorithm chooses seeds as follows, assuming the number of clusters is \( k \).

1. Select an observation uniformly at random from the data set, \( X \). The chosen observation is the first centroid, and is denoted \( c_1 \).
2. Compute distances from each observation to \( c_1 \). Denote the distance between \( c_j \) and the observation \( m \) as \( d(x_m, c_j) \).
3. Select the next centroid, \( c_2 \) at random from \( X \) with probability
To choose center $j$:

- **a** Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.
- **b** For $m = 1, \ldots, n$ and $p = 1, \ldots, j - 1$, select centroid $j$ at random from $X$ with probability

$$\frac{d^2(x_m, c_p)}{\sum_{h \in C_p} d^2(x_h, c_p)},$$

where $C_p$ is the set of all observations closest to centroid $c_p$ and $x_m$ belongs to $C_p$.

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5 Repeat step 4 until $k$ centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that $k$-means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd’s algorithm.

**Algorithms**

- **kmeans** uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all $k$ clusters.

  1 This first phase uses batch updates, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.

  2 This second phase uses online updates, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

- If `Replicates = r > 1` and `Start is plus` (the default), then the software selects $r$ possibly different sets of seeds according to the $k$-means++ algorithm on page 32-2895.

- If you enable the `UseParallel` option in `Options` and `Replicates > 1`, then each worker selects seeds and clusters in parallel.
References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:
- Supported syntaxes are:
  - `idx = kmeans(X,k)`
  - `[idx,C] = kmeans(X,k)`
  - `[idx,C,sumd] = kmeans(X,k)`
  - `[___] = kmeans(___,[Name,Value])`
- Supported name-value pair arguments, and any differences, are:
  - 'Display' — Default value is 'iter'.
  - 'MaxIter'
  - 'Options' — Supports only the 'TolFun' field of the structure array created by `statset`. The default value of 'TolFun' is 1e-4. The `kmeans` function uses the value of 'TolFun' as the termination tolerance for the within-cluster sums of point-to-centroid distances. For example, you can specify `'Options',statset('TolFun',1e-8)`.
  - 'Replicates'
  - 'Start' — Supports only 'plus', 'sample', and a numeric array.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- If the `Start` method uses random selections, the initial centroid cluster positions might not match MATLAB.
- If the number of rows in `X` is fixed, code generation does not remove rows of `X` that contain a NaN.
- The cluster centroid locations in `C` can have a different order than in MATLAB. In this case, the cluster indices in `idx` have corresponding differences.
• If you provide Display, its value must be 'off'.
• If you provide Streams, it must be empty and UseSubstreams must be false.
• When you set the UseParallel option to true:
  • Some computations can execute in parallel even when Replicates is 1. For large data sets, when Replicates is 1, consider setting the UseParallel option to true.
  • kmeans uses parfor to create loops that run in parallel on supported shared-memory multicore platforms. Loops that run in parallel can be faster than loops that run on a single thread. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the parfor-loops as for-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/.
  • To save memory on the device to which you deploy generated code, you can separate training and prediction by using kmeans and pdist2, respectively. Use kmeans to create clusters in MATLAB and use pdist2 in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function. For an example, see “Assign New Data to Existing Clusters and Generate C/C++ Code” on page 32-2886.
  • Starting in R2020a, kmeans returns integer-type (int32) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for stricter single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a
kmedoids

k-medoids clustering

Syntax

idx = kmedoids(X,k)
idx = kmedoids(X,k,Name,Value)
[idx,C] = kmedoids( ___ )
[idx,C,sumd] = kmedoids( ___ )
[idx,C,sumd,D] = kmedoids( ___ )
[idx,C,sumd,D,midx] = kmedoids( ___ )
[idx,C,sumd,D,midx,info] = kmedoids( ___ )

Description

idx = kmedoids(X,k) performs “k-medoids Clustering” on page 32-2911 to partition the observations of the n-by-p matrix X into k clusters, and returns an n-by-1 vector idx containing cluster indices of each observation. Rows of X correspond to points and columns correspond to variables. By default, kmedoids uses squared Euclidean distance metric and the k-means++ algorithm on page 32-2895 for choosing initial cluster medoid positions.

idx = kmedoids(X,k,Name,Value) uses additional options specified by one or more Name,Value pair arguments.

[idx,C] = kmedoids( ___ ) returns the k cluster medoid locations in the k-by-p matrix C.

[idx,C,sumd] = kmedoids( ___ ) returns the within-cluster sums of point-to-medoid distances in the k-by-1 vector sumd.

[idx,C,sumd,D] = kmedoids( ___ ) returns distances from each point to every medoid in the n-by-k matrix D.

[idx,C,sumd,D,midx] = kmedoids( ___ ) returns the indices midx such that C = X(midx,:).

midx is a k-by-1 vector.

[idx,C,sumd,D,midx,info] = kmedoids( ___ ) returns a structure info with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
    randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
Group data into two clusters using kmedoids. Use the cityblock distance metric.

```matlab
opts = statset('Display','iter');
[ii,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

```
rep  iter    sum  
   1      1 209.856
   1      2 209.856
```

Best total sum of distances = 209.856

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

```
info
```

```
info = struct with fields:
    algorithm: 'pam'
    start: 'plus'
    distance: 'cityblock'
    iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```matlab
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
```
Cluster Categorical Data Using k-Medoids

This example uses "Mushroom" data set from the UCI machine learning archive, described in http://archive.ics.uci.edu/ml/datasets/Mushroom. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of 'b' for bell-shaped cap and 'c' for conical. Mushroom color is also categorized with features of 'n' for brown, and 'p' for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used k-means clustering algorithm cannot be meaningfully applied to this data set. k-medoids is a related algorithm that partitions data into k distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.
The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing $k$-medoids to be used for a broader range of problems than $k$-means.

Using $k$-medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5][6][7] from the UCI database (http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/) and saved it in your current directory as a text file named agaricus-lepiota.txt. There is no column headers in the data, so `readtable` uses the default variable names.

```matlab
clear all
data = readtable('agaricus-lepiota.txt','ReadVariableNames',false);
```

Display the first 5 mushrooms with their first few features.

```matlab
data(1:5,1:10)
ans =

<p>| | | | | | | | | | |</p>

<td>'f'</td>
<td>'f'</td>
<td>'w'</td>
<td>'b'</td>
</tr>
</tbody>
</table>
```

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```matlab
labels = data(:,1);
labels = categorical(labels{:,:});
data(:,1) = [];
```

Store the names of predictors (features), which are described in http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names.

```matlab
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ... 'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ... 'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ... 'stalk_surface_below_ring' 'stalk_color_above_ring' ... 'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' .... 'ring_type' 'spore_print_color' 'population' 'habitat'};```

Set the variable names.

```matlab
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as '?'.

```matlab
sum(char(data{:,:}) == '?')
ans =
   2480
```
Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (stalk_root). Remove the column from the table.

data(:,11) = [];

kmedoids only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

cats = categorical(data{:, :});
data = double(cats);

kmedoids can use any distance metric supported by pdist2 to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

v1 = [1 0 2 1];
v2 = [1 1 2 1];

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function pdist2 to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value .2857 means that 6 of the 21 features of the mushroom differ.

pdist2(data(1,:),data(2,:), 'hamming')
ans =
 0.2857

In this example, you’re clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The kmedoids function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the 'replicates' parameter. When 'replicates' is set to a value, n, greater than 1, the k-medoids algorithm is run n times, and the best result is returned.

To run kmedoids to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

rng('default'); % For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data, 2, 'distance', 'hamming', 'replicates', 3);

Let’s assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the confusionmat function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label
information from the IDX variable. IDX contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

predLabels = labels; % Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); % Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); % Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)

confMatrix =

4176  32
816  3100

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))

accuracy =

0.8956

precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))

precision =

0.8365

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

**Input Arguments**

**X — Data**
numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

**k — Number of medoids**
positive integer

Number of medoids in the data, specified as a positive integer.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
Example:
'Distance','euclidean','Replicates',3,'Options',statset('UseParallel',1)
specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel
computing.

**Algorithm — Algorithm to find medoids**

'pam'|'small'|'clara'|'large'

Algorithm to find medoids, specified as the comma-separated pair consisting of 'Algorithm' and
'pam','small','clara', or 'large'. The default algorithm depends on the number of rows of X.

- If the number of rows of X is less than 3000, 'pam' is the default algorithm.
- If the number of rows is between 3000 and 10000, 'small' is the default algorithm.
- For all other cases, 'large' is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the
available algorithms.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pam'</td>
<td>Partitioning Around Medoids (PAM) is the classical algorithm for solving the k-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the 'Start' name-value pair argument. The algorithm proceeds as follows.</td>
</tr>
<tr>
<td>1 Build-step: Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.</td>
<td></td>
</tr>
<tr>
<td>2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.</td>
<td></td>
</tr>
</tbody>
</table>

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.
Algorithm | Description
---|---
'small' | Use an algorithm similar to the k-means algorithm to find k medoids. This option employs a variant of the Lloyd’s iterations based on [2].

The algorithm proceeds as follows.

1. For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid.
2. Update the cluster membership for each data point to reflect the new medoid.

The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the clara or large algorithms, but it may not be the best choice for very large data.

'clara' | Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling.

The algorithm proceeds as follows.

1. Select a subset of the data and apply the PAM algorithm to the subset.
2. Assign points of the full data set to clusters by picking the closest medoid.

The algorithm repeats these steps until the medoids do not change, or other termination criteria are met.

For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples s rows from X (specified by 'NumSamples' name-value pair argument) to perform clustering on. By default, 40+2*k samples are selected.

'large' | This is similar to the small scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, 'PercentNeighbors', controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of r replicates (specified by 'Replicates' name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality.

Example: 'Algorithm','pam'

**OnlinePhase** — Flag to perform PAM-like online update phase

'on' (default) | 'off'
A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of 'OnlinePhase' and 'on' or 'off'.

If it is on, then kmedoids performs a PAM-like update to the medoids after the Lloyd iterations in the small and large algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: OnlinePhase,'off'

Distance — Distance metric
'sqeuclidean' (default) | 'euclidean' | 'seuclidean' | 'cityblock' | 'minkowski' | 'chebychev' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | custom distance function

Distance metric, in p-dimensional space, specified as the comma-separate pair consisting of 'Distance' and 'euclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'mahalanobis', 'cosine', 'correlation', 'spearman', 'hamming', 'jaccard', or a custom distance function.

kmedoids minimizes the sum of medoid to cluster member distances. See pdist for the definition of each distance metric. kmedoids supports all distance metrics supported by pdist.

Example: 'Distance','hamming'

Options — Options to control iterative algorithm to minimize fitting criteria
[] (default) | structure array returned by statset

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. Supported fields of the structure array specify options for controlling the iterative algorithm. This table summarizes the supported fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display</td>
<td>Level of display output. Choices are 'off' (default) and 'iter'.</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of iterations allowed. The default is 100.</td>
</tr>
<tr>
<td>UseParallel</td>
<td>If true, compute in parallel. If Parallel Computing Toolbox is not available, then computation occurs in serial mode. The default is false, meaning serial computation.</td>
</tr>
<tr>
<td>UseSubstreams</td>
<td>Set to true to compute in parallel in a reproducible fashion. The default is false. To compute reproducibly, you must also set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Streams</td>
<td>A RandStream object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see “Speed Up Statistical Computations” or enter help parallelstats at the command line.</td>
</tr>
</tbody>
</table>

Example: 'Options',statset('Display','off')

**Replicates** — **Number of times to repeat clustering using new initial cluster medoid positions**
positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For pam and small, the default is 1. For clara, the default is 5. For large, the default is 3.

Example: 'Replicates',4

**NumSamples** — **Number of samples to take from data when executing clara algorithm**
40+2*k (default) | positive integer

Number of samples to take from the data when executing the clara algorithm, specified as a positive integer. The default number of samples is calculated as 40+2*k.

Example: 'NumSamples',160

**PercentNeighbors** — **Percent of data set to examine using large algorithm**
0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the large algorithm, specified as a positive number.

The program examines percentneighbors*size(X,1) number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: 'PercentNeighbors',0.01

**Start** — **Method for choosing initial cluster medoid positions**
'plus' (default) | 'sample' | 'cluster' | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of 'Start' and 'plus', 'sample', 'cluster', or a matrix. This table summarizes the available methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'plus'</td>
<td>Select k observations from X according to the k-means++ algorithm on page 32-2895 for cluster center initialization.</td>
</tr>
<tr>
<td>'sample'</td>
<td>Select k observations from X at random.</td>
</tr>
<tr>

</tr>
<tr>
<td>'cluster'</td>
<td>Perform preliminary clustering phase on a random subsample (10%) of $X$. This preliminary phase is itself initialized using sample, that is, the observations are selected at random.</td>
</tr>
<tr>
<td>matrix</td>
<td>A custom $k$-by-$p$ matrix of starting locations. In this case, you can pass in [] for the $k$ input argument, and kmedoids infers $k$ from the first dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array’s third dimension.</td>
</tr>
</tbody>
</table>

Example: 'Start','sample'

Data Types: char | string | single | double

## Output Arguments

**idx — Medoid indices**

numeric column vector

Medoid indices, returned as a numeric column vector. idx has as many rows as $X$, and each row indicates the medoid assignment of the corresponding observation.

**C — Cluster medoid locations**

numeric matrix

Cluster medoid locations, returned as a numeric matrix. C is a $k$-by-$p$ matrix, where row $j$ is the medoid of cluster $j$.

**sumd — Within-cluster sums of point-to-medoid distances**

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. sumd is a $k$-by-1 vector, where element $j$ is the sum of point-to-medoid distances within cluster $j$.

**D — Distances from each point to every medoid**

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. D is an $n$-by-$k$ matrix, where element $(j,m)$ is the distance from observation $j$ to medoid $m$.

**midx — Index to $X$**

column vector

Index to $X$, returned as a column vector of indices. midx is a $k$-by-1 vector and the indices satisfy $C = X(midx,:)$.

**info — Algorithm information**

struct

Algorithm information, returned as a struct. info contains options used by the function when executed such as $k$-medoid clustering algorithm (algorithm), method used to choose initial cluster
medoid positions (start), distance metric (distance), number of iterations taken in the best replicate (iterations) and the replicate number of the returned results (bestReplicate).

**More About**

**k-medoids Clustering**

k-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to k-means, and the goal of both methods is to divide a set of measurements or observations into k subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement’s cluster. In the k-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the k-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The k-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between k-medoids and k-means where the centroids returned by k-means may not be within the data set. Hence k-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function kmedoids provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

1. **Build-step:** Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.

2. **Swap-step:** Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to kmedoids, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, kmedoids uses the k-means++ algorithm on page 32-2895 for cluster medoid initialization and the squared Euclidean metric to determine distances.

**Extended Capabilities**

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options`, statset('UseParallel', true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2014b**
knnsearch

Find k-nearest neighbors using searcher object

Syntax

Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch(____)

Description

Idx = knnsearch(Mdl,Y) searches for the nearest neighbor (i.e., the closest point, row, or observation in Mdl.X to each point (i.e., row or observation) in the query data Y using an exhaustive search or a Kd-tree. knnsearch returns Idx, which is a column vector of the indices in Mdl.X representing the nearest neighbors.

Idx = knnsearch(Mdl,Y,Name,Value) returns the indices of the closest points in Mdl.X to Y with additional options specified by one or more Name,Value pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in Mdl.Distance. You can also specify which action to take if the closest distances are tied.

[Idx,D] = knnsearch(____) additionally returns the matrix D using any of the input arguments in the previous syntaxes. D contains the distances between each observation in Y that correspond to the closest observations in Mdl.X. By default, the function arranges the columns of D in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using Kd-tree and Exhaustive Search

knnsearch accepts ExhaustiveSearcher or KDTreeSearcher model objects to search the training data for the nearest neighbors to the query data. An ExhaustiveSearcher model invokes the exhaustive searcher algorithm, and a KDTreeSearcher model defines a Kd-tree, which knnsearch uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:); % Query data

The variable meas contains 4 predictors.

Grow a default four-dimensional Kd-tree.

MdlKDT = KDTreeSearcher(X)
Md1KDT =
   KDTreeSearcher with properties:
       BucketSize: 50
       Distance: 'euclidean'
       DistParameter: []
       X: [145x4 double]

Md1KDT is a KDTreeSearcher model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

Md1ES = ExhaustiveSearcher(X)

Md1ES =
   ExhaustiveSearcher with properties:
       Distance: 'euclidean'
       DistParameter: []
       X: [145x4 double]

Md1KDT is an ExhaustiveSearcher model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a Kd-tree or prepare an exhaustive nearest neighbor searcher using createns.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is 1.

IdxKDT = knnsearch(Md1KDT,Y);
IdxES = knnsearch(Md1ES,Y);
[IdxKDT IdxES]

ans = 5x2
    17   17
     6     6
     1     1
    89    89
   124   124

In this case, the results of the search are the same.

Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a Kd-tree nearest neighbor searcher object by using the createns function. Pass the object and query data to the knnsearch function to find k-nearest neighbors.

Load Fisher's iris data set.

load fisheriris
Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                     % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','minkowski')
```

```
Mdl =
    KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 2
    X: [145x4 double]
```

Because X has four columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (Mdl.X) that are the two nearest neighbors of each point in the query data (Q).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN = 5x2
     17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `IdxNN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of Q(3,:) is X(12,:).

**Include Ties in Nearest Neighbor Search**

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4);                     % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
```
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.
Mdl = KDTreeSearcher(X);

Mdl is a KDTreeSearcher model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (X) that are the seven nearest neighbors of each point in the query data (Y).
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);

Idx and D are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in Idx.

cellfun('length',Idx)
ans = 5×1
8
7
7
7
7

Because cell 1 contains a vector with length greater than \( k = 7 \), query observation 1 (Y(1,:)) is equally close to at least two observations in X.

Display the indices of the nearest neighbors to Y(1,:) and their distances.

nn5 = Idx{1}
nn5 = 1×8
91  98  67  69  71  93  88  95

nn5d = D{1}
nn5d = 1×8
0.1414  0.2646  0.2828  0.3000  0.3464  0.3742  0.3873  0.3873

Training observations 88 and 95 are 0.3873 cm away from query observation 1.

**Compare k-Nearest Neighbors Using Different Distance Metrics**

Train two KDTreeSearcher models using different distance metrics, and compare k-nearest neighbors of query data for the two models.

Load Fisher's iris data set. Consider the petal measurements as predictors.
load fisheriris
X = meas(:,3:4); % Predictors
Y = species; % Response

Train a KDTreeSearcher model object by using the predictors. Specify the Minkowski distance with exponent 5.

KDTreeMdl = KDTreeSearcher(X,'Distance','minkowski','P',5)

KDTreeMdl = 
    KDTreeSearcher with properties:
      BucketSize: 50
      Distance: 'minkowski'
      DistParameter: 5
      X: [150x2 double]

Find the 10 nearest neighbors from X to a query point (newpoint), first using Minkowski then Chebychev distance metrics. The query point must have the same column dimension as the data used to train the model.

newpoint = [5 1.45];
[IdxMk,DMk] = knnsearch(KDTreeMdl,newpoint,'k',10);
[IdxCb,DCb] = knnsearch(KDTreeMdl,newpoint,'k',10,'Distance','chebychev');

IdxMk and IdxCb are 1-by-10 matrices containing the row indices of X corresponding to the nearest neighbors to newpoint using Minkowski and Chebychev distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

Plot the training data, query point, and nearest neighbors.

figure;
gscatter(X(:,1),X(:,2),Y);
title('Fisher''s Iris Data -- Nearest Neighbors');
xlabel('Petal length (cm)');
ylabel('Petal width (cm)');
hold on
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,'LineWidth',2); % Query point
plot(X(IdxMk,1),X(IdxMk,2),'.','Color',[.5 .5 .5],'MarkerSize',10); % Minkowski nearest neighbors
plot(X(IdxCb,1),X(IdxCb,2),'.','Color',[.5 .5 .5],'MarkerSize',10); % Chebychev nearest neighbors
legend('setosa','versicolor','virginica','query point','minkowski','chebychev','Location','Best');
Zoom in on the points of interest.

```matlab
h = gca; % Get current axis handle.
h.XLim = [4.5 5.5];
h.YLim = [1 2];
axis square;
```
Several observations are equal, which is why only eight nearest neighbors are identified in the plot.

**Input Arguments**

**Mdl — Nearest neighbor searcher**  
*ExhaustiveSearcher* model object | *KDTreeSearcher* model object

Nearest neighbor searcher, specified as an *ExhaustiveSearcher* or *KDTreeSearcher* model object, respectively.

If *Mdl* is an *ExhaustiveSearcher* model, then *knnsearch* searches for nearest neighbors using an exhaustive search. Otherwise, *knnsearch* uses the grown Kd-tree to search for nearest neighbors.

**Y — Query data**  
numeric matrix

Query data, specified as a numeric matrix.

*Y* is an *m*-by-*K* matrix. Rows of *Y* correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). *Y* must have the same number of columns as the training data stored in *Mdl.*

Data Types: *single* | *double*
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,..., NameN, ValueN.

Example: 'K', 2, 'Distance', 'minkowski' specifies to find the two nearest neighbors of Mdl.X to each point in Y and to use the Minkowski distance metric.

For Both Nearest Neighbor Searchers

Distance — Distance metric

Mdl.Distance (default) | 'cityblock' | 'euclidean' | 'mahalanobis' | 'minkowski' | 'seuclidean' | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of 'Distance' and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, knnsearch supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
</tbody>
</table>

If Mdl is an ExhaustiveSearcher model object, then knnsearch also supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>

<td>One minus the cosine of the included angle between observations (treated as row vectors).</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the 'Scale' name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>

If Mdl is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). The custom distance function must:

- Have the form function \( D2 = \text{distfun}(ZI,ZJ) \).
- Take as arguments:
  - A 1-by-\( K \) vector \( ZI \) containing a single row from Mdl.X or Y, where \( K \) is the number of columns of Mdl.X.
  - An \( m \)-by-\( K \) matrix \( ZJ \) containing multiple rows of Mdl.X or Y, where \( m \) is a positive integer.
  - Return an \( m \)-by-1 vector of distances \( D2 \), where \( D2(j) \) is the distance between the observations \( ZI \) and \( ZJ(j,:) \).

For more details, see “Distance Metrics” on page 18-11.

Example: 'Distance','minkowski'

**IncludeTies — Flag to include all nearest neighbors**

false (0) (default) | true (1)

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If `IncludeTies` is true, then:

- `knnsearch` includes all nearest neighbors whose distances are equal to the \( k \)th smallest distance in the output arguments, where \( k \) is the number of searched nearest neighbors specified by the 'K' name-value pair argument.
- \( \text{Idx} \) and \( \text{D} \) are \( m \)-by-1 cell arrays such that each cell contains a vector of at least \( k \) indices and distances, respectively. Each vector in \( \text{D} \) contains arranged distances in ascending order. Each row in \( \text{Idx} \) contains the indices of the nearest neighbors corresponding to the distances in \( \text{D} \).

If `IncludeTies` is false, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: 'IncludeTies',true

**K — Number of nearest neighbors**

1 (default) | positive integer

Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of 'K' and a positive integer.
Example: ‘K’, 2  
Data Types: single | double  

P — Exponent for Minkowski distance metric  
2 (default) | positive scalar  

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.  
Example: ‘P’, 3  
Data Types: single | double  

For Kd-Tree Nearest Neighbor Searchers  

SortIndices — Flag to sort returned indices according to distance  
true (1) (default) | false (0)  

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).  

For faster performance, you can set SortIndices to false when the following are true:  
• Y contains many observations that have many nearest neighbors in X.  
• Mdl is a KDTreeSearcher model object.  
• IncludeTies is false.  

In this case, knnsearch returns the indices of the nearest neighbors in no particular order. When SortIndices is true, the function arranges the nearest-neighbor indices in ascending order by distance.  

SortIndices is true by default. When Mdl is an ExhaustiveSearcher model object or IncludeTies is true, the function always sorts the indices.  
Example: 'SortIndices',false  
Data Types: logical  

For Exhaustive Nearest Neighbor Searchers  

Cov — Covariance matrix for Mahalanobis distance metric  
nancov(Mdl.X) (default) | positive definite matrix  

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. Cov is a K-by-K matrix, where K is the number of columns of Mdl.X. If you specify Cov and do not specify 'Distance','mahalanobis', then knnsearch returns an error message.  
Example: 'Cov',eye(3)  
Data Types: single | double  

Scale — Scale parameter value for standardized Euclidean distance metric  
nanstd(Mdl.X) (default) | nonnegative numeric vector
Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length \( K \), where \( K \) is the number of columns of \( \text{Mdl.X} \).

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance', 'seuclidean', then knnsearch returns an error message.

Example: 'Scale', quantile(Mdl.X, 0.75) - quantile(Mdl.X, 0.25)

Data Types: single | double

**Note** If you specify 'Distance', 'Cov', 'P', or 'Scale', then Mdl.Distance and Mdl.DistParameter do not change value.

### Output Arguments

**Idx** — Training data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then Idx is an \( m \)-by-\( k \) numeric matrix, where \( m \) is the number of rows in \( Y \) and \( k \) is the number of searched nearest neighbors specified by the 'K' name-value pair argument. Idx(j,i) indicates that \( \text{Mdl.X}(:,\text{Idx(j,i)}) \) is one of the \( k \) closest observations in \( \text{Mdl.X} \) to the query observation \( Y(j,:) \).
- If you specify 'IncludeTies', true, then Idx is an \( m \)-by-1 cell array such that cell j (Idx{j}) contains a vector of at least \( k \) indices of the closest observations in \( \text{Mdl.X} \) to the query observation \( Y(j,:) \).

If SortIndices is true, then knnsearch arranges the indices in ascending order by distance.

**D** — Distances of nearest neighbors

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then D is an \( m \)-by-\( k \) numeric matrix, where \( m \) is the number of rows in \( Y \) and \( k \) is the number of searched nearest neighbors specified by the 'K' name-value pair argument. D(j,i) is the distance between \( \text{Mdl.X}(:,\text{Idx(j,i)}) \) and the query observation \( Y(j,:) \) with respect to the distance metric.
- If you specify 'IncludeTies', true, then D is an \( m \)-by-1 cell array such that cell j (D{j}) contains a vector of at least \( k \) distances of the closest observations in \( \text{Mdl.X} \) to the query observation \( Y(j,:) \).

If SortIndices is true, then knnsearch arranges the distances in ascending order.
Tips

knnsearch finds the $k$ (positive integer) points in Md1.X that are $k$-nearest for each $Y$ point. In contrast, rangesearch finds all the points in Md1.X that are within distance $r$ (positive scalar) of each $Y$ point.

Alternative Functionality

- knnsearch is an object function that requires an ExhaustiveSearcher or a KDTreeSearcher model object and query data. Under equivalent conditions, the knnsearch object function returns the same results as the knnsearch function when you specify the name-value pair argument 'NSMethod','exhaustive' or 'NSMethod','kdtree', respectively.
- For $k$-nearest neighbors classification, see fitcknn and ClassificationKNN.

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of knnsearch. Arguments not included in this table are fully supported.
### Argument | Notes and Limitations
---|---
Mdl | There are two ways to use Mdl in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.
- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `knnsearch` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `knnsearch` function. Then use `codegen` to generate code for the entry-point function.
- Include `coder.Constant(Mdl)` in the `-args` value of `codegen`.
If `Mdl` is a `KDTreeSearcher` object, and the code generation build type is a MEX function, then `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.
- MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `knnsearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see [https://www.mathworks.com/support/compilers/current_release/](https://www.mathworks.com/support/compilers/current_release/). To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.

'Distance' | • Cannot be a custom distance function.
• Must be a compile-time constant; its value cannot change in the generated code.

'IncludeTies' | Must be a compile-time constant; its value cannot change in the generated code.

'SortIndices' | Not supported. The output arguments are always sorted.

Name-value pair arguments | Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`. 

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Notes and Limitations</th>
</tr>
</thead>
</table>
| Idx      | • When you specify 'IncludeTies' as true, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.  
  • Starting in R2020a, knnsearch returns integer-type (int32) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior. |

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-13.

### Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-13  
“Distance Metrics” on page 18-11

### Introduced in R2010a
**knnsearch**

Find $k$-nearest neighbors using input data

**Syntax**

```matlab
Idx = knnsearch(X,Y)
Idx = knnsearch(X,Y,Name,Value)
[Idx,D] = knnsearch(____)
```

**Description**

$\text{Idx} = \text{knnsearch}(X,Y)$ finds the nearest neighbor in $X$ for each query point in $Y$ and returns the indices of the nearest neighbors in $\text{Idx}$, a column vector. $\text{Idx}$ has the same number of rows as $Y$.

$\text{Idx} = \text{knnsearch}(X,Y,\text{Name,Value})$ returns $\text{Idx}$ with additional options specified using one or more name-value pair arguments. For example, you can specify the number of nearest neighbors to search for and the distance metric used in the search.

$[\text{Idx},D] = \text{knnsearch}(____)$ additionally returns the matrix $D$, using any of the input arguments in the previous syntaxes. $D$ contains the distances between each observation in $Y$ and the corresponding closest observations in $X$.

**Examples**

**Find Nearest Neighbors**

Find the patients in the hospital data set that most closely resemble the patients in $Y$, according to age and weight.

Load the hospital data set.

```matlab
load hospital;
X = [hospital.Age hospital.Weight];
Y = [20 162; 30 169; 40 168; 50 170; 60 171];  % New patients
```

Perform a `knnsearch` between $X$ and $Y$ to find indices of nearest neighbors.

```matlab
Idx = knnsearch(X,Y);
```

Find the patients in $X$ closest in age and weight to those in $Y$.

```matlab
X(Idx,:)
ans = 5×2
    25   171
    25   171
    39   164
    49   170
    50   172
```
Find $k$-Nearest Neighbors Using Different Distance Metrics

Find the 10 nearest neighbors in $X$ to each point in $Y$, first using the Minkowski distance metric and then using the Chebychev distance metric.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas(:,3:4);  % Measurements of original flowers
Y = [5 1.45; 6 2; 2.75 .75];  % New flower data
```

Perform a `knnsearch` between $X$ and the query points $Y$ using Minkowski and Chebychev distance metrics.

```matlab
[mIdx,mD] = knnsearch(X,Y,'K',10,'Distance','minkowski','P',5);
[cIdx,cD] = knnsearch(X,Y,'K',10,'Distance','chebychev');
```

Visualize the results of the two nearest neighbor searches. Plot the training data. Plot the query points with the marker X. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```matlab
gscatter(X(:,1),X(:,2),species)
line(Y(:,1),Y(:,2),'Marker','x','Color','k', ... 
    'Markersize',10,'Linewidth',2,'Linestyle','none')
line(X(mIdx,1),X(mIdx,2),'Color',[.5 .5 .5],'Marker','o', ... 
    'Linestyle','none','Markersize',10)
line(X(cIdx,1),X(cIdx,2),'Color',[.5 .5 .5],'Marker','p', ... 
    'Linestyle','none','Markersize',10)
legend('setosa','versicolor','virginica','query point', ... 
    'minkowski','chebychev','Location','best')
```
Input Arguments

**X — Input data**
numeric matrix

Input data, specified as a numeric matrix. Rows of X correspond to observations, and columns correspond to variables.

Data Types: single | double

**Y — Query points**
numeric matrix

Query points, specified as a numeric matrix. Rows of Y correspond to observations, and columns correspond to variables. Y must have the same number of columns as X.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name,Value** arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: `knnsearch(X,Y,'K',10,'IncludeTies',true,'Distance','cityblock')` searches for 10 nearest neighbors, including ties and using the city block distance.
K — Number of nearest neighbors
1 (default) | positive integer

Number of nearest neighbors to find in X for each point in Y, specified as the comma-separated pair consisting of 'K' and a positive integer.
Example: 'K',10
Data Types: single | double

IncludeTies — Flag to include all nearest neighbors
false (0) (default) | true (1)

Flag to include all nearest neighbors that have the same distance from query points, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If 'IncludeTies' is false, then knnsearch chooses the observation with the smallest index among the observations that have the same distance from a query point.

If 'IncludeTies' is true, then:

• knnsearch includes all nearest neighbors whose distances are equal to the kth smallest distance in the output arguments. To specify k, use the 'K' name-value pair argument.

• Idx and D are m-by-1 cell arrays such that each cell contains a vector of at least k indices and distances, respectively. Each vector in D contains distances arranged in ascending order. Each row in Idx contains the indices of the nearest neighbors corresponding to the distances in D.

Example: 'IncludeTies',true

NSMethod — Nearest neighbor search method
'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and one of these values.

• 'kdtree' — Creates and uses a Kd-tree to find nearest neighbors. 'kdtree' is the default value when the number of columns in X is less than or equal to 10, X is not sparse, and the distance metric is 'euclidean', 'cityblock', 'chebychev', or 'minkowski'. Otherwise, the default value is 'exhaustive'.

The value 'kdtree' is valid only when the distance metric is one of the four metrics noted above.

• 'exhaustive' — Uses the exhaustive search algorithm by computing the distance values from all the points in X to each point in Y.

Example: 'NSMethod','exhaustive'

Distance — Distance metric
'euclidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | function handle | ...

Distance metric knnsearch uses, specified as the comma-separated pair consisting of 'Distance' and one of the values in this table or a function handle.
### Value | Description
--- | ---
'euclidean' | Euclidean distance.
'seuclidean' | Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix Y is scaled by dividing by the corresponding element of the standard deviation computed from X. To specify another scaling, use the 'Scale' name-value pair argument.
'cityblock' | City block distance.
'chebychev' | Chebychev distance (maximum coordinate difference).
'minkowski' | Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'mahalanobis' | Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'cosine' | One minus the cosine of the included angle between observations (treated as vectors).
'correlation' | One minus the sample linear correlation between observations (treated as sequences of values).
'spearman' | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming' | Hamming distance, which is the percentage of coordinates that differ.
'jaccard' | One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.

You can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form function D2 = distfun(ZI,ZJ).
- Take as arguments:
  - A 1-by-n vector ZI containing a single row from X or from the query points Y.
  - An m2-by-n matrix ZJ containing multiple rows of X or Y.
  - Return an m2-by-1 vector of distances D2, whose jth element is the distance between the observations ZI and ZJ(j,:).

For more information, see “Distance Metrics” on page 18-11.

Example: 'Distance','chebychev'

**P — Exponent for Minkowski distance metric**

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double
**Cov** — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix.

This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(4)

Data Types: `single` | `double`

**Scale** — Scale parameter value for standardized Euclidean distance metric

`nansvd(X)` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. 'Scale' has length equal to the number of columns in X. When `knnsearch` computes the standardized Euclidean distance, each coordinate of X is scaled by the corresponding element of 'Scale', as is each query point. This argument is valid only when 'Distance' is 'seuclidean'.

Example: 'Scale', quantile(X, 0.75) - quantile(X, 0.25)

Data Types: `single` | `double`

**BucketSize** — Maximum number of data points in leaf node of Kd-tree

50 (default) | positive integer

Maximum number of data points in the leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer. This argument is valid only when `NSMethod` is 'kdtree'.

Example: 'BucketSize', 20

Data Types: `single` | `double`

**SortIndices** — Flag to sort returned indices according to distance

true (1) (default) | false (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).

For faster performance, you can set `SortIndices` to false when the following are true:

- Y contains many observations that have many nearest neighbors in X.
- `NSMethod` is 'kdtree'.
- `IncludeTies` is false.

In this case, `knnsearch` returns the indices of the nearest neighbors in no particular order. When `SortIndices` is true, the function arranges the nearest-neighbor indices in ascending order by distance.

`SortIndices` is true by default. When `NSMethod` is 'exhaustive' or `IncludeTies` is true, the function always sorts the indices.

Example: 'SortIndices', false

Data Types: `logical`
Output Arguments

**Idx** — Input data indices of nearest neighbors  
numeric matrix | cell array of numeric vectors

Input data indices of the nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (false by default), then `Idx` is an \( m \)-by-\( k \) numeric matrix, where \( m \) is the number of rows in \( Y \) and \( k \) is the number of searched nearest neighbors. `Idx(j,i)` indicates that \( X(Idx(j,i),:) \) is one of the \( k \) closest observations in \( X \) to the query point \( Y(j,:) \).
- If you specify `'IncludeTies',true`, then `Idx` is an \( m \)-by-1 cell array such that cell \( j \) (\( Idx{\{j\}} \)) contains a vector of at least \( k \) indices of the closest observations in \( X \) to the query point \( Y(j,:) \).

If `SortIndices` is true, then `knnsearch` arranges the indices in ascending order by distance.

**D** — Distances of nearest neighbors  
numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query points, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (false by default), then `D` is an \( m \)-by-\( k \) numeric matrix, where \( m \) is the number of rows in \( Y \) and \( k \) is the number of searched nearest neighbors. `D(j,i)` is the distance between \( X(Idx(j,i),:) \) and \( Y(j,:) \) with respect to the distance metric.
- If you specify `'IncludeTies',true`, then `D` is an \( m \)-by-1 cell array such that cell \( j \) (\( D{\{j\}} \)) contains a vector of at least \( k \) distances of the closest observations in \( X \) to the query point \( Y(j,:) \).

If `SortIndices` is true, then `knnsearch` arranges the distances in ascending order.

**Tips**

- For a fixed positive integer \( k \), `knnsearch` finds the \( k \) points in \( X \) that are the nearest to each point in \( Y \). To find all points in \( X \) within a fixed distance of each point in \( Y \), use `rangesearch`.
- `knnsearch` does not save a search object. To create a search object, use `createns`.

**Algorithms**

For information on a specific search algorithm, see “k-Nearest Neighbor Search and Radius Search” on page 18-13.

**Alternative Functionality**

If you set the `knnsearch` function's `NSMethod` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search algorithm or `'kdtree'` for a Kd-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `knnsearch` object function. Unlike the `knnsearch` function, the `knnsearch` object function requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object.
References

Extended Capabilities

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- If X is a tall array, then Y cannot be a tall array. Similarly, if Y is a tall array, then X cannot be a tall array.

For more information, see “Tall Arrays” (MATLAB).

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the 'NSMethod' name-value pair argument is 'exhaustive' when the number of columns in X is greater than 7.
- The value of the 'Distance' name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The value of the 'IncludeTies' name-value pair argument must be a compile-time constant.
- The 'SortIndices' name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include {coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0} in the -args value of codegen.
- When you specify 'IncludeTies' as true, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When knnsearch uses the kd-tree search algorithm, and the code generation build type is a MEX function, codegen generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, codegen generates code using parfor.
  - MEX function for the kd-tree search algorithm — codegen generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

If you generate the MEX function to test the generated code of the parfor version, you can disable the usage of Intel TBB. Set the ExtrinsicCalls property of the MEX configuration object to false. For details, see coder.MexCodeConfig.
- MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of knnsearch uses parfor to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your
compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.  

- Starting in R2020a, `knnsearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'IncludeTies', 'NSMethod', and 'SortIndices' name-value pair arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**
“k-Nearest Neighbor Search and Radius Search” on page 18-13
“Distance Metrics” on page 18-11

**Introduced in R2010a**
kruskalwallis

Kruskal-Wallis test

Syntax

\[
p = \text{kruskalwallis}(x) \\
p = \text{kruskalwallis}(x,\text{group}) \\
p = \text{kruskalwallis}(x,\text{group},\text{displayopt}) \\
[p,\text{tbl},\text{stats}] = \text{kruskalwallis}(\_\_\_)\]

Description

\( p = \text{kruskalwallis}(x) \) returns the \( p \)-value for the null hypothesis that the data in each column of the matrix \( x \) comes from the same distribution, using a Kruskal-Wallis test on page 32-2941. The alternative hypothesis is that not all samples come from the same distribution. \text{kruskalwallis} also returns an ANOVA table and a box plot.

\( p = \text{kruskalwallis}(x,\text{group}) \) returns the \( p \)-value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable \( \text{group} \) comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

\( p = \text{kruskalwallis}(x,\text{group},\text{displayopt}) \) returns the \( p \)-value of the test and lets you display or suppress the ANOVA table and box plot.

\( [p,\text{tbl},\text{stats}] = \text{kruskalwallis}(\_\_\_) \) also returns the ANOVA table as the cell array \( \text{tbl} \) and the structure \( \text{stats} \) containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has \( \mu = 0 \) and \( \sigma = 1 \), and the second distribution has \( \mu = 2 \) and \( \sigma = 1 \).

\[
pd1 = \text{makedist}('\text{Normal}') \\
pd2 = \text{makedist}('\text{Normal}',\text{'}mu',2,\text{'}sigma',1);\]

Create a matrix of sample data by generating random numbers from these two distributions.

\[
rng('\text{default}'); % for reproducibility \\
x = [\text{random}(pd1,20,2),\text{random}(pd2,20,1)];\]

The first two columns of \( x \) contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in \( x \) comes from the same distribution.

\[
p = \text{kruskalwallis}(x)\]
The returned value of $p$ indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in $x$.

### Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has $\mu = 0$ and $\sigma = 1$. The second distribution has $\mu = 2$ and $\sigma = 1$.

```matlab
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];

The first two columns of x contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in x comes from the same distribution. Suppress the output displays, and generate the structure stats to use in further testing.

[p,tbl,stats] = kruskalwallis(x,[],'off')

p = 3.6896e-06

The returned value of p indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure stats to perform additional followup testing. The cell array tbl contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

c = multcompare(stats)

Note: Intervals can be used for testing but are not simultaneous confidence intervals.
The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

**Test for the Same Distribution Across Groups**

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, indicating the type of metal alloy from which the corresponding beam is made.

```matlab
c = 3×6
1.0000 2.0000 -5.1435 7.8000 20.7435 0.3345
1.0000 3.0000 -31.9935 -19.0500 -6.1065 0.0016
2.0000 3.0000 -39.7935 -26.8500 -13.9065 0.0000
```

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, indicating the type of metal alloy from which the corresponding beam is made.
Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

\[ p = \text{kruskalwallis}(\text{strength}, \text{alloy}, 'off') \]

\[ p = 0.0018 \]

The returned value of \( p \) indicates that the test rejects the null hypothesis at the 1% significance level.

**Input Arguments**

- **\( x \) — Sample data**
  
  vector | matrix

  Sample data for the hypothesis test, specified as a vector or an \( m \)-by-\( n \) matrix. If \( x \) is an \( m \)-by-\( n \) matrix, each of the \( n \) columns represents an independent sample containing \( m \) mutually independent observations.

  Data Types: single | double

- **\( \text{group} \) — Grouping variable**
  
  numeric vector | logical vector | character array | string array | cell array of character vectors

  Grouping variable, specified as a numeric or logical vector, a character or string array, or a cell array of character vectors.

  - If \( x \) is a vector, then each element in \( \text{group} \) identifies the group to which the corresponding element in \( x \) belongs, and \( \text{group} \) must be a vector of the same length as \( x \). If a row of \( \text{group} \) contains an empty value, that row and the corresponding observation in \( x \) are disregarded. NaN values in either \( x \) or \( \text{group} \) are similarly ignored.

  - If \( x \) is a matrix, then each column in \( x \) represents a different group, and you can use \( \text{group} \) to specify labels for these columns. The number of elements in \( \text{group} \) and the number of columns in \( x \) must be equal.

  The labels contained in \( \text{group} \) also annotate the box plot.

  Example: {'red','blue','green','blue','red','blue','green','green','red'}

  Data Types: single | double | logical | char | string | cell

- **\( \text{displayopt} \) — Display option**

  'on' (default) | 'off'

  Display option, specified as 'on' or 'off'. If \( \text{displayopt} \) is 'on', \text{kruskalwallis} displays the following figures:

  - An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in \( x \).

  - A box plot of the data in each column of the data matrix \( x \). The box plots are based on the actual data values, rather than on the ranks.

  If \( \text{displayopt} \) is 'off', \text{kruskalwallis} does not display these figures.

  If you specify a value for \( \text{displayopt} \), you must also specify a value for \( \text{group} \). If you do not have a grouping variable, specify \( \text{group} \) as [].

32-2940
Example: 'off'

Output Arguments

p — p-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a
test statistic as extreme as, or more extreme than, the observed value under the null hypothesis.
Small values of p cast doubt on the validity of the null hypothesis.

tbl — ANOVA table
cell array

ANOVA table of test results, returned as a cell array. tbl includes the sums of squares, degrees of
freedom, and other quantities calculated based on the ranks of the data in x, as well as column and
row labels.

stats — Test data
structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of
sample medians by using multcompare, with stats as the input value.

More About

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of
the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data
in x to determine if the samples come from the same population (or, equivalently, from different
populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test
statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking
the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all
observations tied with it. The F-statistic used in classical one-way ANOVA is replaced by a chi-square
statistic, and the p-value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous
distribution, apart from possibly different locations due to group effects, and that all observations are
mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the
stronger assumption that the populations have normal distributions.

Introduced before R2006a
ksdensity

Kernel smoothing function estimate for univariate and bivariate data

Syntax

[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(___ ,Name,Value)
[f,xi,bw] = ksdensity( ___ )
ksdensity( ___ )
ksdensity(ax , ___ )

Description

[f,xi] = ksdensity(x) returns a probability density estimate, f, for the sample data in the vector or two-column matrix x. The estimate is based on a normal kernel function, and is evaluated at equally-spaced points, xi, that cover the range of the data in x. ksdensity estimates the density at 100 points for univariate data, or 900 points for bivariate data.

ksdensity works best with continuously distributed samples.

[f,xi] = ksdensity(x,pts) specifies points (pts) to evaluate f. Here, xi and pts contain identical values.

[f,xi] = ksdensity(___ ,Name,Value) uses additional options specified by one or more name-value pair arguments in addition to any of the input arguments in the previous syntaxes. For example, you can define the function type ksdensity evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

[f,xi,bw] = ksdensity( ___ ) also returns the bandwidth of the kernel smoothing window, bw. The default bandwidth is the optimal for normal densities.

ksdensity( ___ ) plots the kernel smoothing function estimate.

ksdensity(ax, ___ ) plots the results using axes with the handle, ax, instead of the current axes returned by gca.

Examples

Estimate Density

Generate a sample data set from a mixture of two normal distributions.

rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];

Plot the estimated density.
The density estimate shows the bimodality of the sample.

**Estimate Density with Boundary Correction**

Generate a nonnegative sample data set from the half-normal distribution.

```matlab
rng('default') % For reproducibility
pd = makedist('HalfNormal','mu',0,'sigma',1);
x = random(pd,100,1);
```

Estimate pdfs with two different boundary correction methods, log transformation and reflection, by using the 'BoundaryCorrection' name-value pair argument.

```matlab
pts = linspace(0,5,1000); % points to evaluate the estimator
[f1,xi1] = ksdensity(x,pts,'Support','positive');
[f2,xi2] = ksdensity(x,pts,'Support','positive','BoundaryCorrection','reflection');
```

Plot the two estimated pdfs.

```matlab
plot(xi1,f1,xi2,f2)
lgd = legend('log','reflection');
title(lgd, 'Boundary Correction Method')
```
ksdensity uses a boundary correction method when you specify either positive or bounded support. The default boundary correction method is log transformation. When ksdensity transforms the support back, it introduces the $1/x$ term in the kernel density estimator. Therefore, the estimate has a peak near $x = 0$. On the other hand, the reflection method does not cause undesirable peaks near the boundary.

**Estimate Cumulative Distribution Function at Specified Values**

Load the sample data.

```matlab
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```matlab
pts = (min(hospital.Weight):2:max(hospital.Weight));
figure()
ecdf(hospital.Weight)
hold on
[f,xi,bw] = ksdensity(hospital.Weight,pts,'Support','positive',... 
    'Function','cdf');
plot(xi,f,'-g','LineWidth',2)
legend('empirical cdf','kernel-bw:default','Location','northwest')
```
ksdensity seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

bw

bw = 0.1070

Plot the cumulative distribution function estimate using a smaller bandwidth.

[f,xi] = ksdensity(hospital.Weight,pts,'Support','positive',... 'Function','cdf','Bandwidth',0.05);
plot(xi,f,'--r',LineWidth,2)
legend('empirical cdf', 'kernel-bw:default', 'kernel-bw:0.05',... 'Location','northwest')
hold off
The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

**Plot Estimated Cumulative Density Function for Given Number of Points**

Load the sample data.

```matlab
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```matlab
figure()
ksdensity(hospital.Weight,'Support','positive','Function','cdf', ... 'NumPoints',50)
xlabel('Patient weights')
ylabel('Estimated cdf')
```
**Estimate Survivor and Cumulative Hazard for Censored Failure Data**

Generate sample data from an exponential distribution with mean 3.

```matlab
rng('default')  % For reproducibility
t = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```matlab
T = 10;
cens = (t>T);
```

Compute and plot the estimated density function.

```matlab
figure
ksdensity(t,'Support','positive','Censoring',cens);
```
Compute and plot the survivor function.

```matlab
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','survivor');
```
Compute and plot the cumulative hazard function.

```matlab
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','cumhazard');
```
Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'Function','icdf');
```
Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```matlab
rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```matlab
[f,xi,bw] = ksdensity(x);
bw
```

```
bw = 1.5141
```

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```matlab
figure
plot(xi,f);
xlabel('xi')
ylabel('f')
hold on
```
Plot the density using an increased bandwidth value.

\[
[f,xi] = \text{ksdensity}(x,'\text{Bandwidth}',1.8);
\]

plot(xi,f,'--r','\text{LineWidth}',1.5)
A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```matlab
[f,xi] = ksdensity(x,'Bandwidth',0.8);
plot(xi,f,'-.k','LineWidth',1.5)
legend('bw = default','bw = 1.8','bw = 0.8')
hold off
```
A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

**Plot Kernel Density Estimate of Bivariate Data**

Create a two-column vector of points at which to evaluate the density.

```matlab
gridx1 = -0.25:.05:1.25;
gridx2 = 0:.1:15;
[x1,x2] = meshgrid(gridx1, gridx2);
x1 = x1(:);
x2 = x2(:);
xi = [x1 x2];
```

Generate a 30-by-2 matrix containing random numbers from a mixture of bivariate normal distributions.

```matlab
rng('default') % For reproducibility
x = [0+.5*rand(20,1) 5+2.5*rand(20,1); .75+.25*rand(10,1) 8.75+1.25*rand(10,1)];
```

Plot the estimated density of the sample data.

```matlab
figure
ksdensity(x,xi);
```
Input Arguments

**x — Sample data**

column vector | two-column matrix

Sample data for which `ksdensity` returns f values, specified as a column vector or two-column matrix. Use a column vector for univariate data, and a two-column matrix for bivariate data.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

**pts — Points at which to evaluate f**

vector | two-column matrix

Points at which to evaluate f, specified as a vector or two-column matrix. For univariate data, pts can be a row or column vector. The length of the returned output f is equal to the number of points in pts.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

**ax — Axes handle**

handle

Aaxes handle for the figure `ksdensity` plots to, specified as a handle.
For example, if h is a handle for a figure, then ksdensity can plot to that figure as follows.

Example: ksdensity(h,x)

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Censoring',cens,'Kernel','triangle','NumPoints',20,'Function','cdf' specifies that ksdensity estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector cens.

**Bandwidth — Bandwidth of the kernel smoothing window**

optimal value for normal densities (default) | scalar value | two-element vector

The bandwidth of the kernel-smoothing window, which is a function of the number of points in x, specified as the comma-separated pair consisting of 'Bandwidth' and a scalar value. If the sample data is bivariate, Bandwidth can also be a two-element vector. The default is optimal for estimating normal densities [1], but you might want to choose a larger or smaller value to smooth more or less.

If you specify 'BoundaryCorrection' as 'log'(default) and 'Support' as either 'positive' or a vector [L U], ksdensity converts bounded data to be unbounded by using log transformation. The value of 'Bandwidth' is on the scale of the transformed values.

Example: 'Bandwidth',0.8

Data Types: single | double

**BoundaryCorrection — Boundary correction method**

'log' (default) | 'reflection'

Boundary correction method, specified as the comma-separated pair consisting of 'BoundaryCorrection' and 'log' or 'reflection'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'log'</td>
<td>ksdensity converts bounded data x to be unbounded by one of the following</td>
</tr>
<tr>
<td></td>
<td>transformations. Then, it transforms back to the original bounded scale after</td>
</tr>
<tr>
<td></td>
<td>density estimation.</td>
</tr>
<tr>
<td></td>
<td>• For univariate data, if you specify 'Support','positive', then</td>
</tr>
<tr>
<td></td>
<td>ksdensity applies log(x).</td>

<tr>
<td></td>
<td>boundaries, then it returns estimates corresponding to the original support.</td>
</tr>
<tr>
<td></td>
<td>For details, see “Reflection Method” on page 32-2960.</td>
</tr>
</tbody>
</table>
ksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection','reflection'

**Censoring — Logical vector**

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as the comma-separated pair consisting of 'Censoring' and a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring. This name-value pair is only valid for univariate data.

Example: 'Censoring',censdata

Data Types: logical

**Function — Function to estimate**

'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pdf'</td>
<td>Probability density function.</td>
</tr>
<tr>
<td>'cdf'</td>
<td>Cumulative distribution function.</td>
</tr>
<tr>
<td>'icdf'</td>
<td>Inverse cumulative distribution function. ksdensity computes the estimated inverse cdf of the values in x, and evaluates it at the probability values specified in pi. This value is valid only for univariate data.</td>
</tr>
<tr>
<td>'survivor'</td>
<td>Survivor function.</td>
</tr>
<tr>
<td>'cumhazard'</td>
<td>Cumulative hazard function.</td>
</tr>
</tbody>
</table>

Example: 'Function','icdf'

**Kernel — Type of kernel smoother**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'
- A kernel function that is a custom or built-in function. Specify the function as a function handle (for example, @myfunction or @normpdf) or as a character vector or string scalar (for example, 'myfunction' or 'normpdf'). The software calls the specified function with one argument that
is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'Function' is 'pdf', the kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'Function' is 'icdf' returns an error.

For bivariate data, ksdensity applies the same kernel to each dimension.

Example: ‘Kernel’, 'box'

**NumPoints — Number of equally spaced points**

100 (default) | scalar value

Number of equally spaced points in xi, specified as the comma-separated pair consisting of 'NumPoints' and a scalar value. This name-value pair is only valid for univariate data.

For example, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: ‘NumPoints’, 80

Data Types: single | double

**Support — Support for the density**

'unbounded' (default) | 'positive' | two-element vector, [L U] | two-by-two matrix, [L1 L2; U1 U2]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'unbounded'</td>
<td>Default. Allow the density to extend over the whole real line.</td>
</tr>
<tr>
<td>'positive'</td>
<td>Restrict the density to positive values.</td>
</tr>
<tr>
<td>Two-element vector, [L U]</td>
<td>Give the finite lower and upper bounds for the support of the density. This option is only valid for univariate sample data.</td>
</tr>
<tr>
<td>Two-by-two matrix, [L1 L2; U1 U2]</td>
<td>Give the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. This option is only valid for bivariate sample data.</td>
</tr>
</tbody>
</table>

For bivariate data, 'Support' can be a combination of positive, unbounded, or bounded variables specified as [0 -Inf; Inf Inf] or [0 L; Inf U].

Example: ‘Support', 'positive'

Example: ‘Support', [0 10]

Data Types: single | double | char | string

**PlotFcnc — Function used to create kernel density plot**

'surf' (default) | 'contour' | 'plot3' | 'surfc'

Function used to create kernel density plot, specified as the comma-separated pair consisting of 'PlotFcnc' and one of the following.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'surf'</td>
<td>3-D shaded surface plot, created using surf</td>
</tr>
<tr>
<td>'contour'</td>
<td>Contour plot, created using contour</td>
</tr>
<tr>
<td>'plot3'</td>
<td>3-D line plot, created using plot3</td>
</tr>
<tr>
<td>'surfc'</td>
<td>Contour plot under a 3-D shaded surface plot, created using surfc</td>
</tr>
</tbody>
</table>

This name-value pair is only valid for bivariate sample data.

Example: 'PlotFcn','contour'

**Weights — Weights for sample data**

vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length size(x,1), where x is the sample data.

Example: 'Weights',xw

Data Types: single | double

**Output Arguments**

**f — Estimated function values**

vector

Estimated function values, returned as a vector whose length is equal to the number of points in xi or pts.

**xi — Evaluation points**

100 equally spaced points | 900 equally spaced points | vector | two-column matrix

Evaluation points at which ksdensity calculates f, returned as a vector or a two-column matrix. For univariate data, the default is 100 equally-spaced points that cover the range of data in x. For bivariate data, the default is 900 equally-spaced points created using meshgrid from 30 equally-spaced points in each dimension.

**bw — Bandwidth of smoothing window**

scalar value

Bandwidth of smoothing window, returned as a scalar value.

If you specify 'BoundaryCorrection' as 'log'(default) and 'Support' as either 'positive' or a vector [L U], ksdensity converts bounded data to be unbounded by using log transformation. The value of bw is on the scale of the transformed values.

**More About**

**Kernel Distribution**

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data.
A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

The kernel density estimator is the estimated pdf of a random variable. For any real values of \( x \), the kernel density estimator's formula is given by

\[
\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^{n} K\left(\frac{x - x_i}{h}\right),
\]

where \( x_1, x_2, ..., x_n \) are random samples from an unknown distribution, \( n \) is the sample size, \( K(\cdot) \) is the kernel smoothing function, and \( h \) is the bandwidth.

The kernel estimator for the cumulative distribution function (cdf), for any real values of \( x \), is given by

\[
\hat{F}_h(x) = \int_{-\infty}^{x} \hat{f}_h(t) dt = \frac{1}{n} \sum_{i=1}^{n} G\left(\frac{x - x_i}{h}\right),
\]

where \( G(x) = \int_{-\infty}^{x} K(t) dt \).

For more details, see “Kernel Distribution” on page B-78.

**Reflection Method**

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify ‘BoundaryCorrection’, ‘reflection’, \( \text{kdsdensity} \) uses the reflection method. This method augments bounded data by adding reflected data near the boundaries, and estimates the pdf. Then, \( \text{kdsdensity} \) returns the estimated pdf corresponding to the original support with proper normalization, so that the estimated pdf's integral over the original support is equal to one.

If you additionally specify ‘Support’, \([L \ U]\), then \( \text{kdsdensity} \) finds the kernel estimator as follows.

- If ‘Function’ is ‘pdf’, then the kernel density estimator is

\[
\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^{n} \left[ K\left(\frac{x - x_i^-}{h}\right) + K\left(\frac{x - x_i^+}{h}\right) + K\left(\frac{x - x_i}{h}\right) \right]
\]

for \( L \leq x \leq U \), where \( x_i^- = 2L - x_i, x_i^+ = 2U - x_i \), and \( x_i \) is the \( i \)th sample data.

- If ‘Function’ is ‘cdf’, then the kernel estimator for cdf is

\[
\hat{F}_h(x) = \frac{1}{n} \sum_{i=1}^{n} \left[ G\left(\frac{x - x_i^-}{h}\right) + G\left(\frac{x - x_i^+}{h}\right) + G\left(\frac{x - x_i}{h}\right) \right] - \frac{1}{n} \sum_{i=1}^{n} \left[ G\left(\frac{L - x_i^-}{h}\right) + G\left(\frac{L - x_i^+}{h}\right) + G\left(\frac{L - x_i}{h}\right) \right]
\]

for \( L \leq x \leq U \).

- To obtain a kernel estimator for an inverse cdf, a survivor function, or a cumulative hazard function (when ‘Function' is 'icdf', 'survivor', or 'cumhazard'), \( \text{kdsdensity} \) uses both \( \hat{f}_h(x) \) and \( \hat{F}_h(x) \).

If you additionally specify ‘Support’ as ‘positive’ or \([0 \ inf]\), then \( \text{kdsdensity} \) finds the kernel estimator by replacing \([L \ U]\) with \([0 \ inf]\) in the above equations.
References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- Some options that require extra passes or sorting of the input data are not supported:
  - 'BoundaryCorrection'
  - 'Censoring'
  - 'Support' (support is always unbounded).
- Uses standard deviation (instead of median absolute deviation) to compute the bandwidth.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Plotting is not supported.
- Names in name-value pair arguments must be compile-time constants.
- Values in the following name-value pair arguments must also be compile-time constants:
  - 'BoundaryCorrection', 'Function', and 'Kernel'. For example, to use the 'Function', 'cdf' name-value pair argument in the generated code, include {coder.Constant('Function'),coder.Constant('cdf')} in the -args value of codegen.
- The value of the 'Kernel' name-value pair argument cannot be a custom function handle. To specify a custom kernel function, use a character vector or string scalar.
- For the value of the 'Support' name-value pair argument, the compile-time data type must match the runtime data type.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a
ktest

One-sample Kolmogorov-Smirnov test

Syntax

h = kstest(x)

h = kstest(x,Name,Value)

[h,p] = kstest(____)

[h,p,ksstat,cv] = kstest(____)

Description

h = kstest(x) returns a test decision for the null hypothesis that the data in vector x comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test on page 32-2969. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

h = kstest(x,Name,Value) returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

[h,p] = kstest(____) also returns the p-value p of the hypothesis test, using any of the input arguments from the previous syntaxes.

[h,p,ksstat,cv] = kstest(____) also returns the value of the test statistic ksstat and the approximate critical value cv of the test.

Examples

Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using kstest. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the examgrades data set. Create a vector containing the first column of the exam grade data.

load examgrades
test1 = grades(:,1);

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because kstest tests for a standard normal distribution by default.

x = (test1-75)/10;
h = kstest(x)

h = logical
  0
The returned value of \( h = 0 \) indicates that \( \text{kstest} \) fails to reject the null hypothesis at the default 5\% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```matlab
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```

The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

**Specify the Hypothesized Distribution Using a Two-Column Matrix**

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

```matlab
load examgrades;
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector \( x \). Column 2 contains cdf values evaluated at each value in \( x \) for a hypothesized Student’s \( t \) distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.
test_cdf = [x,cdf('tlocationscale',x,75,10,1)];
Test if the data are from the hypothesized distribution.

h = kstest(x,'CDF',test_cdf)

h = logical
   1

The returned value of $h = 1$ indicates that kstest rejects the null hypothesis at the default 5% significance level.

**Specify the Hypothesized Distribution Using a Probability Distribution Object**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```matlab
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's $t$ distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```matlab
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```matlab
h = kstest(x,'CDF',test_cdf)
```

h = logical
   1

The returned value of $h = 1$ indicates that kstest rejects the null hypothesis at the default 5% significance level.

**Test the Hypothesis at Different Significance Levels**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```matlab
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's $t$ distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```matlab
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```matlab
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
```
The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis at the 1\% significance level.

**Conduct a One-Sided Hypothesis Test**

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```matlab
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```matlab
[h,p,k,c] = kstest(x,'Tail','larger')
```

The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis in favor of the alternative hypothesis at the default 5\% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```matlab
[f,x_values] = ecdf(x);
J = plot(x_values,f);
hold on;
K = plot(x_values,normcdf(x_values),'r--');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K],'Empirical CDF','Standard Normal CDF','Location','SE');
```
The plot shows the difference between the empirical cdf of the data vector $x$ and the cdf of the standard normal distribution.

**Input Arguments**

$x$ — Sample data

vector

Sample data, specified as a vector.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: ‘Tail’, ‘larger’, ‘Alpha’, 0.01 specifies a test using the alternative hypothesis that the cdf of the population from which the sample data is drawn is greater than the cdf of the hypothesized distribution, conducted at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)
Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01
Data Types: single | double

CDF — cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of 'CDF' and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible $x$ values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector $x$. If there are values in $x$ not found in column 1 of CDF, kstest approximates $G(x)$ by interpolation. All values in $x$ must lie in the interval between the smallest and largest values in the first column of CDF. By default, kstest tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test on page 32-2969 is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test $x$ against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use lillietest instead.

Data Types: single | double

Tail — Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'unequal' Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is not equal to the cdf of the hypothesized distribution.

'larger' Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is greater than the cdf of the hypothesized distribution.

'smaller' Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector $x$ tend to be larger than expected from the hypothesized distribution, the empirical distribution function of $x$ tends to be smaller, and vice versa.

Example: 'Tail','larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.
**p — p-value**
scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

**ksstat — Test statistic**
nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

**cv — Critical value**
nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

**More About**

**One-Sample Kolmogorov-Smirnov Test**

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from *x* and the hypothesized cdf:

\[ D^* = \max_x (|\hat{F}(x) - G(x)|), \]

where \( \hat{F}(x) \) is the empirical cdf and \( G(x) \) is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from *x* exceeds the hypothesized cdf:

\[ D^* = \max_x (\hat{F}(x) - G(x)), \]

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from *x*:

\[ D^* = \max_x (G(x) - \hat{F}(x)). \]

**kstest** computes the critical value *cv* using an approximate formula or by interpolation in a table. The formula and table cover the range \( 0.01 \leq \alpha \leq 0.2 \) for two-sided tests and \( 0.005 \leq \alpha \leq 0.1 \) for one-sided tests. *cv* is returned as NaN if *alpha* is outside this range.

**Algorithms**

**kstest** decides to reject the null hypothesis by comparing the *p*-value *p* with the significance level *Alpha*, not by comparing the test statistic *ksstat* with the critical value *cv*.
approximate, comparing \texttt{ksstat} with \texttt{cv} occasionally leads to a different conclusion than comparing \texttt{p} with \texttt{Alpha}.

\texttt{adtest} | \texttt{kstest2} | \texttt{lillietest}

**Introduced before R2006a**
### kstest2

Two-sample Kolmogorov-Smirnov test

**Syntax**

\[
h = \text{kstest2}(x_1, x_2) \\
h = \text{kstest2}(x_1, x_2, \text{Name}, \text{Value}) \\
[h, p] = \text{kstest2}(\_\_\_) \\
[h, p, ks2stat] = \text{kstest2}(\_\_\_)
\]

**Description**

\( h = \text{kstest2}(x_1, x_2) \) returns a test decision for the null hypothesis that the data in vectors \( x_1 \) and \( x_2 \) are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test on page 32-2974. The alternative hypothesis is that \( x_1 \) and \( x_2 \) are from different continuous distributions. The result \( h \) is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

\( h = \text{kstest2}(x_1, x_2, \text{Name}, \text{Value}) \) returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

\( [h, p] = \text{kstest2}(\_\_\_) \) also returns the asymptotic \( p \)-value \( p \), using any of the input arguments from the previous syntaxes.

\( [h, p, ks2stat] = \text{kstest2}(\_\_\_\_) \) also returns the test statistic \( ks2stat \).

**Examples**

**Test Two Samples for the Same Distribution**

Generate sample data from two different Weibull distributions.

\[
\begin{align*}
\text{rng}(&1); &\quad \% \text{For reproducibility} \\
x_1 &= \text{wblrnd}(1,1,1,50); \\
x_2 &= \text{wblrnd}(1.2,2,1,50);
\end{align*}
\]

Test the null hypothesis that data in vectors \( x_1 \) and \( x_2 \) comes from populations with the same distribution.

\[
h = \text{kstest2}(x_1, x_2) \\
h = \text{logical} \\
1
\]

The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis at the default 5% significance level.
Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```matlab
rng(1);       % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors \( x_1 \) and \( x_2 \) are from populations with the same distribution at the 1% significance level.

```matlab
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

\( h = \text{logical} \)

\[ h = 0 \]

\( p = 0.0317 \)

The returned value of \( h = 0 \) indicates that \text{kstest} does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```matlab
rng(1);       % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors \( x_1 \) and \( x_2 \) comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of \( x_1 \) is larger than the cdf of the distribution of \( x_2 \).

```matlab
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

\( h = \text{logical} \)

\[ h = 1 \]

\( p = 0.0158 \)

\( k = 0.2800 \)

The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of \( x_1 \) is larger than the cdf of the distribution of \( x_2 \), at the default 5% significance level. The returned value of \( k \) is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

\( x_1 \) — Sample data

vector
Sample data from the first sample, specified as a vector. Data vectors \( x_1 \) and \( x_2 \) do not need to be the same size.

Data Types: single | double

\( x_2 \) — Sample data vector

Sample data from the second sample, specified as a vector. Data vectors \( x_1 \) and \( x_2 \) do not need to be the same size.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','larger','Alpha',0.01` specifies a test using the alternative hypothesis that the empirical cdf of \( x_1 \) is larger than the empirical cdf of \( x_2 \), conducted at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: single | double

**Tail — Type of alternative hypothesis**

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

- `'unequal'` Test the alternative hypothesis that the empirical cdf of \( x_1 \) is unequal to the empirical cdf of \( x_2 \).
- `'larger'` Test the alternative hypothesis that the empirical cdf of \( x_1 \) is larger than the empirical cdf of \( x_2 \).
- `'smaller'` Test the alternative hypothesis that the empirical cdf of \( x_1 \) is smaller than the empirical cdf of \( x_2 \).

If the data values in \( x_1 \) tend to be larger than those in \( x_2 \), the empirical distribution function of \( x_1 \) tends to be smaller than that of \( x_2 \), and vice versa.

Example: `'Tail','larger'`

**Output Arguments**

\( h \) — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.
• If \( h = 1 \), this indicates the rejection of the null hypothesis at the Alpha significance level.
• If \( h = 0 \), this indicates a failure to reject the null hypothesis at the Alpha significance level.

\( p \) — Asymptotic \( p \)-value  
scalar value in the range (0,1)

Asymptotic \( p \)-value of the test, returned as a scalar value in the range (0,1). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic \( p \)-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes \( n_1 \) and \( n_2 \), such that \( (n_1 \times n_2)/(n_1 + n_2) \geq 4 \).

\( \text{ks2stat} \) — Test statistic  
nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of \( x \) in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

\[
D^* = \max_x \left| \hat{F}_1(x) - \hat{F}_2(x) \right|
\]

where \( \hat{F}_1(x) \) is the proportion of \( x_1 \) values less than or equal to \( x \) and \( \hat{F}_2(x) \) is the proportion of \( x_2 \) values less than or equal to \( x \).

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

\[
D^* = \max_x \left( \hat{F}_1(x) - \hat{F}_2(x) \right)
\]

Algorithms

In kstest2, the decision to reject the null hypothesis is based on comparing the \( p \)-value \( p \) with the significance level \( \text{Alpha} \), not by comparing the test statistic \( \text{ks2stat} \) with a critical value.

**Introduced before R2006a**
kurtosis

Kurtosis

Syntax

k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,'all')
k = kurtosis(X,flag,dim)
k = kurtosis(X,flag,vecdim)

Description

k = kurtosis(X) returns the sample kurtosis of X.

- If X is a vector, then kurtosis(X) returns a scalar value that is the kurtosis of the elements in X.
- If X is a matrix, then kurtosis(X) returns a row vector that contains the sample kurtosis of each column in X.
- If X is a multidimensional array, then kurtosis(X) operates along the first nonsingleton dimension of X.

k = kurtosis(X,flag) specifies whether to correct for bias (flag is 0) or not (flag is 1, the default). When X represents a sample from a population, the kurtosis of X is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size. You can set flag to 0 to correct for this systematic bias.

k = kurtosis(X,flag,'all') returns the kurtosis of all elements of X.

k = kurtosis(X,flag,dim) returns the kurtosis along the operating dimension dim of X.

k = kurtosis(X,flag,vecdim) returns the kurtosis over the dimensions specified in the vector vecdim. For example, if X is a 2-by-3-by-4 array, then kurtosis(X,1,[1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the biased kurtosis of the elements on the corresponding page of X.

Examples

Find Kurtosis of Matrix

Set the random seed for reproducibility of the results.

rng('default')

Generate a matrix with 5 rows and 4 columns.

X = randn(5,4)

X = 5×4
Find the sample kurtosis of $X$.

```matlab
k = kurtosis(X)
k = 1×4
    2.7067  1.4069  2.3783  1.1759
```

$k$ is a row vector containing the sample kurtosis of each column in $X$.

**Correct for Bias in Sample Kurtosis**

For an input vector, correct for bias in the calculation of kurtosis by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```matlab
rng('default')
```

Generate a vector of length 10.

```matlab
x = randn(10,1)
x = 10×1
    0.5377
    1.8339
   -2.2588
    0.8622
    0.3188
   -1.3077
   -0.4336
    0.3426
    3.5784
    2.7694
```

Find the biased kurtosis of $x$. By default, `kurtosis` sets the value of `flag` to 1 for computing the biased kurtosis.

```matlab
k1 = kurtosis(x)  % flag is 1 by default
k1 = 2.3121
```

Find the bias-corrected kurtosis of $x$ by setting the value of `flag` to 0.

```matlab
k2 = kurtosis(x,0)
k2 = 2.7483
```
Find Kurtosis Along Given Dimension

Find the kurtosis along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```matlab
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```matlab
X = randn([4,3,2])
```

```matlab
X =
X(:,:,1) =
         0.5377    0.3188    3.5784
         1.8339   -1.3077    2.7694
        -2.2588   -0.4336   -1.3499
         0.8622    0.3426    3.0349
X(:,:,2) =
         0.7254   -0.1241    0.6715
        -0.0631    1.4897   -1.2075
         0.7147    1.4090    0.7172
        -0.2050    1.4172    1.6302
```

Find the kurtosis of `X` along the default dimension.

```matlab
k1 = kurtosis(X)
k1 =
k1(:,:,1) =
         2.1350    1.7060    2.2789
k1(:,:,2) =
         1.0542    2.3278    2.0996
```

By default, `kurtosis` operates along the first dimension of `X` whose size does not equal 1. In this case, this dimension is the first dimension of `X`. Therefore, `k1` is a 1-by-3-by-2 array.

Find the biased kurtosis of `X` along the second dimension.

```matlab
k2 = kurtosis(X,1,2)
k2 =
k2(:,:,1) =
         1.5000
```

32-2978
k2 is a 4-by-1-by-2 array.

Find the biased kurtosis of \( X \) along the third dimension.

\[
k3 = \text{kurtosis}(X, 1, 3)
\]

\[
k3 = \begin{bmatrix}
1.0000 & 1.0000 & 1.0000 \\
1.0000 & 1.0000 & 1.0000 \\
1.0000 & 1.0000 & 1.0000 \\
1.0000 & 1.0000 & 1.0000 \\
\end{bmatrix}
\]

\( k3 \) is a 4-by-3 matrix.

**Find Kurtosis Along Vector of Dimensions**

Find the kurtosis over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

\[
rng('default')
\]

Create a 4-by-3-by-2 array of random numbers.

\[
X = \text{randn([4 3 2])}
\]

\[
X = \\
X(:,:,1) = \\
0.5377  0.3188  3.5784 \\
1.8339 -1.3077  2.7694 \\
-2.2588 -0.4336 -1.3499 \\
0.8622  0.3426  3.0349 \\
X(:,:,2) = \\
0.7254 -0.1241  0.6715 \\
-0.0631  1.4897 -1.2075 \\
0.7147  1.4090  0.7172 \\
-0.2050  1.4172  1.6302
\]
Find the biased kurtosis of $X$.

```
kall = kurtosis(X,1,'all')
kall = 2.8029
```

$kall$ is the biased kurtosis of the entire input data set $X$.

Find the biased kurtosis of each page of $X$ by specifying the first and second dimensions.

```
kpage = kurtosis(X,1,[1 2])
kpage =
kpage(:,:,1) =
    1.9345
kpage(:,:,2) =
    2.5877
```

For example, $kpage(1,1,2)$ is the biased kurtosis of the elements in $X(:,:,2)$.

Find the biased kurtosis of the elements in each $X(i,:,:)$ slice by specifying the second and third dimensions.

```
krow = kurtosis(X,1,[2 3])
krow = 4×1
    3.8457
    1.4306
    1.7094
    2.3378
```

For example, $krow(3)$ is the biased kurtosis of the elements in $X(3,:,:)$.

### Input Arguments

**$X$ — Input data**  
vector | matrix | multidimensional array  

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If $X$ is a vector, then $\text{kurtosis}(X)$ returns a scalar value that is the kurtosis of the elements in $X$.
- If $X$ is a matrix, then $\text{kurtosis}(X)$ returns a row vector that contains the sample kurtosis of each column in $X$.
- If $X$ is a multidimensional array, then $\text{kurtosis}(X)$ operates along the first nonsingleton dimension of $X$.

To specify the operating dimension when $X$ is a matrix or an array, use the `dim` input argument.
**kurtosis** treats NaN values in X as missing values and removes them.

Data Types: single | double

**flag** — Indicator for bias

1 (default) | 0

Indicator for the bias, specified as 0 or 1.

- If flag is 1 (default), then the kurtosis of X is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size.
- If flag is 0, then kurtosis corrects for the systematic bias.

Data Types: single | double | logical

**dim** — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for dim, then the default is the first dimension of X whose size does not equal 1.

Consider the kurtosis of a matrix X:

- If dim is equal to 1, then kurtosis returns a row vector that contains the sample kurtosis of each column in X.
- If dim is equal to 2, then kurtosis returns a column vector that contains the sample kurtosis of each row in X.

If dim is greater than ndims(X) or if size(X, dim) is 1, then kurtosis returns an array of NaNs the same size as X.

Data Types: single | double

**vecdim** — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of vecdim represents a dimension of the input array X. The output k has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and k.

For example, if X is a 2-by-3-by-3 array, then kurtosis(X, 1, [1 2]) returns a 1-by-1-by-3 array. Each element of the output is the biased kurtosis of the elements on the corresponding page of X.

Data Types: single | double
Output Arguments

$k$ — Kurtosis

scalar | vector | matrix | multidimensional array

Kurtosis, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution on page B-119 is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3. Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The kurtosis function does not use this convention.

The kurtosis of a distribution is defined as

\[ k = \frac{E(x - \mu)^4}{\sigma^4}, \]

where \( \mu \) is the mean of \( x \), \( \sigma \) is the standard deviation of \( x \), and \( E(t) \) represents the expected value of the quantity \( t \). The kurtosis function computes a sample version of this population value.

When you set flag to 1, the kurtosis is biased, and the following equation applies:

\[ k_1 = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^4 \left( \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2 \right)^2. \]

When you set flag to 0, kurtosis corrects for the systematic bias, and the following equation applies:

\[ k_0 = \frac{n - 1}{(n - 2)(n - 3)} ((n + 1)k_1 - 3(n - 1)) + 3. \]

This bias-corrected equation requires that \( X \) contain at least four elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.
• The `dim` input argument must be a compile-time constant.
• If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The ‘all’ and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**
“Normal Distribution” on page B-119

**Introduced before R2006a**
**lasso**

Lasso or elastic net regularization for linear models

**Syntax**

B = lasso(X,y)
B = lasso(X,y,Name,Value)
[B,FitInfo] = lasso(____)

**Description**

B = lasso(X,y) returns fitted least-squares regression coefficients for linear models of the predictor data X and the response y. Each column of B corresponds to a particular regularization coefficient in Lambda. By default, lasso performs lasso regularization using a geometric sequence of Lambda values.

B = lasso(X,y,Name,Value) fits regularized regressions with additional options specified by one or more name-value pair arguments. For example, 'Alpha', 0.5 sets elastic net as the regularization method, with the parameter Alpha equal to 0.5.

[B,FitInfo] = lasso(____) also returns the structure FitInfo, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

**Examples**

**Remove Redundant Predictors Using Lasso Regularization**

Construct a data set with redundant predictors and identify those predictors by using lasso.

Create a matrix X of 100 five-dimensional normal variables. Create a response vector y from just two components of X, and add a small amount of noise.

```matlab
rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise
```

Construct the default lasso fit.

B = lasso(X,y);

Find the coefficient vector for the 25th Lambda value in B.

B(:,25)

ans = 5×1

0
1.6093
0
lasso identifies and removes the redundant predictors.

**Create Linear Model Without Intercept Term Using Lasso Regularization**

Create sample data X and y with X a predictor variable and Y the response variable \( y = 0 + 2X + \varepsilon \).

```matlab
rng('default') % For reproducibility
X = rand(100,1);
y = 2*X + randn(100,1)/10;
```

Specify a regularization value, and find the coefficient of the regression model without an intercept term.

```matlab
lambda = 1e-03;
B = lasso(X,y,'Lambda',lambda,'Intercept',false)
```

Warning: When the 'Intercept' value is false, the 'Standardize' value is set to false.

```matlab
B = 1.9825
```

Plot the real values (points) against the predicted values (line).

```matlab
scatter(X,y)
hold on
x = 0:0.1:1;
plot(x,x*B)
hold off
```
Remove Redundant Predictors by Using Cross-Validated Fits

Construct a data set with redundant predictors and identify those predictors by using cross-validated lasso.

Create a matrix \( X \) of 100 five-dimensional normal variables. Create a response vector \( y \) from two components of \( X \), and add a small amount of noise.

```matlab
rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise
```

Construct the lasso fit by using 10-fold cross-validation with labeled predictor variables.

```matlab
[B,FitInfo] = lasso(X,y,'CV',10,'PredictorNames',{'x1','x2','x3','x4','x5'});
```

Display the variables in the model that corresponds to the minimum cross-validated mean squared error (MSE).

```matlab
idxLambdaMinMSE = FitInfo.IndexMinMSE;
minMSEModelPredictors = FitInfo.PredictorNames(B(:,idxLambdaMinMSE)==0)
```
minMSEModelPredictors = 1x2 cell
    {'x2'}    {'x4'}

Display the variables in the sparsest model within one standard error of the minimum MSE.

idxLambda1SE = FitInfo.Index1SE;
sparseModelPredictors = FitInfo.PredictorNames(B(:,idxLambda1SE)~=0)
sparseModelPredictors = 1x2 cell
    {'x2'}    {'x4'}

In this example, lasso identifies the same predictors for the two models and removes the redundant predictors.

**Lasso Plot with Cross-Validated Fits**

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

load acetylene

Create a design matrix with interactions and no constant term.

X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = [] % No constant term

Construct the lasso fit using 10-fold cross-validation. Include the FitInfo output so you can plot the result.

rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);

Plot the cross-validated fits.

lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

**Predict Values Using Elastic Net Regularization**

Predict students' exam scores using lasso and the elastic net method.

Load the examgrades data set.

```matlab
load examgrades
X = grades(:,1:4);
y = grades(:,5);
```

Split the data into training and test sets.

```matlab
n = length(y);
c = cvpartition(n,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = y(idxTrain);
XTest = X(idxTest,:);
yTest = y(idxTest);
```
Find the coefficients of a regularized linear regression model using 10-fold cross-validation and the elastic net method with \( \text{Alpha} = 0.75 \). Use the largest \( \text{Lambda} \) value such that the mean squared error (MSE) is within one standard error of the minimum MSE.

\[
[B, \text{FitInfo}] = \text{lasso}(\text{XTrain}, \text{yTrain}, '\text{Alpha}', 0.75, 'CV', 10);
\]

\( \text{idxLambda1SE} = \text{FitInfo.Index1SE} \);

\( \text{coef} = B(:, \text{idxLambda1SE}) \);

\( \text{coef0} = \text{FitInfo.Intercept}('\text{idxLambda1SE}') \);

Predict exam scores for the test data. Compare the predicted values to the actual exam grades using a reference line.

\[
yhat = \text{XTest} \ast \text{coef} + \text{coef0};
\]

\[
\text{hold on}
\]

\[
\text{scatter(}\text{yTest}, \text{yhat})
\]

\[
\text{plot(}\text{yTest}, \text{yTest})
\]

\[
\text{xlabel('Actual Exam Grades')}
\]

\[
\text{ylabel('Predicted Exam Grades')}
\]

\[
\text{hold off}
\]

**Input Arguments**

\[
\text{X} \rightarrow \text{Predictor data}
\]

numeric matrix
Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: single | double

**y — Response data**

numeric vector

Response data, specified as a numeric vector. y has length n, where n is the number of rows of X. The response y(i) corresponds to the ith row of X.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `lasso(X,y,'Alpha',0.75,'CV',10)` performs elastic net regularization with 10-fold cross-validation. The 'Alpha',0.75 name-value pair argument sets the parameter used in the elastic net optimization.

**AbsTol — Absolute error tolerance**

1e−4 (default) | positive scalar

Absolute error tolerance used to determine the convergence of the “ADMM Algorithm” on page 32-2996, specified as the comma-separated pair consisting of 'AbsTol' and a positive scalar. The algorithm converges when successive estimates of the coefficient vector differ by an amount less than AbsTol.

**Note** This option applies only when you use `lasso` on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Example: 'AbsTol',1e−3

Data Types: single | double

**Alpha — Weight of lasso versus ridge optimization**

1 (default) | positive scalar

Weight of lasso ($L^1$) versus ridge ($L^2$) optimization, specified as the comma-separated pair consisting of 'Alpha' and a positive scalar value in the interval (0,1]. The value $\text{Alpha} = 1$ represents lasso regression, $\text{Alpha}$ close to 0 approaches ridge regression on page 11-106, and other values represent elastic net optimization. See “Elastic Net” on page 32-2995.

Example: 'Alpha',0.5

Data Types: single | double

**B0 — Initial values for x-coefficients in ADMM Algorithm**

vector of zeros (default) | numeric vector

Initial values for x-coefficients in “ADMM Algorithm” on page 32-2996, specified as the comma-separated pair consisting of 'B0' and a numeric vector.
Note  This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types:  single | double

**CV — Cross-validation specification for estimating mean squared error**  

‘resubstitution’ (default) | positive integer scalar | cvpartition object

Cross-validation specification for estimating the mean squared error (MSE), specified as the comma-separated pair consisting of ‘CV’ and one of the following:

- ‘resubstitution’ — lasso uses X and y to fit the model and to estimate the MSE without cross-validation.
- Positive scalar integer K — lasso uses K-fold cross-validation.
- cvpartition object cvp — lasso uses the cross-validation method expressed in cvp. You cannot use a ‘leaveout’ partition with lasso.

Example: ‘CV’,3

**DFmax — Maximum number of nonzero coefficients**  

Inf (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of ‘DFmax’ and a positive integer scalar. lasso returns results only for Lambda values that satisfy this criterion.

Example: ‘DFmax’,5

Data Types:  single | double

**Intercept — Flag for fitting the model with intercept term**  

true (default) | false

Flag for fitting the model with the intercept term, specified as the comma-separated pair consisting of ‘Intercept’ and either true or false. The default value is true, which indicates to include the intercept term in the model. If Intercept is false, then the returned intercept value is 0.

Example: ‘Intercept’,false

Data Types:  logical

**Lambda — Regularization coefficients**  

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of ‘Lambda’ and a vector of nonnegative values. See “Lasso” on page 32-2995.

- If you do not supply Lambda, then lasso calculates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, then lasso ignores LambdaRatio and NumLambda.
- If Standardize is true, then Lambda is the set of values used to fit the models with the X data standardized to have zero mean and a variance of one.
The default is a geometric sequence of NumLambda values, with only the largest value able to produce \( B = \emptyset \).

Example: `'Lambda', linspace(0,1)`

Data Types: `single` | `double`

**LambdaRatio — Ratio of smallest to largest Lambda values**

1e–4 (default) | positive scalar

Ratio of the smallest to the largest Lambda values when you do not supply Lambda, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set `LambdaRatio` = 0, then `lasso` generates a default sequence of Lambda values and replaces the smallest one with 0.

Example: `'LambdaRatio', 1e–2`

Data Types: `single` | `double`

**MaxIter — Maximum number of iterations allowed**

positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.

If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than 1.

Default values are `1e5` for standard data and `1e4` for tall arrays.

Example: `'MaxIter', 1e3`

Data Types: `single` | `double`

**MCReps — Number of Monte Carlo repetitions for cross-validation**

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCReps' and a positive integer scalar.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', then `MCReps` must be 1.
- If CV is a cvpartition of type 'holdout', then `MCReps` must be greater than 1.

Example: `'MCReps', 5`

Data Types: `single` | `double`

**NumLambda — Number of Lambda values**

100 (default) | positive integer scalar

Number of Lambda values `lasso` uses when you do not supply Lambda, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `y`.

Example: `'NumLambda', 50`
Data Types: single | double

Options — Option to cross-validate in parallel and specify random streams
structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of 'Options' and a structure. This option requires Parallel Computing Toolbox.

Create the Options structure with statset. The option fields are:

- **UseParallel** — Set to true to compute in parallel. The default is false.
- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. For reproducibility, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. The default is false.
- **Streams** — A RandStream object or cell array consisting of one such object. If you do not specify Streams, then lasso uses the default stream.

Example: 'Options',statset('UseParallel',true)
Data Types: struct

PredictorNames — Names of predictor variables
{} (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in X, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors.

Example: 'PredictorNames',{'x1','x2','x3','x4'}
Data Types: string | cell

RelTol — Convergence threshold for coordinate descent algorithm
1e–4 (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of 'RelTol' and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the \( L^2 \) norm by a relative amount less than \( \text{RelTol} \).

Example: 'RelTol',5e–3
Data Types: single | double

Rho — Augmented Lagrangian parameter
positive scalar

Augmented Lagrangian parameter \( \rho \) for the “ADMM Algorithm” on page 32-2996, specified as the comma-separated pair consisting of 'Rho' and a positive scalar. The default is automatic selection.

Example: 'Rho',2

Note  This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.
Data Types: single | double

**Standardize — Flag for standardizing predictor data before fitting models**

true (default) | false

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of 'Standardize' and either true or false. If Standardize is true, then the X data is scaled to have zero mean and a variance of one. Standardize affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

If Intercept is false, then the software sets Standardize to false, regardless of the Standardize value you specify.

X and y are always centered when Intercept is true.

Example: 'Standardize',false

Data Types: logical

**U0 — Initial value of scaled dual variable**

vector of zeros (default) | numeric vector

Initial value of the scaled dual variable u in the “ADMM Algorithm” on page 32-2996, specified as the comma-separated pair consisting of 'U0' and a numeric vector.

**Note** This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types: single | double

**Weights — Observation weights**

1/n*ones(n,1) (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. Weights has length n, where n is the number of rows of X. The lasso function scales Weights to sum to 1.

Data Types: single | double

**Output Arguments**

**B — Fitted coefficients**

numeric matrix

Fitted coefficients, returned as a numeric matrix. B is a p-by-L matrix, where p is the number of predictors (columns) in X, and L is the number of Lambda values. You can specify the number of Lambda values using the NumLambda name-value pair argument.

The coefficient corresponding to the intercept term is a field in FitInfo.

Data Types: single | double

**FitInfo — Fit information of models**

structure
Fit information of the linear models, returned as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field in FitInfo</th>

**More About**

**Lasso**

For a given value of $\lambda$, a nonnegative parameter, lasso solves the problem

$$\min_{\hat{\beta}_0, \hat{\beta}} \left( \frac{1}{2N} \sum_{i=1}^{N} \left( y_i - \hat{\beta}_0 - x_i^T \hat{\beta} \right)^2 + \lambda \sum_{j=1}^{p} |\beta_j| \right).$$

- $N$ is the number of observations.
- $y_i$ is the response at observation $i$.
- $x_i$ is data, a vector of length $p$ at observation $i$.
- $\lambda$ is a nonnegative regularization parameter corresponding to one value of Lambda.
- The parameters $\beta_0$ and $\beta$ are a scalar and a vector of length $p$, respectively.

As $\lambda$ increases, the number of nonzero components of $\beta$ decreases.

The lasso problem involves the $L^1$ norm of $\beta$, as contrasted with the elastic net algorithm.

**Elastic Net**

For $\alpha$ strictly between 0 and 1, and nonnegative $\lambda$, elastic net solves the problem
\[
\min_{\beta_0, \beta} \left\{ \frac{1}{2N} \sum_{i=1}^{N} \left( y_i - \beta_0 - x_i^T \beta \right)^2 + \lambda P_{\alpha}(\beta) \right\},
\]

where

\[
P_{\alpha}(\beta) = \frac{(1 - \alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^{p} \left( \frac{(1 - \alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).
\]

Elastic net is the same as lasso when \( \alpha = 1 \). For other values of \( \alpha \), the penalty term \( P_{\alpha}(\beta) \) interpolates between the \( L^1 \) norm of \( \beta \) and the squared \( L^2 \) norm of \( \beta \). As \( \alpha \) shrinks toward 0, elastic net approaches ridge regression.

**Algorithms**

**ADMM Algorithm**

When operating on tall arrays, `lasso` uses an algorithm based on the Alternating Direction Method of Multipliers (ADMM) [5]. The notation used here is the same as in the reference paper. This method solves problems of the form

\[
\text{Minimize } l(x) + g(z)
\]

\[
\text{Subject to } Ax + Bz = c
\]

Using this notation, the lasso regression problem is

\[
\text{Minimize } l(x) + g(z) = \frac{1}{2}\|Ax - b\|_2^2 + \lambda \|z\|_1
\]

\[
\text{Subject to } x - z = 0
\]

Because the loss function \( l(x) = \frac{1}{2}\|Ax - b\|_2^2 \) is quadratic, the iterative updates performed by the algorithm amount to solving a linear system of equations with a single coefficient matrix but several right-hand sides. The updates performed by the algorithm during each iteration are

\[
x^{k+1} = \left( A^T A + \rho I \right)^{-1} \left( A^T b + \rho (x^k - u^k) \right)
\]

\[
z^{k+1} = S_{\lambda/\rho}(x^{k+1} + u^k)
\]

\[
u^{k+1} = u^k + x^{k+1} - z^{k+1}
\]

\( A \) is the dataset (a tall array), \( x \) contains the coefficients, \( \rho \) is the penalty parameter (augmented Lagrangian parameter), \( b \) is the response (a tall array), and \( S \) is the soft thresholding operator.

\[
S_{\kappa}(a) = \begin{cases} 
  a - \kappa, & a > \kappa \\
  0, & |a| \leq \kappa \\
  a + \kappa, & a < \kappa
\end{cases}
\]

`lasso` solves the linear system using Cholesky factorization because the coefficient matrix \( A^T A + \rho I \) is symmetric and positive definite. Because \( \rho \) does not change between iterations, the Cholesky factorization is cached between iterations.
Even though $A$ and $b$ are tall arrays, they appear only in the terms $A^T A$ and $A^T b$. The results of these two matrix multiplications are small enough to fit in memory, so they are precomputed and the iterative updates between iterations are performed entirely within memory.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- With tall arrays, `lasso` uses an algorithm based on ADMM (Alternating Direction Method of Multipliers).
- No elastic net support. The 'Alpha' parameter is always 1.
- No cross-validation ('CV' parameter) support, which includes the related parameter 'MCReps'.
- The output FitInfo does not contain the additional fields 'SE', 'LambdaMinMSE', 'Lambda1SE', 'IndexMinMSE', and 'Index1SE'.
- The 'Options' parameter is not supported because it does not contain options that apply to the ADMM algorithm. You can tune the ADMM algorithm using name-value pair arguments.
- Supported name-value pair arguments are:
  - 'Lambda'
  - 'LambdaRatio'
  - 'NumLambda'
  - 'Standardize'
  - 'PredictorNames'
  - 'RelTol'
  - 'Weights'
- Additional name-value pair arguments to control the ADMM algorithm are:
• 'Rho' — Augmented Lagrangian parameter, \( \rho \). The default value is automatic selection.
• 'AbsTol' — Absolute tolerance used to determine convergence. The default value is \( 1e^{-4} \).
• 'MaxIter' — Maximum number of iterations. The default value is \( 1e4 \).
• 'B0' — Initial values for the coefficients \( x \). The default value is a vector of zeros.
• 'U0' — Initial values of the scaled dual variable \( u \). The default value is a vector of zeros.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options`, `statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

lassoglm

Lasso or elastic net regularization for generalized linear models

Syntax

B = lassoglm(X,y)
B = lassoglm(X,y,distr)
B = lassoglm(X,y,distr,Name,Value)
[B,FitInfo] = lassoglm( ___ )

Description

B = lassoglm(X,y) returns penalized, maximum-likelihood fitted coefficients for generalized linear models of the predictor data X and the response y, where the values in y are assumed to have a normal probability distribution. Each column of B corresponds to a particular regularization coefficient in Lambda. By default, lassoglm performs lasso regularization using a geometric sequence of Lambda values.

B = lassoglm(X,y,distr) performs lasso regularization to fit the models using the probability distribution distr for y.

B = lassoglm(X,y,distr,Name,Value) fits regularized generalized linear regressions with additional options specified by one or more name-value pair arguments. For example, 'Alpha',0.5 sets elastic net as the regularization method, with the parameter Alpha equal to 0.5.

[B,FitInfo] = lassoglm( ___ ) also returns the structure FitInfo, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using lassoglm.

Create a random matrix X with 100 observations and 10 predictors. Create the normally distributed response y using only four of the predictors and a small amount of noise.

rng default
X = randn(100,10);
weights = [0.6;0.5;0.7;0.4];
y = X(:,[2 4 5 7])*weights + randn(100,1)*0.1; % Small added noise

Perform lasso regularization.
B = lassoglm(X,y);

Find the coefficient vector for the 75th Lambda value in B.
B(:,75)
Cross-Validated Lasso Regularization of Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors by using `lassoglm`.

Create data with 20 predictors. Create a Poisson response variable using only three of the predictors plus a constant.

```matlab
rng default % For reproducibility
X = randn(100,20);
weights = [.4;.2;.3];
mu = exp(X(:,[5 10 15])*weights + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```matlab
[B,FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

```matlab
lassoPlot(B,FitInfo,'plottype','CV');
legend('show') % Show legend
```
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```matlab
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
mincoefs = find(B(:,idxLambdaMinDeviance))

mincoefs = 7×1
    3
    5
    6
   10
   11
   15
   16
```

```matlab
idxLambda1SE = FitInfo.Index1SE;
min1coefs = find(B(:,idxLambda1SE))

min1coefs = 3×1
    5
   10
```
The coefficients from the minimum-plus-one standard error point are exactly those coefficients used to create the data.

Predict Values Using Lasso Regularization

Predict whether students got a B or above on their last exam by using `lassoglm`.

Load the `examgrades` data set. Convert the last exam grades to a logical vector, where 1 represents a grade of 80 or above and 0 represents a grade below 80.

```matlab
load examgrades
X = grades(:,1:4);
y = grades(:,5);
yBinom = (y>=80);
```

Partition the data into training and test sets.

```matlab
rng default    % Set the seed for reproducibility
c = cvpartition(yBinom,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = yBinom(idxTrain);
XTest = X(idxTest,:);
yTest = yBinom(idxTest);
```

Perform lasso regularization for generalized linear model regression with 3-fold cross-validation on the training data. Assume the values in `y` are binomially distributed. Choose model coefficients corresponding to the Lambda with minimum expected deviance.

```matlab
[B,FitInfo] = lassoglm(XTrain,yTrain,'binomial','CV',3);
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
B0 = FitInfo.Intercept(idxLambdaMinDeviance);
coef = [B0; B(:,idxLambdaMinDeviance)]
```

```matlab
coef = 5x1
   -21.1911
    0.0235
    0.0670
    0.0693
    0.0949
```

Predict exam grades for the test data using the model coefficients found in the previous step. Specify the link function for a binomial response using `'logit'`. Convert the prediction values to a logical vector.

```matlab
yhat = glmval(coef,XTest,'logit');
yhatBinom = (yhat>=0.5);
```

Determine the accuracy of the predictions using a confusion matrix.
The function correctly predicts 31 exam grades. However, the function incorrectly predicts that 1 student receives a B or above and 4 students receive a grade below a B.

**Input Arguments**

**X — Predictor data**  
numeric matrix  

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.  
Data Types: `single` | `double`

**y — Response data**  
numeric vector | logical vector | categorical array | numeric matrix  

Response data, specified as a numeric vector, logical vector, categorical array, or two-column numeric matrix.

- When `distr` is not `'binomial'`, `y` is a numeric vector or categorical array of length `n`, where `n` is the number of rows in `X`. The response `y(i)` corresponds to row `i` in `X`.
- When `distr` is `'binomial'`, `y` is one of the following:
• Numeric vector of length n, where each entry represents success (1) or failure (0)
• Logical vector of length n, where each entry represents success or failure
• Categorical array of length n, where each entry represents success or failure
• Two-column numeric matrix, where the first column contains the number of successes for each observation and the second column contains the total number of trials

Data Types: single | double | logical | categorical

distr — Distribution of response data

'default' | 'normal' | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of response data, specified as one of the following:
• 'normal'
• 'binomial'
• 'poisson'
• 'gamma'
• 'inverse gaussian'

lassoglm uses the default link function on page 32-3009 corresponding to distr. Specify another link function using the Link name-value pair argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: lassoglm(X,y,'poisson','Alpha',0.5) performs elastic net regularization assuming that the response values are Poisson distributed. The 'Alpha',0.5 name-value pair argument sets the parameter used in the elastic net optimization.

Alpha — Weight of lasso versus ridge optimization

1 (default) | positive scalar

Weight of lasso ($L^1$) versus ridge ($L^2$) optimization, specified as the comma-separated pair consisting of 'Alpha' and a positive scalar value in the interval (0,1]. The value Alpha = 1 represents lasso regression, Alpha close to 0 approaches ridge regression, and other values represent elastic net optimization. See “Elastic Net” on page 32-3010.

Example: 'Alpha',0.75
Data Types: single | double

CV — Cross-validation specification for estimating deviance

'resubstitution' (default) | positive integer scalar | cvpartition object

Cross-validation specification for estimating the deviance, specified as the comma-separated pair consisting of 'CV' and one of the following:
• 'resubstitution' — lassoglm uses X and y to fit the model and to estimate the deviance without cross-validation.
• Positive scalar integer K — lassoglm uses K-fold cross-validation.
• `cvpartition` object `cvp` — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lassoglm`.

Example: 'CV',10

**DFmax** — Maximum number of nonzero coefficients

Inf (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of 'DFmax' and a positive integer scalar. `lassoglm` returns results only for `Lambda` values that satisfy this criterion.

Example: 'DFmax',25

Data Types: `single` | `double`

**Lambda** — Regularization coefficients

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of 'Lambda' and a vector of nonnegative values. See “Lasso” on page 32-3010.

- If you do not supply `Lambda`, then `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, then `lassoglm` ignores `LambdaRatio` and `NumLambda`.
- If `Standardize` is true, then `Lambda` is the set of values used to fit the models with the `X` data standardized to have zero mean and a variance of one.

The default is a geometric sequence of `NumLambda` values, with only the largest value able to produce \( B = 0 \).

Data Types: `single` | `double`

**LambdaRatio** — Ratio of smallest to largest `Lambda` values

1e–4 (default) | positive scalar

Ratio of the smallest to the largest `Lambda` values when you do not supply `Lambda`, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set `LambdaRatio = 0`, then `lassoglm` generates a default sequence of `Lambda` values and replaces the smallest one with 0.

Example: 'LambdaRatio',1e–2

Data Types: `single` | `double`

**Link** — Mapping between mean of response and linear predictor

'comploglog' | 'identity' | 'log' | 'logit' | 'loglog' | ...  

Mapping between the mean \( \mu \) of the response and the linear predictor \( Xb \), specified as the comma-separated pair consisting of 'Link' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'comploglog'</td>
<td>( \log(-\log((1 - \mu))) = Xb )</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'identity', default for the distribution 'normal'</td>
<td>$\mu = Xb$</td>
</tr>
<tr>
<td>'log', default for the distribution 'poisson'</td>
<td>$\log(\mu) = Xb$</td>
</tr>
<tr>
<td>'logit', default for the distribution 'binomial'</td>
<td>$\log(\mu/(1 - \mu)) = Xb$</td>
</tr>
<tr>
<td>'loglog'</td>
<td>$\log(-\log(\mu)) = Xb$</td>
</tr>
<tr>
<td>'probit'</td>
<td>$\Phi^{-1}(\mu) = Xb$, where $\Phi$ is the normal (Gaussian) cumulative distribution function</td>
</tr>
<tr>
<td>'reciprocal', default for the distribution 'gamma'</td>
<td>$\mu^{-1} = Xb$</td>
</tr>
<tr>
<td>$p$ (a number), default for the distribution 'inverse gaussian' (with $p = -2$)</td>
<td>$\mu^p = Xb$</td>
</tr>
<tr>
<td>A cell array of the form {FL FD FI}, containing three function handles created using @, which define the link (FL), the derivative of the link (FD), and the inverse link (FI). Or, a structure of function handles with the field Link containing FL, the field Derivative containing FD, and the field Inverse containing FI.</td>
<td>User-specified link function (see “Custom Link Function” on page 12-12)</td>
</tr>
</tbody>
</table>

Example: 'Link','probit'

Data Types: char | string | single | double | cell

**MaxIter — Maximum number of iterations allowed**

1e4 (default) | positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.

If the algorithm executes MaxIter iterations before reaching the convergence tolerance RelTol, then the function stops iterating and returns a warning message.

The function can return more than one warning when NumLambda is greater than 1.

Example: 'MaxIter',1e3

Data Types: single | double

**MCReps — Number of Monte Carlo repetitions for cross-validation**

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCReps' and a positive integer scalar.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', then MCReps must be 1.
- If CV is a cvpartition of type 'holdout', then MCReps must be greater than 1.
Example: 'MCReps', 2
Data Types: single | double

**NumLambda — Number of Lambda values**
100 (default) | positive integer scalar

Number of Lambda values *lassoglm* uses when you do not supply `Lambda`, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. *lassoglm* can return fewer than `NumLambda` fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors `X`).

Example: 'NumLambda', 150
Data Types: single | double

**Offset — Additional predictor variable**
numeric vector

Additional predictor variable, specified as the comma-separated pair consisting of 'Offset' and a numeric vector with the same number of rows as `X`. The *lassoglm* function keeps the coefficient value of `Offset` fixed at 1.0.

Data Types: single | double

**Options — Option to cross-validate in parallel and specify random streams**
structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of 'Options' and a structure. This option requires Parallel Computing Toolbox.

Create the `Options` structure with `statset`. The option fields are:

- **UseParallel** — Set to `true` to compute in parallel. The default is `false`.
- **UseSubstreams** — Set to `true` to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. The default is `false`.
- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, then *lassoglm* uses the default stream.

Example: 'Options', statset('UseParallel', true)
Data Types: struct

**PredictorNames — Names of predictor variables**

{} (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in `X`, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors.

Example: 'PredictorNames', {'Height', 'Weight', 'Age'}
Data Types: string | cell

**RelTol — Convergence threshold for coordinate descent algorithm**

1e–4 (default) | positive scalar
Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of 'RelTol' and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the $L^2$ norm by a relative amount less than RelTol.

Example: 'RelTol',2e–3
Data Types: single | double

**Standardize — Flag for standardizing predictor data before fitting models**
true (default) | false

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of 'Standardize' and either true or false. If Standardize is true, then the X data is scaled to have zero mean and a variance of one. Standardize affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

Example: 'Standardize',false
Data Types: logical

**Weights — Observation weights**
1/n*ones(n,1) (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. Weights has length n, where n is the number of rows of X. At least two values must be positive.

Data Types: single | double

**Output Arguments**

**B — Fitted coefficients**
numeric matrix

Fitted coefficients, returned as a numeric matrix. B is a p-by-L matrix, where p is the number of predictors (columns) in X, and L is the number of Lambda values. You can specify the number of Lambda values using the NumLambda name-value pair argument.

The coefficient corresponding to the intercept term is a field in FitInfo.

Data Types: single | double

**FitInfo — Fit information of models**
structure

Fit information of the generalized linear models, returned as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field in FitInfo</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intercept</td>
<td>Intercept term $\beta_0$ for each linear model, a 1-by-L vector</td>
</tr>
<tr>
<td>Lambda</td>
<td>Lambda parameters in ascending order, a 1-by-L vector</td>
</tr>
<tr>
<td>Alpha</td>
<td>Value of the Alpha parameter, a scalar</td>
</tr>
</tbody>
</table>
## Field in FitInfo Description

<table>
<thead>
<tr>
<th>Field in FitInfo</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF</td>
<td>Number of nonzero coefficients in B for each value of Lambda, a 1-by-L vector</td>
</tr>
<tr>
<td>Deviance</td>
<td>Deviance of the fitted model for each value of Lambda, a 1-by-L vector</td>
</tr>
<tr>
<td></td>
<td>If the model is cross-validated, then the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross-validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.</td>
</tr>
<tr>
<td>PredictorNames</td>
<td>Value of the PredictorNames parameter, stored as a cell array of character vectors</td>
</tr>
</tbody>
</table>

If you set the CV name-value pair argument to cross-validate, the FitInfo structure contains these additional fields.

## Field in FitInfo Description

</tr>
<tr>
<td>Lambda1SE</td>
<td>Largest Lambda value such that Deviance is within one standard error of the minimum, a scalar</td>
</tr>
<tr>
<td>IndexMinDeviance</td>
<td>Index of Lambda with the value LambdaMinDeviance, a scalar</td>
</tr>
<tr>
<td>Index1SE</td>
<td>Index of Lambda with the value Lambda1SE, a scalar</td>
</tr>
</tbody>
</table>

## More About

### Link Function

A link function \( f(\mu) \) maps a distribution with mean \( \mu \) to a linear model with data \( X \) and coefficient vector \( b \) using the formula

\[
  f(\mu) = Xb.
\]

You can find the formulas for the link functions in the Link name-value pair argument description. This table lists the link functions that are typically used for each distribution.

## Distribution Family Default Link Function Other Typical Link Functions

Lasso

For a nonnegative value of $\lambda$, `lassoglm` solves the problem
\[
\min_{\beta_0, \beta} \left\{ \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right\}.
\]

- The function Deviance in this equation is the deviance of the model fit to the responses using the intercept $\beta_0$ and the predictor coefficients $\beta$. The formula for Deviance depends on the `distr` parameter you supply to `lassoglm`. Minimizing the $\lambda$-penalized deviance is equivalent to maximizing the $\lambda$-penalized loglikelihood.

- $N$ is the number of observations.
- $\lambda$ is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- The parameters $\beta_0$ and $\beta$ are a scalar and a vector of length $p$, respectively.

As $\lambda$ increases, the number of nonzero components of $\beta$ decreases.

The lasso problem involves the $L^1$ norm of $\beta$, as contrasted with the elastic net algorithm.

Elastic Net

For $\alpha$ strictly between 0 and 1, and nonnegative $\lambda$, elastic net solves the problem
\[
\min_{\beta_0, \beta} \left\{ \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right\},
\]

where
\[
P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).
\]

Elastic net is the same as lasso when $\alpha = 1$. For other values of $\alpha$, the penalty term $P_\alpha(\beta)$ interpolates between the $L^1$ norm of $\beta$ and the squared $L^2$ norm of $\beta$. As $\alpha$ shrinks toward 0, elastic net approaches ridge regression.

References

**Extended Capabilities**

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2012a**
**lassoPlot**

Trace plot of lasso fit

**Syntax**

```plaintext
lassoPlot(B)
lassoPlot(B,FitInfo)
lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(___)
```

**Description**

`lassoPlot(B)` creates a trace plot of the values in `B` against the $L^1$ norm of `B`.

`lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `PlotType` name-value pair.

`lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot(___)`, for any previous input syntax, returns a handle `ax` to the plot axis, and a handle `figh` to the figure window.

**Input Arguments**

**B**

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. `B` is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of `B` is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

**FitInfo**

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.
- `FitInfo` is a vector — `lassoPlot` forms the x-axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Parent**

Axis in which to draw the plot.
**Default:** New plot

**PlotType**

Plot type when you specify a `FitInfo` vector or structure:

<table>
<thead>
<tr>
<th>PlotType</th>
<th>Plot</th>
</tr>
</thead>
<tbody>
<tr>
<td>'L1'</td>
<td>lassoPlot creates the x-axis from the $L^1$ norm of the coefficients in $B$. The x-axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of $B$.</td>
</tr>
<tr>
<td>'Lambda'</td>
<td>lassoPlot creates the x-axis from the Lambda field of <code>FitInfo</code>. The x-axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of $B$. When you choose this value, <code>FitInfo</code> must be a structure.</td>
</tr>
</tbody>
</table>
| 'CV'     | • For each Lambda, lassoPlot plots an estimate of the mean squared prediction error on new data for the model fitted by lasso with that value of Lambda.  
          • lassoPlot plots error bars for the estimates. When you choose this value, `FitInfo` must be a cross-validated structure. |

If you include a cross-validated `FitInfo` structure, lassoPlot also indicates two specific Lambda values with green and blue dashed lines.

- A green, dashed line indicates the value of Lambda with a minimum cross-validated mean squared error (MSE).
- A blue, dashed line indicates the greatest Lambda that is within one standard error of the minimum MSE. This Lambda value makes the sparsest model with relatively low MSE.

To display the label for each plot in the legend of the figure, type `legend('show')` in the Command Window.

**Default: 'L1'**

**PredictorNames**

String array or cell array of character vectors to label each coefficient of $B$. If the length of `PredictorNames` is less than the number of rows of $B$, the remaining labels are padded with default values.

lassoPlot uses `PredictorNames` in `FitInfo` only if:

- You created `FitInfo` with a call to lasso that included a `PredictorNames` name-value pair.
- You call lassoPlot without a `PredictorNames` name-value pair.
- You include `FitInfo` in your lassoPlot call.

For an example, see “Lasso Plot with Default Plot Type” on page 32-3014.
Default: \{'B1', 'B2', \ldots\}\n
XScale
- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

Default: 'linear', except 'log' for the 'CV' plot type

Output Arguments

ax
Handle to the axis of the plot (see “Axes Appearance” (MATLAB)).

figh
Handle to the figure window (see “Special Object Identifiers” (MATLAB)).

Examples

Lasso Plot with Default Plot Type

Load the sample data
load acetylene

Prepare the design matrix for lasso fit with interactions.

\[ X = [x1 \ x2 \ x3]; \]
\[ D = \text{x2fx}(X, 'interaction'); \]
\[ D(:,1) = []; \] % No constant term

The x2fx function returns the quadratic model in the order of a constant term, linear terms and interaction terms: constant term, x1, x2, x3, x1.*x2, x1.*x3, and x2.*x3

Fit a regularized model of the data using lasso.
\[ B = \text{lasso}(D,y); \]

Plot the lasso fits with labeled coefficients by using the PredictorNames name-value pair.
\[ \text{lassoPlot}(B, 'PredictorNames', \{'x1', 'x2', 'x3', 'x1.*x2', 'x1.*x3', 'x2.*x3'\}); \]
\[ \text{legend('show', 'Location', 'NorthWest')} \] % Show legend
Each line represents a trace of the values in B for a single predictor variable: \( x_1 \), \( x_2 \), \( x_3 \), \( x_1 \cdot x_2 \), \( x_1 \cdot x_3 \), and \( x_2 \cdot x_3 \).

Display a data tip for the trace plot. A data tip appears when you hover over a data tip.
A data tip displays these lines of information: the name of the selected coefficient with a fitted value, the L1 norm of a set of coefficients including the selected coefficient, and the index of the corresponding Lambda.

**Lasso Plot with Lambda Plot Type**

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = [] ; % No constant term
```

Fit a regularized model of the data with `lasso`.

```
[B,FitInfo] = lasso(D,y);
```

Plot the fits with the Lambda plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');
```
Lasso Plot with Cross-Validated Fits

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```matlab
load acetylene
```

Create a design matrix with interactions and no constant term.

```matlab
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the `FitInfo` output so you can plot the result.

```matlab
rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```matlab
lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
```
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Class: qrandstream

Less than or equal relation for handles

Syntax

h1 <= h2

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

h1 <= h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise <= result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = le(h1, h2) stores the result in a logical array of the same dimensions.

learnerCoderConfigurer

Create coder configurer of machine learning model

Syntax

configurer = learnerCoderConfigurer(Mdl,X)
configurer = learnerCoderConfigurer(Mdl,X,Name,Value)

Description

After training a machine learning model, create a coder configurer for the model by using learnerCoderConfigurer. Use the object functions and properties of the configurer to specify code generation options and to generate C/C++ code for the predict and update functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use learnerCoderConfigurer for the highlighted step.

configurer = learnerCoderConfigurer(Mdl,X) returns the coder configurer configurer for the machine learning model Mdl. Specify the predictor data X for the predict function of Mdl.

configurer = learnerCoderConfigurer(Mdl,X,Name,Value) returns a coder configurer with additional options specified by one or more name-value pair arguments. For example, you can specify the number of output arguments in the predict function, the file name of generated C/C++ code, and the verbosity level of the coder configurer.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the predict and update functions of the model by using a coder configurer.

Load the carsmall data set and train a support vector machine (SVM) regression model.

load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
Mdl is a RegressionSVM object.

Create a coder configurer for the RegressionSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

```matlab
configurer = learnerCoderConfigurer(Mdl,X)
```

```matlab
configurer =  
RegressionSVMCoderConfigurer with properties:  
  Update Inputs:  
     Alpha: [1x1 LearnerCoderInput]  
    SupportVectors: [1x1 LearnerCoderInput]  
       Scale: [1x1 LearnerCoderInput]  
       Bias: [1x1 LearnerCoderInput]  
  Predict Inputs:  
          X: [1x1 LearnerCoderInput]  
  Code Generation Parameters:  
         NumOutputs: 1  
    OutputFileName: 'RegressionSVMModel'
```

Properties, Methods

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a RegressionSVM object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the predict and update functions of the SVM regression model (Mdl) with default settings.

```matlab
generateCode(configurer)
generateCode creates these files in output folder: 'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the predict and update functions of Mdl, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the predict.m, update.m, and initialize.m files by using the type function.

```matlab
type predict.m
```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
initialize('update',varargin{:});
end

type initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 29-Feb-2020 10:40:03
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
    % Update struct fields: Alpha
    % SupportVectors
    % Scale
    % Bias
    model = update(model,varargin{:});
    case 'predict'
    % Predict Inputs: X
    X = varargin{1};
    if nargin == 2
        [varargout{1:nargout}] = predict(model,X);
    else
        PVPairs = cell(1,nargin-2);
        for i = 1:nargin-2
            PVPairs{1,i} = varargin{i+1};
        end
        [varargout{1:nargout}] = predict(model,X,PVPairs{:});
    end
end

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));

Mdl is a ClassificationSVM object.

**Create Coder Configurer**

Create a coder configurer for the ClassificationSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

`configurer = learnerCoderConfigurer(Mdl,X(1:50,:),'NumOutputs',2);`

`configurer` is a ClassificationSVMCoderConfigurer object, which is a coder configurer of a ClassificationSVM object.

**Specify Coder Attributes of Parameters**

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of X so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```matlab
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is Inf and the size is variable, meaning that X can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. X contains 34 predictors, so the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be false.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of SupportVectors so that you can update the support vectors in the generated code.

```matlab
configurer.SupportVectors.SizeVector = [250 34];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints. SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

```matlab
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints. VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the
modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```matlab
generateCode(configurer)
```

`generateCode` creates these files in output folder:
- `initialize.m`
- `predict.m`
- `update.m`
- `ClassificationSVMModel.mat`

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the codegen\mex\ClassificationSVMModel folder and copies the MEX function to the current folder.

**Verify Generated Code**

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```matlab
[label,score] = predict(Mdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```matlab
isequal(label,label_mex)
```

```matlab
ans = logical
 1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```matlab
find(abs(score-score_mex) > 1e-8)
```

```matlab
ans =
    0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance `1e–8`.

**Retrain Model and Update Parameters in Generated Code**

Retrain the model using the entire data set.
retrainedMdl = fitcsvm(X,Y);

Extract parameters to update by using validatedUpdateInputs. This function detects the modified model parameters in retrainedMdl and validates whether the modified parameter values satisfy the coder attributes of the parameters.

params = validatedUpdateInputs(configurer,retrainedMdl);

Update parameters in the generated code.

ClassificationSVMModel('update',params)

**Verify Generated Code**

Compare the outputs from the predict function of retrainedMdl and the predict function in the updated MEX function.

```matlab
[label,score] = predict(retrainedMdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
isequal(label,label_mex)
an = logical
1

find(abs(score-score_mex) > 1e-8)
an =
   0x1 empty double column vector
```

The comparison confirms that labels and labels_mex are equal, and the score values are equal within the tolerance.

**Input Arguments**

**Mdl — Machine learning model**

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in this table of supported models.

<table>
<thead>
<tr>
<th>Model</th>
<th>Full/Compact Model Object</th>
<th>Training Function</th>
</tr>
</thead>
<tbody>
<tr>

<td>RegressionLinear</td>
<td>fitrlinear</td>
</tr>
</tbody>
</table>

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

**X — Predictor data**
numeric matrix

Predictor data for the `predict` function of `Mdl`, specified as an `n`-by-`p` numeric matrix, where `n` is the number of observations and `p` is the number of predictor variables. To instead specify `X` as a `p`-by-`n` matrix, where the observations correspond to columns, you must set the `'ObservationsIn'` name-value pair argument to `'columns'`. This option is available only for linear models and ECOC models with linear binary learners.

The `predict` function of a machine learning model predicts labels for classification and responses for regression for given predictor data. After creating the coder configurer `configurer`, you can use the `generateCode` function to generate C/C++ code for the `predict` function of `Mdl`. The generated code accepts predictor data that has the same size and data type of `X`. You can specify whether each dimension has a variable size or fixed size after creating `configurer`.

For example, if you want to generate C/C++ code that predicts labels using 100 observations with three predictor variables, then specify `X` as `zeros(100,3)`. The `learnerCoderConfigurer` function uses only the size and data type of `X`, not its values. Therefore, `X` can be predictor data or a MATLAB expression that represents the set of values with a certain data type. The output `configurer` stores the size and data type of `X` in the `X` property of `configurer`. You can modify the size and data type of `X` after creating `configurer`. For example, change the number of observations to 200 and the data type to `single`.

```matlab
cointurer.X.SizeVector = [200 3];
cointurer.X.DataType = 'single';
```

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify `X` as `zeros(100,3)` and change the `VariableDimensions` property.

```matlab
cointurer.X.VariableDimensions = [1 0];
```

[1 0] indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

```matlab
cointurer.X.SizeVector = [Inf 3];
```

Data Types: `single` | `double`
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: configurer = learnerCoderConfigurer(Mdl, X, 'NumOutputs', 2, 'OutputFileName', 'myModel') sets the number of outputs in predict to 2 and specifies the file name 'myModel' for the generated C/C++ code.

NumOutputs — Number of outputs in predict

1 (default) | positive integer

Number of output arguments in the predict function of the machine learning model Mdl, specified as the comma-separated pair consisting of 'NumOutputs' and a positive integer n.

This table lists the outputs for the predict function of different models. predict in the generated C/C++ code returns the first n outputs of the predict function in the order given in the Outputs column.

<table>
<thead>
<tr>
<th>Model</th>
<th>predict Function of Model</th>
<th>Outputs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary decision tree for multiclass</td>
<td>predict</td>
<td>label (predicted class labels), score (posterior probabilities), node (node numbers for predicted classes), cnum (class numbers of predicted labels)</td>
</tr>
<tr>
<td>classification</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SVM for one-class and binary classification</td>
<td>predict</td>
<td>label (predicted class labels), score (scores or posterior probabilities)</td>
</tr>
<tr>
<td>Linear model for binary classification</td>
<td>predict</td>
<td>Label (predicted class labels), Score (classification scores)</td>
</tr>
<tr>
<td>Multiclass model for SVMs and linear models</td>
<td>predict</td>
<td>label (predicted class labels), NegLoss (negated average binary losses), PBScore (positive-class scores)</td>
</tr>
<tr>
<td>Binary decision tree for regression</td>
<td>predict</td>
<td>Yfit (predicted responses), node (node numbers for predictions)</td>
</tr>
<tr>
<td>SVM regression</td>
<td>predict</td>
<td>yfit (predicted responses)</td>
</tr>
<tr>
<td>Linear regression</td>
<td>predict</td>
<td>YHat (predicted responses)</td>
</tr>
</tbody>
</table>

For example, if you specify 'NumOutputs', 1 for an SVM classification model, then predict returns predicted class labels in the generated C/C++ code.

After creating the coder configurer configurer, you can modify the number of outputs by using dot notation.

configurer.NumOutputs = 2;

The 'NumOutputs' name-value pair argument is equivalent to the '-nargout' compiler option of codegen. This option specifies the number of output arguments in the entry-point function of code generation. The object function generateCode of a coder configurer generates two entry-point functions—predict.m and update.m for the predict and update functions of Mdl, respectively—and generates C/C++ code for the two entry-point functions. The specified value for 'NumOutputs' corresponds to the number of output arguments in predict.m.
Example: 'NumOutputs', 2
Data Types: single | double

**OutputFileName — File name of generated C/C++ code**

Mdl object name plus 'Model' (default) | character vector | string scalar

File name of the generated C/C++ code, specified as the comma-separated pair consisting of 'OutputFileName' and a character vector or string scalar.

The object function `generateCode` of a coder configurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

The default file name is the object name of Mdl followed by 'Model'. For example, if Mdl is a `CompactClassificationSVM` or `ClassificationSVM` object, then the default name is 'ClassificationSVMModel'.

After creating the coder configurer `configurer`, you can modify the file name by using dot notation.

```matlab
callerer.OutputFileName = 'myModel';
```

Example: 'OutputFileName', 'myModel'

Data Types: char | string

**Verbose — Verbosity level**

true (logical 1) (default) | false (logical 0)

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line for the coder configurer `configurer`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true (1)</td>
<td>The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.</td>
</tr>
<tr>
<td>false (0)</td>
<td>The software does not display notification messages.</td>
</tr>
</tbody>
</table>

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```matlab
callerer.Verbose = false;
```

Example: 'Verbose', false

Data Types: logical
**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and either 'rows' or 'columns'. If you set 'ObservationsIn' to 'columns', then the predictor data X must be oriented so that the observations correspond to columns.

**Note** The 'columns' option is available only for linear models and ECOC models with linear binary learners.

Example: 'ObservationsIn', 'columns'

**Output Arguments**

**configurer — Coder configurer**
coder configurer object

Coder configurer of a machine learning model, returned as one of the coder configurer objects in this table.

<table>
<thead>
<tr>
<th>Model</th>
<th>Coder Configurer Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary decision tree for multiclass</td>
<td>ClassificationTreeCoderConfigurer</td>
</tr>
<tr>
<td>classification</td>
<td></td>
</tr>
<tr>
<td>SVM for one-class and binary</td>
<td>ClassificationSVMCoderConfigurer</td>
</tr>
<tr>
<td>classification</td>
<td></td>
</tr>
<tr>
<td>Linear model for binary classification</td>
<td>ClassificationLinearCoderConfigurer</td>
</tr>
<tr>
<td>Multiclass model for SVMs and linear</td>
<td>ClassificationECOCCoderConfigurer</td>
</tr>
<tr>
<td>models</td>
<td></td>
</tr>
<tr>
<td>Binary decision tree for regression</td>
<td>RegressionTreeCoderConfigurer</td>
</tr>
<tr>
<td>Support vector machine (SVM) regression</td>
<td>RegressionSVMCoderConfigurer</td>
</tr>
<tr>
<td>Linear regression</td>
<td>RegressionLinearCoderConfigurer</td>
</tr>
</tbody>
</table>

Use the object functions and properties of a coder configurer object to configure code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model.

**Introduced in R2018b**
length

Class: dataset

(Not Recommended) Length of dataset array

**Note** The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB table documentation for more information.

**Syntax**

```
n = length(A)
```

**Description**

`n = length(A)` returns the number of observations in the dataset `A`. `length` is equivalent to `size(A,1)`.

**See Also**

`size`
levelcounts

(Not Recommended) Element counts by level of a nominal or ordinal array

**Note**  The nominal and ordinal array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

C = levelcounts(A)
C = levelcounts(A,dim)

**Description**

C = levelcounts(A) returns counts of the number of elements in the nominal or ordinal array A equal to each possible level in A.

- If A is a vector, then C is a vector containing as many elements as the number of levels in A.
- If A is a matrix, then C is a matrix of column counts.
- If A is an N-dimensional array, then levelcounts operates along the first nonsingleton dimension.

C = levelcounts(A,dim) operates along the dimension dim.

**Examples**

**Count Observations in Each Level**

Create a nominal array from data in a cell array.

colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
{[blue','green','red']})

colors = 3x3 nominal
    red   blue    green
   green   red    blue
   blue   red    green

Count the number of observations of each level in each column.

levelcounts(colors)

ans = 3x3

    1   1   1
    1   0   2
    1   2   0
Count the number of observations of each level in each row.

```plaintext
levelcounts(colors, 2)
```

```plaintext
ans = 3x3
    1  1  1
    1  1  1
    1  1  1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```plaintext
summary(colors)
```

```plaintext
  blue    1    1    1
  green   1    0    2
    red   1    2    0
```

You can also count elements in each row.

```plaintext
summary(colors, 2)
```

```plaintext
    blue  green  red
    1    1    1
    1    1    1
    1    1    1
```

**Input Arguments**

A — Nominal or ordinal array
nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with `nominal` or `ordinal`.

**dim** — Dimension along which to count
positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is 1, then `levelcounts` counts along each column, while if the dimension is 2, then `levelcounts` counts along each row.

Data Types: `double` | `single`

**See Also**

`nominal` | `ordinal` | `summary`

**Introduced in R2007a**
leverage

Leverage

Syntax

h = leverage(data)
h = leverage(data, model)

Description

h = leverage(data) finds the leverage of each row (point) in the matrix data for a linear additive regression model.

h = leverage(data, model) finds the leverage on a regression, using a specified model type, where model can be one of the following:

• 'linear' - includes constant and linear terms
• 'interaction' - includes constant, linear, and cross product terms
• 'quadratic' - includes interactions and squared terms
• 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to 2p/n where n is the number of observations and p is the number of parameters in the model. For the Hald data set this value is 0.7692.

load hald
h = max(leverage(ingredients,'linear'))
h =
0.7004

Since 0.7004 < 0.7692, there are no high leverage points using this rule.

Algorithms

[Q,R] = qr(x2fx(data,'model'),0);
leverage = (sum(Q'.*Q'))'

### lhsdesign

Latin hypercube sample

#### Syntax

\[
X = \text{lhsdesign}(n,p) \\
X = \text{lhsdesign}(...,\text{'smooth','off'}) \\
X = \text{lhsdesign}(...,\text{'criterion',criterion}) \\
X = \text{lhsdesign}(...,\text{'iterations',k})
\]

#### Description

\(X = \text{lhsdesign}(n,p)\) returns an \(n\)-by-\(p\) matrix, \(X\), containing a Latin hypercube sample of \(n\) values on each of \(p\) variables. For each column of \(X\), the \(n\) values are randomly distributed with one from each interval \((0,1/n), (1/n,2/n), \ldots, (1-1/n,1)\), and they are randomly permuted.

\(X = \text{lhsdesign}(...,\text{'smooth','off'})\) produces points at the midpoints of the above intervals: \(0.5/n, 1.5/n, \ldots, 1-0.5/n\). The default is 'on'.

\(X = \text{lhsdesign}(...,\text{'criterion',criterion})\) iteratively generates Latin hypercube samples to find the best one according to \(criterion\), which can be 'none', 'maximin', or 'correlation'.

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>No iteration.</td>
</tr>
<tr>
<td>'maximin'</td>
<td>Maximize minimum distance between points. This is the default.</td>
</tr>
<tr>
<td>'correlation'</td>
<td>Reduce correlation.</td>
</tr>
</tbody>
</table>

\(X = \text{lhsdesign}(...,\text{'iterations',k})\) iterates up to \(k\) times in an attempt to improve the design according to the specified criterion. The default is \(k = 5\).

#### See Also

**Introduced before R2006a**
**lhsnorm**

Latin hypercube sample from normal distribution

**Syntax**

```matlab
X = lhsnorm(mu,sigma,n)
X = lhsnorm(mu,sigma,n,flag)
[X,Z] = lhsnorm(...)
```

**Description**

`X = lhsnorm(mu,sigma,n)` returns an `n`-by-`p` matrix, `X`, containing a Latin hypercube sample of size `n` from a `p`-dimensional multivariate normal distribution with mean vector, `mu`, and covariance matrix, `sigma`. `X` is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu,sigma,n,flag)` controls the amount of smoothing in the sample. If `flag` is `'off'`, each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values $G(0.5/n)$, $G(1.5/n)$, ..., $G(1-0.5/n)$, where $G$ is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is `'on'` (the default), each column has points uniformly distributed on the probability scale. For example, in place of $0.5/n$ you use a value having a uniform distribution on the interval $(0/n,1/n)$.

`[X,Z] = lhsnorm(...)` also returns `Z`, the original multivariate normal sample before the marginals are adjusted to obtain `X`.

**Introduced before R2006a**
**lillietest**

Lilliefors test

**Syntax**

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest(___)
[h,p,kstat,critval] = lillietest(__)
```

**Description**

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the `p`-value using a Monte Carlo approximation.

`[h,p] = lillietest(___)` also returns the `p`-value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest(__)` also returns the test statistic `kstat` and the critical value `critval` for the test.

**Examples**

**Test for Normal Distribution**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig
[h,p,k,c] = lillietest(MPG)
```

Warning: P is less than the smallest tabulated value, returning 0.001.

```
h = 1
p = 1.0000e-03
k = 0.0789
```

The test statistic `k` is greater than the critical value `c`, so `lillietest` returns a result of `h = 1` to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates
that the returned \( p \)-value is less than the smallest value in the table of precomputed values. To find a more accurate \( p \)-value, use MCTol to run a Monte Carlo approximation. See "Determine the \( p \)-value Using Monte Carlo Approximation" on page 32-3040.

**Test the Hypothesis at Different Significance Levels**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```matlab
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```matlab
[h,p] = lillietest(x,'Alpha',0.01)
```

\[ h = 0 \]
\[ p = 0.0348 \]

The returned value of \( h = 0 \) indicates that lillietest does not reject the null hypothesis at the 1% significance level.

**Test for Exponential Distribution**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```matlab
load carbig
```

```matlab
h = lillietest(MPG,'Distribution','exponential')
```

\[ h = 1 \]

The returned value of \( h = 1 \) indicates that lillietest rejects the null hypothesis at the default 5% significance level.

**Test for Weibull Distribution**

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (wblplot).

Generate samples from a Weibull distribution.

```matlab
rng('default')
data1 = wblrnd(0.5,2,[500,1]);
```

Perform the Lilliefors test by using the lillietest. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```matlab
h1 = lillietest(log(data1),'Distribution','extreme value')
```

32-3038
The returned value of $h_1 = 0$ indicates that `lillietest` fails to reject the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data1)
```

![Weibull Probability Plot](image)

The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.
```
data2 = lognrnd(5,2,[500,1]);
```

Perform the Lilliefors test.
```
h2 = lillietest(log(data2), 'Distribution', 'extreme value')
h2 = 1
```

The returned value of $h_2 = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data2)
```
The plot indicates that the data does not follow a Weibull distribution.

**Determine the p-value Using Monte Carlo Approximation**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the p-value using a Monte Carlo approximation with a maximum Monte Carlo standard error of 1e-4.

```matlab
load carbig
[h,p] = lillietest(MPG,'MCTol',1e-4)
```

h = 1

p = 8.3333e-06

The returned value of h = 1 indicates that lillietest rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

**Input Arguments**

- **x** — Sample data
  
  vector
Sample data, specified as a vector.
Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: ‘Distribution’, ‘exponential’, ‘Alpha’, 0.01 tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

Alpha — Significance level
0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of ‘Alpha’ and a scalar value in the range (0,1).

• If MCTol is not used, Alpha must be in the range [0.001, 0.50].
• If MCTol is used, Alpha must be in the range (0,1).

Example: ‘Alpha’, 0.01
Data Types: single | double

Distribution — Distribution family
‘normal’ (default) | ‘exponential’ | ‘extreme value’

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of ‘Distr’ and one of the following.

• ‘normal’ — Normal distribution
• ‘exponential’ — Exponential distribution
• ‘extreme value’ — Extreme value distribution

• To test x for a lognormal distribution, test if \( \log(x) \) has a normal distribution.
• To test x for a Weibull distribution, test if \( \log(x) \) has an extreme value distribution.

Example: ‘Distribution’, ‘exponential’

MCTol — Maximum Monte Carlo standard error
scalar value in the range (0,1)

Maximum Monte Carlo standard error on page 32-3043 for \( p \), the \( p \)-value of the test, specified as the comma-separated pair consisting of ‘MCTol’ and a scalar value in the range (0,1).

Example: ‘MCTol’, 0.001
Data Types: single | double
Output Arguments

**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as 1 or 0.

- If \( h = 1 \), this indicates the rejection of the null hypothesis at the \( \alpha \) significance level.
- If \( h = 0 \), this indicates a failure to reject the null hypothesis at the \( \alpha \) significance level.

**p — p-value**

Scalar value in the range \( (0,1) \)

\( p \)-value of the test, returned as a scalar value in the range \( (0,1) \). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \( p \) cast doubt on the validity of the null hypothesis.

- If \( \text{MCTol} \) is not used, \( p \) is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range \([0.001,0.50]\). \text{lillietest} warns when \( p \) is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If \( \text{MCTol} \) is used, \text{lillietest} conducts a Monte Carlo simulation to compute a more accurate \( p \) -value, and \( p \) is returned as a scalar value in the range \( (0,1) \).

**kstat — Test statistic**

Nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

**critval — Critical value**

Nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

More About

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

\[
D^* = \max_x |\hat{F}(x) - G(x)|,
\]

where \( \hat{F}(x) \) is the empirical cdf of the sample data and \( G(x) \) is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

\text{lillietest} can be used to test whether the data vector \( x \) has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test \( x \) for a lognormal distribution, test if \( \log(x) \) has a normal distribution.
• To test \( x \) for a Weibull distribution, test if \( \log(x) \) has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

**Monte Carlo Standard Error**

The Monte Carlo standard error is the error due to simulating the \( p \)-value.

The Monte Carlo standard error is calculated as:

\[
SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{mcreps}},
\]

where \( \hat{p} \) is the estimated \( p \)-value of the hypothesis test, and \( mcreps \) is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, \( mcreps \), is determined such that the Monte Carlo standard error for \( \hat{p} \) less than the value specified for \( MCTol \).

**Algorithms**

To compute the critical value for the hypothesis test, \texttt{lillietest} interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by \texttt{lillietest} is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate \( p \)-value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the \( MCTol \) input argument can be used to run a Monte Carlo simulation to calculate the \( p \)-value more exactly.

When the computed value of the test statistic is greater than the critical value, \texttt{lillietest} rejects the null hypothesis at significance level \( \text{Alpha} \).

\texttt{lillietest} treats \texttt{NaN} values in \( x \) as missing values and ignores them.

**Introduced before R2006a**
**LinearModel**

Linear regression model

**Description**

LinearModel is a fitted linear regression model object. A regression model describes the relationship between a response and predictors. The linearity in a linear regression model refers to the linearity of the predictor coefficients.

Use the properties of a LinearModel object to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

**Creation**

Create a LinearModel object by using fitlm or stepwiselm.

fitlm fits a linear regression model to data using a fixed model specification. Use addTerms, removeTerms, or step to add or remove terms from the model. Alternatively, use stepwiselm to fit a model using stepwise linear regression.

**Properties**

**Coefficient Estimates**

**CoefficientCovariance** — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p-by-p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see "Coefficient Standard Errors and Confidence Intervals" on page 11-57.

Data Types: single | double

**CoefficientNames** — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: cell

**Coefficients** — Coefficient values

table
This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t-statistic for a test that the coefficient is zero
- **pValue** — p-value for the t-statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```matlab
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

**NumCoefficients — Number of model coefficients**

Positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

**NumEstimatedCoefficients — Number of estimated coefficients**

Positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

**Summary Statistics**

**DFE — Degrees of freedom for error**

Positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

**Diagnostics — Observation diagnostics**

Table
This property is read-only.

Observation diagnostics, specified as a table that contains one row for each observation and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leverage</td>
<td>Diagonal elements of HatMatrix</td>
<td>Leverage for each observation indicates to what extent the fit is determined by the observed predictor values. A value close to 1 indicates that the fit is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates that the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. A Leverage value greater than 2*P/N indicates high leverage.</td>
</tr>
<tr>
<td>CooksDistance</td>
<td>Cook's distance</td>
<td>CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance greater than three times the mean Cook's distance can be an outlier.</td>
</tr>
<tr>
<td>Dffits</td>
<td>Delete-1 scaled differences in fitted values</td>
<td>Dffits is the scaled change in the fitted values for each observation that results from excluding that observation from the fit. Values greater than 2*sqrt(P/N) in absolute value can be considered influential.</td>
</tr>
<tr>
<td>S2_i</td>
<td>Delete-1 variance</td>
<td>S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These estimates can be compared with the mean squared error (MSE) value, stored in the MSE property.</td>
</tr>
<tr>
<td>CovRatio</td>
<td>Delete-1 ratio of determinant of covariance</td>
<td>CovRatio is the ratio of the determinant of the coefficient covariance matrix, with each observation deleted in turn, to the determinant of the covariance matrix for the full model. Values greater than 1 + 3<em>P/N or less than 1 – 3</em>P/N indicate influential points.</td>
</tr>
<tr>
<td>Dfbetas</td>
<td>Delete-1 scaled differences in coefficient estimates</td>
<td>Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that results from excluding each observation in turn. Values greater than 3/sqrt(N) in absolute value indicate that the observation has a significant influence on the corresponding coefficient.</td>
</tr>
<tr>
<td>HatMatrix</td>
<td>Projection matrix to compute fitted from observed responses</td>
<td>HatMatrix is an N-by-N matrix such that Fitted = HatMatrix*Y, where Y is the response vector and Fitted is the vector of fitted response values.</td>
</tr>
</tbody>
</table>

Diagnostics contains information that is helpful in finding outliers and influential observations. Delete-1 diagnostics capture the changes that result from excluding each observation in turn from the fit. For more details, see “Hat Matrix and Leverage” on page 11-76, “Cook’s Distance” on page 11-54, and “Delete-1 Statistics” on page 11-62.
Use plotDiagnostics to plot observation diagnostics.

Rows not used in the fit because of missing values (in ObservationInfo.Missing) or excluded values (in ObservationInfo.Excluded) contain NaN values in the CooksDistance, Dffits, S2_i, and CovRatio columns and zeros in the Leverage, Dfbetas, and HatMatrix columns.

To obtain any of these columns as an array, index into the property using dot notation. For example, obtain the delete-1 variance vector in the model mdl:

\[
S2i = mdl.Diagnostics.S2_i;
\]

Data Types: table

**Fitted** — Fitted response values based on input data

numeric vector

This property is read-only.

Fitted (predicted) response values based on input data, specified as an \( n \)-by-1 numeric vector. \( n \) is the number of observations in the input data. Use predict to compute predictions for other predictor values, or to compute confidence bounds on Fitted.

Data Types: single | double

**LogLikelihood** — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of response values, specified as a numeric value, based on the assumption that each response value follows a normal distribution. The mean of the normal distribution is the fitted (predicted) response value, and the variance is the MSE.

Data Types: single | double

**ModelCriterion** — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. \( \text{AIC} = -2\log L + 2m \), where \( \log L \) is the loglikelihood and \( m \) is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. \( \text{AICc} = \text{AIC} + \frac{2m(m + 1)}{(n - m - 1)} \), where \( n \) is the number of observations.
- **BIC** — Bayesian information criterion. \( \text{BIC} = -2\log L + m\log(n) \).
- **CAIC** — Consistent Akaike information criterion. \( \text{CAIC} = -2\log L + m\log(n) + 1 \).

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.
To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```matlab
iaic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

**MSE — Mean squared error**

numeric value

This property is read-only.

Mean squared error (residuals), specified as a numeric value.

\[
MSE = \frac{SSE}{DFE},
\]

where \(MSE\) is the mean squared error, \(SSE\) is the sum of squared errors, and \(DFE\) is the degrees of freedom.

Data Types: `single` | `double`

**Residuals — Residuals for fitted model**

table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw</td>
<td>Observed minus fitted values</td>
</tr>
<tr>
<td>Pearson</td>
<td>Raw residuals divided by the root mean squared error (RMSE)</td>
</tr>
<tr>
<td>Standardized</td>
<td>Raw residuals divided by their estimated standard deviation</td>
</tr>
<tr>
<td>Studentized</td>
<td>Raw residual divided by an independent estimate of the residual standard deviation. The residual for observation (i) is divided by an estimate of the error standard deviation based on all observations except observation (i).</td>
</tr>
</tbody>
</table>

Use `plotResiduals` to create a plot of the residuals. For details, see “Residuals” on page 11-79.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the raw residual vector `r` in the model `mdl`:

```matlab
r = mdl.Residuals.Raw
```

Data Types: `table`

**RMSE — Root mean squared error**

numeric value

This property is read-only.

Root mean squared error (residuals), specified as a numeric value.
\[ RMSE = \sqrt{\text{MSE}}, \]

where \( RMSE \) is the root mean squared error and \( \text{MSE} \) is the mean squared error.

Data Types: \text{single} | \text{double}

\textbf{Rsquared — R-squared value for model structure}

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- \texttt{Ordinary} — Ordinary (unadjusted) R-squared
- \texttt{Adjusted} — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the \( \text{SSR} \) and \( \text{SST} \) properties:

\[ \text{Rsquared} = \frac{\text{SSR}}{\text{SST}}, \]

where \( \text{SST} \) is the total sum of squares, and \( \text{SSR} \) is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-60.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model \( \text{mdl} \):

\[
r2 = \text{mdl.Rsquared.Adjusted}
\]

Data Types: \text{struct}

\textbf{SSE — Sum of squared errors}

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}, \]

where \( \text{SST} \) is the total sum of squares, \( \text{SSE} \) is the sum of squared errors, and \( \text{SSR} \) is the regression sum of squares.

Data Types: \text{single} | \text{double}

\textbf{SSR — Regression sum of squares}

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}, \]

where \( \text{SST} \) is the total sum of squares, \( \text{SSE} \) is the sum of squared errors, and \( \text{SSR} \) is the regression sum of squares.
Data Types: single | double

**SST — Total sum of squares**
numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector \( y \) from the \( \text{mean}(y) \).

The Pythagorean theorem implies
\[
SST = SSE + SSR,
\]
where \( SST \) is the total sum of squares, \( SSE \) is the sum of squared errors, and \( SSR \) is the regression sum of squares.

Data Types: single | double

**Fitting Method**

**Robust — Robust fit information**
structure

This property is read-only.

Robust fit information, specified as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WgtFun</td>
<td>Robust weighting function, such as 'bisquare' (see 'RobustOpts')</td>
</tr>
<tr>
<td>Tune</td>
<td>Tuning constant. This field is empty ([]) if WgtFun is 'ols' or if WgtFun is a function handle for a custom weight function with the default tuning constant 1.</td>
</tr>
<tr>
<td>Weights</td>
<td>Vector of weights used in the final iteration of robust fit. This field is empty for a CompactLinearModel object.</td>
</tr>
</tbody>
</table>

This structure is empty unless you fit the model using robust regression.

Data Types: struct

**Steps — Stepwise fitting information**
structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Formula representing the starting model</td>
</tr>
<tr>
<td>Lower</td>
<td>Formula representing the lower bound model. The terms in Lower must remain in the model.</td>
</tr>
<tr>
<td>Upper</td>
<td>Formula representing the upper bound model. The model cannot contain more terms than Upper.</td>
</tr>
<tr>
<td>Criterion</td>
<td>Criterion used for the stepwise algorithm, such as 'sse'</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>PEnter</td>
<td>Threshold for Criterion to add a term</td>
</tr>
<tr>
<td>PRemove</td>
<td>Threshold for Criterion to remove a term</td>
</tr>
<tr>
<td>History</td>
<td>Table representing the steps taken in the fit</td>
</tr>
</tbody>
</table>

The **History** table contains one row for each step, including the initial fit, and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Action taken during the step:</td>
</tr>
<tr>
<td></td>
<td>• 'Start' — First step</td>
</tr>
<tr>
<td></td>
<td>• 'Add' — A term is added</td>
</tr>
<tr>
<td></td>
<td>• 'Remove' — A term is removed</td>
</tr>
<tr>
<td>TermName</td>
<td>• If <strong>Action</strong> is 'Start', <strong>TermName</strong> specifies the starting model</td>
</tr>
<tr>
<td></td>
<td>specification.</td>
</tr>
<tr>
<td></td>
<td>• If <strong>Action</strong> is 'Add' or 'Remove', <strong>TermName</strong> specifies the term added</td>
</tr>
<tr>
<td></td>
<td>or removed in the step.</td>
</tr>
<tr>
<td>Terms</td>
<td>Model specification in a &quot;Terms Matrix&quot; on page 32-3061</td>
</tr>
<tr>
<td>DF</td>
<td>Regression degrees of freedom after the step</td>
</tr>
<tr>
<td>delDF</td>
<td>Change in regression degrees of freedom from the previous step</td>
</tr>
<tr>
<td></td>
<td>(negative for steps that remove a term)</td>
</tr>
<tr>
<td>Deviance</td>
<td>Deviance (residual sum of squares) at the step</td>
</tr>
<tr>
<td></td>
<td>(only for a generalized linear regression model)</td>
</tr>
<tr>
<td>FStat</td>
<td>F-statistic that leads to the step</td>
</tr>
<tr>
<td>PValue</td>
<td>p-value of the F-statistic</td>
</tr>
</tbody>
</table>

The structure is empty unless you fit the model using stepwise regression.

**Data Types:** struct

**Input Data**

**Formula — Model information**

*LinearFormula* object

This property is read-only.

Model information, specified as a *LinearFormula* object.

Display the formula of the fitted model *mdl* using dot notation:

```
mdl.Formula
```

**NumObservations — Number of observations**

*positive integer*

This property is read-only.

32-3051
Number of observations the fitting function used in fitting, specified as a positive integer. 
\texttt{NumObservations} is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the 'Exclude' name-value pair argument) or rows with missing values.

Data Types: double

\textbf{NumPredictors — Number of predictor variables}

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

\textbf{NumVariables — Number of variables}

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. 
\texttt{NumVariables} is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

\texttt{NumVariables} also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

\textbf{ObservationInfo — Observation information}

table

This property is read-only.

Observation information, specified as an \( n \)-by-4 table, where \( n \) is equal to the number of rows of input data. 
\texttt{ObservationInfo} contains the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>Observation weights, specified as a numeric value. The default value is 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>Indicator of excluded observations, specified as a logical value. The value is \texttt{true} if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.</td>
</tr>
<tr>
<td>Missing</td>
<td>Indicator of missing observations, specified as a logical value. The value is \texttt{true} if the observation is missing.</td>
</tr>
<tr>
<td>Subset</td>
<td>Indicator of whether or not the fitting function uses the observation, specified as a logical value. The value is \texttt{true} if the observation is not excluded or missing, meaning the fitting function uses the observation.</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector \( w \) of the model \( 	exttt{mdl} \):

\[ w = 	exttt{mdl.ObservationInfo.Weights} \]

Data Types: table
**ObservationNames — Observation names**
cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array.

Data Types: cell

**PredictorNames — Names of predictors used to fit model**
cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: cell

**ResponseName — Response variable name**
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

**VariableInfo — Information about variables**
table

This property is read-only.

Information about variables contained in Variables, specified as a table with one row for each variable and the columns described in this table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'</td>
</tr>
<tr>
<td>Range</td>
<td>Variable range, specified as a cell array of vectors</td>
</tr>
<tr>
<td></td>
<td>- Continuous variable — Two-element vector ([min, max]), the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>- Categorical variable — Vector of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Indicator of which variables are in the fitted model, specified as a logical vector. The value is true if the model includes the variable.</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Indicator of categorical variables, specified as a logical vector. The value is true if the variable is categorical.</td>
</tr>
</tbody>
</table>
VariableInfo also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

**VariableNames — Names of variables**
cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1','x2','...','xn','y'}.

VariableNames also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: cell

**Variables — Input data**
table

This property is read-only.

Input data, specified as a table. Variables contains both predictor and response values. If the fit is based on a table or dataset array, Variables contains all the data from the table or dataset array. Otherwise, Variables is a table created from the input data matrix X and the response vector y.

Variables also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

**Object Functions**

**Create CompactLinearModel**
compact  Compact linear regression model

**Add or Remove Terms from Linear Model**
addTerms  Add terms to linear regression model
removeTerms  Remove terms from linear regression model
step  Improve linear regression model by adding or removing terms

**Predict Responses**
feval  Predict responses of linear regression model using one input for each predictor
predict  Predict responses of linear regression model
random  Simulate responses with random noise for linear regression model
Evaluate Linear Model
anova          Analysis of variance for linear regression model
coeffCI        Confidence intervals of coefficient estimates of linear regression model
coeffTest      Linear hypothesis test on linear regression model coefficients
dwtest         Durbin-Watson test with linear regression model object

Visualize Linear Model and Summary Statistics
plot            Scatter plot or added variable plot of linear regression model
plotAdded       Added variable plot of linear regression model
plotAdjustedResponse Adjusted response plot of linear regression model
plotDiagnostics Plot observation diagnostics of linear regression model
plotEffects     Plot main effects of predictors in linear regression model
plotInteraction Plot interaction effects of two predictors in linear regression model
plotPartialDependence Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotResiduals   Plot residuals of linear regression model
plotSlice       Plot of slices through fitted linear regression surface

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the carsmall data set, a matrix input data set.

load carsmall
X = [Weight, Horsepower, Acceleration];

Fit a linear regression model by using fitlm.

mdl = fitlm(X, MPG)

mdl = Linear regression model:
    y ~ 1 + x1 + x2 + x3

Estimated Coefficients:
                          Estimate     SE         tStat     pValue
    ________________________    __________    _________    __________
    (Intercept)               47.977       3.8785        12.37    4.8957e-21
    x1            -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
    x3              -0.011583      0.19333    -0.059913       0.95236

Number of observations: 93, Error degrees of freedom: 89
Root Mean Squared Error: 4.09
R-squared: 0.752,  Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27

The model display includes the model formula, estimated coefficients, and model summary statistics.
The model formula in the display, \( y \sim 1 + x_1 + x_2 + x_3 \), corresponds to \( y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \epsilon \).

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```plaintext
mdl.Coefficients
ans=4×4 table
       Estimate  SE  tStat   pValue
(Intercept)     47.977  3.8785  12.37    4.8957e-21
    x1     -0.0065416  0.0011274 -5.8023    9.8742e-08
     x2      -0.042943  0.024313  -1.7663       0.08078
     x3      -0.011583  0.19333  -0.059913       0.95236
```

The `Coefficient` property includes these columns:

- **Estimate** — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (intercept) is 47.977.
- **SE** — Standard error of the coefficients.
- **tStat** — \( t \)-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that \( tStat = \frac{Estimate}{SE} \). For example, the \( t \)-statistic for the intercept is \( 47.977/3.8785 = 12.37 \).
- **pValue** — \( p \)-value for the \( t \)-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the \( p \)-value of the \( t \)-statistic for \( x_2 \) is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- **Number of observations** — Number of rows without any NaN values. For example, `Number of observations` is 93 because the MPG data vector has six NaN values and the Horsepower data vector has one NaN value for a different observation, where the number of rows in \( X \) and MPG is 100.
- **Error degrees of freedom** — \( n - p \), where \( n \) is the number of observations, and \( p \) is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the error degrees of freedom is \( 93 - 4 = 89 \).
- **Root mean squared error** — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- **R-squared and Adjusted R-squared** — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the R-squared value suggests that the model explains approximately 75% of the variability in the response variable MPG.
- **F-statistic vs. constant model** — Test statistic for the F-test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- **p-value** — \( p \)-value for the F-test on the model. For example, the model is significant with a \( p \)-value of 7.3816e-27.

You can find these statistics in the model properties (`NumObservations`, `DFE`, `RMSE`, and `Rsquared`) and by using the `anova` function.
anova(mdl,'summary')

**Linear Regression with Categorical Predictor**

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use anova to test the significance of the categorical variable.

**Model with Categorical Predictor**

Load the carsmall data set and create a linear regression model of MPG as a function of Model_Year. To treat the numeric vector Model_Year as a categorical variable, identify the predictor using the 'CategoricalVars' name-value pair argument.

```matlab
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl = 
  Linear regression model: 
    MPG ~ 1 + Model_Year
```

**Estimated Coefficients:**

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>17.69</td>
<td>1.0328</td>
<td>17.127</td>
<td>3.2371e-30</td>
</tr>
<tr>
<td>Model_Year_76</td>
<td>3.8839</td>
<td>1.4059</td>
<td>2.7625</td>
<td>0.0069402</td>
</tr>
<tr>
<td>Model_Year_82</td>
<td>14.02</td>
<td>1.4369</td>
<td>9.7571</td>
<td>8.2164e-16</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15

The model formula in the display, **MPG ~ 1 + Model_Year**, corresponds to

\[
\text{MPG} = \beta_0 + \beta_1 \text{I}_{\text{Year} = 76} + \beta_2 \text{I}_{\text{Year} = 82} + \epsilon,
\]

where \( \text{I}_{\text{Year} = 76} \) and \( \text{I}_{\text{Year} = 82} \) are indicator variables whose value is one if the value of Model_Year is 76 and 82, respectively. The Model_Year variable includes three distinct values, which you can check by using the unique function.

```matlab
unique(Model_Year)
```

ans = 3×1

32-3057
fitlm chooses the smallest value in Model_Year as a reference level ('70') and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

**Model with Full Indicator Variables**

You can interpret the model formula of mdl as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```matlab
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

mdl =

Linear regression model:

$$MPG \sim Model\_Year\_70 + Model\_Year\_76 + Model\_Year\_82$$

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>

</tr>
<tr>
<td>Model_Year_76</td>
<td>21.574</td>
<td>0.95387</td>
<td>22.617</td>
<td>4.0156e-39</td>
</tr>
<tr>
<td>Model_Year_82</td>
<td>31.71</td>
<td>0.99896</td>
<td>31.743</td>
<td>5.2234e-51</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56

**Choose Reference Level in Model**

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable Year:

```matlab
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```matlab
categories(Year)
an = 3x1 cell
   {'}70'{
   {'}76'{
```
If you use `Year` as a predictor variable, then `fitlm` chooses the first category '70' as a reference level. Reorder `Year` by using the `reordercats` function.

```matlab
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
ans = 3x1 cell
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is '76'. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```matlab
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```matlab
mdl2 = \nLinear regression model: \nMPG ~ 1 + Model_Year
Estimated Coefficients: \n    Estimate  SE      tStat    pValue
    _______  ____    _______    __________
(Intercept)       21.574     0.95387     22.617    4.0156e-39
Model_Year_70    -3.8839      1.4059    -2.7625     0.0069402
Model_Year_82     10.136      1.3812     7.3385    8.7634e-11
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses '76' as a reference level and includes two indicator variables $I_{Year = 70}$ and $I_{Year = 82}$.

**Evaluate Categorical Predictor**

The model display of `mdl2` includes a p-value of each term to test whether or not the corresponding coefficient is equal to zero. Each p-value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the 'components' (default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```matlab
anova(mdl2,'components')
```

```matlab
ans=2×5 table
    SumSq    DF    MeanSq   F       pValue
    _______    __    _______    _____    __________
Model_Year          3190.1    2    1595.1    51.56    1.0694e-15
Error              2815.2    91    30.936
```

32-3059
The component ANOVA table includes the \( p \)-value of the Model_Year variable, which is smaller than the \( p \)-values of the indicator variables.

**Fit Robust Linear Regression Model**

Load the hald data set, which measures the effect of cement composition on its hardening heat.

```matlab
load hald
```

This data set includes the variables ingredients and heat. The matrix ingredients contains the percent composition of four chemicals present in the cement. The vector heat contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```matlab
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```matlab
mdl =
Linear regression model (robust fit):
  y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:

<table>
<thead>
<tr>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>60.09</td>
<td>75.818</td>
<td>0.79256</td>
</tr>
<tr>
<td>x1</td>
<td>1.5753</td>
<td>0.80585</td>
<td>1.9548</td>
</tr>
<tr>
<td>x2</td>
<td>0.5322</td>
<td>0.78315</td>
<td>0.67957</td>
</tr>
<tr>
<td>x3</td>
<td>0.13346</td>
<td>0.8166</td>
<td>0.16343</td>
</tr>
<tr>
<td>x4</td>
<td>-0.12052</td>
<td>0.7672</td>
<td>-0.15709</td>
</tr>
</tbody>
</table>
```

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-103, which compares the results of a robust fit to a standard least-squares fit.

**Fit Linear Model Using Stepwise Regression**

Load the hald data set, which measures the effect of cement composition on its hardening heat.

```matlab
load hald
```

This data set includes the variables ingredients and heat. The matrix ingredients contains the percent composition of four chemicals present in the cement. The vector heat contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

mdl =
Linear regression model:  
y ~ 1 + x1 + x2

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>52.577</td>
<td>2.2862</td>
<td>22.998</td>
<td>5.4566e-10</td>
</tr>
<tr>
<td>x1</td>
<td>1.4683</td>
<td>0.1213</td>
<td>12.105</td>
<td>2.6922e-07</td>
</tr>
<tr>
<td>x2</td>
<td>0.66225</td>
<td>0.045855</td>
<td>14.442</td>
<td>5.029e-08</td>
</tr>
</tbody>
</table>

Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979, Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09

By default, the starting model is a constant model. stepwiselm performs forward selection and adds the x4, x1, and x2 terms (in that order), because the corresponding p-values are less than the PEnter value of 0.06. stepwiselm then uses backward elimination and removes x4 from the model because, once x2 is in the model, the p-value of x4 is greater than the default value of PRemove, 0.1.

More About

Terms Matrix

A terms matrix T is a t-by-(p + 1) matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and +1 accounts for the response variable. The value of T(i,j) is the exponent of variable j in term i.

For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of T represents one term:

- [0 0 0 0] — Constant term or intercept
- [0 1 0 0] — B; equivalently, A^0 * B^1 * C^0
- [1 0 1 0] — A*C
- [2 0 0 0] — A^2
- [0 1 2 0] — B*(C^2)

The θ at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include θ for the response variable in the last column of each row.
Alternative Functionality

- For reduced computation time on high-dimensional data sets, fit a linear regression model using the `fitrlinear` function.
- To regularize a regression, use `fitrlinear`, `lasso`, `ridge`, or `plsregress`.
  - `fitrlinear` regularizes a regression for high-dimensional data sets using lasso or ridge regression.
  - `lasso` removes redundant predictors in linear regression using lasso or elastic net.
  - `ridge` regularizes a regression with correlated terms using ridge regression.
  - `plsregress` regularizes a regression with correlated terms using partial least squares.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitlm` or `stepwiselm`, you cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the `'CategoricalVars'` name-value pair argument. Code generation does not support categorical predictors. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics
“Linear Regression” on page 11-8
“What Is a Linear Regression Model?” on page 11-5

Introduced in R2012a
LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl,formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G).

Input Arguments

tbl — Input data
`table | dataset array``

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`. Data Types: `table`

formula — Formula for model specification
character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For a full description, see “Formula” on page 32-3076.

Example: 'y ~ treatment +(1|block)'

X — Fixed-effects design matrix
`n-by-p` matrix

Fixed-effects design matrix, specified as an `n-by-p` matrix, where `n` is the number of observations, and `p` is the number of fixed-effects predictor variables. Each row of `X` corresponds to one observation, and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

y — Response values
`n-by-1` vector
Response values, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations.

Data Types: `single` | `double`

**Z — Random-effects design**

\( n \)-by-\( q \) matrix | cell array of \( R \) \( n \)-by-\( q(r) \) matrices, \( r = 1, 2, ..., R \)

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then \( Z \) must be an \( n \)-by-\( q \) matrix, where \( n \) is the number of observations and \( q \) is the number of variables in the random-effects term.
- If there are \( R \) random-effects terms, then \( Z \) must be a cell array of length \( R \). Each cell of \( Z \) contains an \( n \)-by-\( q(r) \) design matrix \( Z\{r\} \), \( r = 1, 2, ..., R \), corresponding to each random-effects term. Here, \( q(r) \) is the number of random effects term in the \( r \)th random effects design matrix, \( Z\{r\} \).

Data Types: `single` | `double` | `cell`

**G — Grouping variable or variables**

\( n \)-by-1 vector | cell array of \( R \) \( n \)-by-1 vectors

Grouping variable or variables on page 2-45, specified as either of the following.

- If there is one random-effects term, then \( G \) must be an \( n \)-by-1 vector corresponding to a single grouping variable with \( M \) levels or groups.
  - \( G \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.
- If there are multiple random-effects terms, then \( G \) must be a cell array of length \( R \). Each cell of \( G \) contains a grouping variable \( G\{r\} \), \( r = 1, 2, ..., R \), with \( M(r) \) levels.
  - \( G\{r\} \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

**Properties**

**Coefficients — Fixed-effects coefficient estimates**

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

- **Name**
  - Name of the term.
- **Estimate**
  - Estimated value of the coefficient.
- **SE**
  - Standard error of the coefficient.
- **tStat**
  - \( t \)-statistics for testing the null hypothesis that the coefficient is equal to zero.

32-3064
### DF

Degrees of freedom for the *t*-test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. Coefficients always use the 'Residual' method for 'DFMethod'.

### pValue

*p*-value for the *t*-test.

### Lower

Lower limit of the confidence interval for coefficient. Coefficients always use the 95% confidence level, i.e. 'alpha' is 0.05.

### Upper

Upper limit of confidence interval for coefficient. Coefficients always use the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the *coefCI* and *coefTest* methods.

**CoefficientCovariance — Covariance of the estimated fixed-effects coefficients**

*p*-by-*p* matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a *p*-by-*p* matrix, where *p* is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the *covarianceParameters* method.

Data Types: double

**CoefficientNames — Names of the fixed-effects coefficients**

1-by-*p* cell array of character vectors

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by-*p* cell array of character vectors.

Data Types: cell

**DFE — Residual degrees of freedom**

Positive integer value

Residual degrees of freedom, stored as a positive integer value. *DFE* = *n* - *p*, where *n* is the number of observations, and *p* is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the *fixedEffects* and *randomEffects* methods.

Data Types: double

**FitMethod — Method used to fit the linear mixed-effects model**

*ML* | *REML*

Method used to fit the linear mixed-effects model, stored as either of the following.

- **ML**, if the fitting method is maximum likelihood
- **REML**, if the fitting method is restricted maximum likelihood

Data Types: char
Formula — Specification of the fixed- and random-effects terms, and grouping variables

Object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 32-3076.

LogLikelihood — Maximized log or restricted log likelihood

Scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: double

ModelCriterion — Model criterion

Dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

- AIC: Akaike Information Criterion
- BIC: Bayesian Information Criterion
- Loglikelihood: Log likelihood value of the model
- Deviance: -2 times the log likelihood of the model

If \( n \) is the number of observations used in fitting the model, and \( p \) is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - \( n \), when the fitting method is maximum likelihood (ML)
  - \( n - p \), when the fitting method is restricted maximum likelihood (REML)

MSE — ML or REML estimate

Positive scalar value

ML or REML estimate, based on the fitting method used for estimating \( \sigma^2 \), stored as a positive scalar value. \( \sigma^2 \) is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: double

NumCoefficients — Number of fixed-effects coefficients

Positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double
**NumEstimatedCoefficients — Number of estimated fixed-effects coefficients**

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumObservations — Number of observations**

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

Data Types: double

**NumPredictors — Number of predictors**

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumVariables — Total number of variables**

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array tbl, NumVariables is the total number of variables in tbl including the response variable.
- If the fit is based on matrix input, NumVariables is the total number of columns in the predictor matrix or matrices, and response vector.

NumVariables includes variables, if there are any, that are not used as predictors or as the response.

Data Types: double

**ObservationInfo — Information about the observations**

Information about the observations used in the fit, stored as a table.

ObservationInfo has one row for each observation and the following four columns.

- **Weights**
  - The value of the weighted variable for that observation. Default value is 1.

- **Excluded**
  - true, if the observation was excluded from the fit using the 'Exclude' name-value pair argument, false, otherwise. 1 stands for true and 0 stands for false.
Missing

true, if the observation was excluded from the fit because any response or predictor value is missing, false, otherwise.

Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <undefined> value for categorical arrays.

Subset

true, if the observation was used in the fit, false, if it was not used because it is missing or excluded.

Data Types: table

ObservationNames — Names of observations
cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

• If the data is in a table or dataset array, tbl, containing observation names, ObservationNames has those names.
• If the data is provided in matrices, or a table or dataset array without observation names, then ObservationNames is an empty cell array.

Data Types: cell

PredictorNames — Names of predictors
cell array of character vectors

Names of the variables that you use as predictors in the fit, stored as a cell array of character vectors that has the same length as NumPredictors.

Data Types: cell

ResponseName — Names of response variable
character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: char

Rsquared — Proportion of variability in the response explained by the fitted model
structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. Rsquared has two fields.

Ordinary

R-squared value, stored as a scalar value in a structure. Rsquared.Ordinary = 1 – SSE./SST
Adjusted R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

\[
\text{R}^{2}_{\text{Adjusted}} = 1 - \frac{(\text{SSE}/\text{SST})*(\text{DFT}/\text{DFE})}{\text{DFE}}
\]

where \( \text{DFE} = n - p \), \( \text{DFT} = n - 1 \), and \( n \) is the total number of observations, \( p \) is the number of fixed-effects coefficients.

Data Types: struct

**SSE — Error sum of squares**
positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

\[
\text{SSE} = \sum((y - F)^2),
\]
where \( y \) is the response vector, and \( F \) is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: double

**SSR — Regression sum of squares**
positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

\[
\text{SSR} = \sum((F - \text{mean}(F))^2),
\]
where \( F \) is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: double

**SST — Total sum of squares**
positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

\[
\text{SST} = \sum((y - \text{mean}(y))^2) = \text{SSR + SSE},
\]
where \( y \) is the response vector.

Data Types: double

**Variables — Variables**
table

Variables, stored as a table.

- If the fit is based on a table or dataset array \( \text{tbl} \), then \( \text{Variables} \) is identical to \( \text{tbl} \).
- If the fit is based on matrix input, then \( \text{Variables} \) is a table containing all the variables in the predictor matrix or matrices, and response variable.
Data Types: table

**VariableInfo — Information about the variables**

Table

Information about the variables used in the fit, stored as a table.

VariableInfo has one row for each variable and contains the following four columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Class</strong></td>
<td>Class of the variable (‘double’, ‘cell’, ‘nominal’, and so on).</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>Value range of the variable.</td>
</tr>
<tr>
<td><strong>InModel</strong></td>
<td>true, if the variable is a predictor in the fitted model.</td>
</tr>
<tr>
<td><strong>IsCategorical</strong></td>
<td>false, if the variable is not in the fitted model.</td>
</tr>
</tbody>
</table>

Data Types: table

**VariableNames — Names of the variables**

Cell array of character vectors

Names of the variables used in the fit, stored as a cell array of character vectors.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: cell
Methods

anova Analysis of variance for linear mixed-effects model
coefficCI Confidence intervals for coefficients of linear mixed-effects model
coeffTest Hypothesis test on fixed and random effects of linear mixed-effects model
compare Compare linear mixed-effects models
covarianceParameters Extract covariance parameters of linear mixed-effects model
designMatrix Fixed- and random-effects design matrices
disp Display linear mixed-effects model

randomEffects Estimates of random effects and related statistics
residuals Residuals of fitted linear mixed-effects model
response Response vector of the linear mixed-effects model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...     'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Because region is a nominal variable, fitlme takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, I[MidAtl] is the dummy variable representing the region MidAtl. For details, see “Dummy Variables” on page 2-48.

The corresponding model is

\[ y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \ldots + \beta_8 I[\text{Pac}]_i + b_{0m} + \epsilon_{im}, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( \beta_j, j = 0, 1, \ldots, 8, \) are the fixed-effects coefficients, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution, \( b_{0m} \sim N(0, \sigma_b^2) \) and the error term has the distribution, \( \epsilon_{im} \sim N(0, \sigma^2) \).

\[ \text{lme} = \text{fitlme}('\text{flu2,'FluRate ~ 1 + Region + (1|Date)'}) \]

\[ \text{lme} = \]

Linear mixed-effects model fit by ML

Model information:
- Number of observations: 468
- Fixed effects coefficients: 9

<td>0.285</td>
</tr>
</tbody>
</table>

The p-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions WNCentral and ECentral are significantly different relative to the flu rates in region NE.

The confidence limits for the standard deviation of the random-effects term, \( \sigma_b \), do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the compare method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region WNCentral in week 10/9/2005 is

\[
\hat{y}_{\text{WNCentral}, 10/9/2005} = \hat{\beta}_0 + \hat{\beta}_3 [\text{WNCentral}] + \hat{b}_{10/9/2005} \\
= 1.2233 + 0.23687 - 0.1718 \\
= 1.28837.
\]

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```matlab
beta = fixedEffects(lme); 
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS) 
STATS.Level = nominal(STATS.Level); 
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005') 
```

```matlab
y_hat = 1.2884 
```

You can simply display the fitted value using the fitted method.

```matlab
F = fitted(lme); 
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral') 
```

```matlab
ans = 1.2884 
```

Compute the fitted marginal response for region WNCentral in week 10/9/2005.

```matlab
F = fitted(lme,'Conditional',false); 
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral') 
```

```matlab
ans = 1.4602 
```
Linear Mixed-Effects Model with a Random Slope

Load the sample data.
load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1\text{Acc}_i + \beta_2\text{HP} + b_{0m} + b_{1m}\text{Acc}_im + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left( \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where $m$ represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```matlab
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

```matlab
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...     
{ 'Intercept', 'Acceleration', 'Horsepower' },
'RandomEffectPredictors',...
{ { 'Intercept', 'Acceleration' } },
'RandomEffectGroups', { 'Model_Year' },
'FitMethod', 'REML');
```

```
lme = Linear mixed-effects model fit by REML

Model information:
   Number of observations               392
   Fixed effects coefficients            3
   Random effects coefficients           26
   Covariance parameters                 4

Formula:  
   Linear Mixed Formula with 4 predictors.

Model fit statistics:
   AIC      BIC     LogLikelihood     Deviance
     2202.9  2230.7    -1094.5          2188.9

Fixed effects coefficients (95% CIs):

<table>
<thead>
<tr>
<th>Name</th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>DF</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Intercept'</td>
<td>50.064</td>
<td>2.3176</td>
<td>21.602</td>
<td>389</td>
</tr>
<tr>
<td>'Acceleration'</td>
<td>-0.57897</td>
<td>0.13843</td>
<td>-4.1825</td>
<td>389</td>
</tr>
</tbody>
</table>
```
The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (Lower and Upper). The p-values for (pValue) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the compare method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

\[
\text{lme.CoefficientCovariance}
\]

\[
\text{ans} = 3 \times 3
\]

\[
\begin{pmatrix}
5.3711 & -0.2809 & -0.0126 \\
-0.2809 & 0.0192 & 0.0005 \\
-0.0126 & 0.0005 & 0.0001
\end{pmatrix}
\]

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is \( \sqrt{5.3711} \).

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is \(-0.2809\) and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

\[
\text{lme.Rsquared}
\]

32-3075
ans = struct with fields:
    Ordinary: 0.7826
    Adjusted: 0.7815

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

**More About**

**Formula**

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table tbl contains the following:

- A response variable, y
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random_1|g_1) + ... + (random_R|g_R)', the term fixed corresponds to a specification of the fixed-effects design matrix X, random_1 is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly random_R is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>X^k, where k is a positive integer</td>
<td>X, X^2, ..., X^k</td>
</tr>
<tr>
<td>X1 + X2</td>
<td>X1, X2</td>
</tr>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1.*X2 only</td>
</tr>
<tr>
<td>- X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>
Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>

linhypertest

Linear hypothesis test

**Syntax**

```
p = linhypertest(beta,COVB,c,H,dfe)
[p,t,r] = linhypertest(...)```

**Description**

```
p = linhypertest(beta,COVB,c,H,dfe) returns the p value p of a hypothesis
test on a vector of parameters. beta is a vector of k parameter
estimates. COVB is the k-by-k estimated covariance matrix of the
parameter estimates. c and H specify the null hypothesis in the form
H*b = c, where b is the vector of unknown parameters estimated by
beta. dfe is the degrees of freedom for the COVB estimate, or Inf if
COVB is known rather than estimated.
```

beta is required. The remaining arguments have default values:

- COVB = `eye(k)`
- c = `zeros(k,1)`
- H = `eye(K)`
- dfe = Inf

If H is omitted, c must have k elements and it specifies the null hypothesis values for the entire parameter vector.

**Note** The following functions return outputs suitable for use as the COVB input argument to linhypertest: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns COVB directly; the other functions return COVB in stats.covb.

```
[p,t,r] = linhypertest(...) also returns the test statistic t and the rank r of the hypothesis matrix H. If dfe is Inf or is not given, t^r is a chi-square statistic with r degrees of freedom. If dfe is specified as a finite value, t is an F statistic with r and dfe degrees of freedom.
```

linhypertest performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the p-values are exact. For other procedures, the p-values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

**Examples**

Fit a multiple linear model to the data in hald.mat:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
```
beta =
    62.4054
    1.5511
    0.5102
    0.1019
   -0.1441

Perform an F-test that the last two coefficients are both 0:

SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhyptest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391

Introduced in R2007a
linkage
Agglomerative hierarchical cluster tree

Syntax

\[ Z = \text{linkage}(X) \]
\[ Z = \text{linkage}(X,\text{method}) \]
\[ Z = \text{linkage}(X,\text{method},\text{metric}) \]
\[ Z = \text{linkage}(X,\text{method},\text{metric},'\text{savememory}',\text{value}) \]
\[ Z = \text{linkage}(X,\text{method},\text{pdist}\_\text{inputs}) \]
\[ Z = \text{linkage}(y) \]
\[ Z = \text{linkage}(y,\text{method}) \]

Description

\( Z = \text{linkage}(X) \) returns a matrix \( Z \) that encodes a tree containing hierarchical clusters of the rows of the input data matrix \( X \).

\( Z = \text{linkage}(X,\text{method}) \) creates the tree using the specified method, which describes how to measure the distance between clusters. For more information, see “Linkages” on page 32-3087.

\( Z = \text{linkage}(X,\text{method},\text{metric}) \) performs clustering by passing \( \text{metric} \) to the \( \text{pdist} \) function, which computes the distance between the rows of \( X \).

\( Z = \text{linkage}(X,\text{method},\text{metric},'\text{savememory}',\text{value}) \) uses a memory-saving algorithm when \( \text{value} \) is ‘on’, and uses the standard algorithm when \( \text{value} \) is ‘off’.

\( Z = \text{linkage}(X,\text{method},\text{pdist}\_\text{inputs}) \) passes \( \text{pdist}\_\text{inputs} \) to the \( \text{pdist} \) function, which computes the distance between the rows of \( X \). The \( \text{pdist}\_\text{inputs} \) argument consists of the ‘seuclidean’, ‘minkowski’, or ‘mahalanobis’ metric and an additional distance metric option.

\( Z = \text{linkage}(y) \) uses a vector representation \( y \) of a distance matrix. \( y \) is either computed by \( \text{pdist} \) or is a more general dissimilarity matrix conforming to the output format of \( \text{pdist} \).

\( Z = \text{linkage}(y,\text{method}) \) creates the tree using the specified method, which describes how to measure the distance between clusters.

Examples

Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

\[
\text{rng('default')} \% \text{For reproducibility}
\]
\[
X = \text{rand}(20000,3);
\]
Create a hierarchical cluster tree using the `ward` linkage method. In this case, the `'SaveMemory'` option of the `clusterdata` function is set to `'on'` by default. In general, specify the best value for `'SaveMemory'` based on the dimensions of `X` and the available memory.

```
Z = linkage(X,'ward');
```

Cluster the data into a maximum of four groups and plot the result.

```
c = cluster(Z,'Maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

cluster identifies four groups in the data.

**Compare Cluster Assignments to Classes**

Find a maximum of three clusters in the `fisheriris` data set and compare cluster assignments of the flowers to their known classification.

Load the sample data.

```
load fisheriris
```

Create a hierarchical cluster tree using the `'average'` method and the `'chebychev'` metric.

```
Z = linkage(meas,'average','chebychev');
```
Find a maximum of three clusters in the data.

\[ T = \text{cluster}(Z, \text{'maxclust'}, 3); \]

Create a dendrogram plot of \( Z \). To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

\[ \text{cutoff} = \text{median}([Z(\text{end}-2,3) \ Z(\text{end}-1,3)]); \]
\[ \text{dendrogram}(Z, \text{'ColorThreshold'}, \text{cutoff}) \]

Display the last two rows of \( Z \) to see how the three clusters are combined into one. \textit{linkage} combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of 1.7583. \textit{linkage} then combines the 296th (green) cluster with the 298th cluster.

\[ \text{lastTwo} = Z(\text{end}-1: \text{end}, :) \]
\[ \text{lastTwo} = 2 \times 3 \]
\[ \begin{array}{ccc}
293.0000 & 297.0000 & 1.7583 \\
296.0000 & 298.0000 & 3.4445 \\
\end{array} \]

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

\[ \text{crosstab}(T, \text{species}) \]
Observe Clustering Step in Hierarchical Tree

Load the examgrades data set.

```
load examgrades
```

Create a hierarchical tree using `linkage`. Use the 'single' method and the Minkowski metric with an exponent of 3.

```
Z = linkage(grades,'single',{'minkowski',3});
```

Observe the 25th clustering step.

```
Z(25,:)
```

```
ans = 1×3
86.0000 137.0000 4.5307
```

`linkage` combines the 86th observation and the 137th cluster to form a cluster of index 120 + 25 = 145, where 120 is the total number of observations in `grades` and 25 is the row number in `Z`. The shortest distance between the 86th observation and any of the points in the 137th cluster is 4.5307.

Cluster Data Using Dissimilarity Matrix

Create an agglomerative hierarchical cluster tree using a dissimilarity matrix.

Take a dissimilarity matrix `X` and convert it to a vector form that `linkage` accepts by using `squareform`.

```
X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0];
y = squareform(X);
```

Create a cluster tree using `linkage` with the 'complete' method of calculating the distance between clusters. The first two columns of `Z` show how `linkage` combines clusters. The third column of `Z` gives the distance between clusters.

```
Z = linkage(y,'complete')
```

```
Z = 3×3
1 2 1
3 5 4
```
Create a dendrogram plot of Z. The x-axis corresponds to the leaf nodes of the tree, and the y-axis corresponds to the linkage distances between clusters.

dendrogram(Z)

**Input Arguments**

**X** — Input data
numeric matrix

Input data, specified as a numeric matrix with two or more rows. The rows represent observations, and the columns represent categories or dimensions.

Data Types: single | double

**method** — Algorithm for computing distance between clusters
'single' (default) | 'average' | 'centroid' | 'complete' | ... 

Algorithm for computing the distance between clusters, specified as one of the values in this table.
### Method Description

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Unweighted average distance (UPGMA)</td>
</tr>
<tr>
<td>'centroid'</td>
<td>Centroid distance (UPGMC), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'complete'</td>
<td>Farthest distance</td>
</tr>
<tr>
<td>'median'</td>
<td>Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'single'</td>
<td>Shortest distance</td>
</tr>
<tr>
<td>'ward'</td>
<td>Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'weighted'</td>
<td>Weighted average distance (WPGMA)</td>

</table>

For more information on these methods, see “Linkages” on page 32-3087.

#### metric — Distance metric

- 'euclidean'(default)
- 'squaredeuclidean'
- 'seuclidean'
- 'mahalanobis'
- function handle

Distance metric, specified as any metric accepted by the `pdist` function. These metrics are described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance (default).</td>
</tr>
<tr>
<td>'squaredeuclidean'</td>
<td>Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, ( S = \text{nanstd}(X) ). Use DistParameter to specify another value for ( S ).</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance using the sample covariance of ( X, C = \text{nancov}(X) ). Use DistParameter to specify another value for ( C ), where the matrix ( C ) is symmetric and positive definite.</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. Use DistParameter to specify a different exponent ( P ), where ( P ) is a positive scalar value of the exponent.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between points (treated as vectors).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample correlation between points (treated as sequences of values).</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
<tr>

</tbody>
</table>
| @distfun | Custom distance function handle. A distance function has the form  

```plaintext
function D2 = distfun(ZI,ZJ)
% calculation of distance
...
```

where

- ZI is a 1-by-n vector containing a single observation.
- ZJ is an m2-by-n matrix containing multiple observations. distfun must accept a matrix ZJ with an arbitrary number of observations.
- D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For more information, see “Distance Metrics” on page 32-3925.

Use pdist_inputs instead of metric to specify the additional input argument DistParameter of pdist for 'seuclidean', 'minkowski', or 'mahalanobis'.

Data Types: char | string | function_handle

**pdist_inputs — Distance metric and distance metric option**  
cell array

Distance metric and distance metric option, specified as a cell array of the comma-separated pair consisting of the two input arguments Distance and DistParameter of the function pdist. This argument is valid only for specifying 'seuclidean', 'minkowski', or 'mahalanobis'.

Example: `{minkowski,5}`

Data Types: cell

**value — Flag for 'savememory' option**  
'on' | 'off'

Flag for the 'savememory' option, specified as either 'on' or 'off'. The 'on' setting causes linkage to construct clusters without computing the distance matrix. The 'on' setting is available only when method is 'centroid', 'median', or 'ward' and metric is 'euclidean'.

When value is 'on', the linkage run time is proportional to the number of dimensions (number of columns of X). When value is 'off', the linkage memory requirement is proportional to N^2, where N is the number of observations. The best (least-time) setting to use for value depends on the problem dimensions, number of observations, and available memory. The default value setting is a rough approximation of an optimal setting.

The default is 'on' when X has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix. Otherwise, the default is 'off'.

Example: 'savememory','on'

**y — Distances**  
numeric vector
Distances, specified as a numeric vector with the same format as the output of the `pdist` function:

- A row vector of length \( m(m - 1)/2 \), corresponding to pairs of observations in a matrix with \( m \) rows
- Distances arranged in the order \((2,1), (3,1), \ldots, (m,1), (3,2), \ldots, (m,2), \ldots, (m,m - 1)\)

\( y \) can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Data Types: `single` | `double`

### Output Arguments

\[ Z \rightarrow \text{Agglomerative hierarchical cluster tree} \]

numeric matrix

Agglomerative hierarchical cluster tree, returned as a numeric matrix. \( Z \) is an \((m - 1)\)-by-3 matrix, where \( m \) is the number of observations in the original data. Columns 1 and 2 of \( Z \) contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered from 1 to \( m \). Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly formed cluster, corresponding to row \( Z(I,:), \) is assigned the index \( m + I \). The entries \( Z(I,1) \) and \( Z(I,2) \) contain the indices of the two component clusters that form cluster \( m + I \). The \( m - 1 \) higher clusters correspond to the interior nodes of the clustering tree. \( Z(I,3) \) contains the linkage distance between the two clusters merged in row \( Z(I,:). \)

For example, consider building a tree with 30 initial nodes. Suppose that cluster 5 and cluster 7 are combined at step 12, and that the distance between them at that step is 1.5. Then \( Z(12,:), \) is \([5 \ 7 \ 1.5]\). The newly formed cluster has index \( 12 + 30 = 42 \). If cluster 42 appears in a later row, then the function is combining the cluster created at step 12 into a larger cluster.

Data Types: `single` | `double`

### More About

#### Linkages

A linkage is the distance between two clusters.

The following notation describes the linkages used by the various methods:

- Cluster \( r \) is formed from clusters \( p \) and \( q \).
- \( n_r \) is the number of objects in cluster \( r \).
- \( x_{ri} \) is the \( i \)th object in cluster \( r \).
- **Single linkage**, also called nearest neighbor, uses the smallest distance between objects in the two clusters.
  \[
  d(r, s) = \min(dist(x_{ri}, x_{sj})), i \in (i, \ldots, n_r), j \in (1, \ldots, n_s)
  \]
- **Complete linkage**, also called farthest neighbor, uses the largest distance between objects in the two clusters.
  \[
  d(r, s) = \max(dist(x_{ri}, x_{sj})), i \in (1, \ldots, n_r), j \in (1, \ldots, n_s)
  \]
- **Average linkage** uses the average distance between all pairs of objects in any two clusters.
\[ d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj}) \]

- **Centroid linkage** uses the Euclidean distance between the centroids of the two clusters.
  \[ d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2, \]
  where
  \[ \bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri} \]

- **Median linkage** uses the Euclidean distance between weighted centroids of the two clusters.
  \[ d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2, \]
  where \( \bar{x}_r \) and \( \bar{x}_s \) are weighted centroids for the clusters \( r \) and \( s \). If cluster \( r \) was created by combining clusters \( p \) and \( q \), \( \bar{x}_r \) is defined recursively as
  \[ \bar{x}_r = \frac{1}{2}(\bar{x}_p + \bar{x}_q) \]

- **Ward’s linkage** uses the incremental sum of squares, that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares metric is equivalent to the following distance metric \( d(r,s) \), which is the formula `linkage` uses.
  \[ d(r, s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)} \|\bar{x}_r - \bar{x}_s\|_2}, \]
  where
  - \( \| \cdot \|_2 \) is the Euclidean distance.
  - \( \bar{x}_r \) and \( \bar{x}_s \) are the centroids of clusters \( r \) and \( s \).
  - \( n_r \) and \( n_s \) are the number of elements in clusters \( r \) and \( s \).

In some references, Ward’s linkage does not use the factor of 2 multiplying \( n_r n_s \). The `linkage` function uses this factor so that the distance between two singleton clusters is the same as the Euclidean distance.

- **Weighted average linkage** uses a recursive definition for the distance between two clusters. If cluster \( r \) was created by combining clusters \( p \) and \( q \), the distance between \( r \) and another cluster \( s \) is defined as the average of the distance between \( p \) and \( s \) and the distance between \( q \) and \( s \).
  \[ d(r, s) = \frac{(d(p, s) + d(q, s))}{2} \]

**Tips**

- Computing `linkage(y)` can be slow when \( y \) is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, `linkage` checks whether \( y \) is a Euclidean distance. Avoid this time-consuming check by passing in \( X \) instead of \( y \).
The 'centroid' and 'median' methods can produce a cluster tree that is not monotonic. This result occurs when the distance from the union of two clusters, \( r \) and \( s \), to a third cluster is less than the distance between \( r \) and \( s \). In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this result, use another method. This figure shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, and the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. The result is a nonmonotonic tree.

You can provide the output \( Z \) to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

### Topics

“Hierarchical Clustering” on page 16-6

**Introduced before R2006a**
loadCompactModel

(To be removed) Reconstruct model object from saved model for code generation

**Note**  loadCompactModel will be removed in a future release. Use loadLearnerForCoder instead. To update your code, simply replace instances of loadCompactModel with loadLearnerForCoder.

**Syntax**

```matlab
Mdl = loadCompactModel(filename)
```

**Description**

To generate C/C++ code for the object functions (predict, random, knnsearch, or rangesearch) of machine learning models, use saveCompactModel, loadCompactModel, and codegen. After training a machine learning model, save the model by using saveCompactModel. Define an entry-point function that loads the model by using loadCompactModel and calls an object function. Then use codegen or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use loadCompactModel for the highlighted step.

![Flow chart showing the code generation workflow](image)

Mdl = loadCompactModel(filename) reconstructs a classification model, regression model, or nearest neighbor searcher (Mdl) from the model stored in the MATLAB formatted binary file (MAT-file) named filename. You must create the filename file by using saveCompactModel.

**Examples**

**Generate C/C++ Code for Prediction**

After training a machine learning model, save the model by using saveCompactModel. Define an entry-point function that loads the model by using loadCompactModel and calls the predict function of the trained model. Then use codegen to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.
Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```matlab
Mdl = fitcsvm(X,Y);
```

Mdl is a ClassificationSVM model.

Save Model

Save the SVM classification model to the file SVMIris.mat by using saveCompactModel.

```matlab
saveCompactModel(Mdl,'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named classifyIrises that does the following:

- Accept iris flower measurements with columns corresponding to meas, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```matlab
type classifyIrises.m % Display contents of classifyIrises.m file
function label = classifyIrises(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
% CLASSIFYIRISES classifies the iris flower measurements in X using the
% compact SVM model in the file SVMIris.mat, and then returns class
% labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the %#codegen compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using codegen. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass X as the value of the -args option to specify that the generated code must accept an input that has the same data type and array size as the training data X. If the number of observations is
unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

codegen classifyIrises -args {X}

codegen generates the MEX function `classifyIrises_mex` with a platform-dependent extension.

**Verify Generated Code**

Compare the labels classified using `predict`, `classifyIrises`, and `classifyIrises_mex`.

```matlab
label1 = predict(Mdl,X);
label2 = classifyIrises(X);
label3 = classifyIrises_mex(X);
verify_label = isequal(label1,label2,label3)
```

`verify_label` = `logical 1` (true), which means all the inputs are equal. The labels classified all three ways are the same.

**Input Arguments**

- **filename** — Name of MAT-file that contains structure array representing a model object  
  character vector | string scalar

  Name of the MAT-file that contains the structure array representing a model object, specified as a character vector or string scalar. You must create the `filename` file using `saveCompactModel`.

  `loadCompactModel` reconstructs the model stored in the `filename` file at compile time. For supported models, see the `Mdl` input argument of `saveCompactModel`.

  The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `loadCompactModel` appends `.mat`.

  If `filename` does not include a full path, then `loadCompactModel` loads the file from the current folder.

  Example: ‘Mdl’

  Data Types: char | string

**Output Arguments**

- **Mdl** — Machine learning model  
  model object

  Machine learning model, returned as one of these model objects:

  - Classification model object
  - `ClassificationKNN`
• ClassificationLinear
• CompactClassificationDiscriminant
• CompactClassificationECOC
• CompactClassificationEnsemble
• CompactClassificationNaiveBayes
• CompactClassificationSVM

— If you use saveCompactModel to save an SVM model that is equipped to predict posterior probabilities, and use loadCompactModel to load the model, then loadCompactModel cannot restore the ScoreTransform property into the MATLAB Workspace. However, loadCompactModel can load the model, including the ScoreTransform property, at compile time for code generation, within an entry-point function.

• CompactClassificationTree

• Regression model object
• CompactGeneralizedLinearModel
• CompactLinearModel — Suppose you train a linear model by using fitlm and specifying 'RobustOpts' as a structure with an anonymous function handle for the RobustWgtFun field, use saveCompactModel to save the model, and then use loadCompactModel to load the model. In this case, loadCompactModel cannot restore the Robust property into the MATLAB Workspace. However, loadCompactModel can load the model at compile time within an entry-point function for code generation.

• CompactRegressionEnsemble
• CompactRegressionGP
• CompactRegressionSVM
• CompactRegressionTree
• RegressionLinear
• Nearest neighbor searcher object

• ExhaustiveSearcher
• KDTreeSearcher

Algorithms

saveCompactModel prepares a machine learning model (Mdl) for code generation. The function removes some properties that are not required for prediction.

• For a model that has a corresponding compact model, the saveCompactModel function applies the appropriate compact function to the model before saving it.
• For a model that does not have a corresponding compact model, such as ClassificationKNN, ClassificationLinear, RegressionLinear, ExhaustiveSearcher, and KDTreeSearcher, the saveCompactModel function removes properties such as hyperparameter optimization properties, training solver information, and others.

loadCompactModel loads the model saved by saveCompactModel.

Alternative Functionality

• Use a coder configurer created by learnerCoderConfigurer for the models listed in this table.
<table>
<thead>
<tr>
<th>Model</th>
<th>Coder Configurer Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary decision tree for multiclass classification</td>
<td>ClassificationTreeCoderConfigurer</td>
</tr>
<tr>
<td>SVM for one-class and binary classification</td>

</tbody>
</table>

After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-68.

**Compatibility Considerations**

`loadCompactModel` will be removed

*Not recommended starting in R2019b*

`loadCompactModel` will be removed in a future release. Use `loadLearnerForCoder` instead.

`saveLearnerForCoder` and `loadLearnerForCoder` provide broader functionality, including fixed-point code generation for supported models.

This table shows how to update your code to use `loadLearnerForCoder`.

<table>
<thead>
<tr>
<th>Not Recommended</th>
<th>Recommended</th>

Introduced in R2016b
loadLearnerForCoder

Reconstruct model object from saved model for code generation

Syntax

Mdl = loadLearnerForCoder(filename)
Mdl = loadLearnerForCoder(filename,'DataType',T)

Description

To generate C/C++ code for the object functions (predict, random, knnsearch, or rangesearch) of machine learning models, use saveLearnerForCoder, loadLearnerForCoder, and codegen. After training a machine learning model, save the model by using saveLearnerForCoder. Define an entry-point function that loads the model by using loadLearnerForCoder and calls an object function. Then use codegen or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use loadLearnerForCoder for the highlighted step.

Fixed-point C/C++ code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by generateLearnerDataTypeFcn, and use the structure as an input argument of loadLearnerForCoder in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the predict function of a machine learning model. Use loadLearnerForCoder for the highlighted step.

Mdl = loadLearnerForCoder(filename) reconstructs a classification model, regression model, or nearest neighbor searcher (Mdl) from the model stored in the MATLAB formatted binary file (MAT-file) named filename. You must create the filename file by using saveLearnerForCoder.

Mdl = loadLearnerForCoder(filename,'DataType',T) returns a fixed-point version of the model stored in filename. The structure T contains the fields that specify the fixed-point data types for the variables required to use the predict function of the model. Create T using the function generated by generateLearnerDataTypeFcn.

Use this syntax in an entry-point function, and use codegen to generate fixed-point code for the entry-point function. You can use this syntax only when generating code.

The model in filename must be an SVM classification model or an SVM regression model.
Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-16 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-13.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```matlab
Mdl = fitcsvm(X,Y);
```

Mdl is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveLearnerForCoder`.

```matlab
saveLearnerForCoder(Mdl,'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIris` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```matlab
type classifyIris.m % Display contents of classifyIris.m file
function label = classifyIris(X) %#codegen
%CLASSIFYIRIS Classify iris species using SVM Model
% CLASSIFYIRIS classifies the iris flower measurements in X using the SVM
% model in the file SVMIris.mat, and then returns class labels in label.
Mdl = loadLearnerForCoder('SVMIris');
label = predict(Mdl,X);
end
```
Add the `%codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

**Note:** If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

**Generate Code**

Generate code for the entry-point function using codegen. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass X as the value of the -args option to specify that the generated code must accept an input that has the same data type and array size as the training data X. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using coder.typeof. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-38 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```matlab
codegen classifyIris -args {X}
```

codegen generates the MEX function classifyIris_mex with a platform-dependent extension.

**Verify Generated Code**

Compare the labels classified using predict, classifyIris, and classifyIris_mex.

```matlab
label1 = predict(Mdl,X);
label2 = classifyIris(X);
label3 = classifyIris_mex(X);
verify_label = isequal(label1,label2,label3)
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

**Generate Fixed-Point C/C++ Code for Prediction**

After training a machine learning model, save the model using saveLearnerForCoder. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by using the data type function generated by generateLearnerDataTypeFcn. Then, define an entry-point function that loads the model by using both loadLearnerForCoder and the specified fixed-point data types, and calls the predict function of the model. Use codegen to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using codegen, you can use buildInstrumentedMex and showInstrumentationResults to optimize the fixed-point data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using buildInstrumentedMex. View the instrumentation results using showInstrumentationResults; then, based on the results, tune the fixed-point data type.
properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

**Train Model**

Load the ionosphere data set and train a binary SVM classification model.

```matlab
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

Mdl is a `ClassificationSVM` model.

**Save Model**

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```matlab
saveLearnerForCoder(Mdl,'myMdl');
```

**Define Fixed-Point Data Types**

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```matlab
generateLearnerDataTypeFcn('myMdl',X)
generateLearnerDataTypeFcn generates the `myMdl_datatype` function.
```

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```matlab
T = myMdl_datatype('Fixed')
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi`. The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```matlab
T.XDataType
ans =

[]

    DataTypeMode: Fixed-point: binary point scaling
     Signedness: Signed
       WordLength: 16
    FractionLength: 14

    RoundingMethod: Floor
    OverflowAction: Wrap
    ProductMode: FullPrecision
MaxProductWordLength: 128
    SumMode: FullPrecision
MaxSumWordLength: 128
Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

• Accept the predictor data `X` and the fixed-point data type structure `T`.
• Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.
• Predict labels and scores using the loaded model.

type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
    Mdl = loadLearnerForCoder('myMdl','DataType',T);
    [label,score] = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` function.

```
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

codegen generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```
verify_labels = isequal(labels,labels_fx)
verify_labels = logical
    1
```

isequal returns logical 1 (true), which means `labels` and `labels_fx` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
sum(strcmp(labels_fx,labels)==0)/numel(labels_fx)*100
ans = 0
```

Find the maximum of the relative differences between the score outputs.
relDiff_scores = max(abs((scores_fx.double(:,1)-scores(:,1))./scores(:,1)))
relDiff_scores = 0.0055

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see “Tips” on page 32-2392 in `generateLearnerDataTypeFcn`, “Data Type Function” on page 32-2391, and “Fixed-Point Code Generation for Prediction of SVM” on page 31-75.

**Input Arguments**

filename — Name of MAT-file that contains structure array representing a model object
character vector | string scalar

Name of the MAT-file that contains the structure array representing a model object, specified as a character vector or string scalar. You must create the filename file using `saveLearnerForCoder`.

`loadLearnerForCoder` reconstructs the model stored in the filename file at compile time. For supported models, see the `Mdl` input argument of `saveLearnerForCoder`.

The extension of the filename file must be `.mat`. If filename has no extension, then `loadLearnerForCoder` appends `.mat`.

If filename does not include a full path, then `loadLearnerForCoder` loads the file from the current folder.

Example: `'Mdl'`

Data Types: `char` | `string`

T — Fixed-point data types
structure

Fixed-point data types, specified as a structure. This argument is for fixed-point C/C++ code generation.

Create `T` using a function generated by `generateLearnerDataTypeFcn`. For details about the generated function and the structure `T`, see `generateLearnerDataTypeFcn` and “Data Type Function” on page 32-2391.

You can use this argument when the model in the filename file is an SVM classification model (`CompactClassificationSVM`) or an SVM regression model (`CompactRegressionSVM`).

Data Types: `struct`

**Output Arguments**

Mdl — Machine learning model
model object

Machine learning model, returned as one of these model objects:

- Classification model object
  - `ClassificationKNN`
• ClassificationLinear
• CompactClassificationDiscriminant
• CompactClassificationECOC
• CompactClassificationEnsemble
• CompactClassificationNaiveBayes
• CompactClassificationSVM

— If you use `saveLearnerForCoder` to save an SVM model that is equipped to predict posterior probabilities, and use `loadLearnerForCoder` to load the model, then `loadLearnerForCoder` cannot restore the ScoreTransform property into the MATLAB Workspace. However, `loadLearnerForCoder` can load the model, including the ScoreTransform property, at compile time for code generation, within an entry-point function.

• CompactClassificationTree

• Regression model object

• CompactGeneralizedLinearModel
• CompactLinearModel — Suppose you train a linear model by using `fitlm` and specifying `'RobustOpts'` as a structure with an anonymous function handle for the RobustWgtFun field, use `saveLearnerForCoder` to save the model, and then use `loadLearnerForCoder` to load the model. In this case, `loadLearnerForCoder` cannot restore the Robust property into the MATLAB Workspace. However, `loadLearnerForCoder` can load the model at compile time within an entry-point function for code generation.

• CompactRegressionEnsemble
• CompactRegressionGP
• CompactRegressionSVM
• CompactRegressionTree
• RegressionLinear

• Nearest neighbor searcher object

• ExhaustiveSearcher
• KDTreeSearcher

Algorithms

`saveLearnerForCoder` prepares a machine learning model (Mdl) for code generation. The function removes some properties that are not required for prediction.

• For a model that has a corresponding compact model, the `saveLearnerForCoder` function applies the appropriate compact function to the model before saving it.
• For a model that does not have a corresponding compact model, such as ClassificationKNN, ClassificationLinear, RegressionLinear, ExhaustiveSearcher, and KDTreeSearcher, the `saveLearnerForCoder` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadLearnerForCoder` loads the model saved by `saveLearnerForCoder`.

Alternative Functionality

• Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.
After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-68.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- For fixed-point C/C++ code generation, the input argument `T` must be a compile-time constant. For an example, see “Generate Fixed-Point C/C++ Code for Prediction” on page 32-3098.

For more information, see “Introduction to Code Generation” on page 31-2.

**Introduced in R2019b**
logncdf

Lognormal cumulative distribution function

Syntax

\[ p = \text{logncdf}(x) \]
\[ p = \text{logncdf}(x,\mu) \]
\[ p = \text{logncdf}(x,\mu,\sigma) \]
\[ [p,pLo,pUp] = \text{logncdf}(x,\mu,\sigma,\text{pCov}) \]
\[ [p,pLo,pUp] = \text{logncdf}(x,\mu,\sigma,\text{pCov},\alpha) \]
\[ ___ = \text{logncdf}(___,'\text{upper}') \]

Description

\[ p = \text{logncdf}(x) \] returns the cumulative distribution function (cdf) of the standard lognormal distribution, evaluated at the values in \( x \). In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

\[ p = \text{logncdf}(x,\mu) \] returns the cdf of the lognormal distribution with the distribution parameters \( \mu \) (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in \( x \).

\[ p = \text{logncdf}(x,\mu,\sigma) \] returns the cdf of the lognormal distribution with the distribution parameters \( \mu \) (mean of logarithmic values) and \( \sigma \) (standard deviation of logarithmic values), evaluated at the values in \( x \).

\[ [p,pLo,pUp] = \text{logncdf}(x,\mu,\sigma,\text{pCov}) \] also returns the 95% confidence bounds \([pLo,pUp]\) of \( p \) using the estimated parameters \((\mu \text{ and } \sigma)\) and their covariance matrix \(\text{pCov}\).

\[ [p,pLo,pUp] = \text{logncdf}(x,\mu,\sigma,\text{pCov},\alpha) \] specifies the confidence level for the confidence interval \([pLo,pUp]\) to be \(100(1-\alpha)\)%.

\[ ___ = \text{logncdf}(___,'\text{upper}') \] returns the complement of the cdf, evaluated at the values in \( x \), using an algorithm that more accurately computes the extreme upper-tail probabilities. ‘upper’ can follow any of the input argument combinations in the previous syntaxes.

Examples

Compute Lognormal Distribution cdf

Compute the cdf values evaluated at the values in \( x \) for the lognormal distribution with mean \( \mu \) and standard deviation \( \sigma \).

\[ x = 0:0.2:10; \]
\[ \mu = 0; \]
\[ \sigma = 1; \]
\[ p = \text{logncdf}(x,\mu,\sigma); \]
Confidence Interval of Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```matlab
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```matlab
phat = mle(x,'distribution','LogNormal')
phat = 1×2
```

Plot the cdf.

```matlab
plot(x,p)
grid on
xlabel('x')
ylabel('p')
```
muHat = phat(1);
sigmaHat = phat(2);

Estimate the covariance of the distribution parameters by using lognlike. The function lognlike returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

[-,pCov] = lognlike(phat,x)

pCov = 2x2

0.0040  -0.0000
-0.0000   0.0020

Find the cdf value at 0.5 and its 95% confidence interval.

[p,pLo,pUp] = logncdf(0.5,muHat,sigmaHat,pCov)

p = 0.0024
pLo = 0.0016
pUp = 0.0037

p is the cdf value of the lognormal distribution with the parameters muHat and sigmaHat. The interval [pLo,pUp] is the 95% confidence interval of the cdf evaluated at 0.5, considering the uncertainty of muHat and sigmaHat using pCov. The 95% confidence interval means the probability that [pLo,pUp] contains the true cdf value is 0.95.

**Complementary cdf (Tail Distribution)**

Determine the probability that an observation from a standard lognormal distribution will fall on the interval [exp(10),Inf].

p1 = 1 - logncdf(exp(10))

p1 = 0

logncdf(exp(10)) is nearly 1, so p1 becomes 0. Specify 'upper' so that logncdf computes the extreme upper-tail probabilities more accurately.

p2 = logncdf(exp(10),'upper')

p2 = 7.6199e-24

You can also use 'upper' to compute a right-tailed p-value.

**Input Arguments**

- x — Values at which to evaluate cdf
  
  positive scalar value | array of positive scalar values

32-3106
Values at which to evaluate the cdf, specified as a positive scalar value or an array of positive scalar values.

If you specify pCov to compute the confidence interval \([pLo, pUp]\), then \(x\) must be a scalar value.

To evaluate the cdf at multiple values, specify \(x\) using an array. To evaluate the cdfs of multiple distributions, specify \(mu\) and \(sigma\) using arrays. If one or more of the input arguments \(x\), \(mu\), and \(sigma\) are arrays, then the array sizes must be the same. In this case, \texttt{logncdf} expands each scalar input into a constant array of the same size as the array inputs. Each element in \(p\) is the cdf value of the distribution specified by the corresponding elements in \(mu\) and \(sigma\), evaluated at the corresponding element in \(x\).

Example: \([-1, 0, 3, 4]\)

Data Types: \texttt{single} | \texttt{double}

\textbf{mu — Mean of logarithmic values}

\(0\) (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

If you specify \(pCov\) to compute the confidence interval \([pLo, pUp]\), then \(mu\) must be a scalar value.

To evaluate the cdf at multiple values, specify \(x\) using an array. To evaluate the cdfs of multiple distributions, specify \(mu\) and \(sigma\) using arrays. If one or more of the input arguments \(x\), \(mu\), and \(sigma\) are arrays, then the array sizes must be the same. In this case, \texttt{logncdf} expands each scalar input into a constant array of the same size as the array inputs. Each element in \(p\) is the cdf value of the distribution specified by the corresponding elements in \(mu\) and \(sigma\), evaluated at the corresponding element in \(x\).

Example: \([0 1 2; 0 1 2]\)

Data Types: \texttt{single} | \texttt{double}

\textbf{sigma — Standard deviation of logarithmic values}

\(1\) (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify \(pCov\) to compute the confidence interval \([pLo, pUp]\), then \(sigma\) must be a scalar value.

To evaluate the cdf at multiple values, specify \(x\) using an array. To evaluate the cdfs of multiple distributions, specify \(mu\) and \(sigma\) using arrays. If one or more of the input arguments \(x\), \(mu\), and \(sigma\) are arrays, then the array sizes must be the same. In this case, \texttt{logncdf} expands each scalar input into a constant array of the same size as the array inputs. Each element in \(p\) is the cdf value of the distribution specified by the corresponding elements in \(mu\) and \(sigma\), evaluated at the corresponding element in \(x\).

Example: \([1 1 1; 2 2 2]\)

Data Types: \texttt{single} | \texttt{double}

\textbf{pCov — Covariance of estimates}

\(2\)-by-\(2\) numeric matrix
Covariance of the estimates \( \mu \) and \( \sigma \), specified as a 2-by-2 matrix.

If you specify \( \text{pCov} \) to compute the confidence interval \([\text{pLo}, \text{pUp}]\), then \( x \), \( \mu \), and \( \sigma \) must be scalar values.

You can estimate the maximum likelihood estimates of \( \mu \) and \( \sigma \) by using \( \text{mle} \), and estimate the covariance of \( \mu \) and \( \sigma \) by using \( \text{lognlike} \). For an example, see “Confidence Interval of Lognormal cdf Value” on page 32-3105.

Data Types: \text{single} \mid \text{double}

**alpha — Significance level**

0.05 (default) \mid \text{scalar in the range (0,1)}

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is \( 100(1-\alpha)\% \), where \( \alpha \) is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: \text{0.01}

Output Arguments

**p — cdf values**

\text{scalar value} \mid \text{array of scalar values}

\text{cdf values}, evaluated at the values in \( x \), returned as a scalar value or an array of scalar values. \( p \) is the same size as \( x \), \( \mu \), and \( \sigma \) after any necessary scalar expansion. Each element in \( p \) is the cdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

**pLo — Lower confidence bound for \( p \)**

\text{scalar value} \mid \text{array of scalar values}

Lower confidence bound for \( p \), returned as a scalar value or an array of scalar values. \( p\text{Lo} \) has the same size as \( p \).

**pUp — Upper confidence bound for \( p \)**

\text{scalar value} \mid \text{array of scalar values}

Upper confidence bound for \( p \), returned as a scalar value or an array of scalar values. \( p\text{Up} \) has the same size as \( p \).

More About

**Lognormal Distribution**

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The cumulative distribution function (cdf) of the lognormal distribution is

\[
p = F(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \int_x^\infty \frac{1}{t} \exp\left\{ -\frac{(\log t - \mu)^2}{2\sigma^2} \right\} dt, \quad \text{for } x > 0.
\]
Algorithms

- The logncdf function uses the complementary error function erfc. The relationship between logncdf and erfc is

\[
\text{logncdf}(x, 0, 1) = \frac{1}{2} \text{erfc}\left(-\frac{\log x}{\sqrt{2}}\right).
\]

The complementary error function erfc(x) is defined as

\[
\text{erfc}(x) = 2\sqrt{\pi} \int_{x}^{\infty} e^{-t^2} dt.
\]

- The logncdf function computes confidence bounds for p by using the delta method. The normal distribution cdf value of log(x) with the parameters mu and sigma is equivalent to the cdf value of (log(x)–mu)/sigma with the parameters 0 and 1. Therefore, the logncdf function estimates the variance of (log(x)–mu)/sigma using the covariance matrix of mu and sigma by the delta method, and finds the confidence bounds of (log(x)–mu)/sigma using the estimates of this variance. Then, the function transforms the bounds to the scale of p. The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pCov from large samples.

Alternative Functionality

- logncdf is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function cdf, which supports various probability distributions. To use cdf, create a LognormalDistribution probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function logncdf is faster than the generic function cdf.

- Use the Probability Distribution Function app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics
“Lognormal Distribution” on page B-88

Introduced before R2006a
lognfit

Lognormal parameter estimates

Syntax

pHat = lognfit(x)

[pHat,pCI] = lognfit(x)
[pHat,pCI] = lognfit(x,alpha)

[___] = lognfit(x,alpha,censoring)
[___] = lognfit(x,alpha,censoring,freq)
[___] = lognfit(x,alpha,censoring,freq,options)

Description

pHat = lognfit(x) returns unbiased estimates of lognormal distribution parameters, given the sample data in x. pHat(1) and pHat(2) are the mean and standard deviation of logarithmic values, respectively.

[pHat,pCI] = lognfit(x) also returns 95% confidence intervals for the parameter estimates.

[pHat,pCI] = lognfit(x,alpha) specifies the confidence level for the confidence intervals to be 100(1–alpha)%.

[___] = lognfit(x,alpha,censoring) specifies whether each value in x is right-censored or not. Use the logical vector censoring in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With censoring, the phat values are the maximum likelihood estimates (MLEs).

[___] = lognfit(x,alpha,censoring,freq) specifies the frequency or weights of observations.

[___] = lognfit(x,alpha,censoring,freq,options) specifies optimization options for the iterative algorithm lognfit to use to compute MLEs with censoring. Create options by using the function statset.

You can pass in [] for alpha, censoring, and freq to use their default values.

Examples

Estimate Parameters and Confidence Intervals

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);

Find the parameter estimates and the 99% confidence intervals.
\[
[pHat, pCI] = \text{lognfit}(x, 0.01)
\]

\[
pHat = 1 \times 2
\]

\[
\begin{array}{cc}
4.9347 & 1.9979 \\
\end{array}
\]

\[
pCI = 2 \times 2
\]

\[
\begin{array}{cc}
4.7717 & 1.8887 \\
5.0978 & 2.1196 \\
\end{array}
\]

\(pHat(1)\) and \(pHat(2)\) are the mean and standard deviation of logarithmic values, respectively. \(pCI\) contains the 99% confidence intervals of the mean and standard deviation parameters. The values in the first row are the lower bounds, and the values in the second row are the upper bounds.

**Change Algorithm Options**

Find the MLEs of a data set with censoring by using \texttt{lognfit}. Use \texttt{statset} to specify the iterative algorithm options that \texttt{lognfit} uses to compute MLEs for censored data, and then find the MLEs again.

Generate the true times \(x\) that follow the lognormal distribution with the parameters 5 and 2.

\[
\text{rng('default')} \quad \text{\% For reproducibility}
\]

\[
n = 1000; \quad \% \text{Number of samples}
\]

\[
x = \text{lognrnd}(5, 2, n, 1);
\]

Generate the censoring times. Note that the censoring times must be independent of the true times \(x\).

\[
censtime = \text{normrnd}(150, 20, \text{size}(x));
\]

Specify the indicator for the censoring times and the observed times.

\[
censoring = x > \text{censtime};
\]

\[
y = \text{min}(x, \text{censtime});
\]

Find the MLEs of the lognormal distribution parameters. The second input argument of \texttt{lognfit} specifies the confidence level. Pass in \([]\) to use its default value 0.05. The third input argument specifies the censorship information.

\[
pHat = \text{lognfit}(y, [], \text{censoring})
\]

\[
pHat = 1 \times 2
\]

\[
\begin{array}{cc}
4.9535 & 1.9996 \\
\end{array}
\]

Display the default algorithm parameters that \texttt{lognfit} uses to estimate the lognormal distribution parameters.

\[
\text{statset('lognfit')}
\]

\[
\text{ans} = \text{struct with fields:}
\]

\[
\quad \text{Display: 'off'}
\]
MaxFunEvals: 200
MaxIter: 100
TolBnd: 1.0000e-06
TolFun: 1.0000e-08
TolTypeFun: []
TolX: 1.0000e-08
TolTypeX: []
GradObj: []
Jacobian: []
DerivStep: []
FunValCheck: []
Robust: []
RobustWgtFun: []
WgtFun: []
Tune: []
UseParallel: []
UseSubstreams: []
Streams: {};

Save the options using a different name. Change how the results are displayed (Display) and the
termination tolerance for the objective function (TolFun).

```matlab
options = statset('lognfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the
function `statset`.

```matlab
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```matlab
pHat = lognfit(y,[],censoring,[],options)
```

Successful convergence: Norm of gradient less than OPTIONS.TolFun

```matlab
pHat = 1×2
    4.9535    1.9996
```

`lognfit` displays a report on the final iteration.

### Input Arguments

- **x** — Sample data
  vector

  Sample data, specified as a vector.
  
  Data Types: `single` | `double`

- **alpha** — Significance level
  0.05 (default) | scalar in the range (0,1)
Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where $\alpha$ is the probability that the confidence intervals do not contain the true value.

Example: 0.01

Data Types: single | double

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in $x$, specified as a logical vector of the same size as $x$. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: logical

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as $x$. The freq input argument typically contains nonnegative integer counts for the corresponding elements in $x$, but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in $x$.

The default is an array of 1s, meaning one observation per element of $x$.

Data Types: single | double

options — Optimization options

statset('lognfit') (default) | structure

Optimization options, specified as a structure. options determines the control parameters for the iterative algorithm that lognfit uses to compute MLEs for censored data.

Create options by using the function statset or by creating a structure array containing the fields and values described in this table.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display</td>
<td>Amount of information displayed by the algorithm.</td>
<td>'off'</td>
</tr>
<tr>
<td></td>
<td>• 'off' — Displays no information.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 'final' — Displays the final output.</td>
<td></td>
</tr>
<tr>
<td>MaxFunEvals</td>
<td>Maximum number of objective function evaluations allowed, specified as a positive integer.</td>
<td>200</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of iterations allowed, specified as a positive integer.</td>
<td>100</td>
</tr>
</tbody>
</table>
### Field Name | Value | Default Value
--- | --- | ---
**TolBnd** | Lower bound of the standard deviation parameter estimate, specified as a positive scalar. The bounds for the mean and standard deviation parameter estimates are \([-\infty, \infty]\) and \([\text{TolBnd}, \infty]\), respectively. | 1e-6

**TolFun** | Termination tolerance for the objective function value, specified as a positive scalar. | 1e-8

**TolX** | Termination tolerance for the parameters, specified as a positive scalar. | 1e-8

You can also enter `statset('lognfit')` in the Command Window to see the names and default values of the fields that `lognfit` accepts in the options structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: struct

### Output Arguments

**pHat** — Estimates of lognormal distribution parameters
1-by-2 vector

Estimates of lognormal distribution parameters, returned as a 1-by-2 vector. `pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively.

- With no censoring, the `pHat` values are unbiased estimates. To compute the MLEs with no censoring, use the `mle` function.
- With censoring, the `pHat` values are the MLEs. To compute the weighted MLEs, specify the weights of observations by using `freq`.

**pCI** — Confidence intervals for parameter estimates
2-by-2 matrix

Confidence intervals for parameter estimates of the lognormal distribution, returned as a 2-by-2 matrix containing the lower and upper bounds of the 100(1–alpha)% confidence intervals.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

### Algorithms

To compute the confidence intervals, `lognfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on `t` and chi-square distributions.
Alternative Functionality

lognfit is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions mle, fitdist, and paramci and the Distribution Fitter app, which support various probability distributions.

- **mle** returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.
- Create a LognormalDistribution probability distribution object by fitting the distribution to data using the fitdist function or the Distribution Fitter app. The object properties mu and sigma store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to paramci.

“Lognormal Distribution” on page B-88

**Introduced before R2006a**
logninv

Lognormal inverse cumulative distribution function

Syntax

\[
x = \text{logninv}(p)
\]
\[
x = \text{logninv}(p,\mu)
\]
\[
x = \text{logninv}(p,\mu,\sigma)
\]

\[
[x,xLo,xUp] = \text{logninv}(p,\mu,\sigma,pCov)
\]
\[
[x,xLo,xUp] = \text{logninv}(p,\mu,\sigma,pCov,alpha)
\]

Description

\(x = \text{logninv}(p)\) returns the inverse of the standard lognormal cumulative distribution function (cdf), evaluated at the probability values in \(p\). In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

\(x = \text{logninv}(p,\mu)\) returns the inverse of the lognormal cdf with the distribution parameters \(\mu\) (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the probability values in \(p\).

\(x = \text{logninv}(p,\mu,\sigma)\) returns the inverse of the lognormal cdf with the distribution parameters \(\mu\) (mean of logarithmic values) and \(\sigma\) (standard deviation of logarithmic values), evaluated at the probability values in \(p\).

\([x,xLo,xUp] = \text{logninv}(p,\mu,\sigma,pCov)\) also returns the 95% confidence bounds \([xLo,xUp]\) of \(x\) using the estimated parameters (\(\mu\) and \(\sigma\)) and their covariance matrix \(pCov\).

\([x,xLo,xUp] = \text{logninv}(p,\mu,\sigma,pCov,alpha)\) specifies the confidence level for the confidence interval \([xLo,xUp]\) to be 100(1–\(alpha\))%.

Examples

Inverse of Lognormal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in \(p\) for the lognormal distribution with mean \(\mu\) and standard deviation \(\sigma\).

\[
p = 0.005:0.01:0.995;
\]
\[
mu = 1;
\]
\[
sigma = 0.5;
\]
\[
x = \text{logninv}(p,\mu,\sigma);
\]

Plot the inverse cdf.

\[
\text{plot}(p,x)
\]
\[
\text{grid on}
\]
\[
\text{xlabel('p');}
\]
\[
\text{ylabel('x');}
\]
Confidence Interval of Inverse Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using mle.

phat = mle(x,'distribution','LogNormal')

phat = 1x2
     4.9347    1.9969

muHat = phat(1);
sigmaHat = phat(2);
Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

\[ [-, pCov] = \text{lognlike}(\text{phat}, x) \]

\[
pCov = 2 \times 2
\]

\[
\begin{bmatrix}
0.0040 & -0.0000 \\
-0.0000 & 0.0020
\end{bmatrix}
\]

Find the inverse cdf value at 0.5 and its 99% confidence interval.

\[ [x, xLo, xUp] = \text{logninv}(0.5, \muHat, \sigmaHat, pCov, 0.01) \]

\[
x = 139.0364
\]

\[
xLo = 118.1643
\]

\[
xUp = 163.5953
\]

\( x \) is the inverse cdf value using the lognormal distribution with the parameters \( \muHat \) and \( \sigmaHat \). The interval \([xLo, xUp]\) is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of \( \muHat \) and \( \sigmaHat \) using \( pCov \). The 99% confidence interval means the probability that \([xLo, xUp]\) contains the true inverse cdf value is 0.99.

### Input Arguments

- **p** — Probability values at which to evaluate inverse of cdf
  
  scalar value in \([0, 1]\) | array of scalar values
  
  Probability values at which to evaluate the inverse of the cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range \([0, 1]\).
  
  If you specify \( pCov \) to compute the confidence interval \([xLo, xUp]\), then \( p \) must be a scalar value.
  
  To evaluate the icdf at multiple values, specify \( p \) using an array. To evaluate the icdfs of multiple distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( p, \mu, \) and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \( \text{logninv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( p \).
  
  Example: \([0.1, 0.5, 0.9]\)
  
  Data Types: `single` | `double`

- **\( \mu \)** — Mean of logarithmic values
  
  \( \theta \) (default) | scalar value | array of scalar values
  
  Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.
  
  If you specify \( pCov \) to compute the confidence interval \([xLo, xUp]\), then \( \mu \) must be a scalar value.

32-3119
To evaluate the icdf at multiple values, specify \( p \) using an array. To evaluate the icdfs of multiple distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( p \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \( \text{logninv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( p \).

Example: \[
\begin{bmatrix}
0 & 1 & 2 \\
0 & 1 & 2
\end{bmatrix}
\]

Data Types: \( \text{single} \) \| \( \text{double} \)

\( \sigma \) — Standard deviation of logarithmic values

1 (default) \| \text{positive scalar value} \| \text{array of positive scalar values}

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify \( \text{pCov} \) to compute the confidence interval \([x_{\text{Lo}}, x_{\text{Up}}]\), then \( \sigma \) must be a scalar value.

To evaluate the icdf at multiple values, specify \( p \) using an array. To evaluate the icdfs of multiple distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( p \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \( \text{logninv} \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( p \).

Example: \[
\begin{bmatrix}
1 & 1 & 1 \\
2 & 2 & 2
\end{bmatrix}
\]

Data Types: \( \text{single} \) \| \( \text{double} \)

\( \text{pCov} \) — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates \( \mu \) and \( \sigma \), specified as a 2-by-2 matrix.

If you specify \( \text{pCov} \) to compute the confidence interval \([x_{\text{Lo}}, x_{\text{Up}}]\), then \( p \), \( \mu \), and \( \sigma \) must be scalar values.

You can estimate the maximum likelihood estimates of \( \mu \) and \( \sigma \) by using \text{mle}, and estimate the covariance of \( \mu \) and \( \sigma \) by using \text{lognlike}. For an example, see “Confidence Interval of Inverse Lognormal cdf Value” on page 32-3118.

Data Types: \( \text{single} \) \| \( \text{double} \)

\( \alpha \) — Significance level

0.05 (default) \| \text{scalar in the range (0,1)}

Significance level for the confidence interval, specified as a scalar in the range \((0,1)\). The confidence level is \( 100(1-\alpha) \)\%, where \( \alpha \) is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: \( \text{single} \) \| \( \text{double} \)
Output Arguments

\( x \) — icdf values  
scalar value | array of scalar values

icdf values, evaluated at the probability values in \( p \), returned as a scalar value or an array of scalar values. \( x \) is the same size as \( p \), \( \mu \), and \( \sigma \) after any necessary scalar expansion. Each element in \( x \) is the icdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( p \).

\( xLo \) — Lower confidence bound for \( x \)  
scalar value | array of scalar values

Lower confidence bound for \( x \), returned as a scalar value or an array of scalar values. \( xLo \) has the same size as \( x \).

\( xUp \) — Upper confidence bound for \( x \)  
scalar value | array of scalar values

Upper confidence bound for \( x \), returned as a scalar value or an array of scalar values. \( xUp \) has the same size as \( x \).

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The lognormal inverse function is defined in terms of the lognormal cdf as

\[
x = F^{-1}(p \mid \mu, \sigma) = \{ x : F(x \mid \mu, \sigma) = p \}
\]

where

\[
p = F(x \mid \mu, \sigma) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\log x} \exp \left( -\frac{(t - \mu)^2}{2\sigma^2} \right) dt,
\]

for \( x > 0 \).

Algorithms

- The function \( \text{logninv} \) uses the inverse complementary error function \( \text{erfcinv} \). The relationship between \( \text{logninv} \) and \( \text{erfcinv} \) is

\[
\text{logninv}(p, 0, 1) = \exp(-\sqrt{2}\text{erfcinv}(2p)).
\]

The inverse complementary error function \( \text{erfcinv}(x) \) is defined as \( \text{erfcinv}(\text{erfc}(x)) = x \), and the complementary error function \( \text{erfc}(x) \) is defined as

\[
\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-t^2} dt.
\]

- The \( \text{logninv} \) function computes confidence bounds for \( x \) by using the delta method. 

\[
\log(\text{logninv}(p, \mu, \sigma)) \text{ is equivalent to } \mu + \sigma \log(\text{logninv}(p, 0, 1)).
\]

Therefore, the \( \text{logninv} \) function estimates the variance of \( \mu + \sigma \log(\text{logninv}(p, 0, 1)) \).
using the covariance matrix of \( \mu \) and \( \sigma \) by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give approximately the desired confidence level when you estimate \( \mu, \sigma, \) and \( pCov \) from large samples.

**Alternative Functionality**

- `logninv` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `logninv` is faster than the generic function `icdf`.

**Topics**
“Lognormal Distribution” on page B-88

**Introduced before R2006a**
lognlike
Lognormal negative loglikelihood

Syntax

\[
\text{nlogL} = \text{lognlike} (\text{params}, \text{x}) \\
\text{nlogL} = \text{lognlike} (\text{params}, \text{x}, \text{censoring}) \\
\text{nlogL} = \text{lognlike} (\text{params}, \text{x}, \text{censoring}, \text{freq}) \\
[\text{nlogL}, \text{aVar}] = \text{lognlike}(\text{___})
\]

Description

\[\text{nlogL} = \text{lognlike} (\text{params}, \text{x})\] returns the lognormal negative loglikelihood of the distribution parameters (params) given the sample data (x). params(1) and params(2) are the mean and standard deviation of logarithmic values, respectively.

\[\text{nlogL} = \text{lognlike} (\text{params}, \text{x}, \text{censoring})\] specifies whether each value in x is right-censored or not. Use the logical vector censoring in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

\[\text{nlogL} = \text{lognlike} (\text{params}, \text{x}, \text{censoring}, \text{freq})\] specifies the frequency or weights of observations. To specify freq without specifying censoring, you can pass [] for censoring.

\[[\text{nlogL}, \text{aVar}] = \text{lognlike}(\text{___})\] also returns the inverse of the Fisher information matrix aVar, using any of the input argument combinations in the previous syntaxes. If values in params are the maximum likelihood estimates (MLEs) of the parameters, aVar is an approximation to the asymptotic covariance matrix.

Examples

Negative Loglikelihood of MLEs

Find the MLEs of a data set with censoring by using mle, and then find the negative loglikelihood of the MLEs by using lognlike.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```matlab
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using mle.

```matlab
phat = mle(x,'distribution','LogNormal')
phat = 1×2
```

32-3123
Find the negative loglikelihood of the MLEs.

\[
n\log L = \text{lognlike}(\text{phat},x)
\]

\[
n\log L = 7.0453e+03
\]

**Confidence Interval of Lognormal cdf Value**

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

\[
\text{rng('default') \% For reproducibility}
\]
\[
n = 1000; \% Number of samples
\]
\[
x = \text{lognrnd}(5,2,n,1);
\]

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using **mle**.

\[
\text{phat} = \text{mle}(x, \text{'distribution','LogNormal'})
\]

\[
\text{phat} = 1 \times 2
\]

\[
4.9347 \quad 1.9969
\]

\[
\mu\text{Hat} = \text{phat}(1);
\]
\[
\sigma\text{Hat} = \text{phat}(2);
\]

Estimate the covariance of the distribution parameters by using **lognlike**. The function **lognlike** returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

\[
[\text{-},\text{pCov}] = \text{lognlike}(\text{phat},x)
\]

\[
\text{pCov} = 2 \times 2
\]

\[
\begin{array}{cc}
0.0040 & -0.0000 \\
-0.0000 & 0.0020
\end{array}
\]

Find the cdf value at 0.5 and its 95% confidence interval.

\[
[\text{p},\text{pLo},\text{pUp}] = \text{logncdf}(0.5,\mu\text{Hat},\sigma\text{Hat},\text{pCov})
\]

\[
p = 0.0024
\]
\[
p\text{Lo} = 0.0016
\]
\[
p\text{Up} = 0.0037
\]

\(p\) is the cdf value of the lognormal distribution with the parameters \(\mu\text{Hat}\) and \(\sigma\text{Hat}\). The interval \([p\text{Lo},p\text{Up}]\) is the 95% confidence interval of the cdf evaluated at 0.5, considering the
uncertainty of $\muHat$ and $\sigmaHat$ using $pCov$. The 95% confidence interval means the probability that $[pLo,pUp]$ contains the true cdf value is 0.95.

**Input Arguments**

`params` — Lognormal distribution parameters
vector of two numeric values

Lognormal distribution parameters, specified as a vector of two numeric values. `params(1)` and `params(2)` are the mean and standard deviation of logarithmic values, respectively. `params(2)` must be positive.

Example: `[0,1]`

Data Types: `single` | `double`

`x` — Sample data
vector

Sample data, specified as a vector.

Data Types: `single` | `double`

`censoring` — Indicator for censoring
array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

`freq` — Frequency or weights of observations
array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

**Output Arguments**

`nlogL` — Negative loglikelihood
numeric scalar

Negative loglikelihood value of the distribution parameters (`params`) given the sample data (`x`), returned as a numeric scalar.
**aVar** — Inverse of Fisher information matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. **aVar** is based on the observed Fisher information given the observed data (x), not the expected information.

If values in **params** are the MLEs of the parameters, **aVar** is an approximation to the asymptotic variance-covariance matrix (also known as the asymptotic covariance matrix). To find the MLEs, use **mle**.

### Alternative Functionality

**lognlike** is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions **mlecov**, **fitdist**, **negloglik**, and **proflik** and the Distribution Fitter app, which support various probability distributions.

- **mlecov** returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by a custom probability density function. For example, `mlecov(params,x,'pdf',@lognpdf)` returns the asymptotic covariance matrix of the MLEs for the lognormal distribution.
- Create a LognormalDistribution probability distribution object by fitting the distribution to data using the fitdist function or the Distribution Fitter app. The object property **ParameterCovariance** stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to **negloglik** and **proflik**, respectively.

### Topics

“Lognormal Distribution” on page B-88
Introduced before R2006a
lognpdf

Lognormal probability density function

Syntax

\[
\begin{align*}
y &= \text{lognpdf}(x) \\
y &= \text{lognpdf}(x,\mu) \\
y &= \text{lognpdf}(x,\mu,\sigma)
\end{align*}
\]

Description

\( y = \text{lognpdf}(x) \) returns the probability density function (pdf) of the standard lognormal distribution, evaluated at the values in \( x \). In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

\( y = \text{lognpdf}(x,\mu) \) returns the pdf of the lognormal distribution with the distribution parameters \( \mu \) (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in \( x \).

\( y = \text{lognpdf}(x,\mu,\sigma) \) returns the pdf of the lognormal distribution with the distribution parameters \( \mu \) (mean of logarithmic values) and \( \sigma \) (standard deviation of logarithmic values), evaluated at the values in \( x \).

Examples

Compute Lognormal Distribution pdf

Compute the pdf values evaluated at the values in \( x \) for the lognormal distribution with mean \( \mu \) and standard deviation \( \sigma \).

\[
\begin{align*}
x &= 0:0.02:10; \\
\mu &= 0; \\
\sigma &= 1; \\
y &= \text{lognpdf}(x,0,1);
\end{align*}
\]

Plot the pdf.

\[
\begin{align*}
\text{plot}(x,y) \\
\text{grid on} \\
\text{xlabel('x')} \\
\text{ylabel('y')}
\end{align*}
\]
Input Arguments

x — Values at which to evaluate pdf
positive scalar value | array of positive scalar values

Values at which to evaluate the pdf, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify x using an array. To evaluate the pdfs of multiple distributions, specify mu and sigma using arrays. If one or more of the input arguments x, mu, and sigma are arrays, then the array sizes must be the same. In this case, lognpdf expands each scalar input into a constant array of the same size as the array inputs. Each element in y is the pdf value of the distribution specified by the corresponding elements in mu and sigma, evaluated at the corresponding element in x.

Example: [-1, 0, 3, 4]

Data Types: single | double

mu — Mean of logarithmic values
0 (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.
To evaluate the pdf at multiple values, specify \( x \) using an array. To evaluate the pdfs of multiple distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( x \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \( \lognpdf \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

Example: \([0 1 2; 0 1 2]\)

**Data Types:** `single` | `double`

**\( \sigma \) — Standard deviation of logarithmic values**

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify \( x \) using an array. To evaluate the pdfs of multiple distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( x \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \( \lognpdf \) expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

Example: \([1 1 1; 2 2 2]\)

**Data Types:** `single` | `double`

**Output Arguments**

**\( y \) — pdf values**

scalar value | array of scalar values

Pdf values, evaluated at the values in \( x \), returned as a scalar value or an array of scalar values. \( y \) is the same size as \( x \), \( \mu \), and \( \sigma \) after any necessary scalar expansion. Each element in \( y \) is the pdf value of the distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

**More About**

**Lognormal Distribution**

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The probability density function (pdf) of the lognormal distribution is

\[
y = f(x \mid \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp \left\{ -\frac{(\log x - \mu)^2}{2\sigma^2} \right\}, \quad \text{for } x > 0.
\]

**Alternative Functionality**

- \( \lognpdf \) is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input.
argument or specify the probability distribution name and its parameters. Note that the
distribution-specific function `lognpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative
distribution function (cdf) or probability density function (pdf) for a probability distribution.

### Topics

“Lognormal Distribution” on page B-88

**Introduced before R2006a**
**lognrnd**

Lognormal random numbers

**Syntax**

\[ r = \text{lognrnd}(\mu, \sigma) \]
\[ r = \text{lognrnd}(\mu, \sigma, sz_1, \ldots, sz_N) \]
\[ r = \text{lognrnd}(\mu, \sigma, sz) \]

**Description**

\( r = \text{lognrnd}(\mu, \sigma) \) generates a random number from the lognormal distribution with the distribution parameters \( \mu \) (mean of logarithmic values) and \( \sigma \) (standard deviation of logarithmic values).

\( r = \text{lognrnd}(\mu, \sigma, sz_1, \ldots, sz_N) \) generates an array of lognormal random numbers, where \( sz_1, \ldots, sz_N \) indicates the size of each dimension.

\( r = \text{lognrnd}(\mu, \sigma, sz) \) generates an array of lognormal random numbers, where vector \( sz \) specifies \( \text{size}(r) \).

**Examples**

**Generate Lognormal Random Number**

Find the distribution parameters from the mean and variance of a lognormal distribution and generate a lognormal random value from the distribution.

Find the distribution parameters \( \mu \) and \( \sigma \) from the mean and variance.

\[ m = 1; \ % \text{mean} \]
\[ v = 2; \ % \text{variance} \]
\[ \mu = \log((m^2)/\sqrt{v+m^2}) \]
\[ \mu = -0.5493 \]
\[ \sigma = \sqrt{\log(v/(m^2)+1)} \]
\[ \sigma = 1.0481 \]

Generate a lognormal random value.

\[ \text{rng('default')} \ % \text{For reproducibility} \]
\[ r = \text{lognrnd}(\mu, \sigma) \]
\[ r = 1.0144 \]
**Reset Random Number Generator**

Save the current state of the random number generator. Then create a 1-by-5 vector of lognormal random numbers from the lognormal distribution with the parameters 3 and 10.

```matlab
s = rng;
r = lognrnd(3,10,[1,5])
r = 1×5
   10^3 ×
   0.0000    1.8507    0.0000    0.0001    0.0000
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```matlab
rng(s);
r1 = lognrnd(3,10,[1,5])
r1 = 1×5
   10^3 ×
   0.0000    1.8507    0.0000    0.0001    0.0000
```

**Clone Size from Existing Array**

Create a matrix of lognormally distributed random numbers with the same size as an existing array.

```matlab
A = [3 2; -2 1];
sz = size(A);
R = lognrnd(0,1,sz)
R = 2×2
   1.7120    0.1045
   6.2582    2.3683
```

You can combine the previous two lines of code into a single line.

```matlab
R = lognrnd(1,0,size(A));
```

**Input Arguments**

- **mu** — **Mean of logarithmic values**
  - scalar value | array of scalar values
  
  Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

  To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar,
then lognrnd expands the scalar argument into a constant array of the same size as the other argument. Each element in r is the random number generated from the distribution specified by the corresponding elements in mu and sigma.

Example: [0 1 2; 0 1 2]
Data Types: single | double

sigma — Standard deviation of logarithmic values
nonnegative scalar value | array of nonnegative scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If sigma is zero, then the output r is always equal to exp(mu).

To generate random numbers from multiple distributions, specify mu and sigma using arrays. If both mu and sigma are arrays, then the array sizes must be the same. If either mu or sigma is a scalar, then lognrnd expands the scalar argument into a constant array of the same size as the other argument. Each element in r is the random number generated from the distribution specified by the corresponding elements in mu and sigma.

Example: [1 1 1; 2 2 2]
Data Types: single | double

sz1,...,szN — Size of each dimension (as separate arguments)
integers

Size of each dimension, specified as separate arguments of integers. For example, specifying 5,3,2 generates a 5-by-3-by-2 array of random numbers from the lognormal probability distribution.

If either mu or sigma is an array, then the specified dimensions sz1,...,szN must match the common dimensions of mu and sigma after any necessary scalar expansion. The default values of sz1,...,szN are the common dimensions.

- If you specify a single value sz1, then r is a square matrix of size sz1-by-sz1.
- If the size of any dimension is 0 or negative, then r is an empty array.
- Beyond the second dimension, lognrnd ignores trailing dimensions with a size of 1. For example, lognrnd(mu,sigma,3,1,1,1) produces a 3-by-1 vector of random numbers.

Example: 5,3,2
Data Types: single | double

sz — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying [5 3 2] generates a 5-by-3-by-2 array of random numbers from the lognormal probability distribution.

If either mu or sigma is an array, then the specified dimensions sz must match the common dimensions of mu and sigma after any necessary scalar expansion. The default values of sz are the common dimensions.

- If you specify a single value [sz1], then r is a square matrix of size sz1-by-sz1.
• If the size of any dimension is 0 or negative, then \( r \) is an empty array.
• Beyond the second dimension, \texttt{lognrnd} ignores trailing dimensions with a size of 1. For example, 
\texttt{lognrnd(mu, sigma, [3,1,1,1])} produces a 3-by-1 vector of random numbers.

Example: \[5 \ 3 \ 2\]
Data Types: \texttt{single} | \texttt{double}

**Output Arguments**

\( r \) — Lognormal random numbers

scalar value | array of scalar values

Lognormal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by \( sz1, \ldots, szN \) or \( sz \). Each element in \( r \) is the random number generated from the distribution specified by the corresponding elements in \( mu \) and \( sigma \).

**More About**

**Lognormal Distribution**

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean \( m \) and variance \( v \) of a lognormal random variable are functions of the lognormal distribution parameters \( \mu \) and \( \sigma \):

\[
m = \exp(\mu + \sigma^2/2) \\
v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)
\]

Also, you can compute the lognormal distribution parameters \( \mu \) and \( \sigma \) from the mean \( m \) and variance \( v \):

\[
\mu = \log(m^2/\sqrt{v + m^2}) \\
\sigma = \sqrt{\log(v/m^2 + 1)}
\]

**Alternative Functionality**

• \texttt{lognrnd} is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function \texttt{random}, which supports various probability distributions. To use \texttt{random}, create a \texttt{LognormalDistribution} probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function \texttt{lognrnd} is faster than the generic function \texttt{random}.
• To generate random numbers interactively, use \texttt{randtool}, a user interface for random number generation.

**References**

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**Topics**
“Lognormal Distribution” on page B-88

**Introduced before R2006a**
lognstat

Lognormal mean and variance

Syntax

[m,v] = lognstat(mu,sigma)

Description

[m,v] = lognstat(mu,sigma) returns the mean and variance of the lognormal distribution with the distribution parameters mu (mean of logarithmic values) and sigma (standard deviation of logarithmic values).

Examples

Compute Mean and Variance

Compute the mean and variance of the lognormal distribution with parameters mu and sigma.

mu = 0;
sigma = 1;
[m,v] = lognstat(mu,sigma)

m = 1.6487
v = 4.6708

Input Arguments

mu — Mean of logarithmic values
cALAR value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both mu and sigma are arrays, then the array sizes must be the same. If either mu or sigma is a scalar, then lognstat expands the scalar argument into a constant array of the same size as the other argument. Each element in m and v is the mean and variance of the distribution specified by the corresponding elements in mu and sigma.

Example: [0 1 2; 0 1 2]

Data Types: single | double

sigma — Standard deviation of logarithmic values

positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.
To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both \(\mu\) and \(\sigma\) are arrays, then the array sizes must be the same. If either \(\mu\) or \(\sigma\) is a scalar, then \text{lognstat} expands the scalar argument into a constant array of the same size as the other argument. Each element in \(m\) and \(v\) is the mean and variance of the distribution specified by the corresponding elements in \(\mu\) and \(\sigma\).

Example:
\[
\begin{bmatrix}
1 & 1 & 1 \\
2 & 2 & 2 \\
\end{bmatrix}
\]
Data Types: \text{single} | \text{double}

**Output Arguments**

\(m\) — Mean  
n scalar value | array of scalar values

Mean of the lognormal distribution, returned as a scalar value or an array of scalar values. \(m\) is the same size as \(\mu\) and \(\sigma\) after any necessary scalar expansion. Each element in \(m\) is the mean of the lognormal distribution specified by the corresponding elements in \(\mu\) and \(\sigma\).

\(v\) — Variance  
n scalar value | array of scalar values

Variance of the lognormal distribution, returned as a scalar value or an array of scalar values. \(v\) is the same size as \(\mu\) and \(\sigma\) after any necessary scalar expansion. Each element in \(v\) is the variance of the lognormal distribution specified by the corresponding elements in \(\mu\) and \(\sigma\).

**More About**

**Lognormal Distribution**

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean \(m\) and variance \(v\) of a lognormal random variable are functions of the lognormal distribution parameters \(\mu\) and \(\sigma\):

\[
m = \exp\left(\mu + \frac{\sigma^2}{2}\right)
\]

\[
v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)
\]

Also, you can compute the lognormal distribution parameters \(\mu\) and \(\sigma\) from the mean \(m\) and variance \(v\):

\[
\mu = \log\left(m^2/\sqrt{v + m^2}\right)
\]

\[
\sigma = \sqrt{\log\left(v/m^2 + 1\right)}
\]

**Alternative Functionality**

- \text{lognstat} is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (\text{mean}), median (\text{median}), interquartile range (\text{iqr}), variance (\text{var}), and standard deviation (\text{std}). These generic functions support various probability distributions. To use these functions, create a \text{LognormalDistribution} probability distribution object and pass the object as an input argument.

Topics
“Lognormal Distribution” on page B-88

Introduced before R2006a
**logP**

Log unconditional probability density for discriminant analysis classifier

**Syntax**

\[ lp = \text{logP}(\text{obj},Xnew) \]

**Description**

\[ lp = \text{logP}(\text{obj},Xnew) \] returns the log of the unconditional probability density of each row of \( Xnew \), computed using the discriminant analysis model \( \text{obj} \).

**Input Arguments**

- **obj**
  Discriminant analysis classifier, produced using \texttt{fitcdiscr}.

- **Xnew**
  Matrix where each row represents an observation, and each column represents a predictor. The number of columns in \( Xnew \) must equal the number of predictors in \( \text{obj} \).

**Output Arguments**

- **lp**
  Column vector with the same number of rows as \( Xnew \). Each entry is the logarithm of the unconditional probability density of the corresponding row of \( Xnew \).

**Examples**

**Compute Log Unconditional Probability Density of an Observation**

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```matlab
load fisheriris
Mdl = fitcdiscr(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```matlab
logPAverage = logP(Mdl,mean(meas))
```

\[ \text{logPAverage} = -1.7254 \]
More About

Unconditional Probability Density

The unconditional probability density of a point \( x \) of a discriminant analysis model is

\[
P(x) = \sum_{k=1}^{K} P(x, k),
\]

where \( P(x, k) \) is the conditional density of the model at \( x \) for class \( k \), when the total number of classes is \( K \).

The conditional density \( P(x, k) \) is

\[
P(x, k) = \frac{P(k)P(x|k)}{P(k)},
\]

where \( P(k) \) is the prior probability of class \( k \), and \( P(x|k) \) is the conditional density of \( x \) given class \( k \).

The conditional density function of the multivariate normal with 1-by-\( d \) mean \( \mu_k \) and \( d \)-by-\( d \) covariance \( \Sigma_k \) at a 1-by-\( d \) point \( x \) is

\[
P(x|k) = \frac{1}{(2\pi)^{d/2}|\Sigma_k|^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^{\top}\Sigma_k^{-1}(x - \mu_k)\right),
\]

where \( |\Sigma_k| \) is the determinant of \( \Sigma_k \), and \( \Sigma_k^{-1} \) is the inverse matrix.

Topics
“Discriminant Analysis Classification” on page 20-2
**logP**

Log unconditional probability density for naive Bayes classifier

**Syntax**

```matlab
lp = logP(Mdl,tbl)
lp = logP(Mdl,X)
```

**Description**

`lp = logP(Mdl,tbl)` returns the log unconditional probability density on page 32-3144 of the observations (rows) in `tbl` using the naive Bayes model `Mdl`.

You can use `lp` to identify outliers in the training data.

`lp = logP(Mdl,X)` returns the log unconditional probability density on page 32-3144 of the observations (rows) in `X` using the naive Bayes model `Mdl`.

**Input Arguments**

- **Mdl** — Naive Bayes classifier
  
  ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

  Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

- **tbl** — Sample data
  
  table

  Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

  If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

  Data Types: `table`

- **X** — Predictor data
  
  numeric matrix

  Predictor data, specified as a numeric matrix.

  Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` must be the same as the variables that trained `Mdl`.

  Data Types: `double` | `single`
Output Arguments

lp — Log of unconditional probability density
numeric column vector

Log of the unconditional probability density of the predictors, returned as a numeric column vector. lp has as many elements as rows in X, and each element is the log probability density of the corresponding row in X.

If any rows in X contain at least one NaN, then the corresponding element of lp is NaN.

Examples

Compute Unconditional Probability Densities of Observations

Load Fisher's iris data set.

load fisheriris
X = meas;  % Predictors
Y = species;  % Response

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});

Mdl is a trained ClassificationNaiveBayes classifier.

Compute the unconditional probability densities of the in-sample observations.

lp = logP(Mdl,X);
histogram(lp)
xlabel 'Log-unconditional probability'
ylabel 'Frequency'
title 'Histogram: Log-Unconditional Probability'
Identify indices of observations having log-unconditional probability less than -7.

```matlab
idx = find(lp < -7)
```

```plaintext
idx = [61, 118, 132]
```

**More About**

**Unconditional Probability Density**

The unconditional probability density of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

\[
P(X_1, \ldots, X_P) = \sum_{k=1}^{K} P(X_1, \ldots, X_P, Y = k) = \sum_{k=1}^{K} P(X_1, \ldots, X_P \mid Y = k) \pi(Y = k),
\]

where \( \pi(Y = k) \) is the class prior probability. The conditional distribution of the data given the class \( P(X_1, \ldots, X_P \mid Y = k) \) and the class prior probability distributions are training options (i.e., are specified when training the classifier).
**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

loss

Loss of k-nearest neighbor classifier

Syntax

L = loss(mdl,tbl,ResponseVarName)  
L = loss(mdl,tbl,Y)  
L = loss(mdl,X,Y)  
L = loss(____,Name,Value)

Description

L = loss(mdl,tbl,ResponseVarName) returns a scalar representing how well mdl classifies the data in tbl when tbl.ResponseVarName contains the true classifications. If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName.

When computing the loss, the loss function normalizes the class probabilities in tbl.ResponseVarName to the class probabilities used for training, which are stored in the Prior property of mdl.

The meaning of the classification loss (L) depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values. For more details, see “Classification Loss” on page 32-3149.

L = loss(mdl,tbl,Y) returns a scalar representing how well mdl classifies the data in tbl when Y contains the true classifications.

When computing the loss, the loss function normalizes the class probabilities in Y to the class probabilities used for training, which are stored in the Prior property of mdl.

L = loss(mdl,X,Y) returns a scalar representing how well mdl classifies the data in X when Y contains the true classifications.

When computing the loss, the loss function normalizes the class probabilities in Y to the class probabilities used for training, which are stored in the Prior property of mdl.

L = loss(____,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Loss Calculation

Create a k-nearest neighbor classifier for the Fisher iris data, where k = 5.

Load the Fisher iris data set.

load fisheriris

32-3146
Create a classifier for five nearest neighbors.

mdl = fitcknn(meas,species,'NumNeighbors',5);

Examine the loss of the classifier for a mean observation classified as 'versicolor'.

X = mean(meas);
Y = {'versicolor'};
L = loss(mdl,X,Y)

L = 0

All five nearest neighbors classify as 'versicolor'.

**Input Arguments**

**mdl** — *k*-nearest neighbor classifier model
ClassificationKNN object

*k*-nearest neighbor classifier model, specified as a ClassificationKNN object.

**tbl** — Sample data
table

Sample data used to train the model, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName or Y.

If you train mdl using sample data contained in a table, then the input data for loss must also be in a table.

Data Types: table

**ResponseVarName** — Response variable name
name of a variable in tbl

Response variable name, specified as the name of a variable in tbl. If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable is stored as tbl.response, then specify it as 'response'. Otherwise, the software treats all columns of tbl, including tbl.response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**X** — Predictor data
numeric matrix
Predictor data, specified as a numeric matrix. Each row of \( X \) represents one observation, and each column represents one variable.

Data Types: `single` | `double`

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, string array, logical or numeric vector, or cell array of character vectors. Each row of \( Y \) represents the classification of the corresponding row of \( X \).

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(mdl,tbl,'response','LossFun','exponential','Weights','w')` returns the weighted exponential loss of `mdl` classifying the data in `tbl`. Here, `tbl.response` is the response variable, and `tbl.w` is the weight variable.

**LossFun — Loss function**

`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- The following table lists the available loss functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'binodeviance'</code></td>
<td>Binomial deviance</td>
</tr>
<tr>
<td><code>'classiferror'</code></td>
<td>Classification error</td>
</tr>
<tr>
<td><code>'exponential'</code></td>
<td>Exponential</td>
</tr>
<tr>
<td><code>'hinge'</code></td>
<td>Hinge</td>
</tr>
<tr>
<td><code>'logit'</code></td>
<td>Logistic</td>
</tr>
<tr>
<td><code>'mincost'</code></td>
<td>Minimal expected misclassification cost (for</td>
</tr>
<tr>
<td></td>
<td>classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td><code>'quadratic'</code></td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

`'mincost'` is appropriate for classification scores that are posterior probabilities. By default, \( k \)-nearest neighbor models return posterior probabilities as classification scores (see `predict`).

- You can specify a function handle for a custom loss function using `@` (for example, `@lossfun`). Let \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(mdl.	ext{ClassNames}) \)). Your custom loss function must have this form:

\[
\text{function lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]
C is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in \texttt{mdl.ClassNames}. Construct \( C \) by setting \( C(p,q) = 1 \), if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

\( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \texttt{mdl.ClassNames}. The argument \( S \) is a matrix of classification scores, similar to the output of \texttt{predict}.

\( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes the weights to sum to 1.

\( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.

The output argument \texttt{lossvalue} is a scalar. For more details on loss functions, see “Classification Loss” on page 32-3149.

Data Types: \texttt{char} | \texttt{string} | \texttt{function_handle}

\textbf{Weights — Observation weights}

\texttt{ones(size(X,1),1)} (default) | numeric vector | name of a variable in \texttt{tbl}

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in \texttt{tbl}.

If you specify \texttt{Weights} as a numeric vector, then the size of \texttt{Weights} must be equal to the number of rows in \( X \) or \texttt{tbl}.

If you specify \texttt{Weights} as the name of a variable in \texttt{tbl}, the name must be a character vector or string scalar. For example, if the weights are stored as \texttt{tbl.w}, then specify \texttt{Weights} as 'w'. Otherwise, the software treats all columns of \texttt{tbl}, including \texttt{tbl.w}, as predictors.

\texttt{loss} normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply \texttt{Weights}, \texttt{loss} computes the weighted classification loss.

Example: 'Weights','w'

Data Types: \texttt{single} | \texttt{double} | \texttt{char} | \texttt{string}

\textbf{Algorithms}

\textbf{Classification Loss}

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
• $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.

• $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.

• For algorithms that support multiclass classification (that is, $K \geq 3$):

  • $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 0 1 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

  • $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.

  • $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.

• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$
\sum_{j=1}^{n} w_j = 1.
$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `LossFun` name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>$L = \sum_{j=1}^{n} w_j \log{1 + \exp[-2m_j]}$.</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>$L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}$.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>It is the weighted fraction of misclassified observations where $\hat{y}_j$ is the class label corresponding to the class with the maximal posterior probability. $I{x}$ is the indicator function.</td>
</tr>
<tr>
<td>Hinge loss</td>
<td>'hinge'</td>
<td>$L = \sum_{j=1}^{n} w_j \max{0, 1 - m_j}$.</td>
</tr>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.</td>
</tr>
<tr>
<td>Loss Function</td>
<td>Value of LossFun</td>
<td>Equation</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
| Minimal cost   | 'mincost'       | Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, ..., n$.  
1. Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:  
   $$y_j = f(X_j)C.$$  
   $f(X)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the Cost property.  
2. For observation $j$, predict the class label corresponding to the minimum expected classification cost:  
   $$\hat{y}_j = \min_{j = 1, ..., K} (y_j).$$  
3. Using $C$, identify the cost incurred ($c_j$) for making the prediction.  
The weighted, average, minimum cost loss is  
   $$L = \sum_{j=1}^{n} w_j c_j.$$ |
| Quadratic loss | 'quadratic'     | $L = \sum_{j=1}^{n} w_j (1 - m_j)^2$. |

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 

32-3151
True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run fitcknn. The value Cost(i,j) is the cost of classifying an observation into class j if its true class is i. By default, Cost(i,j) = 1 if i ~= j, and Cost(i,j) = 0 if i = j. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl, and you have K classes. You place the observations into a matrix Xnew with one observation per row. The command

\[
\text{[label,score,cost] = predict(mdl,Xnew)}
\]

returns a matrix cost of size Nobs-by-K, among other outputs. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the K classes. \(\text{cost}(n,j)\) is

\[
\sum_{i=1}^{K} \hat{P}(i|Xnew(n))C(j|i),
\]
where

- $K$ is the number of classes.
- $\hat{P}(i|X_{\text{new}}(n))$ is the posterior probability on page 32-4144 of class $i$ for observation $X_{\text{new}}(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as $j$ when its true class is $i$.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

**See Also**

ClassificationKNN | edge | fitcknn | margin

**Introduced in R2012a**
**loss**

**Class:** ClassificationLinear

Classification loss for linear classification models

**Syntax**

$L = \text{loss}(\text{Mdl},X,Y)$

$L = \text{loss}(\_\_\_,\text{Name},\text{Value})$

**Description**

$L = \text{loss}(\text{Mdl},X,Y)$ returns the classification losses on page 32-3161 for the binary, linear classification model $\text{Mdl}$ using predictor data in $X$ and corresponding class labels in $Y$. $L$ contains classification error rates for each regularization strength in $\text{Mdl}$.

$L = \text{loss}(\_\_\_,\text{Name},\text{Value})$ uses any of the previous syntaxes and additional options specified by one or more Name,Value pair arguments. For example, you can specify that columns in the predictor data correspond to observations or specify the classification loss function.

**Input Arguments**

$\text{Mdl} — \text{Binary, linear classification model}$

ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using fitclinear.

$X — \text{Predictor data}$

full matrix | sparse matrix

Predictor data, specified as an $n$-by-$p$ full or sparse matrix. This orientation of $X$ indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of $Y$ and the number of observations in $X$ must be equal.

Data Types: single | double

$Y — \text{Class labels}$

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.
The data type of Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

- The distinct classes in Y must be a subset of Mdl.ClassNames.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**LossFun — Loss function**

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

- 'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see predict).

- Specify your own function by using function handle notation.

Let \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(\text{Mdl.ClassNames}) \), where \( \text{Mdl} \) is the input model). Your function must have this signature:

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in \( \text{Mdl.ClassNames} \).
Construct $C$ by setting $C(p,q) = 1$, if observation $p$ is in class $q$, for each row. Set all other elements of row $p$ to 0.

- $S$ is an $n$-by-$K$ numeric matrix of classification scores. The column order corresponds to the class order in Mdl.ClassNames. $S$ is a matrix of classification scores, similar to the output of predict.
- $W$ is an $n$-by-1 numeric vector of observation weights. If you pass $W$, the software normalizes the weights to sum to 1.
- $Cost$ is a $K$-by-$K$ numeric matrix of misclassification costs. For example, $Cost = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun', @lossfun

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension
'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Weights — Observation weights
numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, loss computes the weighted classification loss.

Let $n$ be the number of observations in $X$.

- `numel(Weights)` must be $n$.
- By default, $Weights$ is $\text{ones}(n,1)$.

*loss* normalizes $Weights$ to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Output Arguments

$L$ — Classification losses
numeric scalar | numeric row vector

Classification losses, returned as a numeric scalar or row vector. The interpretation of $L$ depends on $Weights$ and $LossFun$.

$L$ is the same size as Mdl.Lambda. $L(j)$ is the classification loss of the linear classification model trained using the regularization strength Mdl.Lambda(\text{j}).

Examples
Estimate Test-Sample Classification Loss

Load the NLP data set.

```matlab
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA.

```matlab
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample classification error.

```matlab
ceTrain = loss(CMdl,X(trainIdx,:),Ystats(trainIdx))
ceTrain = 1.3572e-04

cetest = loss(CMdl,X(testIdx,:),Ystats(testIdx))
cetest = 5.2804e-04
```

Because there is one regularization strength in `CMdl`, `ceTrain` and `ceTest` are numeric scalars.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Classification Loss” on page 32-3156, and transpose the predictor data.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a ClassificationLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);

Create an anonymous function that measures linear loss, that is,

\[ L = \frac{\sum_j w_j y_j f_j}{\sum_j w_j}. \]

where \( w_j \) is the weight for observation \( j \), \( y_j \) is response \( j \) (-1 for the negative class, and 1 otherwise), and \( f_j \) is the raw classification score of observation \( j \). Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the LossFun name-value pair argument.

linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);

Estimate the training- and test-sample classification loss using the linear loss function.

ceTrain = loss(CMdl,X(:,trainIdx),Ystats(trainIdx),'LossFun',linearloss,...
'ObservationsIn','columns')

ceTrain = -7.8330

ceTest = loss(CMdl,X(:,testIdx),Ystats(testIdx),'LossFun',linearloss,...
'ObservationsIn','columns')

ceTest = -7.7383

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3157.

load nlpdata
Ystats = Y == 'stats';
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

```matlab
Lambda = logspace(-6,-0.5,11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```matlab
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
        CrossValidatedModel: 'Linear'
            ResponseName: 'Y'
            NumObservations: 31572
                KFold: 1
                    Partition: [1x1 cvpartition]
                        ClassNames: [0 1]
                        ScoreTransform: 'none'
```

Extract the trained linear classification model.

```matlab
Mdl = CVMdl.Trained{1}
```

```matlab
Mdl =
    ClassificationLinear
        ResponseName: 'Y'
            ClassNames: [0 1]
                ScoreTransform: 'logit'
                    Beta: [34023x11 double]
                        Bias: [1x11 double]
                            Lambda: [1x11 double]
                                Learner: 'logistic'
```

"Mdl is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda."

Estimate the test-sample classification error.

```matlab
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.
Md1 = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Md1.Beta~=0);

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff+1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'\log_{10} classification error')
ylabel(h(2),'\log_{10} nonzero-coefficient frequency')
xlabel('\log_{10} Lambda')
title('Test-Sample Statistics')
hold off

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

idxFinal = 7;

Select the model from Md1 with the chosen regularization strength.

Md1Final = selectModels(Md1,idxFinal);
MdlFinal is a ClassificationLinear model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to predict.

**More About**

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 0 1 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  - $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$
\sum_{j=1}^{n} w_j = 1.
$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

1. Estimate the 1-by-\( K \) vector of expected classification costs for observation \( j \):
   \[ y_j = f(X_j)C. \]
   \( f(X) \) is the column vector of class posterior probabilities for binary and multiclass classification. \( C \) is the cost matrix that the input model stores in the \textit{Cost} property.

2. For observation \( j \), predict the class label corresponding to the minimum expected classification cost:
   \[ \hat{y}_j = \min_{j = 1, \ldots, K}(y_j). \]

3. Using \( C \), identify the cost incurred \( (c_j) \) for making the prediction.

The weighted, average, minimum cost loss is
\[ L = \sum_{j=1}^{n} w_j c_j. \]
This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through \([0,1]\).

### Algorithms

By default, observation weights are prior class probabilities. If you supply weights using `Weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to estimate the weighted classification loss.

### Extended Capabilities

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

loss

Classification error

Syntax

\[
L = \text{loss}(\text{obj},X,Y)
\]

\[
L = \text{loss}(\text{obj},X,Y,\text{Name},\text{Value})
\]

Description

\(L = \text{loss}(\text{obj},X,Y)\) returns the classification loss on page 32-3166, which is a scalar representing how well \(\text{obj}\) classifies the data in \(X\), when \(Y\) contains the true classifications.

When computing the loss, \(\text{loss}\) normalizes the class probabilities in \(Y\) to the class probabilities used for training, stored in the \text{Prior} property of \(\text{obj}\).

\(L = \text{loss}(\text{obj},X,Y,\text{Name},\text{Value})\) returns the loss with additional options specified by one or more \text{Name,Value} pair arguments.

Input Arguments

\(\text{obj}\)

Discriminant analysis classifier of class \text{ClassificationDiscriminant} or \text{CompactClassificationDiscriminant}, typically constructed with \text{fitcdiscr}.

\(X\)

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in \(X\) must equal the number of predictors in \(\text{obj}\).

\(Y\)

Class labels, with the same data type as exists in \(\text{obj}\). The number of elements of \(Y\) must equal the number of rows of \(X\).

Name-Value Pair Arguments

Specify optional comma-separated pairs of \text{Name,Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \text{Name1,Value1,...,NameN,ValueN}.

\text{LossFun}

Built-in, loss-function name (character vector or string scalar in the table) or function handle.

- The following table lists the available loss functions. Specify one using the corresponding value.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'\textit{mincost}' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see \texttt{predict}).

- Specify your own function using function handle notation.

Suppose that \(n\) be the number of observations in \(X\) and \(K\) be the number of distinct classes (\(\text{numel(Mdl.ClassNames)}\)). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

where:

- The output argument \(\text{lossvalue}\) is a scalar.
- You choose the function name (\(\text{lossfun}\)).
- \(C\) is an \(n\)-by-\(K\) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \(\text{Mdl.ClassNames}\).
  
  Construct \(C\) by setting \(C(p,q) = 1\) if observation \(p\) is in class \(q\), for each row. Set all other elements of row \(p\) to 0.
- \(S\) is an \(n\)-by-\(K\) numeric matrix of classification scores. The column order corresponds to the class order in \(\text{Mdl.ClassNames}\). \(S\) is a matrix of classification scores, similar to the output of \texttt{predict}.
- \(W\) is an \(n\)-by-1 numeric vector of observation weights. If you pass \(W\), the software normalizes them to sum to 1.
- \(Cost\) is a \(K\)-by-\(K\) numeric matrix of misclassification costs. For example, \(Cost = \text{ones(K)} - \text{eye(K)}\) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using '\texttt{LossFun}',@\texttt{lossfun}.

For more details on loss functions, see “Classification Loss” on page 32-3166.

**Default:** '\textit{mincost}'

**Weights**

Numeric vector of length \(N\), where \(N\) is the number of rows of \(X\). weights are nonnegative. loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply weights, loss computes weighted classification loss.

**Default:** \(\text{ones(N,1)}\)
Output Arguments

\( L \)

Classification loss on page 32-3166, a scalar. The interpretation of \( L \) depends on the values in \( \text{weights} \) and \( \text{lossfun} \).

Examples

**Estimate Classification Error**

Load Fisher's iris data set.

```matlab
load fisheriris
```

Train a discriminant analysis model using all observations in the data.

```matlab
Mdl = fitcdiscr(meas,species);
```

Estimate the classification error of the model using the training observations.

```matlab
L = loss(Mdl,meas,species)
L = 0.0200
```

Alternatively, if \( \text{Mdl} \) is not compact, then you can estimate the training-sample classification error by passing \( \text{Mdl} \) to \text{resubLoss}.

More About

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).
  - \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):
  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_j^* = [-1 -1 1 -1] \).
The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.

- \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>[ L = \sum_{j=1}^{n} w_j \log(1 + \exp(-2m_j)). ]</td>
</tr>

</tr>
<tr>
<td></td>
<td></td>
<td>1. Estimate the 1-by-$K$ vector of expected classification costs for observation $j$: $y_j = f(X_j)C$. $f(X)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the Cost property.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. For observation $j$, predict the class label corresponding to the minimum expected classification cost: $\hat{y}<em>j = \min</em>{j = 1, \ldots, K} {y_j}$.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. Using $C$, identify the cost incurred ($c_j$) for making the prediction. The weighted, average, minimum cost loss is $L = \sum_{j=1}^{n} w_j c_j$.</td>
</tr>
<tr>
<td>Quadratic loss</td>
<td>'quadratic'</td>
<td>$L = \sum_{j=1}^{n} w_j (1 - m_{ij})^2$.</td>
</tr>
</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 
Posterior Probability

The posterior probability that a point $x$ belongs to class $k$ is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with 1-by-$d$ mean $\mu_k$ and $d$-by-$d$ covariance $\Sigma_k$ at a 1-by-$d$ point $x$ is

$$P(x|k) = \frac{1}{(2\pi)^d |\Sigma_k|^{1/2}} \exp\left(-\frac{1}{2} (x - \mu_k) \Sigma_k^{-1} (x - \mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of $\Sigma_k$, and $\Sigma_k^{-1}$ is the inverse matrix.

Let $P(k)$ represent the prior probability of class $k$. Then the posterior probability that an observation $x$ is of class $k$ is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over $k$ of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class $k$ is one over the total number of classes.
- 'empirical' — The prior probability of class $k$ is the number of training samples of class $k$ divided by the total number of training samples.
• Custom — The prior probability of class k is the kth element of the prior vector. See fitcdiscr.

After creating a classification model (Mdl) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where v is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

**Cost**

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

**Topics**

“Discriminant Analysis Classification” on page 20-2
### loss

**Package:**

Classification loss for multiclass error-correcting output codes (ECOC) model

**Syntax**

\[
\begin{align*}
L &= \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName}) \\
L &= \text{loss}(\text{Mdl}, \text{tbl}, \text{Y}) \\
L &= \text{loss}(\text{Mdl}, \text{X}, \text{Y}) \\
L &= \text{loss}(\_\_\_, \text{Name, Value})
\end{align*}
\]

**Description**

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName})
\]

returns the classification loss \( L \), a scalar representing how well the trained multiclass error-correcting output codes (ECOC) model \( \text{Mdl} \) classifies the predictor data in \( \text{tbl} \) compared to the true class labels in \( \text{tbl}.\text{ResponseVarName} \). By default, \text{loss} uses the classification error on page 32-3178 to compute \( L \).

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, \text{Y})
\]

returns the classification loss for the predictor data in table \( \text{tbl} \) and the true class labels in \( \text{Y} \).

\[
L = \text{loss}(\text{Mdl}, \text{X}, \text{Y})
\]

returns the classification loss for the predictor data in matrix \( \text{X} \) and the true class labels in \( \text{Y} \).

\[
L = \text{loss}(\_\_\_, \text{Name, Value})
\]

specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify a decoding scheme, classification loss function, and verbosity level.

**Examples**

### Determine Test-Sample Loss of ECOC Model

Load Fisher's iris data set. Specify the predictor data \( \text{X} \), the response data \( \text{Y} \), and the order of the classes in \( \text{Y} \).

\[
\begin{align*}
\text{load fisheriris} \\
\text{X} &= \text{meas}; \\
\text{Y} &= \text{categorical}('\text{species}'); \\
\text{classOrder} &= \text{unique}(\text{Y}); \quad \% \text{Class order} \\
\text{rng}(1); \quad \% \text{For reproducibility}
\end{align*}
\]

Train an ECOC model using SVM binary classifiers. Specify a 15\% holdout sample, standardize the predictors using an SVM template, and specify the class order.

\[
\begin{align*}
\text{t} &= \text{templateSVM}('\text{Standardize}', \text{true}); \\
\text{PMDl} &= \text{fitcecoc}(\text{X}, \text{Y}, '\text{Holdout}', 0.15, '\text{Learners}', \text{t}, '\text{ClassNames}', \text{classOrder}); \\
\text{Mdl} &= \text{PMDl}.\text{Trained}[1]; \quad \% \text{Extract trained, compact classifier}
\end{align*}
\]

32-3171
PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

Estimate the test-sample classification error, which is the default classification loss.

```matlab
testInds = test(PMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
L = loss(Mdl,XTest,YTest)
L = 0
```

The ECOC model correctly classifies all irises in the test sample.

### Determine ECOC Model Quality Using Custom Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);  % Class order
rng(1) % For reproducibility
Train an ECOC model using SVM binary classifiers. Specify a 15% holdout sample, standardize the predictors using an SVM template, and define the class order.

t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1};           % Extract trained, compact classifier
PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `predict`.

```matlab
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the test-sample custom loss.

```matlab
testInds = test(PMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
loss(Mdl,XTest,YTest,'LossFun',lossfun)
an = 0.0033
```

The average minimal binary loss for the test-sample observations is 0.0033.
Input Arguments

**Mdl — Full or compact multiclass ECOC model**  
*ClassificationECOC* model object | *CompactClassificationECOC* model object

Full or compact multiclass ECOC model, specified as a *ClassificationECOC* or *CompactClassificationECOC* model object.

To create a full or compact ECOC model, see *ClassificationECOC* or *CompactClassificationECOC*.

**tbl — Sample data**  
table

Sample data, specified as a table. Each row of *tbl* corresponds to one observation, and each column corresponds to one predictor variable. Optionally, *tbl* can contain additional columns for the response variable and observation weights. *tbl* must contain all the predictors used to train *Mdl*. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you train *Mdl* using sample data contained in a table, then the input data for *loss* must also be in a table.

**Note**  
If *Mdl.BinaryLearners* contains linear or kernel classification models (*ClassificationLinear* or *ClassificationKernel* model objects), then you cannot specify sample data in a table. Instead, pass a matrix (*X*) and class labels (*Y*).

When training *Mdl*, assume that you set 'Standardize', true for a template object specified in the 'Learners' name-value pair argument of *fitcecoc*. In this case, for the corresponding binary learner *j*, the software standardizes the columns of the new predictor data using the corresponding means in *Mdl.BinaryLearner{j}.Mu* and standard deviations in *Mdl.BinaryLearner{j}.Sigma*.

Data Types: table

**ResponseVarName — Response variable name**  
name of variable in *tbl*

Response variable name, specified as the name of a variable in *tbl*. If *tbl* contains the response variable used to train *Mdl*, then you do not need to specify *ResponseVarName*.

If you specify *ResponseVarName*, then you must do so as a character vector or string scalar. For example, if the response variable is stored as *tbl.y*, then specify *ResponseVarName* as 'y'. Otherwise, the software treats all columns of *tbl*, including *tbl.y*, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**X — Predictor data**  
numeric matrix
Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables in the columns of X must be the same as the variables that trained the classifier Mdl.

The number of rows in X must equal the number of rows in Y.

When training Mdl, assume that you set 'Standardize',true for a template object specified in the 'Learners' name-value pair argument of fitcecoc. In this case, for the corresponding binary learner j, the software standardizes the columns of the new predictor data using the corresponding means in Mdl.BinaryLearner{j}.Mu and standard deviations in Mdl.BinaryLearner{j}.Sigma.

Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must have the same data type as Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The number of rows in Y must equal the number of rows in tbl or X.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: loss(Mdl,X,Y,'BinaryLoss','hinge','LossFun',@lossfun) specifies 'hinge' as the binary learner loss function and the custom function handle @lossfun as the overall loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
The software normalizes binary losses so that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction has this form:

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \( \text{Mdl.CodingMatrix} \).
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default BinaryLoss value depends on the score ranges returned by the binary learners. This table describes some default BinaryLoss values based on the given assumptions.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel classification models of SVM learners.</td>
<td>'hinge'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by AdaboostM1 or GentleBoost.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by LogitBoost.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior',true in fitcecoc.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3178.

Example: 'Decoding','lossbased'

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3178, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

Assume that \( n = \text{size}(X,1) \) is the sample size and \( K \) is the number of classes. Your function must have the signature \( \text{lossvalue} = \text{lossfun}(C,S,W,Cost) \), where:

- The output argument lossvalue is a scalar.
- You specify the function name (lossfun).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in \text{Mdl.ClassNames}.
  
  Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.
- \( S \) is an \( n \)-by-\( K \) numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in \text{Mdl.ClassNames}. The input \( S \) resembles the output argument \text{NegLoss} of \text{predict}.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes its elements to sum to 1.
- \( Cost \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( Cost = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. \text{Mdl.BinaryLearners} must contain \text{ClassificationLinear} models.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', you can experience a significant reduction in execution time.

**Options — Estimation options**

[] (default) | structure array returned by \text{statset}
Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbosity controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: **'Verbose', 1**

Data Types: single | double

**Weights — Observation weights**

ones(size(X,1),1) (default) | numeric vector | name of variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. If you supply weights, then loss computes the weighted loss.

If you specify **Weights** as a numeric vector, then the size of **Weights** must be equal to the number of rows in X or tbl.

If you specify **Weights** as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify **Weights** as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you do not specify your own loss function (using **LossFun**), then the software normalizes **Weights** to sum up to the value of the prior probability in the respective class.

Data Types: single | double | char | string

**Output Arguments**

**L — Classification loss**

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or row vector. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

If **Mdl.BinaryLearners** contains **ClassificationLinear** models, then L is a 1-by-ℓ vector, where ℓ is the number of regularization strengths in the linear classification models (numel(Mdl.BinaryLearners{1}.Lambda)). The value L(j) is the loss for the model trained using regularization strength Mdl.BinaryLearners{1}.Lambda(j).

Otherwise, L is a scalar value.
More About

Classification Error

The classification error is a binary classification error measure that has the form

\[ L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j}, \]

where:

- \( w_j \) is the weight for observation \( j \). The software renormalizes the weights to sum to 1.
- \( e_j = 1 \) if the predicted class of observation \( j \) differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[ \hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{kj}|g(m_{kj}, s_j). \]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[ \hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{kj}|g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}. \]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>[0,1] or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>[0,1]</td>
<td>$[1 - y_j (2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see ”Tall Arrays” (MATLAB).

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the ‘UseParallel’ field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.
For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

loss

Classification error

Syntax

L = loss(ens,tbl,ResponseVarName)
L = loss(ens,tbl,Y)
L = loss(ens,X,Y)
L = loss(___,Name,Value)

Description

L = loss(ens,tbl,ResponseVarName) returns the classification error for ensemble ens computed using table of predictors tbl and true class labels tbl.ResponseVarName.

L = loss(ens,tbl,Y) returns the classification error for ensemble ens computed using table of predictors tbl and true class labels Y.

L = loss(ens,X,Y) returns the classification error for ensemble ens computed using matrix of predictors X and true class labels Y.

L = loss(___,Name,Value) computes classification error with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

When computing the loss, loss normalizes the class probabilities in ResponseVarName or Y to the class probabilities used for training, stored in the Prior property of ens.

Input Arguments

ens

Classification ensemble created with fitensemble, or a compact classification ensemble created with compact.

tbl

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. tbl must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained ens using sample data contained in a table, then the input data for this method must also be in a table.

ResponseVarName

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of tbl, including Y, as predictors when training the model.
Matrix of data to classify. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train ens. X should have the same number of rows as the number of elements in Y.

If you trained ens using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Class labels of observations in tbl or X. Y should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of tbl or X.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

**learners**

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. loss uses only these learners for calculating loss.

**Default:** 1:NumTrained

**Lossfun**

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
• If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```matlab
ens.ScoreTransform = 'doublelogit';
```

• For all other ensemble methods, the software does not support posterior probabilities as classification scores.

• Specify your own function using function handle notation.

Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(ens.ClassNames) \), \( ens \) is the input model). Your function must have this signature:

```matlab
lossvalue = lossfun(C,S,W,Cost)
```

where:

• The output argument `lossvalue` is a scalar.
• You choose the function name (`lossfun`).
• \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

• \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. \( S \) is a matrix of classification scores, similar to the output of `predict`.

• \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

• \( Cost \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( Cost = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3184.

**Default:** 'classiferror'

**mode**

Meaning of the output \( L \):

• 'ensemble' — \( L \) is a scalar value, the loss for the entire ensemble.
• 'individual' — \( L \) is a vector with one element per trained learner.
• 'cumulative' — \( L \) is a vector in which element \( J \) is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

**UseObsForLearner**

A logical matrix of size \( N \)-by-\( T \), where:
N is the number of rows of X.
T is the number of weak learners in ens.

When UseObsForLearner(i,j) is true, learner j is used in predicting the class of row i of X.
Default: true(N,T)

weights

Vector of observation weights, with nonnegative entries. The length of weights must equal the number of rows in X. When you specify weights, loss normalizes the weights so that observation weights in each class sum to the prior probability of that class.
Default: ones(size(X,1),1)

Output Arguments

L

Classification loss on page 32-3184, by default the fraction of misclassified data. L can be a vector; and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error

Load Fisher's iris data set.
load fisheriris
Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);

Estimate the classification error of the model using the training observations.
L = loss(ens,meas,species)
L = 0.0333

Alternatively, if ens is not compact, then you can estimate the training-sample classification error by passing ens to resubLoss.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.
• $L$ is the weighted average classification loss.
• $n$ is the sample size.
• For binary classification:
  • $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  • $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
• For algorithms that support multiclass classification (that is, $K \geq 3$):
  • $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 
 0 1 0]^\top$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  • $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  • $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,$$
\sum_{j=1}^{n} w_j = 1.
$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the ‘LossFun’ name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
</table>
| Binomial deviance      | 'binodeviance'   | $L = \sum_{j=1}^{n} w_j \log\{1 + \exp[-2m_j]\}$.
| Exponential loss       | 'exponential'    | $L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
| Classification error   | 'classiferror'   | $L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$.

It is the weighted fraction of misclassified observations where $\hat{y}_j$ is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.
<table>

loss

Classification error for naive Bayes classifier

Syntax

L = loss(Mdl,tbl,ResponseVarName)
L = loss(Mdl,tbl,Y)
L = loss(Mdl,X,Y)
L = loss(___,Name,Value)

Description

L = loss(Mdl,tbl,ResponseVarName) returns the minimum classification loss (see “Classification Loss” on page 32-3192), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data in table tbl as compared to the true class labels in tbl.ResponseVarName.

loss normalizes the class probabilities in tbl.ResponseVarName to the prior class probabilities fitcnb used for training, stored in the Prior property of Mdl.

L = loss(Mdl,tbl,Y) returns the minimum classification loss (L), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data in table tbl as compared to the true class labels in Y.

loss normalizes the class probabilities in Y to the prior class probabilities fitcnb used for training, stored in the Prior property of Mdl.

L = loss(Mdl,X,Y) returns the minimum classification loss (L), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data (X) as compared to the true class labels (Y).

loss normalizes the class probabilities in Y to the prior class probabilities fitcnb used for training, stored in the Prior property of Mdl.

L = loss(___,Name,Value) returns the classification loss with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier
ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by fitcnb or compact, respectively.

tbl — Sample data
table
Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional columns for the response variable and observation weights. tbl must contain all the predictors used to train Mdl. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained Mdl using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

**ResponseVarName — Response variable name**

Name of a variable in tbl

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored as tbl.y, then specify it as ‘y’. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**X — Predictor data**

Numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained Mdl.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

**Y — Class labels**

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of tbl or X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
**LossFun — Loss function**

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'Mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that `n` be the number of observations in `X` and `K` be the number of distinct classes (numel(`Mdl.ClassNames`), `Mdl` is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.
  Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
- `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an `n`-by-`1` numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
- `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

Specify your function using 'LossFun', `@lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3192.
Data Types: char | string | function_handle

Weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. The software weighs the observations in each row of X or tbl with the corresponding weight in Weights.

If you specify Weights as a vector, then the size of Weights must be equal to the number of rows of X or tbl.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify Weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you do not specify your own loss function, then the software normalizes Weights to add up to 1.

Data Types: double | char | string

Output Arguments

L — Classification loss
scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);      % For reproducibility

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...  
'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.
Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

L = loss(CMdl,XTest,YTest)

L = 0.0476

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.

Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1); % For reproducibility

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},... 'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

L = loss(CMdl,XTest,YTest,'LossFun','classiferror')
L = 0.0476

The classifier misclassified approximately 5% of the test sample observations.

More About
Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
• For binary classification:
  • \(y_j\) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • \(f(X_j)\) is the raw classification score for observation (row) \(j\) of the predictor data \(X\).
  • \(m_j = y_j f(X_j)\) is the classification score for classifying observation \(j\) into the class corresponding to \(y_j\). Positive values of \(m_j\) indicate correct classification and do not contribute much to the average loss. Negative values of \(m_j\) indicate incorrect classification and contribute significantly to the average loss.

• For algorithms that support multiclass classification (that is, \(K \geq 3\)):
  • \(y_j^*\) is a vector of \(K - 1\) zeros, with 1 in the position corresponding to the true, observed class \(y_j\). For example, if the true class of the second observation is the third class and \(K = 4\), then \(y_2^* = [0 0 1 0]^\prime\). The order of the classes corresponds to the order in the ClassNames property of the input model.
  • \(f(X_j)\) is the length \(K\) vector of class scores for observation \(j\) of the predictor data \(X\). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  • \(m_j = y_j^* f(X_j)\). Therefore, \(m_j\) is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation \(j\) is \(w_j\). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>(L = \sum_{j=1}^{n} w_j \log{1 + \exp[-2m_j]}).</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>(L = \sum_{j=1}^{n} w_j \exp(-m_j)).</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>(L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}).</td>
</tr>
</tbody>
</table>
  
  It is the weighted fraction of misclassified observations where \(\hat{y}_j\) is the class label corresponding to the class with the maximal posterior probability. \(I\{x\}\) is the indicator function.
<p>| Hinge loss         | 'hinge'          | (L = \sum_{j=1}^{n} w_j \max{0, 1 - m_j}). |</p>
<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>( L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j)). )</td>
</tr>
</tbody>
</table>
| Minimal cost    | 'mincost'        | Minimal cost. The software computes the weighted minimal cost using this procedure for observations \( j = 1, \ldots, n \).  
1. Estimate the 1-by-\( K \) vector of expected classification costs for observation \( j \):  
   \( y_j = f(X_j)C. \)  
   \( f(X) \) is the column vector of class posterior probabilities for binary and multiclass classification. \( C \) is the cost matrix that the input model stores in the Cost property.  
2. For observation \( j \), predict the class label corresponding to the minimum expected classification cost:  
   \( \hat{y}_j = \min_{j = 1, \ldots, k} (y_j). \)  
3. Using \( C \), identify the cost incurred \( (c_j) \) for making the prediction.  
The weighted, average, minimum cost loss is  
   \( L = \sum_{j=1}^{n} w_j c_j. \)  
| Quadratic loss  | 'quadratic'      | \( L = \sum_{j=1}^{n} w_j (1 - m_j)^2. \)                                 |

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through \([0,1]\).
Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let $K$ be the number of classes.

- True misclassification cost — A $K$-by-$K$ matrix, where element $(i,j)$ indicates the misclassification cost of predicting an observation into class $j$ if its true class is $i$. The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $Mdl.Cost(i,j) = 1$ if $i \neq j$, and $Mdl.Cost(i,j) = 0$ if $i = j$. In other words, the cost is $0$ for correct classification, and $1$ for any incorrect classification.

- Expected misclassification cost — A $K$-dimensional vector, where element $k$ is the weighted average misclassification cost of classifying an observation into class $k$, weighted by the class posterior probabilities. In other words,

$$ c_k = \sum_{j=1}^{K} \hat{P}(Y = j | x_1, ..., x_p)Cost_{jk}. $$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.
For naive Bayes, the posterior probability that a classification is $k$ for a given observation $(x_1, \ldots, x_p)$ is

$$
\hat{P}(Y = k | x_1, \ldots, x_p) = \frac{P(X_1, \ldots, X_p | y = k)\pi(Y = k)}{P(X_1, \ldots, X_p)},
$$

where:

- $P(X_1, \ldots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class $k$. Mdl.DistributionNames stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. Mdl.Prior stores the prior distribution.
- $P(X_1, \ldots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$
P(X_1, \ldots, X_p) = \sum_{k=1}^{K} P(X_1, \ldots, X_p | y = k)\pi(Y = k).
$$

**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

**References**

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see "Tall Arrays" (MATLAB).

“Naive Bayes Classification” on page 21-2
loss

**Package:** classreg.learning.classif

Find classification error for support vector machine (SVM) classifier

**Syntax**

\[
L = \text{loss}(	ext{SVMModel}, \text{TBL}, \text{ResponseVarName})
\]

\[
L = \text{loss}(	ext{SVMModel}, \text{TBL}, Y)
\]

\[
L = \text{loss}(	ext{SVMModel}, X, Y)
\]

\[
L = \text{loss}(\_\_\_, \text{Name}, \text{Value})
\]

**Description**

\[
L = \text{loss}(	ext{SVMModel}, \text{TBL}, \text{ResponseVarName})
\] returns the classification error (see “Classification Loss” on page 32-3202), a scalar representing how well the trained support vector machine (SVM) classifier (SVMModel) classifies the predictor data in table TBL compared to the true class labels in TBL.ResponseVarName.

loss normalizes the class probabilities in TBL.ResponseVarName to the prior class probabilities that fitcsvm used for training, stored in the Prior property of SVMModel.

The classification loss (L) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

\[
L = \text{loss}(	ext{SVMModel}, \text{TBL}, Y)
\] returns the classification error for the predictor data in table TBL and the true class labels in Y.

loss normalizes the class probabilities in Y to the prior class probabilities that fitcsvm used for training, stored in the Prior property of SVMModel.

\[
L = \text{loss}(	ext{SVMModel}, X, Y)
\] returns the classification error based on the predictor data in matrix X compared to the true class labels in Y.

\[
L = \text{loss}(\_\_\_, \text{Name}, \text{Value})
\] specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

**Examples**

**Determine Test Sample Classification Error of SVM Classifiers**

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```
Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```matlab
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},... 'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```matlab
L = loss(CompactSVMModel,XTest,YTest)
L = 0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample.

**Determine Test Sample Hinge Loss of SVM Classifiers**

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```matlab
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},... 'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```matlab
L = loss(CompactSVMModel,XTest,YTest,'LossFun','hinge')
L = 0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are preferred.
Input Arguments

**SVMMModel — SVM classification model**

*ClassificationSVM model object | CompactClassificationSVM model object*

SVM classification model, specified as a *ClassificationSVM* model object or *CompactClassificationSVM* model object returned by *fitcsvm* or *compact*, respectively.

**TBL — Sample data**

*table*

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMMModel using sample data contained in a table, then the input data for loss must also be in a table.

If you set 'Standardize',true in *fitcsvm* when training SVMMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMMModel.Mu and the standard deviations in SVMMModel.Sigma.

Data Types: table

**ResponseVarName — Response variable name**

*name of variable in TBL*

Response variable name, specified as the name of a variable in TBL.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as TBL.Y, then specify ResponseVarName as ‘Y’. Otherwise, the software treats all columns of TBL, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**X — Predictor data**

*numeric matrix*

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMMModel classifier.

The length of Y and the number of rows in X must be equal.
If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of SVMModel.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y must equal the number of rows in TBL or the number of rows in X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: loss(SVMModel,TBL,Y,'Weights',W) weighs the observations in each row of TBL using the corresponding weight in each row of the variable W in TBL.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

• This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior',true when you cross-validate the model using fitcsvm.

• Specify your own function by using function handle notation.
Suppose that \( n \) is the number of observations in \( X \), and \( K \) is the number of distinct classes (\( \text{numel}(	ext{SVMModel.ClassNames}) \)) used to create the input model (\text{SVMModel}). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\text{lossfun}).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in \text{SVMModel.ClassNames}.

  Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores, similar to the output of \text{predict}. The column order corresponds to the class order in \text{SVMModel.ClassNames}.

- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes the weights to sum to 1.

- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using \'LossFun',@\text{lossfun}.\n
For more details on loss functions, see “Classification Loss” on page 32-3202.

Example: \'LossFun','binodeviance'\n
Data Types: char | string | function_handle

**Weights — Observation weights**

\( \text{ones(size}(X,1),1) \) (default) | numeric vector | name of variable in \text{TBL} \n
Observation weights, specified as the comma-separated pair consisting of \'Weights' and a numeric vector or the name of a variable in \text{TBL}. The software weighs the observations in each row of \( X \) or \text{TBL} with the corresponding weight in \text{Weights}.

If you specify \text{Weights} as a numeric vector, then the size of \text{Weights} must be equal to the number of rows in \( X \) or \text{TBL}.

If you specify \text{Weights} as the name of a variable in \text{TBL}, you must do so as a character vector or string scalar. For example, if the weights are stored as \text{TBL.W}, then specify \text{Weights} as \'W\'. Otherwise, the software treats all columns of \text{TBL}, including \text{TBL.W}, as predictors.

If you do not specify your own loss function, then the software normalizes \text{Weights} to sum up to the value of the prior probability in the respective class.

Example: \'Weights','W'\n
Data Types: single | double | char | string
More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).
  - \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):
  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_2^* = [0 0 1 0]' \). The order of the classes corresponds to the order in the ClassNames property of the input model.
  - \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,
    \[
    \sum_{j=1}^{n} w_j = 1.
    \]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>( L = \sum_{j=1}^{n} w_j \log(1 + \exp(-2m_j)) ).</td>
</tr>
<tr>

</tr>
</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through [0,1].
### Classification Score

The SVM classification score for classifying observation $x$ is the signed distance from $x$ to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that $x$ is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for $x$, or the score for predicting $x$ into the positive class.

$$f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \ldots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between $x$ and the support vectors, and the sum includes the training set observations. The negative class classification score for $x$, or the score for predicting $x$ into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)\beta + b.$$

$s$ is the kernel scale and $\beta$ is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

$[L, \text{se}, \text{NLeaf}, \text{bestlevel}] = \text{loss}(\_\_\_)$

Description

$L = \text{loss}(\text{tree}, \text{TBL}, \text{ResponseVarName})$ returns a scalar representing how well tree classifies the data in TBL, when TBL.ResponseVarName contains the true classifications.

When computing the loss, loss normalizes the class probabilities in Y to the class probabilities used for training, stored in the Prior property of tree.

$L = \text{loss}(\text{tree}, \text{TBL}, Y)$ returns a scalar representing how well tree classifies the data in TBL, when Y contains the true classifications.

$L = \text{loss}(\text{tree}, X, Y)$ returns a scalar representing how well tree classifies the data in X, when Y contains the true classifications.

$L = \text{loss}(\_\_\_, \text{Name}, \text{Value})$ returns the loss with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

$[L, \text{se}, \text{NLeaf}, \text{bestlevel}] = \text{loss}(\_\_\_)$ also returns the vector of standard errors of the classification errors (se), the vector of numbers of leaf nodes in the trees of the pruning sequence (NLeaf), and the best pruning level as defined in the TreeSize name-value pair (bestlevel).

Note

loss returns se and further outputs only when the LossFun name-value pair is the default 'classiferror'.

Input Arguments

tree — Trained classification tree
ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, tree is a trained classification model returned by fitctree or compact.

TBL — Sample data
table
Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all the predictors used to train tree. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName or Y.

If you train tree using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

**X — Data to classify**

numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train tree. X must have the same number of rows as the number of elements in Y.

Data Types: single | double

**ResponseVarName — Response variable name**

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify it as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.ResponseVarName, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train tree, and its number of elements must equal the number of rows of X.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**LossFun — Loss function**

'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle
Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see predict).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (numel(tree.ClassNames)). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in tree.ClassNames.

Construct C by setting \(C(p,q) = 1\) if observation \(p\) is in class \(q\), for each row. Set all other elements of row \(p\) to 0.
- S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in tree.ClassNames. S is a matrix of classification scores, similar to the output of predict.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes them to sum to 1.
- Cost is a K-by-K numeric matrix of misclassification costs. For example, \(\text{Cost} = \text{ones}(K) - \text{eye}(K)\) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

For more details on loss functions, see “Classification Loss” on page 32-3213.

Data Types: char | string | function_handle

Weights — Observation weights

ones(size(X,1),1) (default) | name of a variable in TBL | numeric vector of positive values
Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or the name of a variable in TBL.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of rows in X or TBL.

If you specify Weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.W, then specify it as 'W'. Otherwise, the software treats all columns of TBL, including TBL.W, as predictors.

loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply Weights, loss computes weighted classification loss.

Data Types: single | double | char | string

Name,Value arguments associated with pruning subtrees:

**Subtrees** — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most max(tree.PruneList). 0 indicates the full, unpruned tree and max(tree.PruneList) indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then loss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using 0:max(tree.PruneList).

loss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune','on', or by pruning tree using prune.

Example: 'Subtrees','all'

Data Types: single | double | char | string

**TreeSize** — Tree size

'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- 'se' — loss returns the highest pruning level with loss within one standard deviation of the minimum (L+se, where L and se relate to the smallest value in Subtrees).
- 'min' — loss returns the element of Subtrees with smallest loss, usually the smallest element of Subtrees.

Output Arguments

**L** — Classification loss

vector of scalar values
Classification loss on page 32-3213, returned as a vector the length of Subtrees. The meaning of the error depends on the values in Weights and LossFun.

**se — Standard error of loss**
vector of scalar values

Standard error of loss, returned as a vector the length of Subtrees.

**NLeaf — Number of leaf nodes**
vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of Subtrees.

**bestlevel — Best pruning level**
scalar value

Best pruning level as defined in the TreeSize name-value pair, returned as a scalar whose value depends on TreeSize:

- TreeSize = 'se' — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (L+se, where L and se relate to the smallest value in Subtrees).
- TreeSize = 'min' — `loss` returns the element of Subtrees with smallest loss, usually the smallest element of Subtrees.

By default, bestlevel is the pruning level that gives loss within one standard deviation of minimal loss.

**Examples**

**Compute the In-sample Classification Error**

Compute the resubstituted classification error for the ionosphere data set.

```plaintext
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
L = 0.0114
```

**Examine the Classification Error for Each Subtree**

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

```plaintext
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
```
idxTrn(randsample(n,round(0.5*n))) = true;  % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices

Grow a classification tree using the training set.
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));

View the classification tree.
view(Mdl,'Mode','graph');

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
trnLoss = 3×1
• The full, unpruned tree misclassifies about 2.7% of the training observations.
• The tree pruned to level 1 misclassifies about 5.3% of the training observations.
• The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```matlab
valLoss = loss(Mdl, meas(idxVal,:), species(idxVal), 'SubTrees', 0:m)
valLoss = 3×1
0.0369
0.0237
0.3067
```

• The full, unpruned tree misclassifies about 3.7% of the validation observations.
• The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
• The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```matlab
pruneMdl = prune(Mdl, 'Level', 1);
view(pruneMdl, 'Mode', 'graph')
```
More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the
average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

Given this scenario, the following table describes the supported loss functions that you can specify by using the `LossFun` name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>

</tr>
<tr>
<td></td>
<td></td>
<td>( L = \sum_{j=1}^{n} w_j c_j. )</td>
</tr>
</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through \([0,1]\).
True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the Cost name-value pair when you create the classifier using the fitctree method. Cost(i,j) is the cost of classifying an observation into class j if its true class is i. By default, Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier. Suppose you have K classes. You place the observations into a matrix Xnew with one observation per row.

The expected cost matrix CE has size Nobs-by-K. Each row of CE contains the expected (average) cost of classifying the observation into each of the K classes. CE(n,k) is

$$
\sum_{i=1}^{K} \hat{P}(i|Xnew(n))C(k|i),
$$

where
• $K$ is the number of classes.
• $\hat{P}(i|X_{new}(n))$ is the posterior probability of class $i$ for observation $X_{new}(n)$.
• $C(k|i)$ is the true misclassification cost of classifying an observation as $k$ when its true class is $i$.

**Score (tree)**

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

![Classification tree viewer](image)

**Click to display:** Identify

**Magnification:** 100%

**Pruning level:** 0 of 2

```matlab
loss
```
Prune the tree:

tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]

ans = 10×3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
    0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range (0.95, 1) instead of the expected 5 observations.

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:
- Only one output is supported.
- You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

**See Also**
edge | fitctree | margin | predict
**loss**

Regression error

**Syntax**

\[
L = \text{loss}(\text{ens}, \text{tbl}, \text{ResponseVarName})
\]

\[
L = \text{loss}(\text{ens}, \text{tbl}, Y)
\]

\[
L = \text{loss}(\text{ens}, X, Y)
\]

\[
L = \text{loss}(\_\_\_, \text{Name}, \text{Value})
\]

**Description**

\[
L = \text{loss}(\text{ens}, \text{tbl}, \text{ResponseVarName})
\] returns the mean squared error between the predictions of \(\text{ens}\) to the data in \(\text{tbl}\), compared to the true responses \(\text{tbl}.\text{ResponseVarName}\).

\[
L = \text{loss}(\text{ens}, \text{tbl}, Y)
\] returns the mean squared error between the predictions of \(\text{ens}\) to the data in \(\text{tbl}\), compared to the true responses \(Y\).

\[
L = \text{loss}(\text{ens}, X, Y)
\] returns the mean squared error between the predictions of \(\text{ens}\) to the data in \(X\), compared to the true responses \(Y\).

\[
L = \text{loss}(\_\_\_, \text{Name}, \text{Value})
\] computes the error in prediction with additional options specified by one or more \text{Name,Value} pair arguments, using any of the previous syntaxes.

**Input Arguments**

\(\text{ens}\)

A regression ensemble created with \text{fitensemble}, or the \text{compact} method.

\(\text{tbl}\)

Sample data, specified as a table. Each row of \(\text{tbl}\) corresponds to one observation, and each column corresponds to one predictor variable. \(\text{tbl}\) must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained \(\text{ens}\) using sample data contained in a \text{table}, then the input data for this method must also be in a table.

\(\text{ResponseVarName}\)

Response variable name, specified as the name of a variable in \(\text{tbl}\). The response variable must be a numeric vector.

You must specify \text{ResponseVarName} as a character vector or string scalar. For example, if the response variable \(Y\) is stored as \(\text{tbl}.Y\), then specify it as '\(Y\)'. Otherwise, the software treats all columns of \(\text{tbl}\), including \(Y\), as predictors when training the model.
A matrix of predictor values. Each column of $X$ represents one variable, and each row represents one observation.

NaN values in $X$ are taken to be missing values. Observations with all missing values for $X$ are not used in the calculation of loss.

If you trained ens using sample data contained in a matrix, then the input data for this method must also be in a matrix.

$Y$

A numeric column vector with the same number of rows as $tbl$ or $X$. Each entry in $Y$ is the response to the data in the corresponding row of $tbl$ or $X$.

NaN values in $Y$ are taken to be missing values. Observations with missing values for $Y$ are not used in the calculation of loss.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**learners**

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

**Default:** 1:NumTrained

**lossfun**

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, loss calls it as

func($Y$, $Yfit$, $W$)

where $Y$, $Yfit$, and $W$ are numeric vectors of the same length.

- $Y$ is the observed response.
- $Yfit$ is the predicted response.
- $W$ is the observation weights.

The returned value func($Y$, $Yfit$, $W$) should be a scalar.

**Default:** 'mse'

**mode**

Meaning of the output L:

- 'ensemble' — $L$ is a scalar value, the loss for the entire ensemble.
- 'individual' — $L$ is a vector with one element per trained learner.
• 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

**UseObsForLearner**

A logical matrix of size N-by-NumTrained, where N is the number of observations in ens.X, and NumTrained is the number of weak learners. When UseObsForLearner(I,J) is true, predict uses learner J in predicting observation I.

**Default:** true(N,NumTrained)

**weights**

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in “Weighted Mean Squared Error” on page 32-3222.

**Default:** ones(size(Y))

**Output Arguments**

**L**

Weighted mean squared error of predictions. The formula for loss is in “Weighted Mean Squared Error” on page 32-3222.

**Examples**

**Find Mean-Squared Error of Ensemble Predictions**

Find the loss of an ensemble predictor using the carsmall data set.

Load the carsmall data set and select engine displacement, horsepower, and vehicle weight as predictors.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees and find the regression error for predicting MPG.

```matlab
ens = fitrensemble(X,MPG);
L = loss(ens,X,MPG)
L = 0.3463
```

**More About**

**Weighted Mean Squared Error**

Let n be the number of rows of data, $x_j$ be the jth row of data, $y_j$ be the true response to $x_j$, and let $f(x_j)$ be the response prediction of ens to $x_j$. Let $w$ be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \rightarrow w/\sum w$. The mean squared error $L$ is
\[ L = \sum_{j=1}^{n} w_{j}(f(x_j) - y_j)^2. \]

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

fitrensemble | predict
**loss**

Regression error for Gaussian process regression model

**Syntax**

\[
L = \text{loss}(\text{gprMdl},X_{\text{new}},Y_{\text{new}}) \\
L = \text{loss}(\text{gprMdl},X_{\text{new}},Y_{\text{new}},\text{Name,Value})
\]

**Description**

\[
L = \text{loss}(\text{gprMdl},X_{\text{new}},Y_{\text{new}})
\]

returns the mean squared error for the Gaussian process regression (GPR) model \(\text{gpr}\), using the predictors in \(X_{\text{new}}\) and observed response in \(Y_{\text{new}}\).

\[
L = \text{loss}(\text{gprMdl},X_{\text{new}},Y_{\text{new}},\text{Name,Value})
\]

returns the mean squared error for the GPR model, \(\text{gpr}\), with additional options specified by one or more \text{Name,Value} pair arguments. For example, you can specify a custom loss function or the observation weights.

**Input Arguments**

- **gprMdl** — Gaussian process regression model
  
  Gaussian process regression model, specified as a RegressionGP (full) or CompactRegressionGP (compact) object.

- **Xnew** — New observed data
  
  New data, specified as a table or an \(m\)-by-\(d\) matrix, where \(m\) is the number of observations, and \(d\) is the number of predictor variables in the training data.

  If you trained \(\text{gprMdl}\) on a table, then \(X_{\text{new}}\) must be a table that contains all the predictor variables used to train \(\text{gprMdl}\).

  If \(X_{\text{new}}\) is a table, then it can also contain \(Y_{\text{new}}\). And if it does, then you do not have to specify \(Y_{\text{new}}\).

  If you trained \(\text{gprMdl}\) on a matrix, then \(X_{\text{new}}\) must be a numeric matrix with \(d\) columns, and can only contain values for the predictor variables.

  Data Types: single | double | table

- **Ynew** — New response values
  
  \(n\)-by-1 vector

  New observed response values, that correspond to the predictor values in \(X_{\text{new}}\), specified as an \(n\)-by-1 vector. \(n\) is the number of rows in \(X_{\text{new}}\). Each entry in \(Y_{\text{new}}\) is the observed response based on the predictor data in the corresponding row of \(X_{\text{new}}\).

  If \(X_{\text{new}}\) is a table containing new response values, you do not have to specify \(Y_{\text{new}}\).

  Data Types: single | double
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

lossfun — Loss function
'mse' (default) | function handle

Loss function, specified as 'mse' (mean squared error) or a function handle.

If you pass a function handle, say fun, loss calls it as shown below: fun(Y,Ypred,W), where Y, Ypred and W are numeric vectors of length n, and n is the number of rows in Xnew. Y is the observed response, Ypred is the predicted response, and W is the observation weights.

Example: 'lossfun',Fct calls the loss function Fct.

Data Types: char | string | function_handle

weights — Observation weights
vector of 1s (default) | n-by-1 vector

Observation weights, specified as n-by-1 vector, where n is the number of rows in Xnew. By default, the weight of each observation is 1.

Example: 'weights',W uses the observation weights in vector W.

Data Types: double | single

Output Arguments

L — Regression error
scalar value

Regression error for the trained Gaussian process regression model, gprMdl, returned as a scalar value.

Examples

Compute Regression Loss for Test Data

Load the sample data.

load('gprdata.mat')

The data has 8 predictor variables and contains 500 observations in training data and 100 observations in test data. This is simulated data.

Fit a GPR model using the squared exponential kernel function with separate length scales for each predictor. Standardize the predictor values in the training data. Use the exact method for fitting and prediction.

```
gprMdl = fitrgp(Xtrain,ytrain,'FitMethod','exact',...
    'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
    'Standardize',1);
```
Compute the regression error for the test data.

\[ L = \text{loss(gprMdl,Xtest,ytest)} \]

\[ L = 0.6928 \]

Predict the responses for test data.

\[ ypredtest = \text{predict(gprMdl,Xtest);} \]

Plot the test response along with the predictions.

\[ \text{figure; plot(ytest,'r'); hold on; plot(ypredtest,'b'); legend('Data','Predictions','Location','Best');} \]

Manually compute the regression loss.

\[ L = (ytest - ypredtest)'*(ytest - ypredtest)/\text{length(ytest)} \]

\[ L = 0.6928 \]
Specify Custom Loss Function

Load the sample data and store in a table.

```matlab
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
    'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```matlab
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```matlab
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```matlab
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = loss(mdl,tbl,'lossfun',fun)
L = 0.2345
```

Alternatives

You can use `resubLoss` to compute the regression error for the trained GPR model at the observations in the training data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

See Also

`CompactRegressionGP` | `RegressionGP` | `compact` | `fitrgp` | `predict` | `resubLoss`

Introduced in R2015b
loss

Regression error for support vector machine regression model

Syntax

$L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})$
$L = \text{loss}(\text{mdl}, \text{tbl}, \text{Y})$
$L = \text{loss}(\text{mdl}, \text{X}, \text{Y})$
$L = \text{loss}(\text{___}, \text{Name}, \text{Value})$

Description

$L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})$ returns the loss for the predictions of the support vector machine (SVM) regression model, $\text{mdl}$, based on the predictor data in the table $\text{tbl}$ and the true response values in $\text{tbl.ResponseVarName}$. 

$L = \text{loss}(\text{mdl}, \text{tbl}, \text{Y})$ returns the loss for the predictions of the support vector machine (SVM) regression model, $\text{mdl}$, based on the predictor data in the table $\text{X}$ and the true response values in the vector $\text{Y}$. 

$L = \text{loss}(\text{mdl}, \text{X}, \text{Y})$ returns the loss for the predictions of the support vector machine (SVM) regression model, $\text{mdl}$, based on the predictor data in $\text{X}$ and the true responses in $\text{Y}$. 

$L = \text{loss}(\text{___}, \text{Name}, \text{Value})$ returns the loss with additional options specified by one or more $\text{Name,Value}$ pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

Input Arguments

$\text{mdl}$ — SVM regression model
RegressionSVM model | CompactRegressionSVM model

SVM regression model, specified as a RegressionSVM model or CompactRegressionSVM model returned by fitrsvm or compact, respectively.

$\text{tbl}$ — Sample data

table

Sample data, specified as a table. Each row of $\text{tbl}$ corresponds to one observation, and each column corresponds to one predictor variable. Optionally, $\text{tbl}$ can contain additional columns for the response variable and observation weights. $\text{tbl}$ must contain all of the predictors used to train $\text{mdl}$. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained $\text{mdl}$ using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

$\text{ResponseVarName}$ — Response variable name

name of a variable in $\text{tbl}$
Response variable name, specified as the name of a variable in tbl. The response variable must be a numeric vector.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as tbl.Y, then specify ResponseVarName as ‘Y’. Otherwise, the software treats all columns of tbl, including Y, as predictors when training the model.

Data Types: char | string

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix or table. Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

If you trained mdl using a matrix of predictor values, then X must be a numeric matrix with p columns. p is the number of predictors used to train mdl.

The length of Y and the number of rows of X must be equal.

Data Types: single | double

**Y — Observed response values**
vector of numeric values

Observed response values, specified as a vector of length n containing numeric values. Each entry in Y is the observed response based on the predictor data in the corresponding row of X.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**LossFun — Loss function**
'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'mse', 'epsiloninsensitive', or a function handle.

- The following table lists the available loss functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Loss Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mse'</td>
<td>“Weighted Mean Squared Error” on page 32-3231</td>
</tr>
<tr>
<td>'epsiloninsensitive'</td>
<td>“Epsilon-Insensitive Loss Function” on page 32-3231</td>
</tr>
</tbody>
</table>

- Specify your own function using function handle notation.

Your function must have the signature lossvalue = lossfun(Y,Yfit,W), where:
The output argument `lossvalue` is a scalar value.
You choose the function name (`lossfun`).
`Y` is an `n`-by-1 numeric vector of observed response values.
`Yfit` is an `n`-by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in `X` (similar to the output of `predict`).
`W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.

Specify your function using `'LossFun',@lossfun`.

Example: `'LossFun','epsiloninsensitive'`

Data Types: `char` | `string` | `function_handle`

**Weights** — Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` must be the same length as the number of rows in `X`. The software weights the observations in each row of `X` using the corresponding weight value in `Weights`.

Weights are normalized to sum to 1.

Data Types: `single` | `double`

**Output Arguments**

**L** — Regression loss

scalar value

Regression loss, returned as a scalar value.

**Examples**

**Calculate Test Sample Loss for SVM Regression Model**

This example shows how to train an SVM regression model, then calculate the resubstitution mean square error and epsilon-insensitive error.

Load the `carsmall` sample data.

```matlab
load carsmall
rng default  % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`), and `MPG` as the response variable (`Y`).

```matlab
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. Standardize the data.

```matlab
mdl = fitrsvm(X,Y,'Standardize',true);
```

`mdl` is a ` RegressionSVM` model.
Determine how well the trained model generalizes to new predictor values by estimating the test sample mean square error and epsilon-insensitive error:

\[
\text{lossMSE} = \text{loss}(	ext{mdl},X,Y) \\
\text{lossEI} = \text{loss}(	ext{mdl},X,Y,'LossFun','epsiloninsensitive')
\]

\[
\text{lossMSE} = 17.0256 \\
\text{lossEI} = 2.2506
\]

**More About**

**Weighted Mean Squared Error**

The weighted mean squared error is calculated as follows:

\[
mse = \frac{\sum_{j=1}^{n} w_j (f(x_j) - y_j)^2}{\sum_{j=1}^{n} w_j},
\]

where:

- \( n \) is the number of rows of data
- \( x_j \) is the \( j \)th row of data
- \( y_j \) is the true response to \( x_j \)
- \( f(x_j) \) is the response prediction of the SVM regression model \( \text{mdl} \) to \( x_j \)
- \( w \) is the vector of weights.

The weights in \( w \) are all equal to one by default. You can specify different values for weights using the `Weights` name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

**Epsilon-Insensitive Loss Function**

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (\( \varepsilon \)) of the function value. It is formally described as:

\[
Loss_{\varepsilon} = \begin{cases} 
0, & \text{if } |y - f(x)| \leq \varepsilon \\
|y - f(x)| - \varepsilon, & \text{otherwise}.
\end{cases}
\]

The mean epsilon-insensitive loss is calculated as follows:

\[
Loss = \frac{\sum_{j=1}^{n} w_j \max(0, |y_j - f(x_j)| - \varepsilon)}{\sum_{j=1}^{n} w_j},
\]
where:

- \( n \) is the number of rows of data
- \( x_j \) is the \( j \)th row of data
- \( y_j \) is the true response to \( x_j \)
- \( f(x_j) \) is the response prediction of the SVM regression model \( mdl \) to \( x_j \)
- \( w \) is the vector of weights.

The weights in \( w \) are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

**Tips**

- If \( mdl \) is a cross-validated RegressionPartitionedSVM model, use \( kfoldLoss \) instead of \( loss \) to calculate the regression error.

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

CompactRegressionSVM | RegressionSVM | fitrsvm | kfoldLoss

*Introduced in R2015b*
**loss**

Regression error

**Syntax**

\[ L = \text{loss} \left( \text{tree}, \text{tbl}, \text{ResponseVarName} \right) \]  
\[ L = \text{loss} \left( \text{tree}, x, y \right) \]  
\[ L = \text{loss} \left( \_\_\_, \text{Name,Value} \right) \]  
\[ [L, se, NLeaf, bestlevel] = \text{loss} \left( \_\_\_ \right) \]

**Description**

\[ L = \text{loss} \left( \text{tree}, \text{tbl}, \text{ResponseVarName} \right) \] returns the mean squared error between the predictions of \text{tree} to the data in \text{tbl}, compared to the true responses \text{tbl.ResponseVarName}.

\[ L = \text{loss} \left( \text{tree}, x, y \right) \] returns the mean squared error between the predictions of \text{tree} to the data in \text{x}, compared to the true responses \text{y}.

\[ L = \text{loss} \left( \_\_\_, \text{Name,Value} \right) \] computes the error in prediction with additional options specified by one or more \text{Name,Value} pair arguments, using any of the previous syntaxes.

\[ [L, se, NLeaf, bestlevel] = \text{loss} \left( \_\_\_ \right) \] also returns the standard error of the loss (se), the number of leaves (terminal nodes) in the tree (NLeaf), and the optimal pruning level for \text{tree} (bestlevel).

**Input Arguments**

- **tree** — Trained regression tree  
  RegressionTree object | CompactRegressionTree object  
  Trained regression tree, specified as a RegressionTree object constructed by \text{fitrtree} or a CompactRegressionTree object constructed by \text{compact}.

- **x** — Predictor values  
  matrix of floating-point values  
  Predictor values, specified as matrix of floating-point values. Each column of \text{x} represents one variable, and each row represents one observation.
  Data Types: single | double

- **ResponseVarName** — Response variable name  
  name of a variable in \text{tbl}  
  Response variable name, specified as the name of a variable in \text{tbl}.
  You must specify \text{ResponseVarName} as a character vector or string scalar. For example, if the response variable \text{y} is stored as \text{tbl.y}, then specify \text{ResponseVarName} as '\text{y}' . Otherwise, the software treats all columns of \text{tbl}, including \text{y}, as predictors when training the model.
  Data Types: char | string
**y — Response data**

Response data, specified as a numeric column vector with the same number of rows as x. Each entry in y is the response to the data in the corresponding row of x.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**LossFun — Loss function**

`'mse'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle for loss, or 'mse' representing mean-squared error. If you pass a function handle fun, loss calls fun as:

```matlab
fun(Y,Yfit,W)
```

- Y is the vector of true responses.
- Yfit is the vector of predicted responses.
- W is the observation weights. If you pass W, the elements are normalized to sum to 1.

All the vectors have the same number of rows as Y.

Example: `'LossFun','mse'`

Data Types: function_handle | char | string

**Subtrees — Pruning level**

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then loss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

loss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune','on', or by pruning tree using prune.

Example: `'Subtrees','all'`

Data Types: single | double | char | string
**TreeSize — Tree size**

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

Example: `'TreeSize','min'`

**Weights — Observation weights**

`ones(size(X,1),1)` (default) | vector of scalar values | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `x` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `x` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a variable name. For example, if weights vector `W` is stored as `tbl.W`, then specify `Weights` as `'W'`. Otherwise, the software treats all columns of `tbl`, including `W`, as predictors when training the model.

Data Types: `single` | `double` | `char` | `string`

**Output Arguments**

**L — Classification error**

vector of scalar values

Classification error, returned as a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

**se — Standard error of loss**

vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

**NLeaf — Number of leaf nodes**

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

**bestlevel — Best pruning level**

scalar value

Best pruning level as defined in the `TreeSize name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (L+se, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.  

32-3235
Examples

Compute the In-Sample MSE

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using all observations.
tree = fitrtree(X,MPG);

Estimate the in-sample MSE.
L = loss(tree,X,MPG)
L = 4.8952

Find the Pruning Level Yielding the Optimal In-sample Loss

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using all observations.
Mdl = fitrtree(X,MPG);

View the regression tree.
view(Mdl,'Mode','graph');
Find the best pruning level that yields the optimal in-sample loss.

```matlab
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG,'Subtrees','all');
bestLevel = 1
```

The best pruning level is level 1.

Prune the tree to level 1.

```matlab
pruneMdl = prune(Mdl,'Level',bestLevel);
view(pruneMdl,'Mode','graph');
```
Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;

Partition the data into training (50%) and validation (50%) sets.

n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices

Grow a regression tree using the training set.
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));

View the regression tree.
view(Mdl,'Mode','graph');

The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)

trnLoss = 7x1

5.9789
- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```matlab
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

```matlab
valLoss = 7×1
32.1205
31.5035
32.0541
30.8183
26.3535
30.0137
38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 4.

```matlab
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```
More About

Mean Squared Error

The mean squared error $m$ of the predictions $f(X_n)$ with weight vector $w$ is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Only one output is supported.
• You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays” (MATLAB).

**See Also**

fitrtree|predict
loss

Class: FeatureSelectionNCAClassification

Evaluate accuracy of learned feature weights on test data

Syntax

err = loss(mdl,X,Y)
err = loss(mdl,X,Y,Name,Value)

Description

err = loss(mdl,X,Y) computes the misclassification error of the model mdl, for the predictors in X and the class labels in Y.

err = loss(mdl,X,Y,Name,Value) computes the classification error with additional options specified by one or more Name,Value pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

X — Predictor variable values

n-by-p matrix

Predictor variable values, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables.

Data Types: single|double

Y — Class labels

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length n | character matrix with n rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length n, or character matrix with n rows, where n is the number of observations. Element i or row i of Y is the class label corresponding to row i of X (observation i).

Data Types: single|double|logical|char|string|cell|categorical

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
**LossFunction — Loss function type**

'classiferror' (default) | 'quadratic'

Loss function type, specified as a comma-separated pair consisting of 'Loss Function' and one of the following.

- 'classiferror' — Misclassification error, defined as
  \[
  \frac{1}{n} \sum_{i=1}^{n} I(k_i \neq t_i),
  \]
  where \(k_i\) is the predicted class and \(t_i\) is the true class for observation \(i\). \(I(k_i \neq t_i)\) is the indicator for when the \(k_i\) is not the same as \(t_i\).

- 'quadratic' — Quadratic loss function, defined as
  \[
  \frac{1}{n} \sum_{i=1}^{n} \sum_{k=1}^{c} (p_{ik} - I(i,k))^2,
  \]
  where \(c\) is the number of classes, \(p_{ik}\) is the estimate probability that \(i\)th observation belongs to class \(k\), and \(I(i,k)\) is the indicator that \(i\)th observation belongs to class \(k\).

Example: 'LossFunction','quadratic'

**Output Arguments**

**err** — Smaller-the-better accuracy measure for learned feature weights

scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the **LossFunction** name-value pair argument.

**Examples**

**Tune NCA Model for Classification**

Load the sample data.

```matlab
load('twodimclassdata.mat');
```

This data set is simulated using the scheme described in [1]. This is a two-class classification problem in two dimensions. Data from the first class (class -1) are drawn from two bivariate normal distributions \(N(\mu_1, \Sigma)\) or \(N(\mu_2, \Sigma)\) with equal probability, where \(\mu_1 = [-0.75, -1.5]\), \(\mu_2 = [0.75, 1.5]\), and \(\Sigma = I_2\). Similarly, data from the second class (class 1) are drawn from two bivariate normal distributions \(N(\mu_3, \Sigma)\) or \(N(\mu_4, \Sigma)\) with equal probability, where \(\mu_3 = [1.5, -1.5]\), \(\mu_4 = [-1.5, 1.5]\), and \(\Sigma = I_2\). The normal distribution parameters used to create this data set result in tighter clusters in data than the data used in [1].

Create a scatter plot of the data grouped by the class.

```matlab
figure
gscatter(X(:,1),X(:,2),y)
```
Add 100 irrelevant features to $X$. First generate data from a Normal distribution with a mean of 0 and a variance of 20.

```matlab
n = size(X,1);
rng('default')
XwithBadFeatures = [X,randn(n,100)*sqrt(20)];
```

Normalize the data so that all points are between 0 and 1.

```matlab
XwithBadFeatures = bsxfun(@rdivide,...
    bsxfun(@minus,XwithBadFeatures,min(XwithBadFeatures,[],1)), ...
    range(XwithBadFeatures,1));
X = XwithBadFeatures;
```

Fit a neighborhood component analysis (NCA) model to the data using the default Lambda (regularization parameter, $\lambda$) value. Use the LBFGS solver and display the convergence information.

```matlab
ncamdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
    'Solver','lbfgs');
```

```
Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

Infinity norm of the final gradient = 9.404e-08
Two norm of the final step     = 8.947e-04, TolX   = 1.000e-06
Relative infinity norm of the final gradient = 9.404e-08, TolFun = 1.000e-06
EXIT: Local minimum found.

Plot the feature weights. The weights of the irrelevant features should be very close to zero.

```matlab
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

![Feature weights plot](image)

Predict the classes using the NCA model and compute the confusion matrix.
ypred = predict(ncaMdl,X);
confusionchart(y,ypred)

Confusion matrix shows that 40 of the data that are in class -1 are predicted as belonging to class -1. 60 of the data from class -1 are predicted to be in class 1. Similarly, 94 of the data from class 1 are predicted to be from class 1 and 6 of them are predicted to be from class -1. The prediction accuracy for class -1 is not good.

All weights are very close to zero, which indicates that the value of λ used in training the model is too large. When $\lambda \to \infty$, all features weights approach to zero. Hence, it is important to tune the regularization parameter in most cases to detect the relevant features.

Use five-fold cross-validation to tune λ for feature selection by using fscnca. Tuning λ means finding the λ value that will produce the minimum classification loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, cvpartition assigns four-fifths of the data as a training set and one-fifth of the data as a test set. Again for each fold, cvpartition creates a stratified partition, where each partition has roughly the same proportion of classes.

```matlab
cvp = cvpartition(y,'kfold',5);
numtestsets = cvp.NumTestSets;
lambdavalues = linspace(0,2,20)/length(y);
lossvalues = zeros(length(lambdavalues),numtestsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.
3. Compute the classification loss for the corresponding test set in the fold using the nca model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```matlab
for i = 1:length(lambdavalues)
    for k = 1:numtestsets
        % Extract the training set from the partition object
        Xtrain = X(cvp.training(k),:);
        ytrain = y(cvp.training(k),:);

        % Extract the test set from the partition object
        Xtest  = X(cvp.test(k),:);
        ytest  = y(cvp.test(k),:);

        % Train an NCA model for classification using the training set
        ncaMdl = fscnca(Xtrain,ytrain,'FitMethod','exact',...
                        'Solver','lbfgs','Lambda',lambdavalues(i));

        % Compute the classification loss for the test set using the NCA
        % model
        lossvalues(i,k) = loss(ncaMdl,Xtest,ytest, ... 
                               'LossFunction','quadratic');
    end
end
```

Plot the average loss values of the folds versus the λ values. If the λ value that corresponds to the minimum loss falls on the boundary of the tested λ values, the range of λ values should be reconsidered.

```matlab
figure
plot(lambdavalues,mean(lossvalues,2),'ro-')
xlabel('Lambda values')
ylabel('Loss values')
grid on
```
Find the $\lambda$ value that corresponds to the minimum average loss.

\[
[-, \text{idx}] = \text{min}(\text{mean}(\text{lossvalues}, 2)); \quad \% \text{Find the index}
\]

\[
\text{bestlambda} = \text{lambdavalues}(\text{idx}) \quad \% \text{Find the best lambda value}
\]

\[
\text{bestlambda} = 0.0037
\]

Fit the NCA model to all of the data using the best $\lambda$ value. Use the LBFGS solver and display the convergence information.

\[
\text{ncaMdl} = \text{fscnca}(X, y, '\text{FitMethod}', '\text{exact}', '\text{Verbose}', 1, \ldots
\quad \text{\emph{Solver}}', '\text{lbfgs}', '\text{Lambda}', \text{bestlambda});
\]

\[
\text{o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe}
\]
Plot the feature weights.

```matlab
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```
fscnca correctly figures out that the first two features are relevant and that the rest are not. The first two features are not individually informative, but when taken together result in an accurate classification model.

Predict the classes using the new model and compute the accuracy.

```matlab
ypred = predict(ncaMdl,X);
confusionchart(y,ypred)
```
Confusion matrix shows that prediction accuracy for class -1 has improved. 88 of the data from class -1 are predicted to be from -1, and 12 of them are predicted to be from class 1. 92 of the data from class 1 are predicted to be from class 1 and 8 of them are predicted to be from class -1.

FeatureSelectionNCAClassification | fscnca | predict | refit

Introduced in R2016b
loss

Class: FeatureSelectionNCARegression
Evaluate accuracy of learned feature weights on test data

Syntax

err = loss(mdl,X,Y)
err = loss(mdl,X,Y,Name,Value)

Description

err = loss(mdl,X,Y) returns the mean squared error as the measure of accuracy in err, for the
model mdl, predictor values in X, and response values in Y.

err = loss(mdl,X,Y,Name,Value) returns the measure of accuracy, err, with the additional
option specified by the Name,Value pair argument.

Input Arguments

mdl — Neighborhood component analysis model for regression
FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, specified as a
FeatureSelectionNCARegression object.

X — Predictor variable values
n-by-p matrix

Predictor variable values, specified as an n-by-p matrix, where n is the number of observations and p
is the number of predictor variables.

Data Types: single | double

Y — Response values
numeric real vector of length n

Response values, specified as a numeric real vector of length n, where n is the number of
observations.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and
Value is the corresponding value. Name must appear inside quotes. You can specify several name and
value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

LossFunction — Loss function type

'mse' (default) | 'mad'
Loss function type, specified as a comma-separated pair consisting of 'Loss Function' and one of the following.

<table>
<thead>
<tr>
<th>Loss Function Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mse'</td>
<td>Mean squared error</td>
</tr>
<tr>
<td>'mad'</td>
<td>Mean absolute deviation</td>
</tr>
</tbody>
</table>

Example: 'LossFunction','mse'

Output Arguments

err — Smaller-the-better accuracy measure for learned feature weights
scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the LossFunction name-value pair argument.

Examples

Tune NCA Model for Regression Using loss and predict

Load the sample data.

Download the housing data [1], from the UCI Machine Learning Repository [2]. The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```matlab
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Divide the data into training and test sets using the 4th predictor as the grouping variable for a stratified partitioning. This ensures that each partition includes similar amount of observations from each group.

```matlab
rng(1) % For reproducibility
cvp = cvpartition(X(:,4),'Holdout',56);
Xtrain = X(cvp.training,:);
ytrain = y(cvp.training,:);
Xtest  = X(cvp.test,:);
ytest  = y(cvp.test,:);
```

cvpartition randomly assigns 56 observations into a test set and the rest of the data into a training set.

Perform Feature Selection Using Default Settings

Perform feature selection using NCA model for regression. Standardize the predictor values.

```matlab
nca = fsrnca(Xtrain,ytrain,'Standardize',1);
```
Plot the feature weights.

```matlab
figure()
pplot(nca.FeatureWeights,'ro')
```

The weights of irrelevant features are expected to approach zero. `fsrnca` identifies two features as irrelevant.

Compute the regression loss.

```matlab
L = loss(nca,Xtest,ytest,'LossFunction','mad')
L = 2.5394
```

Compute the predicted response values for the test set and plot them versus the actual response.

```matlab
ypred = predict(nca,Xtest);
figure()
pplot(ypred,ytest,'bo')
xlabel('Predicted response')
ylabel('Actual response')
```
A perfect fit versus the actual values forms a 45 degree straight line. In this plot, the predicted and actual response values seem to be scattered around this line. Tuning $\lambda$ (regularization parameter) value usually helps improve the performance.

**Tune the regularization parameter using 10-fold cross-validation**

Tuning $\lambda$ means finding the $\lambda$ value that will produce the minimum regression loss. Here are the steps for tuning $\lambda$ using 10-fold cross-validation:

1. First partition the data into 10 folds. For each fold, `cvpartition` assigns 1/10th of the data as a training set, and 9/10th of the data as a test set.

   ```
   n = length(ytrain);
   cvp = cvpartition(Xtrain(:,4),'kfold',10);
   numvalidsets = cvp.NumTestSets;
   ```

   Assign the $\lambda$ values for the search. Create an array to store the loss values.

   ```
   lambdavals = linspace(0,2,30)*std(ytrain)/n;
   lossvals = zeros(length(lambdavals),numvalidsets);
   ```

2. Train the neighborhood component analysis (nca) model for each $\lambda$ value using the training set in each fold.

3. Fit a Gaussian process regression (gpr) model using the selected features. Next, compute the regression loss for the corresponding test set in the fold using the gpr model. Record the loss value.
4. Repeat this for each $\lambda$ value and each fold.

```matlab
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y,'FitMethod','exact',...
                     'Lambda',lambdavals(i),...
                     'Standardize',1,'LossFunction','mad');

        % Select features using the feature weights and a relative threshold.
        tol    = 1e-3;
        selidx = nca.FeatureWeights > tol*max(1,max(nca.FeatureWeights));

        % Fit a non-ARD GPR model using selected features.
        gpr = fitrgp(X(:,selidx),y,'Standardize',1,....
                     'KernelFunction','squaredexponential','Verbose',0);

        lossvals(i,k) = loss(gpr,Xvalid(:,selidx),yvalid);
    end
end

Compute the average loss obtained from the folds for each $\lambda$ value. Plot the mean loss versus the $\lambda$ values.

```matlab
meanloss = mean(lossvals,2);
figure;
plot(lambdavals,meanloss,'ro-');
xlabel('Lambda');
ylabel('Loss (MSE)');
grid on;
```
Find the $\lambda$ value that produces the minimum loss value.

```matlab
[-,idx] = min(meanloss);
bestlambda = lambdavals(idx)
```

`bestlambda = 0.0251`

Perform feature selection for regression using the best $\lambda$ value. Standardize the predictor values.

```matlab
nca2 = fsrnca(Xtrain,ytrain,'Standardize',1,'Lambda',bestlambda,...
    'LossFunction','mad');
```

Plot the feature weights.

```matlab
figure()
plot(nca.FeatureWeights,'ro')
```
Compute the loss using the new nca model on the test data, which is not used to select the features.

\[ L_2 = \text{loss(nca2, Xtest, ytest, 'LossFunction', 'mad')} \]

\[ L_2 = 2.0560 \]

Tuning the regularization parameter helps identify the relevant features and reduces the loss.

Plot the predicted versus the actual response values in the test set.

\[ \text{ypred = predict(nca2, Xtest); figure; plot(ypred, ytest, 'bo');} \]
The predicted response values seem to be closer to the actual values as well.

FeatureSelectionNCARegression | fsrnca | predict | refit

Introduced in R2016b
loss

Class: RegressionLinear
Regression loss for linear regression models

Syntax
L = loss(Mdl,X,Y)
L = loss(____,Name,Value)

Description
L = loss(Mdl,X,Y) returns the mean squared error (MSE) for the linear regression model Mdl using predictor data in X and corresponding responses in Y. L contains an MSE for each regularization strength in Mdl.

L = loss(____,Name,Value) uses any of the previous syntaxes and additional options specified by one or more Name,Value pair arguments. For example, specify that columns in the predictor data correspond to observations or specify the regression loss function.

Input Arguments
Mdl — Linear regression model
RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create a RegressionLinear model object using fitrlinear.

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix. This orientation of X indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Response data
numeric vector

Response data, specified as an n-dimensional numeric vector. The length of Y and the number of observations in X must be equal.
Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding value. Also, in the table, \( f(x) = x\beta + b \).
  - \( \beta \) is a vector of \( p \) coefficients.
  - \( x \) is an observation from \( p \) predictor variables.
  - \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'epsiloninsensitive'</td>
<td>Epsilon-insensitive loss: ( \ell[y, f(x)] = \max[0,</td>
</tr>
<tr>
<td>'mse'</td>
<td>MSE: ( \ell[y, f(x)] = (y - f(x))^2 )</td>
</tr>
</tbody>
</table>

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let \( n \) be the number of observations in \( X \). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(Y,Yhat,W)
\]

where:
- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( Y \) is an \( n \)-dimensional vector of observed responses. \( \text{loss} \) passes the input argument \( Y \) in for \( Y \).
- \( Yhat \) is an \( n \)-dimensional vector of predicted responses, which is similar to the output of \( \text{predict} \).
- \( W \) is an \( n \)-by-1 numeric vector of observation weights.

Specify your function using 'LossFun',\( @ \text{lossfun} \).

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension
'
rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.
Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in optimization-execution time.

Weights — Observation weights
numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, loss computes the weighted classification loss.

Let \( n \) be the number of observations in \( X \).

- \( \text{numel(Weights)} \) must be \( n \).
- By default, \( \text{Weights} \) is \( \text{ones}(n,1) \).

Data Types: double | single

Output Arguments

L — Regression losses
numeric scalar | numeric row vector

Regression losses, returned as a numeric scalar or row vector. The interpretation of \( L \) depends on `Weights` and `LossFun`.

\( L \) is the same size as `Mdl.Lambda`. \( L(j) \) is the regression loss of the linear regression model trained using the regularization strength `Mdl.Lambda(j)`.

Note If `Mdl.FittedLoss` is 'mse', then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution (training) error, then there is a discrepancy between the MSE and optimization results that `fitrlinear` returns.

Examples

Estimate Test-Sample Mean Squared Error

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```
Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```matlab
CVMdl = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMdl.Trained{1}
```

```
Mdl = RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
    Bias: -0.0066
    Lambda: 1.4286e-04
    Learner: 'svm'
```

Properties, Methods

CVMdl is a RegressionPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a RegressionLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample MSE.

```matlab
mseTrain = loss(Mdl,X(trainIdx,:),Y(trainIdx))
mseTrain = 0.1496
mseTest = loss(Mdl,X(testIdx,:),Y(testIdx))
mseTest = 0.1798
```

Because there is one regularization strength in Mdl, mseTrain and mseTest are numeric scalars.

Specify Custom Regression Loss

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.
CVMdl = fitrlinear(X,Y,'Holdout',0.3,'ObservationsIn','columns');
Mdl = CVMdl.Trained{1}

Mdl =
  RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
  Beta: [1000x1 double]
  Bias: -0.0066
  Lambda: 1.4286e-04
  Learner: 'svm'

Properties, Methods

CVMdl is a RegressionPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a RegressionLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \sum_{j=1}^{n} w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 
0.5\hat{e}_j^2; & |\hat{e}_j| \leq 1 \\
|\hat{e}_j| - 0.5; & |\hat{e}_j| > 1 
\end{cases}.$$

$\hat{e}_j$ is the residual for observation $j$. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ... 
((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);

Estimate the training set and test set regression loss using the Huber loss function.

eTrain = loss(Mdl,X(:,trainIdx),Y(trainIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
eTrain = -0.4186

eTest = loss(Mdl,X(:,testIdx),Y(testIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
eTest = -0.4010
Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```plaintext
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \(10^{-4}\) through \(10^{-1}\).

\[ \text{Lambda} = \logspace(-4,-1,15); \]

Hold out 30% of the data for testing. Identify the test-sample indices.

```plaintext
cvp = cvpartition(numel(Y),'Holdout',0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, optimizing the objective function using SpaRSA, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```plaintext
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso','CVPartition',cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```plaintext
ans = 15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```plaintext
mse = loss(Mdl1,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```plaintext
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta==0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off

Select the index or indices of Lambda that balance minimal classification error and predictor-variable sparsity (for example, Lambda(11)).

idx = 11;
MdlFinal = selectModels(Mdl,idx);

MdlFinal is a trained RegressionLinear model object that uses Lambda(11) as a regularization strength.

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.
For more information, see “Tall Arrays” (MATLAB).

RegressionLinear | fitrlinear | predict

Introduced in R2016a
**lowerparams**

Lower Pareto tail parameters

**Syntax**

```matlab
params = lowerparams(pd)
```

**Description**

`params = lowerparams(pd)` returns the two-element vector `params`, which includes the shape and scale parameters of the generalized Pareto distribution (GPD) in the lower tail of `pd`.

`lowerparams` does not return the location parameter of the GPD. The location parameter is the quantile value corresponding to the lower tail cumulative probability. Use the `boundary` function to return the location parameter.

**Examples**

**Parameters of Lower Pareto Tail**

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data by using `paretotails`. Find the distribution parameters of the lower Pareto tail by using the object function `lowerparams`.

Generate a sample data set containing 20% outliers.

```matlab
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```matlab
pd = paretotails(x,0.1,0.9)
```

```matlab
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251  (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
  -1.33251 < x < 1.80149  (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf  (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the shape and scale parameters of the fitted GPD of the lower tail by using the `lowerparams` function.

```matlab
params = lowerparams(pd)
```
params = 1x2
    -0.0064    0.5670

You can also get the lower Pareto tail parameters by using the `LowerParameters` property. Access the `LowerParameters` property by using dot notation.

```matlab
pd.LowerParameters
ans = 1x2
    -0.0064    0.5670
```

The location parameter of the GPD is equal to the quantile value of the lower tail cumulative probability. Return the location parameter by using the `boundary` function.

```matlab
[p,q] = boundary(pd)
p = 2x1
    0.1000
    0.9000
q = 2x1
   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles. `q(2)` is the location parameter of the GPD of the lower tail.

Use the `upperparams` function or the `UpperParameters` property to get the upper Pareto tail parameters.

### Input Arguments

- **pd** — Piecewise distribution with Pareto tails
  paretotails object

  Piecewise distribution with Pareto tails, specified as a `paretotails` object.

Introduced in R2007a
lt

Class: qrandstream

Less than relation for handles

Syntax

h1 < h2

Description

h1 < h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise < result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = lt(h1, h2) stores the result in a logical array of the same dimensions.

See Also

eq | ge | gt | le | ne | qrandstream
**lsline**

Add least-squares line to scatter plot

**Syntax**

```
lsline
lsline(ax)
h = lsline(____)
```

**Description**

`lsline` superimposes a least-squares line on each scatter plot in the current axes.

`lsline` ignores data points that are connected with solid, dashed, or dash-dot lines ('-', '--', or '.-') because it does not consider them to be scatter plots. To produce scatter plots, use the MATLAB `scatter` and `plot` functions.

`lsline(ax)` superimposes a least-squares line on the scatter plot in the axes specified by `ax` instead of the current axes (`gca`).

`h = lsline(____)` returns a column vector of least-squares line objects `h` using any of the previous syntaxes. Use `h` to modify the properties of a specific least-squares line after you create it. For a list of properties, see Line Properties.

**Examples**

**Plot Least-Squares Line**

Generate three sets of sample data and plot each set on the same figure.

```
x = 1:10;
rng default;  % For reproducibility
figure;
y1 = x + randn(1,10);
scatter(x,y1,25,'b','*')
hold on
y2 = 2*x + randn(1,10);
plot(x,y2,'mo')
y3 = 3*x + randn(1,10);
plot(x,y3,'rx:')
```
Add a least-squares line for each set of sample data.

\texttt{lsline}
Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```matlab
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define ax1 as the top half of the figure, and ax2 as the bottom half of the figure. Create the first scatter plot on the top axis using y1, and the second scatter plot on the bottom axis using y2.

```matlab
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);
scatter(ax1,x,y1)
scatter(ax2,x,y2)
```
Superimpose a least-squares line on the top plot, and a reference line at the mean of the y2 values in the bottom plot.

```
lsline(ax1) % This is equivalent to refline(ax1)
```

```
mu = mean(y2);
refline(ax2,[0 mu])
```
Use Least-Squares Line Object to Modify Line Properties

Define the x-variable and two different y-variables to use for the plots.

```matlab
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define ax1 as the top half of the figure, and ax2 as the bottom half of the figure. Create the first scatter plot on the top axis using y1, and the second scatter plot on the bottom axis using y2.

```matlab
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);
scatter(ax1,x,y1)
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot. Then, use the least-squares line object h1 to change the line color to red.

```matlab
h1 = lsline(ax1);
h1.Color = 'r';
```
Superimpose a least-squares line on the bottom plot. Then, use the least-squares line object h2 to increase the line width to 5.

```matlab
h2 = lsline(ax2);
h2.LineWidth = 5;
```

### Input Arguments

`ax` — Target axes

gca (default) | axes object

Target axes, specified as an `axes` object. If you do not specify the axes and if the current axes are Cartesian axes, then the `lsline` function uses the current axes.

### Output Arguments

`h` — One or more least-squares line objects

scalar | vector

One or more least-squares line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific least-squares line. For a list of properties, see Chart Line.
See Also
(gca | gline | plot | refcurve | reline | scatter)

Introduced before R2006a
**mad**

Mean or median absolute deviation

**Syntax**

\[ y = \text{mad}(X) \]
\[ y = \text{mad}(X,\text{flag}) \]
\[ y = \text{mad}(X,\text{flag},'\text{all}') \]
\[ y = \text{mad}(X,\text{flag},\text{dim}) \]
\[ y = \text{mad}(X,\text{flag},\text{vecdim}) \]

**Description**

\[ y = \text{mad}(X) \] returns the mean absolute deviation of the values in \( X \).

- If \( X \) is a vector, then \( \text{mad} \) returns the mean or median absolute deviation of the values in \( X \).
- If \( X \) is a matrix, then \( \text{mad} \) returns a row vector containing the mean or median absolute deviation of each column of \( X \).
- If \( X \) is a multidimensional array, then \( \text{mad} \) operates along the first nonsingleton dimension of \( X \).

\[ y = \text{mad}(X,\text{flag}) \] specifies whether to compute the mean absolute deviation (\( \text{flag} = 0 \), the default) or the median absolute deviation (\( \text{flag} = 1 \)).

\[ y = \text{mad}(X,\text{flag},'\text{all}') \] returns the mean or median absolute deviation of all elements of \( X \).

\[ y = \text{mad}(X,\text{flag},\text{dim}) \] returns the mean or median absolute deviation along the operating dimension \( \text{dim} \) of \( X \).

\[ y = \text{mad}(X,\text{flag},\text{vecdim}) \] returns the mean or median absolute deviation over the dimensions specified in the vector \( \text{vecdim} \). For example, if \( X \) is a 2-by-3-by-4 array, then \( \text{mad}(X,0,[1 2]) \) returns a 1-by-1-by-4 array. Each element of the output array is the mean absolute deviation of the elements on the corresponding page of \( X \).

**Examples**

**Compare Robustness of Scale Estimates**

Compare the robustness of the standard deviation, mean absolute deviation, and median absolute deviation in the presence of outliers.

Create a data set \( x \) of normally distributed data. Create another data set \( xo \) that contains the elements of \( x \) and an additional outlier:

```matlab
rng('default') % For reproducibility
x = normrnd(0,1,1,50);
xo = [x 10];
```

Compute the ratio of the standard deviations of the two data sets.
\[ r_1 = \frac{\text{std}(x_0)}{\text{std}(x)} \]
\[ r_1 = 1.4633 \]

Compute the ratio of the mean absolute deviations of the two data sets.

\[ r_2 = \frac{\text{mad}(x_0)}{\text{mad}(x)} \]
\[ r_2 = 1.1833 \]

Compute the ratio of the median absolute deviations of the two data sets.

\[ r_3 = \frac{\text{mad}(x_0,1)}{\text{mad}(x,1)} \]
\[ r_3 = 1.0336 \]

In this case, the median absolute deviation is less influenced by the outlier compared to the other two scale estimates.

**Mean and Median Absolute Deviations of All Values**

Find the mean and median absolute deviations of all the values in an array.

Create a 3-by-5-by-2 array \( X \) and add an outlier:

\[
X = \text{reshape}(1:30,[3 5 2]);
X(6) = 100
\]

\[
X =
X(:,:,1) =
\begin{array}{cccc}
1 & 4 & 7 & 10 \\
2 & 5 & 8 & 11 \\
3 & 100 & 9 & 12 \\
\end{array}
X(:,:,2) =
\begin{array}{cccc}
16 & 19 & 22 & 25 \\
17 & 20 & 23 & 26 \\
18 & 21 & 24 & 27 \\
\end{array}
\]

Find the mean and median absolute deviations of the elements in \( X \).

\[
\text{meandev} = \text{mad}(X,0,'\text{all}')
\]
\[
\text{meandev} = 10.1178
\]

\[
\text{mediandev} = \text{mad}(X,1,'\text{all}')
\]
\[
\text{mediandev} = 7.5000
\]

\text{meandev} \text{ is the mean absolute deviation of all the elements in } X, \text{ and } \text{mediandev} \text{ is the median absolute deviation of all the elements in } X.
Find Median Absolute Deviation Along Given Dimension

Find the median absolute deviation along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

rng('default')

Create a 1-by-3-by-2 array of random numbers.

X = randn([1,3,2])

X(:,:,1) =
0.5377    1.8339   -2.2588

X(:,:,2) =
0.8622    0.3188   -1.3077

Find the median absolute deviation of X along the default dimension.

Y2 = mad(X,1)  % Flag is set to 1 for the median absolute deviation

Y2(:,:,1) =
1.2962

Y2(:,:,2) =
0.5434

By default, mad operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the second dimension of X. Therefore, Y2 is a 1-by-1-by-2 array.

Find the median absolute deviation of X along the third dimension.

Y3 = mad(X,1,3)

Y3 = 1x3

0.1623    0.7576    0.4756

Y3 is a 1-by-3 matrix.
Find Mean Absolute Deviation Along Vector of Dimensions

Find the mean absolute deviation over multiple dimensions by using the \texttt{vecdim} input argument.

Set the random seed for reproducibility of the results.

\begin{verbatim}
rng('default')
\end{verbatim}

Create a 4-by-3-by-2 array of random numbers.

\begin{verbatim}
X = randn([4 3 2])
\end{verbatim}

\begin{verbatim}
X(:,:,1) =
  0.5377   0.3188   3.5784
  1.8339  -1.3077   2.7694
 -2.2588  -0.4336  -1.3499
  0.8622   0.3426   3.0349

X(:,:,2) =
  0.7254  -0.1241   0.6715
 -0.0631   1.4897  -1.2075
  0.7147   1.4090   0.7172
 -0.2050   1.4172   1.6302
\end{verbatim}

Find the mean absolute deviation of each page of \texttt{X} by specifying the first and second dimensions.

\begin{verbatim}
ypage = mad(X,0,[1 2])
\end{verbatim}

\begin{verbatim}
ypage =
ypage(:,:,1) =
  1.4626

ypage(:,:,2) =
  0.6652
\end{verbatim}

For example, \texttt{ypage(:,:,2)} is the mean absolute deviation of all the elements in \texttt{X(:,:,2)}, and is equivalent to specifying \texttt{mad(X(:,:,2),0,'all')}.

Find the mean absolute deviation of the elements in each \texttt{X(:,i,:)} slice by specifying the first and third dimensions.

\begin{verbatim}
ycol = mad(X,0,[1 3])
\end{verbatim}

\begin{verbatim}
ycol = 1x3
  0.8330   0.7872   1.5227
\end{verbatim}

For example, \texttt{ycol(3)} is the mean absolute deviation of all the elements in \texttt{X(:,3,:)}, and is equivalent to specifying \texttt{mad(X(:,3,:),0,'all')}.
Input Arguments

**X — Input data**  
vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then mad returns the mean or median absolute deviation of the values in X.
- If X is a matrix, then mad returns a row vector containing the mean or median absolute deviation of each column of X.
- If X is a multidimensional array, then mad operates along the first nonsingleton dimension of X.

To specify the operating dimension when X is a matrix or an array, use the dim input argument.

mad treats NaNs as missing values and removes them.

Data Types: single | double

**flag — Indicator for the type of deviation**  
0 (default) | 1

Indicator for the type of deviation, specified as 0 or 1.

- If flag is 0 (default), then mad computes the mean absolute deviation, mean(abs(X - mean(X))).
- If flag is 1, then mad computes the median absolute deviation, median(abs(X - median(X))).

Data Types: single | double | logical

**dim — Dimension**  
positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for dim, then the default is the first dimension of X whose size does not equal 1.

Consider the mean absolute deviation of a matrix X:

- If dim is equal to 1, then mad(X) returns a row vector that contains the mean absolute deviation of each column in X.
- If dim is equal to 2, then mad(X) returns a column vector that contains the mean absolute deviation of each row in X.

Data Types: single | double

**vecdim — Vector of dimensions**  
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of vecdim represents a dimension of the input array X. The output y has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and y.
For example, if \( X \) is a 2-by-3-by-3 array, then \( \text{mad}(X,0,[1 2]) \) returns a 1-by-1-by-3 array. Each element of the output array is the mean absolute deviation of the elements on the corresponding page of \( X \).

Data Types: single | double

**Output Arguments**

\( y \) — Mean or median absolute deviation

scalar | vector | matrix | multidimensional array

Mean or median absolute deviation, returned as a scalar, vector, matrix, or multidimensional array. If \( \text{flag} \) is 0 (default), then \( y \) is the mean absolute deviation of the values in \( X \), \( \text{mean} (\text{abs}(X - \text{mean}(X))) \). If \( \text{flag} \) is 1, then \( y \) is the median absolute deviation of the values in \( X \), \( \text{median} (\text{abs}(X - \text{median}(X))) \).

**Tips**

- For normally distributed data, multiply \( \text{mad} \) by one of the following factors to obtain an estimate of the normal scale parameter \( \sigma \):
  - \( \text{sigma} = 1.253 * \text{mad}(X,0) \) — For mean absolute deviation
  - \( \text{sigma} = 1.4826 * \text{mad}(X,1) \) — For median absolute deviation

**References**

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.
• Empty dim input is not supported.
• The dim input argument must be a compile-time constant.
• If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
mahal

Mahalanobis distance

Syntax

d2 = mahal(Y,X)

Description

d2 = mahal(Y,X) returns the squared Mahalanobis distance on page 32-3289 of each observation in Y to the reference samples in X.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate a correlated bivariate sample data set.

rng('default') % For reproducibility
X = mvnrnd([0;0],[1 .9;.9 1],1000);

Specify four observations that are equidistant from the mean of X in Euclidean distance.
Y = [1 1;1 -1;-1 1;-1 -1];

Compute the Mahalanobis distance of each observation in Y to the reference samples in X.

d2_mahal = mahal(Y,X)

    d2_mahal = 4x1
            1.1095
            20.3632
            19.5939
            1.0137

Compute the squared Euclidean distance of each observation in Y from the mean of X.

d2_Euclidean = sum((Y-mean(X)).^2,2)

    d2_Euclidean = 4x1
                2.0931
                2.0399
                1.9625
                1.9094

Plot X and Y by using scatter and use marker color to visualize the Mahalanobis distance of Y to the reference samples in X.
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
scatter(Y(:,1),Y(:,2),100,d2_mahal,'o','filled')
hb = colorbar;
ylabel(hb,'Mahalanobis Distance')
legend('X','Y','Location','best')

All observations in Y ([1,1], [-1,-1], [1,-1], and [-1,1]) are equidistant from the mean of X in Euclidean distance. However, [1,1] and [-1,-1] are much closer to X than [1,-1] and [-1,1] in Mahalanobis distance. Because Mahalanobis distance considers the covariance of the data and the scales of the different variables, it is useful for detecting outliers.

Input Arguments

Y — Data
n-by-m numeric matrix

Data, specified as an n-by-m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

X and Y must have the same number of columns, but can have different numbers of rows.

Data Types: single | double

X — Reference samples
p-by-m numeric matrix
Reference samples, specified as a $p$-by-$m$ numeric matrix, where $p$ is the number of samples and $m$ is the number of variables in each sample.

$X$ and $Y$ must have the same number of columns, but can have different numbers of rows. $X$ must have more rows than columns.

Data Types: single | double

**Output Arguments**

$d2$ — Squared Mahalanobis distance

$n$-by-1 numeric vector

Squared Mahalanobis distance on page 32-3289 of each observation in $Y$ to the reference samples in $X$, returned as an $n$-by-1 numeric vector, where $n$ is the number of observations in $X$.

**More About**

**Mahalanobis Distance**

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector $y$ to a distribution with mean $\mu$ and covariance $\Sigma$ is

$$d = \sqrt{(y - \mu)^T \Sigma^{-1} (y - \mu)}.$$

This distance represents how far $y$ is from the mean in number of standard deviations.

`mahal` returns the squared Mahalanobis distance $d^2$ from an observation in $Y$ to the reference samples in $X$. In the `mahal` function, $\mu$ and $\Sigma$ are the sample mean and covariance of the reference samples, respectively.

**See Also**

`mahal` | `pdist`

Introduced before R2006a
mahal

Mahalanobis distance to class means

Syntax

M = mahal(obj,X)
M = mahal(obj,X,Name,Value)

Description

M = mahal(obj,X) returns the squared Mahalanobis distances from observations in X to the class means in obj.

M = mahal(obj,X,Name,Value) computes the squared Mahalanobis distance with additional options specified by one or more Name,Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with fitcdiscr.

X

Numeric matrix of size n-by-p, where p is the number of predictors in obj, and n is any positive integer. mahal computes the Mahalanobis distances from the rows of X to each of the K means of the classes in obj.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

ClassLabels

Class labels consisting of n elements of obj.Y, where n is the number of rows of X.

Output Arguments

M

Size and meaning of output M depends on whether the ClassLabels name-value pair is present:

- No ClassLabels — M is a numeric matrix of size n-by-K, where K is the number of classes in obj, and n is the number of rows in X. M(i,j) is the squared Mahalanobis distance from the ith row of X to the mean of class j.
- ClassLabels exists — M is a column vector with n elements. M(i) is the squared Mahalanobis distance from the ith row of X to the mean for the class of the ith element of ClassLabels.
Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```matlab
load fisheriris
obj = fitcdiscr(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))
```

```matlab
mahadist =
    220.0667    5.0254   30.5804
```

More About

Mahalanobis Distance

The Mahalanobis distance \( d(x,y) \) between \( n \)-dimensional points \( x \) and \( y \), with respect to a given \( n \)-by-\( n \) covariance matrix \( S \), is

\[
d(x,y) = \sqrt{(x - y)^T S^{-1} (x - y)}.\]

CompactClassificationDiscriminant | fitcdiscr | gmdistribution | mahal

Topics

“Discriminant Analysis Classification” on page 20-2
mahal

Mahalanobis distance to Gaussian mixture component

Syntax

d2 = mahal(gm,X)

Description

d2 = mahal(gm,X) returns the squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm.

Examples

Measure Mahalanobis Distance

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the mvnrnd function. Fit a Gaussian mixture model (GMM) to the generated data by using the fitgmdist function, and then compute Mahalanobis distances between the generated data and the mixture components of the fitted GMM.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

rng('default') % For reproducibility
mu1 = [1 2];          % Mean of the 1st component
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5];        % Mean of the 2nd component
sigma2 = [1 0; 0 1];  % Covariance of the 2nd component

Generate an equal number of random variates from each component, and combine the two sets of random variates.

r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

gm = fitgmdist(X,2)

gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:   -2.9617   -4.9727
Component 2:
Mixing proportion: 0.500000
Mean: 0.9539  2.0261

fitgmdist fits a GMM to X using two mixture components. The means of Component 1 and Component 2 are [-2.9617, -4.9727] and [0.9539, 2.0261], which are close to mu2 and mu1, respectively.

Compute the Mahalanobis distance of each point in X to each component of gm.

d2 = mahal(gm,X);

Plot X by using scatter and use marker color to visualize the Mahalanobis distance to Component 1.

scatter(X(:,1),X(:,2),10,d2(:,1),'.') % Scatter plot with points of size 10
        c = colorbar;
        ylabel(c,'Mahalanobis Distance to Component 1')

Input Arguments

gm — Gaussian mixture distribution
gmdistribution object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a gmdistribution object.
You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

**X — Data**

*n*-by-`m` numeric matrix

Data, specified as an `n`-by-`m` numeric matrix, where `n` is the number of observations and `m` is the number of variables in each observation.

If a row of `X` contains `NaN`s, then `mahal` excludes the row from the computation. The corresponding value in `d2` is `NaN`.

Data Types: `single` | `double`

**Output Arguments**

**d2 — Squared Mahalanobis distance**

*n*-by-`k` numeric matrix

Squared Mahalanobis distance of each observation in `X` to each Gaussian mixture component in `gm`, returned as an `n`-by-`k` numeric matrix, where `n` is the number of observations in `X` and `k` is the number of mixture components in `gm`.

`d2(i,j)` is the squared distance of observation `i` to the `j`th Gaussian mixture component.

**More About**

**Mahalanobis Distance**

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector `x` to a distribution with mean `μ` and covariance `Σ` is

\[ d = \sqrt{(x - \mu)' \Sigma^{-1} (x - \mu)}. \]

This distance represents how far `x` is from the mean in number of standard deviations.

`mahal` returns the squared Mahalanobis distance `d^2` from an observation in `X` to a mixture component in `gm`.

**Introduced in R2007b**
maineffectsplot

Main effects plot for grouped data

Syntax

maineffectsplot(Y,GROUP)
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)
[figh,AXESH] = maineffectsplot(...)

Description

maineffectsplot(Y,GROUP) displays main effects plots for the group means of matrix Y with groups defined by entries in GROUP, which can be a cell array or a matrix. Y is a numeric matrix or vector. If Y is a matrix, the rows represent different observations and the columns represent replications of each observation. If GROUP is a cell array, then each cell of GROUP must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If GROUP is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as Y. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of Y as a function of one grouping variable.

maineffectsplot(Y,GROUP,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:

- 'varnames' — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ... .
- 'statistic' — Values that indicate whether the group mean or the group standard deviation should be plotted. Use 'mean' or 'std'. The default is 'mean'. If the value is 'std', Y is required to have multiple columns.
- 'parent' — A handle to the figure window for the plots. The default is the current figure window.

[figh,AXESH] = maineffectsplot(...) returns the handle figh to the figure window and an array of handles AXESH to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

load carsmall;

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

maineffectsplot(Weight,{Model_Year,Cylinders}, ...
    'varnames',{[Model Year','# of Cylinders']})

Introduced in R2006b
**ClassificationDiscriminant.make**

**Class:** ClassificationDiscriminant

(Not Recommended) Construct discriminant analysis classifier from parameters

---

**Note** ClassificationDiscriminant.make is not recommended. Use makecdiscr instead.

---

**Syntax**

```matlab
cobj = ClassificationDiscriminant.make(Mu,Sigma)
cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)
```

**Description**

`cobj = ClassificationDiscriminant.make(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

- **Mu** — Class means
  matrix of scalar values

  Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

  Data Types: `single` | `double`

- **Sigma** — Within-class covariance
  matrix of scalar values

  Within-class covariance, specified as a matrix of scalar values.

  - For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size p-by-p, where p is the number of predictors.
  - For a quadratic discriminant, `Sigma` is an array of size p-by-p-by-K, where K is the number of classes. For each i, `Sigma(:,:,i)` is a symmetric, positive semidefinite matrix.

  Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. 

---

32-3297
**ClassNames — Class names**
numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names as ordered in Mu, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

ClassNames names the classes, as ordered in Mu.

Default is 1:K, where K is the number of classes (the number of rows of Mu).

Data Types: single | double | logical | char | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i. Alternatively, Cost can be a structure S having two fields: S.ClassNames containing the group names as a variable of the same type as y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.

Data Types: single | double | struct

**PredictorNames — Predictor variable names**
{‘X1’, ‘X2’, ...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X.

Data Types: cell

**Prior — Prior probabilities**
‘uniform’ (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- ‘uniform’, a character vector meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as ClassNames.
  - S.ClassProbs containing a vector of corresponding probabilities.

Data Types: single | double | struct

**ResponseName — Response variable name**
‘Y’ (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable y.
Example: 'ResponseName','Response'

Data Types: char

Output Arguments

cobj — Discriminant analysis classifier
discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class
CompactClassificationDiscriminant. You can use the predict method to predict classification
labels for new data.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the
Fisher iris data.

load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

cobj = makecdiscr(Mu,Sigma)
cobj = makecdiscr(Mu,Sigma,Name,Value)

Description

cobj = makecdiscr(Mu,Sigma) constructs a compact discriminant analysis classifier from the class means Mu and covariance matrix Sigma.

cobj = makecdiscr(Mu,Sigma,Name,Value) constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);  
mm2 = repmat(mu(2,:),50,1);  
mm3 = repmat(mu(3,:),50,1);  
cc = meas;  
cc(1:50,:) = cc(1:50,:) - mm1;  
cc(51:100,:) = cc(51:100,:) - mm2;  
cc(101:150,:) = cc(101:150,:) - mm3;  
sigstar = cc' * cc / 147;  % unbiased estimator of sigma  
cpct = makecdiscr(mu,sigstar,...  
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
    classreg.learning.classif.CompactClassificationDiscriminant
    PredictorNames: {'x1'  'x2'  'x3'  'x4'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    DiscrimType: 'linear'
    Mu: [3x4 double]
    Coefs: [3x3 struct]

32-3301
Properties, Methods

Input Arguments

**Mu — Class means**
matrix of scalar values

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

Data Types: single | double

**Sigma — Within-class covariance**
matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, Sigma is a symmetric, positive semidefinite matrix of size p-by-p, where p is the number of predictors.
- For a quadratic discriminant, Sigma is an array of size p-by-p-by-K, where K is the number of classes. For each i, Sigma(:,:,i) is a symmetric, positive semidefinite matrix.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'ClassNames',{'setosa' 'versicolor' 'virginica'} specifies a discriminant analysis classifier that uses 'setosa', 'versicolor', and 'virginica' as the grouping variables.

**ClassNames — Class names**
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class names as ordered in Mu, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

The default is 1:K, where K is the number of classes (the number of rows of Mu).

Example: 'ClassNames',{'setosa' 'versicolor' 'virginica'}

Data Types: single | double | logical | char | string | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i.
Alternatively, Cost can be a structure S having two fields: S.ClassNames containing the group names as a variable of the same type as y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if \( i \neq j \), and Cost(i,j)=0 if \( i=j \).

Data Types: single | double | struct

**PredictorNames — Predictor variable names**

{’X1’,’X2’,...} (default) | string array | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X.

Data Types: string | cell

**Prior — Prior probabilities**

’uniform’ (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- ’uniform’, meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as ClassNames
  - S.ClassProbs containing a vector of corresponding probabilities

Data Types: char | string | single | double | struct

**ResponseName — Response variable name**

’Y’ (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar containing the name of the response variable y.

Example: 'ResponseName','Response'

Data Types: char | string

**Output Arguments**

**cobj — Discriminant analysis classifier**

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class CompactClassificationDiscriminant. You can use the predict method to predict classification labels for new data.

**Tips**

- You can change the discriminant type using dot notation after constructing cobj:
cobj.DiscrimType = 'discrimType'

where discrimType is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

• cobj is a linear classifier when Sigma is a matrix. cobj is a quadratic classifier when Sigma is a three-dimensional array.

Topics
“Discriminant Analysis Classification” on page 20-2

Introduced in R2014a
**makedist**

Create probability distribution object

**Syntax**

```matlab
pd = makedist(distname)
pd = makedist(distname,Name,Value)
list = makedist
makedist -reset
```

**Description**

`pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

`list = makedist` returns a cell array `list` containing a list of the probability distributions that `makedist` can create.

`makedist -reset` resets the list of distributions by searching the path for files contained in a package named `prob` and implementing classes derived from `ProbabilityDistribution`. Use this syntax after you define a custom distribution function. For details, see “Define Custom Distributions Using the Distribution Fitter App” on page 5-78.

**Examples**

**Create a Normal Distribution Object**

Create a normal distribution object using the default parameter values.

```matlab
pd = makedist('Normal')
```

```matlab
d = NormalDistribution
   Normal distribution
   mu = 0
   sigma = 1
```

Compute the interquartile range of the distribution.

```matlab
r = iqr(pd)
r = 1.3490
```
Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```matlab
pd = makedist('Gamma')
```

```
GammaDistribution
   a = 1
   b = 1
```

Compute the mean of the gamma distribution.

```matlab
mean = mean(pd)
```

```matlab
mean = 1
```

Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values \( \mu = 75 \) and \( \sigma = 10 \).

```matlab
pd = makedist('Normal','mu',75,'sigma',10)
```

```
NormalDistribution
   mu = 75
   sigma = 10
```

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value \( a = 3 \) and the default value \( b = 1 \).

```matlab
pd = makedist('Gamma','a',3)
```

```
GammaDistribution
   a = 3
   b = 1
```
## Input Arguments

**distname — Distribution name**  
character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by `distname` determines the type of the returned probability distribution object.

#### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `makedist('Normal','mu',10)` specifies a normal distribution with parameter mu equal to 10, and parameter sigma equal to the default value of 1.

**Beta Distribution**

- **a — First shape parameter**
  1 (default) | positive scalar value
  Example: 'a',3
  Data Types: single | double

- **b — Second shape parameter**
  1 (default) | positive scalar value
  Example: 'b',5
  Data Types: single | double

**Binomial Distribution**

- **N — Number of trials**
  1 (default) | positive integer value
  Example: 'N',25
  Data Types: single | double

- **p — Probability of success**
  0.5 (default) | scalar value in the range [0,1]
  Example: 'p',0.25
  Data Types: single | double

**Birnbaum-Saunders Distribution**

- **beta — Scale parameter**
  1 (default) | positive scalar value
  Example: 'beta',2
  Data Types: single | double

- **gamma — Shape parameter**
  1 (default) | nonnegative scalar value
  Example: 'gamma',0
  Data Types: single | double
Burr Distribution

**alpha — Scale parameter**
1 (default) | positive scalar value
Example: 'alpha', 2
Data Types: single | double

**c — First shape parameter**
1 (default) | positive scalar value
Example: 'c', 2
Data Types: single | double

**k — Second shape parameter**
1 (default) | positive scalar value
Example: 'k', 5
Data Types: single | double

Exponential Distribution

**mu — Mean parameter**
1 (default) | positive scalar value
Example: 'mu', 5
Data Types: single | double

Extreme Value Distribution

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu', -2
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma', 2
Data Types: single | double

Gamma Distribution

**a — Shape parameter**
1 (default) | positive scalar value
Example: 'a', 2
Data Types: single | double

**b — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'b', 0
Data Types: single | double
Generalized Extreme Value Distribution

**k — Shape parameter**
0 (default) | scalar value
Example: 'k',0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu',1
Data Types: single | double

Generalized Pareto Distribution

**k — Shape parameter**
1 (default) | scalar value
Example: 'k',0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double

**theta — Location parameter**
1 (default) | scalar value
Example: 'theta',2
Data Types: single | double

Half-Normal Distribution

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu',1
Data Types: single | double

**sigma — Shape parameter**
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double
Inverse Gaussian Distribution

**μ** — Scale parameter
1 (default) | positive scalar value
Example: ‘μ’, 2
Data Types: single | double

**λ** — Shape parameter
1 (default) | positive scalar value
Example: ‘λ’, 4
Data Types: single | double

Logistic Distribution

**μ** — Mean
0 (default) | scalar value
Example: ‘μ’, 2
Data Types: single | double

**σ** — Scale parameter
1 (default) | nonnegative scalar value
Example: ‘σ’, 4
Data Types: single | double

Loglogistic Distribution

**μ** — Mean of logarithmic values
0 (default) | scalar value
Example: ‘μ’, 2
Data Types: single | double

**σ** — Scale parameter of logarithmic values
1 (default) | nonnegative scalar value
Example: ‘σ’, 4
Data Types: single | double

Lognormal Distribution

**μ** — Mean of logarithmic values
0 (default) | scalar value
Example: ‘μ’, 2
Data Types: single | double

**σ** — Standard deviation of logarithmic values
1 (default) | nonnegative scalar value
Example: ‘σ’, 2
Data Types: single | double
**Multinomial Distribution**

**probabilities — Outcome probabilities**

```
[0.500 0.500] (default) | vector of scalar values in the range [0,1]
```

Outcome probabilities, specified as a vector of scalar values in the range [0,1]. The probabilities sum to 1 and correspond to outcomes [1, 2, ..., k], where k is the number of elements in the probabilities vector.

Example: `'probabilities',[0.1 0.2 0.5 0.2]` gives the probabilities that the outcome is 1, 2, 3, or 4, respectively.

Data Types: `single` | `double`

**Nakagami Distribution**

**mu — Shape parameter**

```
1 (default) | positive scalar value
```

Example: `'mu',5`

Data Types: `single` | `double`

**omega — Scale parameter**

```
1 (default) | positive scalar value
```

Example: `'omega',5`

Data Types: `single` | `double`

**Negative Binomial Distribution**

**R — Number of successes**

```
1 (default) | positive scalar value
```

Example: `'R',5`

Data Types: `single` | `double`

**p — Probability of success**

```
0.5 (default) | scalar value in the range (0,1]
```

Example: `'p',0.1`

Data Types: `single` | `double`

**Normal Distribution**

**mu — Mean**

```
0 (default) | scalar value
```

Example: `'mu',2`

Data Types: `single` | `double`

**sigma — Standard deviation**

```
1 (default) | nonnegative scalar value
```

Example: `'sigma',2`

Data Types: `single` | `double`
**Piecewise Linear Distribution**

**x — Data values**
1 (default) | monotonically increasing vector of scalar values
Example: 'x', [1 2 3]
Data Types: single | double

**Fx — cdf values**
1 (default) | monotonically increasing vector of scalar values that start at 0 and end at 1
Example: 'Fx', [0.2 0.5 1]
Data Types: single | double

**Poisson Distribution**

**lambda — Mean**
1 (default) | nonnegative scalar value
Example: 'lambda', 5
Data Types: single | double

**Rayleigh Distribution**

**b — Defining parameter**
1 (default) | positive scalar value
Example: 'b', 3
Data Types: single | double

**Rician Distribution**

**s — Noncentrality parameter**
1 (default) | nonnegative scalar value
Example: 's', 0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | positive scalar value
Example: 'sigma', 2
Data Types: single | double

**Stable Distribution**

**alpha — First shape parameter**
2 (default) | scalar value in the range (0,2]
Example: 'alpha', 1
Data Types: single | double

**beta — Second shape parameter**
0 (default) | scalar value in the range [-1,1]
Example: 'beta', 0.5
Data Types: single | double

**gam — Scale parameter**
1 (default) | scalar value in the range (0,∞)
Example: 'gam', 2
Data Types: single | double

**delta — Location parameter**
0 (default) | scalar value
Example: 'delta', 5
Data Types: single | double

**t Location-Scale Distribution**

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu', -2
Data Types: single | double

**sigma — Scale parameter**
1 (default) | positive scalar value
Example: 'sigma', 2
Data Types: single | double

**nu — Degrees of freedom**
5 (default) | positive scalar value
Example: 'nu', 20
Data Types: single | double

**Triangular Distribution**

**a — Lower limit**
0 (default) | scalar value
Example: 'a', -2
Data Types: single | double

**b — Peak location**
0.5 (default) | scalar value greater than or equal to a
Example: 'b', 1
Data Types: single | double

**c — Upper limit**
1 (default) | scalar value greater than or equal to b
Example: 'c', 5
Data Types: single | double
Uniform Distribution

**lower — Lower parameter**

- 0 (default) | scalar value
- Example: 'lower', -4
- Data Types: single | double

**upper — Upper parameter**

- 1 (default) | scalar value greater than lower
- Example: 'upper', 2
- Data Types: single | double

Weibull Distribution

**a — Scale parameter**

- 1 (default) | positive scalar value
- Example: 'a', 2
- Data Types: single | double

**b — Shape parameter**

- 1 (default) | positive scalar value
- Example: 'b', 5
- Data Types: single | double

Output Arguments

**pd — Probability distribution**

- probability distribution object
  - Probability distribution, returned as a probability distribution object of the type specified by `distname`.

**list — List of probability distributions**

- cell array of character vectors
  - List of probability distributions that `makedist` can create, returned as a cell array of character vectors.

Alternative Functionality

**App**

The **Distribution Fitter** app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

Introduced in R2013a
**manova**

**Class:** RepeatedMeasuresModel

Multivariate analysis of variance

**Syntax**

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova(___)
```

**Description**

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (manova) for the repeated measures model `rm`.

`manovatbl = manova(rm,Name,Value)` also returns manova results with additional options, specified by one or more `Name,Value` pair arguments.

`[manovatbl,A,C,D] = manova(____)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form `A*B*C = D`, where `D` is zero.

**Input Arguments**

- **rm** — Repeated measures model
  RepeatedMeasuresModel object

  Repeated measures model, returned as a `RepeatedMeasuresModel` object.

  For properties and methods of this object, see `RepeatedMeasuresModel`.

- **Name-Value Pair Arguments**

  Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

  - **WithinModel** — Model specifying within-subjects hypothesis test
    'separatemeans' (default) | model specification using formula | r-by-nc matrix

    Model specifying the within-subjects hypothesis test, specified as one of the following:
    - 'separatemeans' — Compute a separate mean for each group, and test for equality among the means.
    - Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, tbl contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
    - An r-by-nc matrix, C, specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model rm, then the output tbl contains a separate manova for each column of Y*C.
Example: 'WithinModel', 'separatemeans'

Data Types: single | double | char | string

**By — Single between-subjects factor**

color vector | string scalar

Single between-subjects factor, specified as the comma-separated pair consisting of 'By' and a character vector or string scalar. manova performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, Drug, then you can specify that factor to perform manova as follows.

Example: 'By', 'Drug'

Data Types: char | string

**Output Arguments**

**manovatbl — Results of multivariate analysis of variance**

table

Results of multivariate analysis of variance for the repeated measures model rm, returned as a table.

manova uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks’ Lambda
- Pillai’s trace
- Hotelling-Lawley trace
- Roy’s maximum root statistic

For details, see “Multivariate Analysis of Variance for Repeated Measures” on page 9-59.

manova returns the results for these tests for each group. manovatbl contains the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Within</td>
<td>Within-subject terms</td>
</tr>
<tr>
<td>Between</td>
<td>Between-subject terms</td>
</tr>
<tr>
<td>Statistic</td>
<td>Name of the statistic computed</td>
</tr>
<tr>
<td>Value</td>
<td>Value of the corresponding statistic</td>
</tr>
<tr>
<td>F</td>
<td>F-statistic value</td>
</tr>
<tr>
<td>RSquare</td>
<td>Measure for variance explained</td>
</tr>
<tr>
<td>df1</td>
<td>Numerator degrees of freedom</td>
</tr>
<tr>
<td>df2</td>
<td>Denominator degrees of freedom</td>
</tr>
<tr>
<td>pValue</td>
<td>p-value for the corresponding F-statistic value</td>
</tr>
</tbody>
</table>

Data Types: table
**A — Specification based on between-subjects model**

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of B (within time hypothesis). If `manovatbl` contains multiple hypothesis tests, A might be a cell array.

Data Types: single | double | cell

**C — Specification based on within-subjects model**

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of B (between time hypotheses). If `manovatbl` contains multiple hypothesis tests, C might be a cell array.

Data Types: single | double | cell

**D — Hypothesis value**

0

Hypothesis value, returned as 0.

**Examples**

**Perform Multivariate Analysis of Variance**

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```matlab
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...;
    'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4],',VariableNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance.

```matlab
manova(rm)
```

```
ans=8×9 table
Within       Between      Statistic      Value        F       RSquare    df1    df2      pValue
________    ___________    _________    _________    ______    _______    ___    ___    ___________

\end{array}
\]

Return Arrays of the Hypothesis Test

Load the sample data.

\text{load fisheriris}

The column vector \text{species} consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix \text{meas} consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

\[ t = \text{table}(	ext{species}, \text{meas}(:,1), \text{meas}(:,2), \text{meas}(:,3), \text{meas}(:,4), \ldots) \]

\[ '\text{VariableNames}', \{ '\text{species}', '\text{meas1}', '\text{meas2}', '\text{meas3}', '\text{meas4}' \}; \]

\[ \text{Meas} = \text{dataset}([1 2 3 4], '\text{VarNames}', '\{' \text{\textquotesingle} \text{Measurements} \text{\textquoteright} \}); \]

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

\[ \text{rm} = \text{fitrm}(t, '\text{meas1}-\text{meas4}-\text{species}', '\text{WithinDesign}', \text{Meas}); \]

Perform multivariate analysis of variance. Also return the arrays for constructing the hypothesis test.

\[ [\text{manovatbl}, A, C, D] = \text{manova}(\text{rm}) \]

\text{manovatbl}=8\times9 \text{ table }
