</tr>
<tr>
<td></td>
<td>methods additionally do not support 'Weights'.</td>
</tr>
<tr>
<td>'TreeBagger'</td>
<td>• <em>TreeBagger</em> creates a random forest by generating trees on disjoint chunks of</td>
</tr>
<tr>
<td></td>
<td>the data. When more data is available</td>
</tr>
</tbody>
</table>
than is required to create the random forest, the data is subsampled. For a similar example, see Random Forests for Big Data (Genuer, Poggi, Tuleau-Malot, Villa-Vialaneix 2015).

Depending on how the data is stored, it is possible that some chunks of data contain observations from only a few classes out of all the classes. In this case, `TreeBagger` might produce inferior results compared to the case where each chunk of data contains observations from most of the classes.

### Dimensionality Reduction

<table>

**More About**

- “Tall Arrays” (MATLAB)
- “Functions That Support Tall Arrays (A - Z)” (MATLAB)
Logistic Regression with Tall Arrays

This example shows how to use logistic regression and other techniques to perform data analysis on tall arrays. Tall arrays represent data that is too large to fit into computer memory.

Define Execution Environment

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB® session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the mapreducer function to change the execution environment. Set the global execution environment to be the local MATLAB session.

mapreducer(0)

Get Data into MATLAB

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that datastore replaces them with NaN values. Select a subset of the variables to work with, and include the name of the airline (UniqueCarrier) as a categorical variable. Create a tall table on top of the datastore.

ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.SelectedVariableNames = {'DayOfWeek','UniqueCarrier','ArrDelay','DepDelay','Distance'};
ds.SelectedFormats{2} = '%C';
tt = tall(ds);
tt.DayOfWeek = categorical(tt.DayOfWeek,1:7,...
    {'Sun','Mon','Tues','Wed','Thu','Fri','Sat'},'Ordinal',true)

    tt =
    Mx5 tall table
    DayOfWeek    UniqueCarrier    ArrDelay    DepDelay    Distance
    _______    _____________    ________    ________    ________
Late Flights

Determine the flights that are late by 20 minutes or more by defining a logical variable that is true for a late flight. Add this variable to the tall table of data, noting that it is not yet evaluated. A preview of this variable includes the first few rows.

\[
\text{tt.LateFlight} = \text{tt.ArrDelay} \geq 20
\]

\[
\begin{array}{cccccc}
\text{DayOfWeek} & \text{UniqueCarrier} & \text{ArrDelay} & \text{DepDelay} & \text{Distance} & \text{LateFlight} \\
: & : & : & : & : & : \\
: & : & : & : & : & : \\
\end{array}
\]

Calculate the mean of \text{LateFlight} to determine the overall proportion of late flights. Use \text{gather} to trigger evaluation of the tall array and bring the result into memory.

\[
\text{m} = \text{mean(tt.LateFlight)}
\]

\[
\begin{array}{c}
\text{m} = \\
\text{tall double} \\
? \\
\end{array}
\]

\[
\text{m} = \text{gather(m)}
\]

Evaluating tall expression using the Local MATLAB Session:

- Pass 2 of 2: Completed in 1.6 sec
Evaluation completed in 3.5 sec

m =

0.1580

Late Flights by Carrier

Examine whether certain types of flights tend to be late. First, check to see if certain carriers are more likely to have late flights.

```
tt.LateFlight = double(tt.LateFlight);
late_by_carrier = gather(grpstats(tt,'UniqueCarrier','mean','DataVar','LateFlight'))
```

Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 4.3 sec
Evaluation completed in 5.3 sec

```
late_by_carrier =

</tr>
<tr>
<td>'Wed'</td>
<td>Wed</td>
<td>18240</td>
<td>0.18399</td>
</tr>
</tbody>
</table>
```

Wednesdays and Thursdays have the highest proportion of late flights, while Fridays have the lowest proportion.
**Late Flights by Distance**

Check to see if longer or shorter flights tend to be late. First, look at the density of the flight distance for flights that are late, and compare that with flights that are on time.

```matlab
ksdensity(tt.Distance(tt.LateFlight==1))
hold on
ksdensity(tt.Distance(tt.LateFlight==0))
hold off
legend('Late','On time')
```

Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 2: Completed in 1.7 sec
- Pass 2 of 2: Completed in 1.4 sec
Evaluation completed in 3.8 sec

Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 2: Completed in 1.4 sec
- Pass 2 of 2: Completed in 1.1 sec
Evaluation completed in 3.1 sec
Flight distance does not make a dramatic difference in whether a flight is early or late. However, the density appears to be slightly higher for on-time flights at distances of about 400 miles. The density is also higher for late flights at distances of about 2000 miles. Calculate some simple descriptive statistics for the late and on-time flights.

```matlab
late_by_distance = gather(grpstats(tt,'LateFlight',{mean,std},'DataVar','Distance'))
```

Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.8 sec
Evaluation completed in 2.3 sec

```matlab
late_by_distance =

2x5 table
```
Late flights are about 60 miles longer on average, although this value makes up only a small portion of the standard deviation of the distance values.

**Logistic Regression Model**

Build a model for the probability of a late flight, using both continuous variables (such as Distance) and categorical variables (such as DayOfWeek) to predict the probabilities. This model can help to determine if the previous results observed for each predictor individually also hold true when you consider them together.

```matlab
glm = fitglm(tt,'LateFlight~Distance+DayOfWeek','Distribution','binomial')
```

```
Iteration [1]:     100% completed
Iteration [2]:     100% completed
Iteration [3]:     100% completed
Iteration [4]:     100% completed
Iteration [5]:     100% completed

glm =

Compact generalized linear regression model:
  logit(LateFlight) ~ 1 + DayOfWeek + Distance
  Distribution = Binomial

Estimated Coefficients:
             Estimate      SE      tStat     pValue
(Intercept)        -1.855  0.023052    -80.469   0
DayOfWeek_Mon     -0.072603  0.029798     -2.4365  0.01483
DayOfWeek_Tues      0.026909  0.029239      0.92029  0.35742
```

The model confirms that the previously observed conclusions hold true here as well:

- The Wednesday and Thursday coefficients are positive, indicating a higher probability of a late flight on those days. The Friday coefficient is negative, indicating a lower probability.
- The Distance coefficient is positive, indicating that longer flights have a higher probability of being late.

All of these coefficients have very small p-values. This is common with data sets that have many observations, since one can reliably estimate small effects with large amounts of data. In fact, the uncertainty in the model is larger than the uncertainty in the estimates for the parameters in the model.

**Prediction with Model**

Predict the probability of a late flight for each day of the week, and for distances ranging from 0 to 3000 miles. Create a table to hold the predictor values by indexing the first 100 rows in the original table `tt`.

```matlab
x = gather(tt(1:100,{'Distance' 'DayOfWeek'}));
x.Distance = linspace(0,3000)';
x.DayOfWeek(:) = 'Sun';
plot(x.Distance,predict(glm,x));

days = {'Sun' 'Mon' 'Tues' 'Wed' 'Thu' 'Fri' 'Sat'};
hold on
for j=2:length(days)
    x.DayOfWeek(:) = days{j};
    plot(x.Distance,predict(glm,x));
end
legend(days)
```
According to this model, a Wednesday or Thursday flight of 500 miles has the same probability of being late, about 18%, as a Friday flight of about 3000 miles.

Since these probabilities are all much less than 50%, the model is unlikely to predict that any given flight will be late using this information. Investigate the model more by focusing on the flights for which the model predicts a probability of 20% or more of being late, and compare that to the actual results.

\[ C = \text{gather} \left( \text{crosstab} \left( tt.\text{LateFlight}, \text{predict} \left( \text{glm}, tt \right) > .20 \right) \right) \]
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.7 sec
Evaluation completed in 1.9 sec

C =

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>99613</td>
<td>4391</td>
</tr>
<tr>
<td>18394</td>
<td>1125</td>
</tr>
</tbody>
</table>

Among the flights predicted to have a 20% or higher probability of being late, about 20% were late \( \frac{1125}{1125 + 4391} \). Among the remainder, less than 16% were late \( \frac{18394}{18394 + 99613} \).
Bayesian Optimization with Tall Arrays

This example shows how to use Bayesian optimization to select optimal parameters for training a kernel classifier by using the 'OptimizeHyperparameters' name-value pair argument. The sample data set airlinesmall.csv is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses the tall table to run the optimization procedure.

Get Data into MATLAB®

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. For folders that contain a collection of files, you can specify the entire folder location, or use the wildcard character, '*.csv', to include multiple files with the same file extension in the datastore. Select a subset of the variables to work with, and treat 'NA' values as missing data so that datastore replaces them with NaN values. Create a tall table that contains the data in the datastore.

```matlab
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek','DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

```
tt =

Mx7 tall table

<table>
<thead>
<tr>
<th>Month</th>
<th>DayofMonth</th>
<th>DayOfWeek</th>
<th>DepTime</th>
<th>ArrDelay</th>
<th>Distance</th>
<th>DepDelay</th>
</tr>
</thead>
<tbody>
<tr>

<td>10</td>
<td>6</td>
<td>859</td>
<td>11</td>
<td>954</td>
<td>-1</td>
</tr>
</tbody>
</table>
```
When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment.

### Prepare Class Labels and Predictor Data

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

\[
Y = tt.\text{DepDelay} > 10 \quad \text{Class labels}
\]

\[
Y =
\begin{bmatrix}
1 \\
0 \\
1 \\
1 \\
0 \\
1 \\
0 \\
0 \\
\vdots
\end{bmatrix}
M\times1 \text{ tall logical array}
\]

Create a tall array for the predictor data.

\[
X = tt(:,1:end-1) \quad \text{Predictor data}
\]

\[
M\times6 \text{ tall double matrix}
\begin{bmatrix}
10 & 21 & 3 & 642 & 8 & 308 \\
10 & 26 & 1 & 1021 & 8 & 296 \\
10 & 23 & 5 & 2055 & 21 & 480 \\
10 & 23 & 5 & 1332 & 13 & 296 \\
10 & 22 & 4 & 629 & 4 & 373 \\
10 & 28 & 3 & 1446 & 59 & 308 \\
10 & 8 & 4 & 928 & 3 & 447 \\
\end{bmatrix}
\]
Remove rows in X and Y that contain missing data.

\[
R = \text{rmmissing}([X \ Y]); \quad \% \text{Data with missing entries removed}
X = R(:,1:end-1);
Y = R(:,end);
\]

**Perform Bayesian Optimization Using `OptimizeHyperparameters`**

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument.

Standardize the predictor variables.

\[
Z = \text{zscore}(X);
\]

Find the optimal values for the 'KernelScale' and 'Lambda' name-value pair arguments that minimize five-fold cross-validation loss. For reproducibility, set the random seed for tall arrays and use the 'expected-improvement-plus' acquisition function.

\[
\text{rng}('\text{default}')
tallrng('\text{default}') \quad \% \text{For reproducibility}
\]

\[
\text{Mdl} = \text{fitckernel}(Z,Y,\text{'}\text{Verbose}',0,\text{'}\text{OptimizeHyperparameters}',\text{'}auto',...\text{'}\text{HyperparameterOptimizationOptions}',\text{struct}(\text{'}\text{AcquisitionFunctionName}',\text{'}expected-improvement-plus\text{')}));
\]

Properties, Methods

Perform Bayesian Optimization by Using bayesopt

Alternatively, you can use the bayesopt function to find the optimal values of hyperparameters.

Split the data set into training and test sets. Specify a 1/3 holdout sample for the test set.
rng('default')
tallrng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',1/3);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set

Extract training and testing data and standardize the predictor data.

Ytrain = Y(trainingInds); % Training class labels
Xtrain = X(trainingInds,:);
[Ztrain,mu,stddev] = zscore(Xtrain); % Standardized training data

Ytest = Y(testInds); % Testing class labels
Xtest = X(testInds,:);
Ztest = (Xtest-mu)./stddev; % Standardized test data

Define the variables sigma and lambda to find the optimal values for the 'KernelScale' and 'Lambda' name-value pair arguments. Use optimizableVariable and specify a wide range for the variables because optimal values are unknown. Apply logarithmic transformation to the variables to search for the optimal values on a log scale.

N = gather(numel(Ytrain)); % Evaluate the length of the tall training array in memory

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1 sec
Evaluation completed in 1.3 sec

sigma = optimizableVariable('sigma',[1e-3,1e3],'Transform','log');
lambda = optimizableVariable('lambda',[(1e-3)/N, (1e3)/N],'Transform','log');

Create the objective function for Bayesian optimization. The objective function takes in a table that contains the variables sigma and lambda, and then computes the classification loss value for the binary Gaussian kernel classification model trained using the fitckernel function. Set 'Verbose',0 within fitckernel to suppress the iterative display of diagnostic information.

minfn = @(z)gather(loss(fitckernel(Ztrain,Ytrain, ...
    'KernelScale',z.sigma,'Lambda',z.lambda,'Verbose',0), ...
    Ztest,Ytest));

Optimize the parameters [sigma,lambda] of the kernel classification model with respect to the classification loss by using bayesopt. By default, bayesopt displays iterative information about the optimization at the command line. For reproducibility, set
the `AcquisitionFunctionName` option to 'expected-improvement-plus'. The default acquisition function depends on run time and, therefore, can give varying results.

```matlab
results = bayesopt(minfn,[sigma,lambda],'
```

Return the best feasible point in the Bayesian model results by using the bestPoint function. Use the default criterion min-visited-upper-confidence-interval, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

zbest = bestPoint(results)
The table `zbest` contains the optimal estimated values for the 'KernelScale' and 'Lambda' name-value pair arguments. You can specify these values when training a new optimized kernel classifier by using

```matlab
Mdl = fitckernel(Ztrain,Ytrain,'KernelScale',zbest.sigma,'Lambda',zbest.lambda)
```

For tall arrays, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters by using only partial data. Use the `datasample` function and specify 'Replace','false' to sample data without replacement.

Quick Start Parallel Computing for Statistics and Machine Learning Toolbox

Note To use parallel computing as described in this chapter, you must have a Parallel Computing Toolbox license.

In this section...
“What Is Parallel Statistics Functionality?” on page 30-2
“How To Compute in Parallel” on page 30-5

What Is Parallel Statistics Functionality?

You can use any of the Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox constructs such as `parfor` and `spmd`. However, some functions, such as those with interactive displays, can lose functionality in parallel. In particular, displays and interactive usage are not effective on workers (see “Vocabulary for Parallel Computation” on page 30-9).

Additionally, the following functions are enhanced to use parallel computing internally. These functions use `parfor` internally to parallelize calculations.

- `bayesopt`
- `bootci`
- `bootstrp`
- `candexch`
- `compare`
- `cordexch`
- `crossval`
- `daugment`
- `dcovary`
- `jackknife`
- `kmeans`
The following functions for fitting multiclass models for support vector machines and other classifiers are also enhanced to use parallel computing internally.

- **fitcecoc**
- Methods of the class `ClassificationECOC`:
  - `resubEdge`
  - `resubLoss`
  - `resubMargin`
  - `resubPredict`
  - `crossval`
- Methods of the class `CompactClassificationECOC`
  - `edge`
  - `loss`
  - `margin`
  - `predict`
- Methods of the class `ClassificationPartitionedECOC`
• `kfoldEdge`
• `kfoldLoss`
• `kfoldMargin`
• `kfoldPredict`

• Methods of the class `ClassificationPartitionedLinearECOC`
  • `kfoldEdge`
  • `kfoldLoss`
  • `kfoldMargin`
  • `kfoldPredict`

The following functions perform hyperparameter optimization in parallel.

• `fitcdiscr`
• `fitcecoc`
• `fitctree`
• `fitclinear`
• `fitcknn`
• `fitrgp`
• `fitrtree`
• `fitcensemble`
• `fitcnb`
• `fitcsvm`
• `fitrensemble`
• `fitrlinear`
• `fitrsvm`
• `fitrkernel`
• `fitckernel`

This chapter gives the simplest way to use these enhanced functions in parallel. For more advanced topics, including the issues of reproducibility and nested `parfor` loops, see the other sections in this chapter.

For information on parallel statistical computing at the command line, enter
help parallelstats

**How To Compute in Parallel**

To have a function compute in parallel:

1. “Set Up a Parallel Environment” on page 30-5
2. “Set the UseParallel Option to true” on page 30-5
3. “Call the Function Using the Options Structure” on page 30-5

**Set Up a Parallel Environment**

To run a statistical computation in parallel, first set up a parallel environment.

**Note** Setting up a parallel environment can take several seconds.

For a multicore machine, enter the following at the MATLAB command line:

```
parpool(n)
```

*n* is the number of workers you want to use.

**Set the UseParallel Option to true**

Create an options structure with the `statset` function. To run in parallel, set the `UseParallel` option to `true`:

```
paroptions = statset('UseParallel',true);
```

**Call the Function Using the Options Structure**

Call your function with syntax that uses the options structure. For example:

```
% Run crossval in parallel
cvMse = crossval('mse',x,y,'predfun',regf,'Options',paroptions);

% Run bootstrap in parallel
sts = bootstrap(100,@(x)[mean(x) std(x)],y,'Options',paroptions);

% Run TreeBagger in parallel
b = TreeBagger(50,meas,spec,'OOBPred','on','Options',paroptions);
```

After you have finished computing in parallel, close the parallel environment:

deletemypool

**Tip** To save time, keep the pool open if you expect to compute in parallel again soon.
Use Parallel Processing for Regression TreeBagger Workflow

This example shows you how to:

- Use an ensemble of bagged regression trees to estimate feature importance.
- Improve computation speed by using parallel computing.

The sample data is a database of 1985 car imports with 205 observations, 25 predictors, and 1 response, which is insurance risk rating, or "symboling." The first 15 variables are numeric and the last 10 are categorical. The symboling index takes integer values from -3 to 3.

Load the sample data and separate it into predictor and response arrays.

```matlab
load imports-85;
Y = X(:,1);
X = X(:,2:end);
```

Set up the parallel environment to use two cores.

```matlab
mypool = parpool(2)
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 2 workers.

```matlab
mypool =
```

Pool with properties:

```matlab
    Connected: true
    NumWorkers: 2
    Cluster: local
    AttachedFiles: {}
    AutoAddClientPath: true
    IdleTimeout: 30 minutes (30 minutes remaining)
    SpmdEnabled: true
```

Set the options to use parallel processing.

```matlab
paroptions = statset('UseParallel',true);
```
Estimate feature importance using leaf size 1 and 5000 trees in parallel. Time the function for comparison purposes.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ... 
    'cat',16:25,'MinLeafSize',1,'Options',paroptions);
toc
```

Elapsed time is 47.468605 seconds.

Perform the same computation in serial for timing comparison.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ... 
    'cat',16:25,'MinLeafSize',1);
toc
```

Elapsed time is 105.114259 seconds.

The results show that computing in parallel takes a fraction of the time it takes to compute serially. Note that the elapsed time can vary depending on your operating system.

Subtleties in Parallel Computing

There are two main subtleties in parallel computations:

- Nested parallel evaluations (see “No Nested parfor Loops” on page 30-13). Only the outermost `parfor` loop runs in parallel, the others run serially.
- Reproducible results when using random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-15). How can you get exactly the same results when repeatedly running a parallel computation that uses random numbers?

Vocabulary for Parallel Computation

- worker — An independent MATLAB session that runs code distributed by the client.
- client — The MATLAB session with which you interact, and that distributes jobs to workers.
- `parfor` — A Parallel Computing Toolbox function that distributes independent code segments to workers (see “Working with parfor” on page 30-12).
- random stream — A pseudorandom number generator, and the sequence of values it generates. MATLAB implements random streams with the `RandStream` class.
- reproducible computation — A computation that can be exactly replicated, even in the presence of random numbers (see “Reproducibility in Parallel Statistical Computations” on page 30-15).
Why Run in Parallel?

The main reason to run statistical computations in parallel is to gain speed, meaning to reduce the execution time of your program or functions. “Factors Affecting Speed” on page 30-10 discusses the main items affecting the speed of programs or functions. “Factors Affecting Results” on page 30-11 discusses details that can cause a parallel run to give different results than a serial run.

Note Some Statistics and Machine Learning Toolbox functions have built-in parallel computing capabilities. See Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2. You can also use any Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox functions such as parfor loops. To decide when to call functions in parallel, consider the factors affecting speed and results.

Factors Affecting Speed

Some factors that can affect the speed of execution of parallel processing are:

- Parallel environment setup. It takes time to run parpool to begin computing in parallel. If your computation is fast, the setup time can exceed any time saved by computing in parallel.
- Parallel overhead. There is overhead in communication and coordination when running in parallel. If function evaluations are fast, this overhead could be an appreciable part of the total computation time. Thus, solving a problem in parallel can be slower than solving the problem serially. For an example, see Improving Optimization Performance with Parallel Computing in MATLAB Digest, March 2009.
- No nested parfor loops. This is described in “Working with parfor” on page 30-12. parfor does not work in parallel when called from within another parfor loop. If you have programmed your custom functions to take advantage of parallel processing, the
limitation of no nested parfor loops can cause a parallel function to run slower than expected.

- When executing serially, parfor loops run slightly slower than for loops.
- Passing parameters. Parameters are automatically passed to worker sessions during the execution of parallel computations. If there are many parameters, or they take a large amount of memory, passing parameters can slow the execution of your computation.
- Contention for resources: network and computing. If the pool of workers has low bandwidth or high latency, parallel computation can be slow.

**Factors Affecting Results**

Some factors can affect results when using parallel processing. You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. Some important factors are:

- Persistent or global variables. If any functions use persistent or global variables, these variables can take different values on different worker processors. The body of a parfor loop cannot contain global or persistent variable declarations.
- Accessing external files. The order of computations is not guaranteed during parallel processing, so external files can be accessed in unpredictable order, leading to unpredictable results. Furthermore, if multiple processors try to read an external file simultaneously, the file can become locked, leading to a read error, and halting function execution.
- Noncomputational functions, such as input, plot, and keyboard, can behave badly when used in your custom functions. Do not use these functions in a parfor loop, because they can cause a worker to become nonresponsive, since it is waiting for input.
- parfor does not allow break or return statements.
- The random numbers you use can affect the results of your computations. See “Reproducibility in Parallel Statistical Computations” on page 30-15.

For advice on converting for loops to use parfor, see “Parallel for-Loops (parfor)” (Parallel Computing Toolbox).
Working with parfor

</thead>
<tbody>
<tr>
<td>“How Statistical Functions Use parfor” on page 30-12</td>
</tr>
<tr>
<td>“Characteristics of parfor” on page 30-13</td>
</tr>
</tbody>
</table>

**How Statistical Functions Use parfor**

parfor is a Parallel Computing Toolbox function similar to a for loop. Parallel statistical functions call parfor internally. parfor distributes computations to worker processors.

Characteristics of parfor

You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. For advice on using parfor, see “Parallel for-Loops (parfor)” (Parallel Computing Toolbox).

No Nested parfor Loops

parfor does not work in parallel when called from within another parfor loop, or from an spmd block. Parallelization occurs only at the outermost level.
Suppose, for example, you want to apply `jackknife` to your function `userfcn`, which calls `parfor`, and you want to call `jackknife` in a loop. The following figure shows three cases:

1. The outermost loop is `parfor`. Only that loop runs in parallel.
2. The outermost `parfor` loop is in `jackknife`. Only `jackknife` runs in parallel.
3. The outermost `parfor` loop is in `userfcn`. `userfcn` uses `parfor` in parallel.

**Bold** indicates the function that runs in parallel

```
1  parfor i=1:10
   x(i)=jackknife(@userfcn,...)
end
```

```
2  for i=1:10
   x(i)=jackknife(@userfcn,...)
end
```

```
3  for i=1:10
   x(i)=jackknife(@userfcn,...)
end
```

**When parfor Runs in Parallel**

For help converting nested loops to use `parfor`, see “Convert for-Loops Into parfor-Loops” (Parallel Computing Toolbox).

See also Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 30-2.
Reproducibility in Parallel Statistical Computations

In this section...

| “Issues and Considerations in Reproducing Parallel Computations” on page 30-15 |
| “Running Reproducible Parallel Computations” on page 30-15 |
| “Parallel Statistical Computation Using Random Numbers” on page 30-16 |

Issues and Considerations in Reproducing Parallel Computations

A reproducible computation is one that gives the same results every time it runs. Reproducibility is important for:

- **Debugging** — To correct an anomalous result, you need to reproduce the result.
- **Confidence** — When you can reproduce results, you can investigate and understand them.
- **Modifying existing code** — When you change existing code, you want to ensure that you do not break anything.

Generally, you do not need to ensure reproducibility for your computation. Often, when you want reproducibility, the simplest technique is to run in serial instead of in parallel. In serial computation you can simply call the `rng` function as follows:

```matlab
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

This section addresses the case when your function uses random numbers, and you want reproducible results in parallel. This section also addresses the case when you want the same results in parallel as in serial.

Running Reproducible Parallel Computations

To run a Statistics and Machine Learning Toolbox function reproducingly:

1. Set the `UseSubstreams` option to `true`.  
**Parallel Statistical Computation Using Random Numbers**

**What Are Substreams?**

A substream is a portion of a random stream that RandStream can access quickly. There is a number $M$ such that for any positive integer $k$, RandStream can go to the $kM$th pseudorandom number in the stream. From that point, RandStream can generate the subsequent entries in the stream. Currently, RandStream has $M = 2^{72}$, about $5 \times 10^{21}$, or more.

<table>
<thead>
<tr>
<th>Beginning of stream</th>
<th>$M$</th>
<th>$2M$</th>
<th>$3M$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Substream 1</td>
<td>Substream 2</td>
<td>Substream 3</td>
<td></td>
</tr>
</tbody>
</table>

For example, to use the 'mlfg6331_64' stream for reproducible computation:

1. Create an appropriate options structure:
   ```
s = RandStream('mlfg6331_64');
options = statset('UseParallel',true, ...
                 'Streams',s,'UseSubstreams',true);
```
3. Reset the random stream:
   ```
   reset(s);
   ```

For an example of a parallel computation run this reproducible way, see “Reproducible Parallel Bootstrap” on page 30-27.
The entries in different substreams have good statistical properties, similar to the properties of entries in a single stream: independence, and lack of $k$-way correlation at various lags. The substreams are so long that you can view the substreams as being independent streams, as in the following picture.

<table>
<thead>
<tr>
<th>Substream 1</th>
<th>Substream 2</th>
<th>Substream 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random Number 1</td>
<td>Random Number 1</td>
<td>Random Number 1</td>
</tr>
<tr>
<td>Random Number 2</td>
<td>Random Number 2</td>
<td>Random Number 2</td>
</tr>
<tr>
<td>Random Number 3</td>
<td>Random Number 3</td>
<td>Random Number 3</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

Two RandStream stream types support substreams: 'mlfg6331_64' and 'mrg32k3a'.

**How Substreams Enable Reproducible Parallel Computations**

When MATLAB performs computations in parallel with `parfor`, each worker receives loop iterations in an unpredictable order. Therefore, you cannot predict which worker gets which iteration, so cannot determine the random numbers associated with each iteration.

Substreams allow MATLAB to tie each iteration to a particular sequence of random numbers. `parfor` gives each iteration an index. The iteration uses the index as the substream number. Since the random numbers are associated with the iterations, not with the workers, the entire computation is reproducible.

To obtain reproducible results, simply reset the stream, and all the substreams generate identical random numbers when called again. This method succeeds when all the workers use the same stream, and the stream supports substreams. This concludes the discussion of how the procedure in “Running Reproducible Parallel Computations” on page 30-15 gives reproducible parallel results.

**Random Numbers on the Client or Workers**

A few functions generate random numbers on the client before distributing them to parallel workers. The workers do not use random numbers, so operate purely deterministically. For these functions, you can run a parallel computation reproducibly using any random stream type.
The functions that operate this way include:

- crossval
- plsregress
- sequentialfs

To obtain identical results, reset the random stream on the client, or the random stream you pass to the client. For example:

```matlab
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

While this method enables you to run reproducibly in parallel, the results can differ from a serial computation. The reason for the difference is `parfor` loops run in reverse order from `for` loops. Therefore, a serial computation can generate random numbers in a different order than a parallel computation. For unequivocal reproducibility, use the technique in “Running Reproducible Parallel Computations” on page 30-15.

**Distributing Streams Explicitly**

For testing or comparison using particular random number algorithms, you must set the random number generators. How do you set these generators in parallel, or initialize streams on each worker in a particular way? Or you might want to run a computation using a different sequence of random numbers than any other you have run. How can you ensure the sequence you use is statistically independent?

Parallel Statistics and Machine Learning Toolbox functions allow you to set random streams on each worker explicitly. For information on creating multiple streams, enter `help RandStream/create` at the command line. To create four independent streams using the 'mrg32k3a' generator:

```matlab
s = RandStream.create('mrg32k3a','NumStreams',4,...
    'CellOutput',true);
```

Pass these streams to a statistical function using the `Streams` option. For example:

```matlab
parpool(4) % if you have at least 4 cores
s = RandStream.create('mrg32k3a','NumStreams',4,...
    'CellOutput',true); % create 4 independent streams
paroptions = statset('UseParallel',true,...
    'Streams',s); % set the 4 different streams
```
x = [randn(700,1); 4 + 2*randn(300,1)];
latt = -4:0.01:12;
myfun = @(X) ksdensity(X,latt);
pdfestimate = myfun(x);
B = bootstrp(200,myfun,x,'Options',paroptions);

This method of distributing streams gives each worker a different stream for the computation. However, it does not allow for a reproducible computation, because the workers perform the 200 bootstraps in an unpredictable order. If you want to perform a reproducible computation, use substreams as described in “Running Reproducible Parallel Computations” on page 30-15.

If you set the UseSubstreams option to true, then set the Streams option to a single random stream of the type that supports substreams ('mlfg6331_64' or 'mrg32k3a'). This setting gives reproducible computations.
Implement Jackknife Using Parallel Computing

This example is from the jackknife function reference page, but runs in parallel.

```matlab
mypool=parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

    Pool with properties:
    
    AttachedFiles: {0x1 cell}
    NumWorkers: 2
    IdleTimeout: 30
    Cluster: [1x1 parallel.cluster.Local]
    RequestQueue: [1x1 parallel.RequestQueue]
    SpmdEnabled: 1

opts = statset('UseParallel',true);
sigma = 5;
rng('default')
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y,1,'Options',opts);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =

    -0.2500

jbias =

    -0.3378

This simple example is not a good candidate for parallel computation:

% How long to compute in serial?
tic;m = jackknife(@var,y,1);toc
Elapsed time is 0.022771 seconds.

% How long to compute in parallel?
tic;m = jackknife(@var,y,1,'Options',opts);toc
Elapsed time is 0.299066 seconds.
```
jackknife does not use random numbers, so gives the same results every time, whether run in parallel or serial.
Implement Cross-Validation Using Parallel Computing

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Simple Parallel Cross Validation” on page 30-22</td>
</tr>
<tr>
<td>“Reproducible Parallel Cross Validation” on page 30-23</td>
</tr>
</tbody>
</table>

**Simple Parallel Cross Validation**

This example is the same as the first in the `crossval` function reference page, but runs in parallel.

```matlab
cmypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.

cmypool = 

    Pool with properties:

    AttachedFiles: {0x1 cell}
    NumWorkers: 2
    IdleTimeout: 30
    Cluster: [1x1 parallel.cluster.Local]
    RequestQueue: [1x1 parallel.RequestQueue]
    SpmdEnabled: 1

copts = statset('UseParallel',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)
cvMse =

    0.1028

This simple example is not a good candidate for parallel computation:

```matlab
% How long to compute in serial?
tic;cvMse = crossval('mse',X,y,'Predfun',regf);toc
Elapsed time is 0.073438 seconds.
```
Reproducible Parallel Cross Validation

To run crossval in parallel in a reproducible fashion, set the options and reset the random stream appropriately (see “Running Reproducible Parallel Computations” on page 30-15).

% How long to compute in parallel?
tic;cvMse = crossval('mse',X,y,'Predfun',regf,...
    'Options',opts);toc
Elapsed time is 0.289585 seconds.

mypool = parpool()

Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

    Pool with properties:

    AttachedFiles: {0x1 cell}
    NumWorkers: 2
    IdleTimeout: 30
    Cluster: [1x1 parallel.cluster.Local]
    RequestQueue: [1x1 parallel.RequestQueue]
    SpmdEnabled: 1

s = RandStream('mlfg6331_64');
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)
cvMse =
    0.1020

Reset the stream:
reset(s)
cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

0.1020
Bootstrap in Serial and Parallel

Here is an example timing a bootstrap in parallel versus in serial. The example generates data from a mixture of two Gaussians, constructs a nonparametric estimate of the resulting data, and uses a bootstrap to get a sense of the sampling variability.

1. Generate the data:

   ```matlab
   % Generate a random sample of size 1000,
   % from a mixture of two Gaussian distributions
   x = [randn(700,1); 4 + 2*randn(300,1)];
   ``

2. Construct a nonparametric estimate of the density from the data:

   ```matlab
   latt = -4:0.01:12;
   myfun = @(X) ksdensity(X,latt);
   pdfestimate = myfun(x);
   ``

3. Bootstrap the estimate to get a sense of its sampling variability. Run the bootstrap in serial for timing comparison.

   ```matlab
   tic;B = bootstrp(200,myfun,x);toc
   Elapsed time is 10.878654 seconds.
   ``

4. Run the bootstrap in parallel for timing comparison:

   ```matlab
   mypool = parpool()
   Starting parpool using the 'local' profile ... connected to 2 workers.
   mypool =
   
   Pool with properties:
   
   AttachedFiles: {0x1 cell}
   NumWorkers: 2
   IdleTimeout: 30
   Cluster: [1x1 parallel.cluster.Local]
RequestQueue: [1x1 parallel.RequestQueue]
SpmdEnabled: 1

opt = statset('UseParallel',true);
tic;B = bootstrap(200,myfun,x,'Options',opt);toc

Elapsed time is 6.304077 seconds.

Computing in parallel is nearly twice as fast as computing in serial for this example.

Overlay the ksdensity density estimate with the 200 bootstrapped estimates obtained in the parallel bootstrap. You can get a sense of how to assess the accuracy of the density estimate from this plot.

hold on
for i=1:size(B,1),
    plot(latt,B(i,:),c:)
end
plot(latt,pdfestimate);
xlabel('x');ylabel('Density estimate')
Reproducible Parallel Bootstrap

To run the example in parallel in a reproducible fashion, set the options appropriately (see “Running Reproducible Parallel Computations” on page 30-15). First set up the problem and parallel environment as in “Bootstrap in Serial and Parallel” on page 30-25. Then set the options to use substreams along with a stream that supports substreams.

```matlab
s = RandStream('mlfg6331_64'); % has substreams
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);
B2 = bootstrp(200,myfun,x,'Options',opts);
```

To rerun the bootstrap and get the same result:
reset(s) % set the stream to initial state
B3 = bootstrap(200,myfun,x,'Options',opts);
isequal(B2,B3) % check if same results

ans =
  1

Generating C/C++ code requires MATLAB Coder. MATLAB Coder generates readable and portable C and C++ code from Statistics and Machine Learning Toolbox functions that support code generation. You can integrate the generated code into your projects as source code, static libraries, or dynamic libraries. You can also use the generated code within the MATLAB environment to accelerate computationally intensive portions of your MATLAB code.

For a list of the code-generation-enabled functions in Statistics and Machine Learning Toolbox, see “Code Generation Support, Usage Notes, and Limitations” on page 31-49. For the code generation usage notes and limitations for each function, see the Code Generation section on the function reference page. Note that the MATLAB Coder limitations apply to Statistics and Machine Learning Toolbox for code generation. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder). In addition to these limitations, code generation in Statistics and Machine Learning Toolbox does not support sparse matrix.

Code Generation Workflows

You can generate C/C++ code for the Statistics and Machine Learning Toolbox functions in several ways.

- General code generation workflow for functions that are not the object functions of machine learning models

![Code Generation Workflow Diagram](https://example.com/code_generation_diagram.png)

Define an *entry-point* function that calls the function that supports code generation, generate C/C++ code for the entry-point function by using `codegen`, and then verify the generated code. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any
function at the top level using `codegen`, you must define an entry-point function. All functions within the entry-point function must support code generation.

For details, see “General Code Generation Workflow” on page 31-5.

- Code generation workflow for the object function (`predict`, `random`, `knnsearch`, or `rangesearch`) of a machine learning model

Save a trained model by using `saveCompactModel`, and define an entry-point function that loads the saved model by using `loadCompactModel` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code. The input arguments of the entry-point function cannot be classification or regression model objects. Therefore, you need to work around this limitation by using `saveCompactModel` and `loadCompactModel`.

For details, see these examples

- “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10
- “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20
- “Code Generation for Nearest Neighbor Searcher” on page 31-15
- “Code Generation and Classification Learner App” on page 31-31
- “Specify Variable-Size Arguments for Code Generation” on page 31-57
- Code generation workflow for the `predict` and `update` functions of an SVM model:
Create a coder configurer by using `learnerCoderConfigurer`, generate code by using `generateCode`, and then verify the generated code. You can configure code generation options and specify the coder attributes of the model parameters using object properties. After you retrain the model with new data or settings, you can update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code.

For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-90.

**Code Generation Applications**

Code generation for the Statistics and Machine Learning Toolbox functions also works with other toolboxes such as Simulink®, System object™, and Stateflow®, as described in these examples:

- “Predict Class Labels Using MATLAB Function Block” on page 31-43
- “System Objects for Classification and Code Generation” on page 31-64
- “Predict Class Labels Using Stateflow” on page 31-75

For more applications of code generation, see these examples:

- “Code Generation for Image Classification”
- “Human Activity Recognition Simulink Model for Smartphone Deployment” on page 31-80

General Code Generation Workflow

The general code generation workflow for the Statistics and Machine Learning Toolbox functions that are not the object functions of machine learning models is the same as the workflow described in MATLAB Coder. For details, see “Getting Started with MATLAB Coder” (MATLAB Coder). To learn how to generate code for the object functions of machine learning models, see “Introduction to Code Generation” on page 31-2.

This example briefly explains the general code generation workflow as summarized in this flow chart:

![Flow Chart](image)

**Define Entry-Point Function**

An entry-point function, also known as the top-level or primary function, is a function you define for code generation. Because you cannot call any function at the top level using codegen, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code for the entry-point function by using codegen. All functions within the entry-point function must support code generation.

Add the %#codegen compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

For example, to generate code that estimates the interquartile range of a data set using iqr, define this function.

```matlab
function r = iqrCodeGen(x) %#codegen
%IQRCODEGEN Estimate interquartile range
% iqrCodeGen returns the interquartile range of the data x,
% a single- or double-precision vector.
r = iqr(x);
end
```

You can allow for optional input arguments by specifying varargin as an input argument. For details, see “Code Generation for Variable Length Argument Lists”
(MATLAB Coder) and “Specify Variable-Size Arguments for Code Generation” on page 31-57.

**Generate Code**

**Set Up Compiler**

To generate C/C++ code, you must have access to a compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. To view and change the default C compiler, enter:

```mex -setup```

For more details, see “Change Default Compiler” (MATLAB).

**Generate Code Using codegen**

After setting up your compiler, generate code for the entry-point function by using `codegen` or the MATLAB Coder app. To learn how to generate code using the MATLAB Coder app, see “Generate MEX Functions by Using the MATLAB Coder App” (MATLAB Coder).

To generate code at the command line, use `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

- To specify the data type and exact input array size, pass a MATLAB expression that represents the set of values with a certain data type and array size. For example, to specify that the generated code from `iqrCodeGen.m` must accept a double-precision numeric column vector with 100 elements, enter:

```testX = randn(100,1);
codegen iqrCodeGen -args {testX} -report```

The `-report` flag generates a code generation report. See “Code Generation Reports” (MATLAB Coder).

- To specify that at least one of the dimensions can have any length, use the `-args` option with `coder.typeof` as follows.

```-args {coder.typeof(example_value, size_vector, variable_dims)}````
The values of `example_value`, `size_vector`, and `variable_dims` specify the properties of the input array that the generated code can accept.

- An input array has the same data type as the example values in `example_value`.
- `size_vector` is the array size of an input array if the corresponding `variable_dims` value is `false`.
- `size_vector` is the upper bound of the array size if the corresponding `variable_dims` value is `true`.
- `variable_dims` specifies whether each dimension of the array has a variable size or a fixed size. A value of `true` (logical `1`) means that the corresponding dimension has a variable size; a value of `false` (logical `0`) means that the corresponding dimension has a fixed size.

Specifying a variable-size input is convenient when you have data with an unknown number of observations at compile time. For example, to specify that the generated code from `iqrCodeGen.m` can accept a double-precision numeric column vector of any length, enter:

```matlab
testX = coder.typeof(0,[Inf,1],[1,0]);
codegen iqrCodeGen -args {testX} -report
```

0 for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[Inf,1]` for the `size_vector` value and `[1,0]` for the `variable_dims` value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be 1.

- To specify a character array, such as supported name-value pair arguments, specify the character array as a constant using `coder.Constant`. For example, suppose that `'Name'` is a valid name-value pair argument for `iqrCodeGen.m`, and the corresponding value `value` is numeric. Then enter:

```matlab
codegen iqrCodeGen -args {testX,coder.Constant('Name'),value} -report
```

For more details, see “C Code Generation at the Command Line” (MATLAB Coder) and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

**Build Type**

MATLAB Coder can generate code for these types:

- MEX function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen`. By default, `codegen` generates a MEX function with a platform-dependent extension in your current folder. For example, suppose that you generate the code on a 64-bit Windows® platform. Then, `codegen` generates the MEX function file `iqrCodeGen_mex.mexw64` in your current folder. A MEX function is a C/C++ program that is executable from the Command Window. Generating a MEX function allows you to analyze its input and output arguments using MATLAB tools before deploying the function outside the MATLAB environment.

For more details on setting code generation options, see the `-config` option of `codegen` and “Configure Build Settings” (MATLAB Coder).

**Code Generation Report**

You can use the `-report` flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see “Code Generation Reports” (MATLAB Coder).

**Verify Generated Code**

Pass some data to verify whether `iqr`, `iqrCodeGen`, and `iqrCodeGen_mex` return the same interquartile range.

```matlab
testX = randn(100,1);
r = iqr(testX);
r_entrypoint = iqrCodeGen(testX);
r_mex = iqrCodeGen_mex(testX);
```

Compare the outputs by using `isequal`.

```matlab
isequal(r,r_entrypoint,r_mex)
```

`isequal` returns logical 1 (true) if all the inputs are equal.

You can also verify the MEX function using a test file and `coder.runTest`. For details, see “Testing Code Generated from MATLAB Code” (MATLAB Coder).

More About
• “Introduction to Code Generation” on page 31-2
• “Code Generation Support, Usage Notes, and Limitations” on page 31-49
This example shows how to generate code for the prediction of classification and regression model objects at the command line. You can also generate code using the MATLAB® Coder™ app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20 for details.

Certain classification and regression model objects have a `predict` or `random` function that supports code generation. For a list of the model objects and object functions that support code generation, see “Code Generation Support, Usage Notes, and Limitations” on page 31-49. Prediction using these object functions requires a trained classification or regression model object, but the `-args` option of `codegen` does not accept these objects. Work around this limitation by using `saveCompactModel` and `loadCompactModel` as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.

After you train a model, save the trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code.

**Train Classification Model**

Train a classification model object equipped with a code-generation-enabled `predict` function. In this case, train a support vector machine (SVM) classification model.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
Y = species(inds);
Mdl = fitcsvm(X,Y);
```

This step can include data preprocessing, feature selection, and optimizing the model using cross-validation, for example.
Save Model Using `saveCompactModel`

Save the classification model to the file `SVMModel.mat` by using `saveCompactModel`.

```matlab
saveCompactModel(Mdl,'SVMModel');
```

`saveCompactModel` makes the full classification model `Mdl` compact, and then saves it to the MATLAB binary file `SVMModel.mat` as a structure array in the current folder.

Define Entry-Point Function

An entry-point function, also known as the top-level or primary function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Define an entry-point function that returns predicted labels for input predictor data. Within the function, load the trained classification model by using `loadCompactModel`, and then pass the loaded model to `predict`. In this case, define the `predictLabelsSVM` function, which predicts labels using the SVM model `Mdl`.

```matlab
type predictLabelsSVM.m % Display contents of predictLabelsSVM.m file

function label = predictLabelsSVM(x) %#codegen
    %PREDICTLABELSSVM Label new observations using trained SVM model Mdl
    % predictLabelsSVM predicts the vector of labels label using
    % the saved SVM model Mdl and the predictor data x.
    Mdl = loadCompactModel('SVMModel');
    label = predict(Mdl,x);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

**Note:** If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.
Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate Code Using codegen

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

In this case, pass X as a value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data X.

```python
codegen predictLabelsSVM -args {X}
```

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-57 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

Build Type

MATLAB Coder can generate code for the following build types:

- MEX function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen`. By default, `codegen` generates a MEX function with a platform-dependent extension in your current folder. If you generate the code on a 64-bit Windows® platform, then the generated MEX function file is `predictLabelsSVM_mex.mexw64`. A MEX function is a C/C++ program that is executable from the Command Window. Generating a MEX file allows you to...
analyze its input and output arguments using MATLAB tools before deploying the function outside the MATLAB environment.

For more details on setting code generation options, see the -config option of codegen and “Configure Build Settings” (MATLAB Coder).

**Code Generation Report**

You can use the -report flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see “Code Generation Reports” (MATLAB Coder).

**Verify Generated Code**

Pass some predictor data to verify whether predict, predictLabelsSVM, and the MEX function return the same labels.

```matlab
labels1 = predict(Mdl,X);
labels2 = predictLabelsSVM(X);
labels3 = predictLabelsSVM_mex(X);
```

Compare the predicted labels by using isequal.

```matlab
verifyMEX = isequal(labels1,labels2,labels3)
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the predict function, predictLabelsSVM function, and MEX function return the same labels.

Code Generation for Nearest Neighbor Searcher

The object functions \texttt{knnsearch} and \texttt{rangesearch} of the nearest neighbor searcher objects, \texttt{ExhaustiveSearcher} and \texttt{KDTreeSearcher}, support code generation. This example shows how to generate code for finding the nearest neighbor using an exhaustive searcher object at the command line. The example shows two different ways to generate code, depending on the way you use the object: load the object by using \texttt{loadCompactModel} in an entry-point function, and pass a compile-time constant object to the generated code.

\textbf{Train Exhaustive Nearest Neighbor Searcher}

Load Fisher's iris data set.

\begin{verbatim}
load fisheriris
\end{verbatim}

Remove five irises randomly from the predictor data to use as a query set.

\begin{verbatim}
rng('default'); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
\end{verbatim}

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the 'Distance' and 'P' name-value pair arguments to use the Minkowski distance with an exponent of 1 for finding the nearest neighbor.

\begin{verbatim}
Mdl = ExhaustiveSearcher(X,'Distance','minkowski','P',1);
\end{verbatim}

Find the index of the training data (X) that is the nearest neighbor of each point in the query data (Y).

\begin{verbatim}
Idx = knnsearch(Mdl,Y);
\end{verbatim}

\textbf{Generate Code Using saveCompactModel and loadCompactModel}

Generate code that loads an exhaustive searcher, takes query data as an input argument, and then finds the nearest neighbor.

Save the exhaustive searcher to a file using \texttt{saveCompactModel}.

\begin{verbatim}
saveCompactModel(Mdl,'searcherModel')
\end{verbatim}
saveCompactModel saves the model to the MATLAB binary file searcherModel.mat as a structure array in the current folder.

Define the entry-point function myknnsearch1 that takes query data as an input argument. Within the function, load the searcher object by using loadCompactModel, and then pass the loaded model to knnsearch.

```matlab
function idx = myknnsearch1(x) %#codegen
Mdl = loadCompactModel('searcherModel');
idx = knnsearch(Mdl,x);
end
```

**Note:** If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function files, myknnsearch1.m, myknnsearch2.m, and myknnsearch3.m.

Generate code for myknnsearch1 by using codegen. Specify the data type and dimension of the input argument by using coder.typeof so that the generated code accepts a variable-size array.

```matlab
codegen myknnsearch1 -args {coder.typeof(Y,[Inf,4],[1,0])}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch1\html\report.mldatx').

For more detailed code generation example that uses saveCompactModel and loadCompactModel, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10. For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 31-57.

Pass the query data (Y) to verify that myknnsearch1 and the MEX file return the same indices.

```matlab
myIdx1 = myknnsearch1(Y);
myIdx1_mex = myknnsearch1_mex(Y);
```

Compare myIdx1 and myIdx1_mex by using isequal.

```matlab
verifyMEX1 = isequal(Idx,myIdx1,myIdx1_mex)
```
isequal returns logical 1 (true) if all the inputs are equal. This comparison confirms that myknnsearch1 and the MEX file return the same results.

**Generate Code with Constant Folded Model Object**

Nearest neighbor searcher objects can be an input argument of a function you define for code generation. The `-args` option of codegen accept a compile-time constant searcher object.

Define the entry-point function `myknnsearch2` that takes both an exhaustive searcher model and query data as input arguments instead of loading the model in the function.

```matlab
type myknnsearch2.m % Display contents of myknnsearch2.m file
function idx = myknnsearch2(Mdl,x) %#codegen
    idx = knnsearch(Mdl,x);
end
```

To generate code that takes the model object as well as the query data, designate the model object as a compile-time constant by using `coder.Constant` and include the constant folded model object in the `-args` value of codegen.

```matlab
codegen myknnsearch2 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0])}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch2\html\report.mldatx').

The code generation workflow with a constant folded model object follows general code generation workflow. For details, see “General Code Generation Workflow” on page 31-5.

Verify that `myknnsearch2` and the MEX file return the same results.

```matlab
myIdx2 = myknnsearch2(Mdl,Y);
myIdx2_mex = myknnsearch2_mex(Mdl,Y);
verifyMEX2 = isequal(Idx,myIdx2,myIdx2_mex)
```

```matlab
verifyMEX2 = logical
    1
```
Generate Code with Name-Value Pair Arguments

Define the entry-point function `myknnsearch3` that takes a model object, query data, and name-value pair arguments. You can allow for optional name-value arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```matlab
type myknnsearch3.m % Display contents of myknnsearch3.m file
function idx = myknnsearch3(Mdl,x,varargin) %#codegen
    idx = knnsearch(Mdl,x,varargin{:});
end
```

To generate code that allows a user-defined exponent for the Minkowski distance, include `{coder.Constant('P'),0}` in the `-args` value of `codegen`. Use `coder.Constant` because the name of a name-value pair argument must be a compile-time constant.

```matlab
codegen myknnsearch3 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0]),coder.Constant('P'),0}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnsearch3\html\report.mldatx')

Verify that `myknnsearch3` and the MEX file return the same results.

```matlab
newIdx = knnsearch(Mdl,Y,'P',2);
myIdx3 = myknnsearch3(Mdl,Y,'P',2);
myIdx3_mex = myknnsearch3_mex(Mdl,Y,'P',2);
verifyMEX3 = isequal(newIdx,myIdx3,myIdx3_mex)
```

`verifyMEX3 = logical 1`

Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App

This example shows how to generate C/C++ code for the prediction of classification and regression model objects by using the MATLAB® Coder™ app. You can also generate code at the command line using codegen. See “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10 for details.

Certain classification and regression model objects have a predict or random function that supports code generation. For a list of the model objects and object functions that support code generation, see “Code Generation Support, Usage Notes, and Limitations” on page 31-49. Prediction using these object functions requires a trained classification or regression model object, but an entry-point function for code generation cannot have these objects as input variables. Work around this limitation by using saveCompactModel and loadCompactModel as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.

In this example, you train a classification ensemble model using k-nearest-neighbor weak learners and save the trained model by using saveCompactModel. Then, define an entry-point function that loads the saved model by using loadCompactModel and calls the object function. Write a script to test the entry-point function. Finally, generate code by using the MATLAB Coder app and verify the generated code.

**Train Classification Model**

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```matlab
load ionosphere
```

Train a classification ensemble model with k-nearest-neighbor weak learners by using the random subspace method. For details of classifications that use a random subspace ensemble, see “Random Subspace Classification” on page 18-133.

```matlab
rng('default')  % For reproducibility
learner = templateKNN('NumNeighbors',2);
```
Mdl = fitcensemble(X,Y,'Method','Subspace','NPredToSample',5,...
    'Learners',learner,'NumLearningCycles',13);

**Save Model Using saveCompactModel**

Save the trained ensemble model to a file named `knnEnsemble.mat` in your current folder.

```
saveCompactModel(Mdl,'knnEnsemble')
```

SaveCompactModel makes the full classification model `Mdl` compact, and then saves it to the MATLAB binary file `knnEnsemble.mat` as a structure array in the current folder.

**Define Entry-Point Function**

An entry-point function, also known as the top-level or primary function, is a function you define for code generation. You must define an entry-point function that calls code-generation-enabled functions and generate C/C++ code from the entry-point function. All functions within the entry-point function must support code generation.

In a new file in your current folder, define an entry-point function named `myknnEnsemblePredict` that does the following:

- Accept input data (`X`), the file name of the saved model (`fileName`), and valid name-value pair arguments of the `predict` function (`varargin`).
- Load a trained ensemble model by using `loadCompactModel`.
- Predict labels and corresponding scores from the loaded model.

You can allow for optional name-value arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type myknnEnsemblePredict.m % Display the contents of myknnEnsemblePredict.m file.

function [label,score] = myknnEnsemblePredict(X,fileName,varargin) %#codegen
    CompactMdl = loadCompactModel(fileName);
    [label,score] = predict(CompactMdl,X,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you
diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

**Note:** If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file (myknnEnsemblePredict.m) and the test file (test_myknnEnsemblePredict.m, described later on).

**Set Up Compiler**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

**Create Test File**

Write a test script that calls the myknnEnsemblePredict function. In the test script, specify the input arguments and name-value pair arguments that you use in the generated code. You use this test script to define input types automatically when generating code using the MATLAB Coder app.

In this example, create the `test_myknnEnsemblePredict.m` file in your current folder, as shown.

```matlab
type test_myknnEnsemblePredict.m % Display the contents of test_myknnEnsemblePredict.m

% Load Sample data
load ionosphere

% Test myknnEnsemblePredict
[label,score] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:13);
```

For details, see “Automatically Define Input Types by Using the App” (MATLAB Coder).

**Generate Code Using MATLAB Coder App**

The MATLAB Coder app generates C or C++ code from MATLAB® code. The workflow-based user interface steps you through the code generation process. The following steps describe a brief workflow of the MATLAB Code App. For more details, see MATLAB Coder and “C Code Generation Using the MATLAB Coder App” (MATLAB Coder).

1. **Open the MATLAB Code App and Select the Entry-Point Function File.**
On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to open the apps gallery. Under **Code Generation**, click **MATLAB Coder**. The app opens the **Select Source Files** page. Enter or select the name of the entry-point function, `myknnEnsemblePredict`.

![MATLAB Coder - myknnEnsemblePredict.prj](image)

Click **Next** to go to the **Define Input Types** page.

### 2. Define Input Types

Because C uses static typing, MATLAB Coder must determine the properties of all variables in the MATLAB files at compile time. Therefore, you need to specify the properties of the entry-point function inputs.
Enter or select the test script `test_myknnEnsemblePredict` and click **Autodefine Input Types**.

The MATLAB Coder app recognizes input types of the `myknnEnsemblePredict` function based on the test script.

Modify the input types:

- **X** — The app infers that input `X` is `double(351 x 34)`. The number of predictors must be fixed to be the same as the number of predictors in the trained model. However, you can have a different number of observations for prediction. If the number of observations is unknown, change `double(351 x 34)` to `double(:351 x 34)` or
double(:inf x 34). The setting double(:351 x 34) allows the number of observations up to 351, and the setting double(:inf x 34) allows an unbounded number of observations. In this example, specify double(:inf x 34) by clicking 351 and selecting :inf.

- **fileName** — Click **char**, select **Define Constant**, and type the file name with single quotes, 'knnEnsemble'.

- **vargrign{1}** — Names in name-value pair arguments must be compile-time constants. Click **char**, select **Define Constant**, and type 'Learners'.

- **vargrign{2}** — To allow user-defined indices up to 13 weak learners in the generated code, change double(1 x 13) to double(1 x :13).
Click **Next** to go to the **Check for Run-Time Issues** page. This optional step generates a MEX file, runs the MEX function, and reports issues. Click **Next** to go to the **Generate Code** page.

### 3. Generate C Code

Set **Build type** to MEX and click **Generate**. The app generates a MEX function, `myknnEnsemblePredict_mex`, which you can use to analyze its input and output arguments in MATLAB before deploying the function outside the MATLAB environment. Depending on the specified build type, MATLAB Coder generates a MEX function or standalone C/C++ code compiled to a static library, dynamic linked library, or executable. For details on setting a build type, see “Configure Build Settings” (MATLAB Coder).
Click **Next** to go to the **Finish Workflow** page.

**4. Review the Finish Workflow Page**

The **Finish Workflow** page indicates that code generation succeeded. This page also provides a project summary and links to generated output.

---

**MEX Generated Successfully**

You can now use the MEX function to accelerate MATLAB code. [Learn more](#)

**Project Summary**

---

**Generate Code Using Script**

You can convert a MATLAB Coder project to the equivalent script of MATLAB commands after you define input types. Then you run the script to generate code. For details, see “Convert MATLAB Coder Project to MATLAB Script” (MATLAB Coder).
On the MATLAB Coder app toolbar, click the **Open action menu** button.

Select **Convert to script**, and then click **Save**. The app creates the file `myknnEnsemblePredict_script.m`, which reproduces the project in a configuration object and runs the `codegen` function.

Display the contents of the file `myknnEnsemblePredict_script.m`.

```matlab
type myknnEnsemblePredict_script.m

% MYKNNENSEMBLEPREDICT_SCRIPT   Generate MEX-function myknnEnsemblePredict_mex
% from myknnEnsemblePredict.
%
% Script generated from project 'myknnEnsemblePredict.prj' on 17-Nov-2017.
% See also CODER, CODER.CONFIG, CODER.TYPEOF, CODEGEN.
%
% Create configuration object of class 'coder.MexCodeConfig'.
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.ReportPotentialDifferences = false;

% Define argument types for entry-point 'myknnEnsemblePredict'.
ARGS = cell(1,1);
ARGS{1} = cell(4,1);
ARGS{1}{1} = coder.typeof(0,[Inf 34],[1 0]);
ARGS{1}{2} = coder.Constant('knnEnsemble');
ARGS{1}{3} = coder.Constant('Learners');
ARGS{1}{4} = coder.typeof(0,[1 13],[0 1]);

% Invoke MATLAB Coder.
codegen -config cfg myknnEnsemblePredict -args ARGS{1} -nargout 2

Run the script.

myknnEnsemblePredict_script

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\myknnEnsemblePredict\html\report.mldatx').
Verify Generated Code

Pass some predictor data to verify that `myknnEnsemblePredict` and the MEX function return the same results.

```matlab
[label1,score1] = predict(Mdl,X,'Learners',1:10);
[label2,score2] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:10);
[label3,score3] = myknnEnsemblePredict_mex(X,'knnEnsemble','Learners',1:10);
```

Compare `label1`, `label2`, and `label3` by using `isequal`.

```matlab
isequal(label1,label2,label3)
ans = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal.

The `score3` output from the MEX function might include round-off differences compared with the output from the `predict` function. In this case, compare `score1` and `score3`, allowing a small tolerance.

```matlab
find(abs(score1-score3) > 1e-12)
ans =
   0x1 empty double column vector
```

`find` returns an empty vector if the element-wise absolute difference between `score1` and `score3` is not larger than the specified tolerance `1e-12`. The comparisons confirm that `myknnEnsemblePredict` and the MEX function return the same results.

• “C Code Generation Using the MATLAB Coder App” (MATLAB Coder)
Code Generation and Classification Learner App

Classification Learner is well suited for choosing and training classification models interactively, but it does not generate C/C++ code that labels data based on a trained model. The Generate Code feature in the Export section of the Classification Learner app generates MATLAB code for training a model but does not generate C/C++ code. This example shows how to generate C code from a function that predicts labels using an exported classification model. The example builds a model that predicts the credit rating of a business given various financial ratios, according to these steps:

1 Use the credit rating data set in the file CreditRating_Historical.dat, which is included with Statistics and Machine Learning Toolbox.
2 Reduce the data dimensionality using principal component analysis (PCA).
3 Train a set of models that support code generation for label prediction.
4 Export the model with the minimum 5-fold, cross-validated classification accuracy.
5 Generate C code from an entry-point function that transforms the new predictor data and then predicts corresponding labels using the exported model.

Load Sample Data

Load sample data and import the data into the Classification Learner app. Review the data using scatter plots and remove unnecessary predictors.

Use `readtable` to load the historical credit rating data set in the file CreditRating_Historical.dat into a table.

```
creditrating = readtable('CreditRating_Historical.dat');
```

On the Apps tab, click Classification Learner.

In Classification Learner, on the Classification Learner tab, in the File section, click New Session and select From Workspace.

In the New Session dialog box, select the table `creditrating`. All variables, except the one identified as the response, are double-precision numeric vectors. Click Start Session to compare classification models based on the 5-fold, cross-validated classification accuracy.
Classification Learner loads the data and plots a scatter plot of the variables WC_TA versus ID. Because identification numbers are not helpful to display in a plot, choose RE_TA for X under Predictors.

The scatter plot suggests that the two variables can separate the classes AAA, BBB, BB, and CCC fairly well. However, the observations corresponding to the remaining classes are mixed into these classes.

Identification numbers are not helpful for prediction. Therefore, in the Features section, click Feature Selection and then clear the ID check box. You can also remove unnecessary predictors from the beginning by using the check boxes in the New Session.
dialog box. This example shows how to remove unused predictors for code generation when you have included all predictors.

**Enable PCA**

Enable PCA to reduce the data dimensionality.

In the **Features** section, click **PCA**, and then select **Enable PCA**. This action applies PCA to the predictor data, and then transforms the data before training the models. Classification Learner uses only components that collectively explain 95% of the variability.

**Train Models**

Train a set of models that support code generation for label prediction.

Select the following classification models and options, which support code generation for label prediction, and then perform cross-validation (for more details, see “Code Generation Support, Usage Notes, and Limitations” on page 31-49). To select each model, in the **Model Type** section, click **Show more** arrow, and then click the model. After selecting a model and specifying any options, close any open menus, and then click **Train** in the **Training** section.

#### Current Model

**Model 4: Trained**

**Results**

- Accuracy: 70.6%
- Prediction speed: ~4900 obs/sec
- Training time: 15,313 sec
Select the model that yields the maximum 5-fold, cross-validated classification accuracy, which is the error-correcting output codes (ECOC) model of Fine Gaussian SVM learners. With PCA enabled, Classification Learner uses two predictors out of six.

In the **Plots** section, click **Confusion Matrix**.
The model does well distinguishing between A, B, and C classes. However, the model does not do as well distinguishing between particular levels within those groups, the lower B levels in particular.

**Export Model to Workspace**

Export the model to the MATLAB Workspace and save the model using `saveCompactModel`.

In the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box.

The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationSVM` of `trainedModel` contains the compact model.

At the command line, save the compact model to a file called `ClassificationLearnerModel.mat` in your current folder.

```matlab
saveCompactModel(trainedModel.ClassificationSVM,'ClassificationLearnerModel')
```

**Generate C Code for Prediction**

Prediction using the object functions requires a trained model object, but the -args option of `codegen` does not accept such objects. Work around this limitation by using `saveCompactModel` and `loadCompactModel`. Save a trained model by using `saveCompactModel`. Then, define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Finally, use `codegen` to generate code for the entry-point function.

**Preprocess Data**

Preprocess new data in the same way you preprocess the training data.

To preprocess, you need the following three model parameters:

- **removeVars** — Column vector of at most \( p \) elements identifying indices of variables to remove from the data, where \( p \) is the number of predictor variables in the raw data
- **pcaCenters** — Row vector of exactly \( q \) PCA centers
- **pcaCoefficients** — \( q \)-by-\( r \) matrix of PCA coefficients, where \( r \) is at most \( q \)
Specify the indices of predictor variables that you removed while selecting data using **Feature Selection** in Classification Learner. Extract the PCA statistics from `trainedModel`.

```matlab
removeVars = 1;
pcaCenters = trainedModel.PCACenters;
pcaCoefficients = trainedModel.PCACoefficients;
```

Save the model parameters to a file named `ModelParameters.mat` in your current folder.

```matlab
save('ModelParameters.mat','removeVars','pcaCenters','pcaCoefficients');
```

**Define Entry-Point Function**

An entry-point function is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and then generate C/C++ code for the entry-point function by using `codegen`.

In your current folder, define a function named `mypredictCL.m` that:

- Accepts a numeric matrix (`X`) of raw observations containing the same predictor variables as the ones passed into Classification Learner
- Loads the classification model in `ClassificationLearnerModel.mat` and the model parameters in `ModelParameters.mat`
- Removes the predictor variables corresponding to the indices in `removeVars`
- Transforms the remaining predictor data using the PCA centers (`pcaCenters`) and coefficients (`pcaCoefficients`) estimated by Classification Learner
- Returns predicted labels using the model

```matlab
function label = mypredictCL(X) %#codegen
%MYPREDICTCL Classify credit rating using model exported from
%Classification Learner
% MYPREDICTCL loads trained classification model (SVM) and model
% parameters (removeVars, pcaCenters, and pcaCoefficients), removes the
% columns of the raw matrix of predictor data in X corresponding to the
% indices in removeVars, transforms the resulting matrix using the PCA
% centers in pcaCenters and PCA coefficients in pcaCoefficients, and then
% uses the transformed data to classify credit ratings. X is a numeric
% matrix with n rows and 7 columns. label is an n-by-1 cell array of
% predicted labels.
```
% Load trained classification model and model parameters
SVM = loadCompactModel('ClassificationLearnerModel');
data = coder.load('ModelParameters');
removeVars = data.removeVars;
pcaCenters = data.pcaCenters;
pcaCoefficients = data.pcaCoefficients;
SVM = loadCompactModel('ClassificationLearnerModel');

% Remove unused predictor variables
keepvars = 1:size(X,2);
idx = ~ismember(keepvars,removeVars);
keepvars = keepvars(idx);
XwoID = X(:,keepvars);

% Transform predictors via PCA
Xpca = bsxfun(@minus,XwoID,pcaCenters)*pcaCoefficients;

% Generate label from SVM
label = predict(SVM,Xpca);
end

**Generate Code**

Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify variable-size arguments using `coder.typeof` and generate code using the arguments.

Create a double-precision matrix called `x` for code generation using `coder.typeof`. Specify that the number of rows of `x` is arbitrary, but that `x` must have `p` columns.

```matlab
p = size(creditrating,2) - 1;
x = coder.typeof(0,[Inf,p],[1 0]);
```

For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 31-57.

Generate a MEX function from `mypredictCL.m`. Use the `-args` option to specify `x` as an argument.

```bash
codegen mypredictCL -args x
```
codegen generates the MEX file `mypredictCL_mex.mexw64` in your current folder. The file extension depends on your platform.

**Verify Generated Code**

Verify that the MEX function returns the expected labels.

Remove the response variable from the original data set, and then randomly draw 15 observations.

```matlab
rng('default'); % For reproducibility
m = 15;
testsampT = datasample(creditrating(:,1:(end - 1)),m);
```

Predict corresponding labels by using `predictFcn` in the classification model trained by Classification Learner.

```matlab
testLabels = trainedModel.predictFcn(testsampT);
```

Convert the resulting table to a matrix.

```matlab
testsamp = table2array(testsampT);
```

The columns of `testsamp` correspond to the columns of the predictor data loaded by Classification Learner.

Pass the test data to `mypredictCL`. The function `mypredictCL` predicts corresponding labels by using `predict` and the classification model trained by Classification Learner.

```matlab
testLabelsPredict = mypredictCL(testsamp);
```

Predict corresponding labels by using the generated MEX function `mypredictCL_mex`.

```matlab
testLabelsMEX = mypredictCL_mex(testsamp);
```

Compare the sets of predictions.

```matlab
isequal(testLabels,testLabelsMEX,testLabelsPredict)
```

```matlab
ans =
    logical

    1
```
isequal returns logical 1 (true) if all the inputs are equal. `predictFcn`, `mypredictCL`, and the MEX function return the same values.

Predict Class Labels Using MATLAB Function Block

This example shows how to add a MATLAB Function block to a Simulink® for label prediction. The MATLAB Function block accepts streaming data, and predicts the label and classification score using a trained, support vector machine (SVM) classification model. For details on using the MATLAB Function block, see “Create Model That Uses MATLAB Function Block” (Simulink).

The `ionosphere` data set, which is included in the Statistics and Machine Learning Toolbox™, contains radar-return qualities (`Y`) and predictor data (`X`). Radar returns are either of good quality (`'g'`) or of bad quality (`'b'`).

Load the `ionosphere` data set. Determine the sample size.

```matlab
load ionosphere
n = numel(Y)
```

```matlab
n = 351
```

The MATLAB Function block cannot return cell arrays. So, convert the response variable to a logical vector whose elements are 1 if the radar returns are good, and 0 otherwise.

```matlab
Y = strcmp(Y,'g');
```

Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```matlab
prsntX = X(1:300,:);
prsntY = Y(1:300);
ftrX = X(301:end,:);
ftrY = Y(301:end);
```

Train an SVM model using all, presently available data. Specify predictor data standardization.

```matlab
Mdl = fitcsvm(prsntX,prsntY,'Standardize',true);
```
Mdl is a ClassificationSVM model. At the command line, you can use Mdl to make predictions for new observations. However, you cannot use Mdl as an input argument in a function meant for code generation.

Prepare Mdl to be loaded within the function using saveCompactModel.

saveCompactModel(Mdl,'SVMIonosphere');

saveCompactModel compacts Mdl, and then saves it in the MAT-file SVMIonosphere.mat.

Define a function named svmIonospherePredict.m that predicts whether a radar return is of good quality. The function should:

- Include the code generation directive %#codegen somewhere in the function.
- Accept radar-return predictor data. The data must be commensurate with X except for the number of rows.
- Load SVMIonosphere.mat using loadCompactModel.
- Return predicted labels and classification scores for predicting the quality of the radar return as good (that is, the positive-class score).

```
function [label,score] = svmIonospherePredict(X) %#codegen
%svmIonospherePredict Predict radar-return quality using SVM model
% svmIonospherePredict predicts labels and estimates classification
% scores of the radar returns in the numeric matrix of preditor data X
% using the compact SVM model in the file SVMIonosphere.mat. Rows of X
% correspond to observations and columns to predictor variables. label
% is the predicted label and score is the confidence measure for
% classifying the radar-return quality as good.
%
% Copyright 2016 The MathWorks Inc.
Mdl = loadCompactModel('SVMIonosphere');
[label,bothscores] = predict(Mdl,X);
score = bothscores(:,2);
end
```

svmIonospherePredict.m is located in your mlr/help/toolbox/stats/examples folder, where mlr is the value of matlabroot.

Load the Simulink® model slexSVMIonospherePredictExample.slx.
SimMdlName = 'slexSVMIonospherePredictExample';
open_system(SimMdlName);

The figure displays the Simulink® model. When the input node detects a radar return, it
directs that observation into the MATLAB Function block that dispatches to
svmIonospherePredict.m. After predicting the label and score, the model returns
these values to the workspace and displays the values within the model one at a time.
When you load slexSVMIonospherePredictExample.slx, MATLAB® also loads the
data set that it requires called radarReturnInput. However, this example shows how to
construct the required data set.

The model expects to receive input data as a structure array called radarReturnInput
containing these fields:

- **time** - The points in time at which the observations enter the model. In the example,
  the duration includes the integers from 0 though 50. The orientation must correspond
to the observations in the predictor data. So, for this example, time must be a column
  vector.
- **signals** - A 1-by-1 structure array describing the input data, and containing the fields
  values and dimensions. values is a matrix of predictor data. dimensions is the
  number of predictor variables.

Create an appropriate structure array for future radar returns.
radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);

You can change the name from radarReturnInput, and then specify the new name in the model. However, Simulink® expects the structure array to contain the described field names.

Simulate the model using the data held out of training, that is, the data in radarReturnInput.

sim(SimMdlName);

The figure shows the model after it processes all observations in radarReturnInput one at a time. The predicted label of \( X(351,:) \) is 1 and its positive-class score is 1.431. The variables tout, yout, and svmlogsout appear in the workspace. yout and svmlogsout are SimulinkData.Dataset objects containing the predicted labels and scores. For more details, see “Data Format for Logged Simulation Data” (Simulink).

Extract the simulation data from the simulation log.
labelsSL = svmlogsout.getElement(1).Values.Data;
scoresSL = svmlogsout.getElement(2).Values.Data;

labelsSL is a 51-by-1 numeric vector of predicted labels. labelsSL(j) = 1 means that the SVM model predicts that radar return j in the future sample is of good quality, and 0 means otherwise. scoresSL is a 51-by-1 numeric vector of positive-class scores, that is, signed distances from the decision boundary. Positive scores correspond to predicted labels of 1, and negative scores correspond to predicted labels of 0.

Predict labels and positive-class scores at the command line using `predict`.

[labelCMD,scoresCMD] = predict(Mdl,ftrX);
scoresCMD = scoresCMD(:,2);

labelCMD and scoresCMD are commensurate with labelsSL and scoresSL.

Compare the future-sample, positive-class scores returned by `slexSVMIonospherePredictExample` to those returned by calling `predict` at the command line.

err = sum((scoresCMD - scoresSL).^2);
err < eps

ans =

    logical
    1

The sum of squared deviations between the sets of scores is negligible.

If you also have a Simulink® Coder™ license, then you can generate C code from `slexSVMIonospherePredictExample.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Code Generation Support, Usage Notes, and Limitations

Generating C/C++ code requires MATLAB Coder. MATLAB Coder generates C/C++ code for the Statistics and Machine Learning Toolbox functions that support code generation, given these conditions:

- You cannot call any function at the top level when generating code by using `codegen`. Instead, call the function within an `entry-point` function, and then generate code from the entry-point function. The entry-point function, also known as the `top-level` or `primary` function, is a function you define for code generation. All functions within the entry-point function must support code generation.

- The MATLAB Coder limitations also apply to Statistics and Machine Learning Toolbox for code generation. In particular, code generation does not support categorical arrays and tables. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).

To learn about code generation, see “Introduction to Code Generation” on page 31-2.

This table lists the Statistics and Machine Learning Toolbox functions that support code generation.

An asterisk (*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

Specify Variable-Size Arguments for Code Generation

This example shows how to specify variable-size input arguments when you generate code for the object functions of classification and regression model objects. Variable-size data is data whose size might change at run time. Specifying variable-size input arguments is convenient when you have data with an unknown size at compile time. This example also describes how to include name-value pair arguments in an entry-point function and how to specify them when generating code.

For more detailed code generation workflow examples, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10 and “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20.

**Train Classification Model**

Load Fisher's iris data set. Convert the labels to a character matrix.

```matlab
load fisheriris
species = char(species);
```

Train a classification tree using the entire data set.

```matlab
Mdl = fitctree(meas,species);
```

*Mdl* is a *ClassificationTree* model.

**Save Model Using saveCompactModel**

Save the trained classification tree to a file named *ClassTreeIris.mat* in your current folder by using *saveCompactModel*.

```matlab
MdlName = 'ClassTreeIris';
saveCompactModel(Mdl,MdlName);
```

**Define Entry-Point Function**

In your current folder, define an entry-point function named *mypredictTree.m* that does the following:

- Accept measurements with columns corresponding to *meas* and accept valid name-value pair arguments.
• Load a trained classification tree by using `loadCompactModel`.
• Predict labels and corresponding scores, node numbers, and class numbers from the loaded classification tree.

You can allow for optional name-value pair arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
function [label,score,node,cnum] = mypredictTree(x,savedmdl,varargin) %#codegen
%MYPREDICTTREE Predict iris species using classification tree
%MYPREDICTTREE predicts iris species for the n observations in the
% n-by-4 matrix x using the classification tree stored in the MAT-file
% whose name is in savedmdl, and then returns the predictions in the
% array label. Each row of x contains the lengths and widths of the petal
% and sepal of an iris (see the fisheriris data set). For other output
% argument descriptions, see the predict reference page.
CompactMdl = loadCompactModel(savedmdl);
[label,score,node,cnum] = predict(CompactMdl,x,varargin{:});
end
```

**Note:** If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

### Generate Code

### Specify Variable-Size Arguments

Because C and C++ are statically typed languages, you must determine the properties of all variables in an entry-point function at compile time using the `-args` option of `codegen`.

Use `coder.Constant` to specify a compile-time constant input.

```
coder.Constant(v)
```

`coder.Constant(v)` creates a `coder.Constant` type variable whose values are constant, the same as `v`, during code generation.

Use `coder.typeof` to specify a variable-size input.

```
coder.typeof(example_value, size_vector, variable_dims)
```
The values of example_value, size_vector, and variable_dims specify the properties of the input array that the generated code can accept.

- An input array has the same data type as the example values in example_value.
- size_vector is the array size of an input array if the corresponding variable_dims value is false.
- size_vector is the upper bound of the array size if the corresponding variable_dims value is true.
- variable_dims specifies whether each dimension of the array has a variable size or a fixed size. A value of true (logical 1) means that the corresponding dimension has a variable size; a value of false (logical 0) means that the corresponding dimension has a fixed size.

The entry-point function mypredictTree accepts predictor data, the MAT-file name containing the trained model object, and optional name-value pair arguments. Suppose that you want to generate code that accepts a variable-size array for predictor data and the 'Subtrees' name-value pair argument with a variable-size vector for its value. Then you have four input arguments: predictor data, the MAT-file name, and the name and value of the 'Subtrees' name-value pair argument.

Define a 4-by-1 cell array and assign each input argument type of the entry-point function to each cell.

ARGS = cell(4,1);

For the first input, use coder.typeof to specify that the predictor data variable is double-precision with the same number of columns as the predictor data used in training the model, but that the number of observations (rows) is arbitrary.

p = numel(Mdl.PredictorNames);
ARGS{1} = coder.typeof(0,[Inf,p],[1,0]);

0 for the example_value value implies that the data type is double because double is the default numeric data type of MATLAB. [Inf,p] for the size_vector value and [1,0] for the variable_dims value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be p.

The second input is the MAT-file name, which must be a compile-time constant. Use coder.Constant to specify the type of the second input.

ARGS{2} = coder.Constant(MdlName);
The last two inputs are the name and value of the 'Subtrees' name-value pair argument. Names of name-value pair arguments must be compile-time constants.

ARGS{3} = coder.Constant('Subtrees');

Use coder.typeof to specify that the value of 'Subtrees' is a double-precision row vector and that the upper bound of the row vector size is \( \max(\text{Mdl.PruneList}) \).

\[ m = \max(\text{Mdl.PruneList}); \]
\[ \text{ARGS}{4} = \text{coder.typeof}(0,[1,m],[0,1]); \]

Again, 0 for the example_value value implies that the data type is double because double is the default numeric data type of MATLAB. [1,m] for the size_vector value and [0,1] for the variable_dims value imply that the size of the first dimension is fixed to be 1, and the size of the second dimension is variable and its upper bound is \( m \).

**Generate Code Using codegen**

Generate a MEX function from the entry-point function mypredictTree using the cell array ARGS, which includes input argument types for mypredictTree. Specify the input argument types using the -args option. Specify the number of output arguments in the generated entry-point function using the -nargout option. The generate code includes the specified number of output arguments in the order in which they occur in the entry-point function definition.

```bash
codegen mypredictTree -args ARGS -nargout 2
```

codegen generates the MEX function mypredictTree_mex with a platform-dependent extension in your current folder.

The predict function accepts single-precision values, double-precision values, and 'all' for the 'SubTrees' name-value pair argument. However, you can specify only double-precision values when you use the MEX function for prediction because the data type specified by ARGS{4} is double.

**Verify Generated Code**

Predict labels for a random selection of 15 values from the training data using the generated MEX function and the subtree at pruning level 1. Compare the labels from the MEX function with those predicted by predict.

```bash
rng('default'); % For reproducibility
Xnew = datasample(meas,15);
```
[labelMEX, scoreMEX] = mypredictTree_mex(Xnew, MdlName, 'Subtrees', 1);
[labelPREDICT, scorePREDICT] = predict(Mdl, Xnew, 'Subtrees', 1);

labelPREDICT

labelPREDICT = 15x10 char array
'virginica'
'virginica'
'setosa'
'virginica'
'versicolor'
'setosa'
'setosa'
'versicolor'
'virginica'
'virginica'
'setosa'
'virginica'
'versicolor'
'virginica'
'versicolor'
'virginica'

labelMEX

labelMEX = 15x1 cell array
{'virginica'}
{'virginica'}
{'setosa'}
{'virginica'}
{'versicolor'}
{'setosa'}
{'setosa'}
{'versicolor'}
{'virginica'}
{'virginica'}
{'setosa'}
{'virginica'}
{'virginica'}
{'setosa'}
{'virginica'}
{'versicolor'}

The predicted labels are the same as the MEX function labels except for the data type. When the response data type is char and codegen cannot determine that the value of
Subtrees is a scalar, then the output from the generated code is a cell array of character vectors.

For the comparison, you can convert labelsPREDICT to a cell array and use isequal.

cell_labelPREDICT = cellstr(labelPREDICT);
verifyLabel = isequal(labelMEX,cell_labelPREDICT)

verifyLabel = logical
1

isequal returns logical 1 (true), which means all the inputs are equal.

Compare the second outputs as well. scoreMex might include round-off differences compared with scorePREDICT. In this case, compare scoreMEX and scorePREDICT, allowing a small tolerance.

find(abs(scorePREDICT-scoreMEX) > 1e-8)

ans =
0x1 empty double column vector

find returns an empty vector if the element-wise absolute difference between scorePREDICT and scoreMEX is not larger than the specified tolerance 1e-8. The comparison confirms that scorePREDICT and scoreMEX are equal within the tolerance 1e–8.

System Objects for Classification and Code Generation

This example shows how to generate C code from a MATLAB® System object™ that classifies images of digits using a trained classification model. This example also shows how to use the System object for classification in Simulink®. A benefit of using System objects over a MATLAB function is System objects are more appropriate for processing large amounts of streaming data. For more details, see “What Are System Objects?” (MATLAB).

This example is based on “Code Generation for Image Classification”, which is an alternative workflow to “Digit Classification Using HOG Features” (Computer Vision System Toolbox).

Load Data

Load the digitimages.

load digitimages.mat

images is a 28-by-28-by-3000 array of uint16 integers. Each page is a raster image of a digit. Each element is a pixel intensity. Corresponding labels are in the 3000-by-1 numeric vector Y. For more details, enter Description at the command line.

Store the number of observations and number of predictor variables. Create a data partition that specifies to hold out 20% of the data. Extract training and test set indices from the data partition.

rng(1); % For reproducibility
n = size(images,3);
p = numel(images(:,:,1));
cvp = cvpartition(n,'Holdout',0.20);
idxTrn = training(cvp);
idxTest = test(cvp);

Rescale Data

Rescale the pixel intensities so that they range in the interval [0,1] within each image. Specifically, suppose $p_{ij}$ is pixel intensity $j$ within image $i$. For image $i$, rescale all of its pixel intensities using this formula:

$$
\hat{p}_{ij} = \frac{p_{ij} - \min_j(p_{ij})}{\max_j(p_{ij}) - \min_j(p_{ij})}.
$$
\( X = \text{double(images)}; \)

\[
\begin{align*}
\text{for } i &= 1:n \\
\quad \text{min}X &= \text{min}(\text{min}(X(:,:,i))); \\
\quad \text{max}X &= \text{max}(\text{max}(X(:,:,i))); \\
\quad X(:,:,i) &= (X(:,:,i) - \text{min}X)/(\text{max}X - \text{min}X);
\end{align*}
\]

\textbf{Reshape Data}

For code generation, the predictor data for training must be in a table of numeric variables or a numeric matrix.

Reshape the data to a matrix such that predictor variables correspond to columns and images to rows. Because \textit{reshape} takes elements column-wise, transpose its result.

\( X = \text{reshape}(X,[p,n])'; \)

\textbf{Train and Optimize Classification Models}

Cross-validate an ECOC model of SVM binary learners and a random forest based on the training observations. Use 5-fold cross-validation.

For the ECOC model, specify predictor standardization and optimize classification error over the ECOC coding design and the SVM box constraint. Explore all combinations of these values:

- For the ECOC coding design, use one-versus-one and one-versus-all.
- For the SVM box constraint, use three logarithmically-spaced values from 0.1 to 100 each. For all models, store the 5-fold cross-validated misclassification rates.

\[
\begin{align*}
\text{coding} &= \{'\text{onevsone}', '\text{onevsall}'\}; \\
\text{boxconstraint} &= \text{logspace(-1,2,3)}; \\
\text{cvLossECOC} &= \text{nan}\left(\text{numel(coding)},\text{numel(boxconstraint)}\right); \quad \% \text{For preallocation}
\end{align*}
\]

\[
\begin{align*}
\text{for } i &= 1:\text{numel(coding)} \\
\quad \text{for } j &= 1:\text{numel(boxconstraint)} \\
\quad \quad \text{t} &= \text{templateSVM('BoxConstraint',boxconstraint(j),'Standardize',true);} \\
\quad \quad \text{CVMdl} &= \text{fitcecoc}(X(idxTrn,:),Y(idxTrn),'Learners',t,'KFold',5,... \\
\quad \quad \quad \quad \quad \quad \quad 'Coding',coding{i}); \\
\quad \quad \text{cvLossECOC}(i,j) &= \text{kfoldLoss}(CVMdl); \\
\quad \quad \text{fprintf('cvLossECOC = %f for model using %s coding and box constraint=%f\n',...} \\
\quad \quad \quad \quad \quad \quad \quad \text{cvLossECOC(i,j),coding{i},boxconstraint(j))}
\end{align*}
\]
cvLossECOC = 0.058333 for model using onevsone coding and box constraint=0.100000
cvLossECOC = 0.057083 for model using onevsone coding and box constraint=3.162278
cvLossECOC = 0.050000 for model using onevsone coding and box constraint=100.000000
cvLossECOC = 0.120417 for model using onevsall coding and box constraint=0.100000
cvLossECOC = 0.121667 for model using onevsall coding and box constraint=3.162278
cvLossECOC = 0.127917 for model using onevsall coding and box constraint=100.000000

For the random forest, vary the maximum number of splits using the values in the sequence \( \{3^2, 3^3, \ldots, 3^m\} \). \( m \) is such that \( 3^m \) is no greater than \( n - 1 \).

\[
n = \text{size}(X,1);
m = \text{floor}(\log(n - 1)/\log(3));
\text{maxNumSplits} = 3.(^2:m);
\text{cvLossRF} = \text{nan}(\text{numel}(\text{maxNumSplits}));
\text{for } i = 1:\text{numel}(\text{maxNumSplits})
\text{t} = \text{templateTree('MaxNumSplits',maxNumSplits(i))};
\text{CVMdl} = \text{fitensemble}(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t,...
'KFold',5);
\text{cvLossRF(i)} = \text{kfoldLoss(CVMdl)};
\text{fprintf('cvLossRF = %f for model using %d as the maximum number of splits\n',...}
\text{cvLossRF(i)},\text{maxNumSplits}(i))
\text{end}
\]

cvLossRF = 0.323750 for model using 9 as the maximum number of splits
cvLossRF = 0.198333 for model using 27 as the maximum number of splits
cvLossRF = 0.075417 for model using 81 as the maximum number of splits
cvLossRF = 0.017083 for model using 243 as the maximum number of splits
cvLossRF = 0.012083 for model using 729 as the maximum number of splits
cvLossRF = 0.012083 for model using 2187 as the maximum number of splits

For each algorithm, determine the hyperparameter indices that yield the minimal misclassification rates.

\[
\text{minCVLossECOC} = \text{min}(\text{cvLossECOC}(:))
\text{linIdx} = \text{find}(\text{cvLossECOC} == \text{minCVLossECOC},1);
[\text{bestI},\text{bestJ}] = \text{ind2sub(size(cvLossECOC),linIdx)};
\text{bestCoding} = \text{coding{bestI}}
\text{bestBoxConstraint} = \text{boxconstraint(bestJ)}
\]

\[
\text{minCVLossRF} = \text{min}(\text{cvLossRF}(:))
\text{linIdx} = \text{find}(\text{cvLossRF} == \text{minCVLossRF},1);
\]
[bestI, bestJ] = ind2sub(size(cvLossRF), linIdx);
bestMNS = maxNumSplits(bestI)

minCVLossECOC =

0.0500

bestCoding =

'onevsone'

bestBoxConstraint =

100

minCVLossRF =

0.0121

bestMNS =

729

The random forest achieves a smaller cross-validated misclassification rate.

Train an ECOC model and a random forest using the training data. Supply the optimal hyperparameter combinations.

t = templateSVM('BoxConstraint', bestBoxConstraint, 'Standardize', true);
MdlECOC = fitcecoc(X(idxTrn,:), Y(idxTrn), 'Learners', t, 'Coding', bestCoding);
t = templateTree('MaxNumSplits', bestMNS);
MdlRF = fitcensemble(X(idxTrn,:), Y(idxTrn), 'Method', 'bag', 'Learners', t);

Create a variable for the test sample images, and use the trained models to predict test sample labels.

testImages = X(idxTest,:);
testLabelsECOC = predict(MdlECOC, testImages);
testLabelsRF = predict(MdlRF, testImages);
**Save Classification Model to Disk**

MdlECOC and MdlRF are predictive classification models, but you must prepare them for code generation. Save MdlECOC and MdlRF to your present working directory using `saveCompactModel`.

```matlab
saveCompactModel(MdlECOC,'DigitImagesECOC');
saveCompactModel(MdlRF,'DigitImagesRF');
```

**Create System Object for Prediction**

Create two System objects that, one for the ECOC model and the other for the random forest, that:

- Load the previously saved trained model using `loadCompactModel`
- Makes sequential predictions by the `step` method
- Enforces no size changes to the input data
- Enforces double-precision, scalar output

```matlab
classdef ECOCClassifier < matlab.System
    % ECOCCLASSIFIER Predict image labels from trained ECOC model
    %
    % ECOCCLASSIFIER loads the trained ECOC model from
    % |'DigitImagesECOC.mat'|, and predicts labels for new observations
    % based on the trained model. The ECOC model in
    % |'DigitImagesECOC.mat'| was cross-validated using the training data
    % in the sample data |digitimages.mat|.
    properties(Access = private)
        CompactMdl % The compacted, trained ECOC model
    end

    methods(Access = protected)
        function setupImpl(obj)
            % Load ECOC model from file
            obj.CompactMdl = loadCompactModel('DigitImagesECOC');
        end

        function y = stepImpl(obj,u)
            y = predict(obj.CompactMdl,u);
        end
```
function flag = isInputSizeMutableImpl(obj,index)
    % Return false if input size is not allowed to change while
    % system is running
    flag = false;
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end
end

classdef RFClassifier < matlab.System
    % RFCLASSIFIER Predict image labels from trained random forest
    %
    % RFCLASSIFIER loads the trained random forest from
    % '|DigitImagesRF.mat|', and predicts labels for new observations based
    % on the trained model. The random forest in '|DigitImagesRF.mat|
    % was cross-validated using the training data in the sample data
    % |digitimages.mat|.

    properties(Access = private)
        CompactMdl % The compacted, trained random forest
    end

    methods(Access = protected)
        function setupImpl(obj)
            % Load random forest from file
            obj.CompactMdl = loadCompactModel('DigitImagesRF');
        end

        function y = stepImpl(obj,u)
            y = predict(obj.CompactMdl,u);
        end

        function flag = isInputSizeMutableImpl(obj,index)
            % Return false if input size is not allowed to change while
        end
end
% system is running
flag = false;
end

function dataout = getOutputDataTypeImpl(~)
dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
sizeout = [1 1];
end
end
end

For System object basic requirements, see “Define Basic System Objects” (MATLAB).

**Define Prediction Functions for Code Generation**

Define two MATLAB functions called `predictDigitECOCSo.m` and `predictDigitRFSo.m`. The functions should:

- Include the code generation directive `%#codegen`.
- Accept image data commensurate with X.
- Predict labels using the `ECOCClassifier` and `RFClassifier` System objects, respectively.
- Return predicted labels.

```matlab
function label = predictDigitECOCSo(X) %#codegen
%PREDICTDIGITECOCSO Classify digit in image using ECOC Model System object
% PREDICTDIGITECOCSO classifies the 28-by-28 images in the rows of X
% using the compact ECOC model in the System object ECOCClassifier, and
% then returns class labels in label.
classifier = ECOCClassifier;
label = step(classifier,X);
end
```

```matlab
function label = predictDigitRFSo(X) %#codegen
%PREDICTDIGITRFSO Classify digit in image using RF Model System object
% PREDICTDIGITRFSO classifies the 28-by-28 images in the rows of X
```
% using the compact random forest in the System object RFClassifier, and
% then returns class labels in label.
classifier = RFClassifier;
label = step(classifier,X);
end

Compile MATLAB Function to MEX File

Compile the prediction function that achieves better test-sample accuracy to a MEX file using `codegen`. Specify the test set images using the `-args` argument.

```matlab
if(minCVLossECOC <= minCVLossRF)
    codegen predictDigitECOCSO -args testImages
else
    codegen predictDigitRFSO -args testImages
end
```

Verify that the generated MEX file produces the same predictions as the MATLAB function.

```matlab
if(minCVLossECOC <= minCVLossRF)
    mexLabels = predictDigitECOCSO_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsECOC) == numel(testLabelsECOC)
else
    mexLabels = predictDigitRFSO_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsRF) == numel(testLabelsRF)
end
```

`verifyMEX` is 1, which indicates that the predictions made by the generated MEX file and the corresponding MATLAB function are the same.

Predict Labels Using System Objects in Simulink

Create a video file that displays the test-set images frame by frame.

```matlab
v = VideoWriter('testImages.avi','Uncompressed AVI');
v.FrameRate = 1;
```
open(v);  
dim = sqrt(p)*[1 1];  
for j = 1:size(testImages,1)  
  writeVideo(v,reshape(testImages(j,:),dim));  
end  
close(v);  

Define a function called scalePixelIntensities.m that converts RGB images to grayscale, and then scales the resulting pixel intensities so that their values are in the interval [0,1].

\[
\text{function } x = \text{scalePixelIntensities}(\text{imdat})
\]

%SCALEPIXELINTENSITIES Scales image pixel intensities
% SCALEPIXELINTENSITIES scales the pixel intensities of the image such
% that the result x is a row vector of values in the interval [0,1].

\[
\text{imdat} = \text{rgb2gray}(\text{imdat});
\]

\[
\text{minimdat} = \text{min}(\text{min}(\text{imdat}));
\]

\[
\text{maximdat} = \text{max}(\text{max}(\text{imdat}));
\]

\[
\text{x} = (\text{imdat} - \text{minimdat})/(\text{maximdat} - \text{minimdat});
\]

end

Load the Simulink® model slexClassifyAndDisplayDigitImages.slx.

SimMdlName = 'slexClassifyAndDisplayDigitImages';  
open_system(SimMdlName);
The figure displays the Simulink® model. At the beginning of simulation, the From Multimedia File block loads the video file of the test-set images. For each image in the video:

1. The From Multimedia File block converts and outputs the image to a 28-by-28 matrix of pixel intensities.
2. The Process Data block scales the pixel intensities using `scalePixelIntensities.m`, and outputs a 1-by-784 vector of scaled intensities.
3. The Classification Subsystem block predicts labels given the processed image data. The block chooses the System object that minimizes classification error. In this case, the block chooses the random forest. The block outputs a double-precision scalar label.
4. The Data Type Conversion block converts the label to an `int32` scalar.
5. The Insert Text block embeds the predicted label on the current frame.
6. The To Video Display block displays the annotated frame.

Simulate the model.

`sim(SimMdlName)`

The model displays all 600 test-set images and its prediction quickly; the last image remains in the video display. You can generate predictions and display them with corresponding images one by one by pressing the **Step Forward** button instead.
If you also have a Simulink® Coder™ license, then you can generate C code from `slexClassifyAndDisplayDigitImages.slx` in Simulink® or from the command line using `rtwbuild`. For more details, see “Generate C Code for a Model” (Simulink Coder).

Predict Class Labels Using Stateflow

This example shows how to use a Stateflow® chart for label prediction. The example trains a discriminant analysis model for the Fisher iris data set by using `fitcdiscr`, and defines a function for code generation that loads the trained model and predicts labels for new data. The Stateflow chart in this example accepts streaming data and predicts labels using the function you define.

Fisher's iris data set, which is included in Statistics and Machine Learning Toolbox™, contains species (`species`) and measurements (`meas`) on sepal length, sepal width, petal length, and petal width for 150 iris specimens. The data set contains 50 specimens from each of three species: setosa, versicolor, and virginica.

Load the Fisher iris data set.

```matlab
load fisheriris
```

Convert `species` to an index vector where 1, 2, and 3 correspond to setosa, versicolor, and virginica, respectively.

```matlab
species = grp2idx(species);
```

Partition the data into a training set and a test set.

```matlab
rng('default') % For reproducibility
idx1 = randperm(150,75)';
idx2 = setdiff((1:150)',idx1);
X = meas(idx1,:);
Y = species(idx1,:);
trainX = meas(idx2,:);
trainY = species(idx2,:);
```

Use `trainX` and `trainY` to train a model, and use `X` and `Y` to test the trained model.

Train a quadratic discriminant analysis model.

```matlab
Mdl = fitcdiscr(trainX,trainY,'DiscrimType','quadratic');
```

`Mdl` is a `ClassificationDiscriminant` model. At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function for code generation. Prepare `Mdl` to be loaded within the function by using `saveCompactModel`.

```matlab
saveCompactModel(Mdl,'DiscrIris');
```
saveCompactModel compacts Mdl and saves it in the MAT-file DiscrIris.mat.

To display the predicted species in the display box of the Stateflow® model, define an enumeration class by using a classdef block in the MATLAB file IrisSpecies.m.

```matlab
classdef IrisSpecies < Simulink.IntEnumType
    enumeration
        Setosa(1)
        Versicolor(2)
        Virginica(3)
    end
end
```

For details about enumerated data, see “Define Enumerated Data Types” (Stateflow).

Define a function named mypredict.m that predicts the iris species from new measurement data by using the trained model. The function should:

- Include the code generation directive %#codegen somewhere in the function.
- Accept iris measurement data. The data must be consistent with X except for the number of rows.
- Load DiscrIris.mat using loadCompactModel.
- Return predicted iris species.

```matlab
function label = mypredict(X) %#codegen
    %MYPREDICT Predict species of iris flowers using discriminant model
    % mypredict predicts species of iris flowers using the compact
    % discriminant model in the file DiscrIris.mat. Rows of X correspond to
    % observations and columns correspond to predictor variables. label is
    % the predicted species.
    mdl = loadCompactModel('DiscrIris');
    labelTemp = predict(mdl,X);
    label = IrisSpecies(labelTemp);
end
```

Open the Simulink® model sf_countflowers.slx.

```matlab
sfName = 'sf_countflowers';
open_system(sfName);
```
The figures display the Simulink® model and the flow graph contained in the Stateflow® chart. When the input node detects measurement data, it directs the data into the chart. The chart then predicts a species of iris flower and counts the number of flowers for each species. The chart returns the predicted species to the workspace and displays the species within the model, one at a time. The data store memory block NumFlowers stores the number of flowers for each species.

The chart expects to receive input data as a structure array called fisheririsInput containing these fields:

- **time** - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 through 74. The orientation of time must correspond to the observations in the predictor data. So, for this example, time must be a column vector.

- **signals** - A 1-by-1 structure array describing the input data and containing the fields values and dimensions. The values field is a matrix of predictor data. The dimensions field is the number of predictor variables.

Create an appropriate structure array for iris flower measurements.

```matlab
fisheririsInput.time = [0:74]';
fisheririsInput.signals.dimensions = 4;
fisheririsInput.signals.values = X;
```
You can change the name from fisheririsInput, and then specify the new name in the model. However, Stateflow® expects the structure array to contain the described field names. For more details, see “Loading Data Structures to Root-Level Inputs” (Simulink).

Simulate the model.

```matlab
sim(sfName)
```

The figure shows the model after it processes all observations in fisheririsInput, one at a time. The predicted species of \( X(75,:) \) is virginica. The number of setosa, versicolor, and virginica in \( X \) is 22, 22, and 31, respectively.

The variable `logsout` appears in the workspace. `logsout` is a `SimulinkData.Dataset` object containing the predicted species. Extract the predicted species data from the simulation log.

```matlab
labelSF = logsout.getElement(1).Values.Data;
```

Predict species at the command line using `predict`. 

```matlab
31-78
```
labelCMD = predict(Mdl,X);

Compare the predicted species returned by \texttt{sf\_countflowers} to those returned by calling \texttt{predict} at the command line.

\texttt{isequal(labelCMD,labelSF)}

\texttt{ans =}

\texttt{logical}

\texttt{1}

\texttt{isequal} returns logical 1 (true) if all the inputs are equal. This comparison confirms that \texttt{sf\_countflowers} returns the expected results.

If you also have a Simulink® Coder™ license, then you can generate C code from \texttt{sf\_countflowers.slx} in Simulink® or from the command line using \texttt{rtwbuild}. For more details, see “Generate C Code for a Model” (Simulink Coder).

Human Activity Recognition Simulink Model for Smartphone Deployment

This example shows how to prepare a Simulink® model that classifies human activity based on smartphone sensor signals for code generation and smartphone deployment. The example provides two Simulink models that are ready for deployment to an Android device and an iOS device. After you install the required support package for a target device, train the classification model and deploy the Simulink model to the device.

**Prerequisites**

Simulink support packages are required for the Simulink models in this example.

- Download and Install Simulink Support Package for Android Devices (required for Android deployment)
- Download and Install Simulink Support Package for Apple iOS Devices (required for iOS deployment)

**Load Sample Data Set**

Load the humanactivity data set.

```matlab
load humanactivity
```

The `humanactivity` data set contains 24,075 observations of five different physical human activities: Sitting, Standing, Walking, Running, and Dancing. Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The data set contains the following variables:

- `actid` — Response vector containing the activity IDs in integers: 1, 2, 3, 4, and 5 representing Sitting, Standing, Walking, Running, and Dancing, respectively
- `actnames` — Activity names corresponding to the integer activity IDs
- `feat` — Feature matrix of 60 features for 24,075 observations
- `featlabels` — Labels of the 60 features

The Sensor HAR (human activity recognition) App [1] was used to create the `humanactivity` data set. When measuring the raw acceleration data with this app, a person placed a smartphone in a pocket so that the smartphone was upside down and the screen faced toward the person. The software then calibrated the measured raw data accordingly and extracted the 60 features from the calibrated data. For details about the
calibration and feature extraction, see [2] and [3], respectively. The Simulink models
described later also use the raw acceleration data and include blocks for calibration and
feature extraction.

**Prepare Data**

This example uses 90% of the observations to train a model that classifies the five types of
human activities and 10% of the observations to validate the trained model. Use
cvpartition to specify a 10% holdout for the test set.

```matlab
rng('default') % For reproducibility
Partition = cvpartition(actid,'Holdout',0.10);
trainingInds = training(Partition); % Indices for the training set
XTrain = feat(trainingInds,:);
YTrain = actid(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = feat(testInds,:);
YTest = actid(testInds);
```

Convert the feature matrix \( X_{\text{Train}} \) and the response vector \( Y_{\text{Train}} \) into a table to load
the training data set in the Classification Learner app.

```matlab
tTrain = array2table([XTrain YTrain]);
```

Specify the variable name for each column of the table.

```matlab
tTrain.Properties.VariableNames = [featlabels' 'Activities'];
```

**Train Boosted Tree Ensemble Using Classification Learner App**

Train a classification model by using the Classification Learner app. To open the
Classification Learner app, enter classificationLearner at the command line.
Alternatively, click the Apps tab, and click the arrow at the right of the Apps section to
open the gallery. Then, under Machine Learning, click Classification Learner.

On the Classification Learner tab, in the File section, click New Session and select
From Workspace.

In the New Session dialog box, click the arrow for Workspace Variable, and then select
the table \( t\text{Train} \). Classification Learner detects the predictors and the response from the
table.
The default option is 5-fold cross-validation, which protects against overfitting. Click **Start Session**. Classification Learner loads the data set and plots a scatter plot of the first two features.
On the **Classification Learner** tab, click the arrow at the right of the **Model Type** section to open the gallery. Then, under **Ensemble Classifiers**, click **Boosted Trees**.

The Current Model pane of the Data Browser displays the default settings of the boosted tree ensemble model.
On the Classification Learner tab, in the Training section, click Train. When the training is complete, the History pane of the Data Browser displays the 5-fold, cross-validated classification accuracy.

On the Classification Learner tab, in the Export section, click Export Model, and then select Export Compact Model. Click OK in the dialog box. The structure trainedModel appears in the MATLAB Workspace. The field ClassificationEnsemble of trainedModel contains the compact model. Extract the trained model from the structure.

```matlab
classificationEnsemble = trainedModel.ClassificationEnsemble;
```
Train Boosted Tree Ensemble at Command Line

Alternatively, you can train the same classification model at the command line.

template = templateTree('MaxNumSplits',20);
classificationEnsemble = fitcensemble(XTrain,YTrain, ...  'Method','AdaBoostM2', ...  'NumLearningCycles',30, ...  'Learners',template, ...  'LearnRate',0.1, ...  'ClassNames',[1; 2; 3; 4; 5]);

Perform 5-fold cross-validation for classificationEnsemble and compute the validation accuracy.

partitionedModel = crossval(classificationEnsemble,'KFold',5);
validationAccuracy = 1-kfoldLoss(partitionedModel)

validationAccuracy = 0.9831

Evaluate Performance on Test Data

Evaluate performance on the test data set.

testAccuracy = 1-loss(classificationEnsemble,XTest,YTest)

testAccuracy = 0.9763

The trained model correctly classifies 97.63% of the human activities on the test data set. This result confirms that the trained model does not overfit to the training data set.

Note that the accuracy values can vary slightly depending on your operating system.

Save Trained Model

For code generation including a classification model object, use saveCompactModel and loadCompactModel.

Save the trained model by using saveCompactModel.

saveCompactModel(classificationEnsemble,'EnsembleModel.mat');

The function block predictActivity in the Simulink models loads the trained model by using loadCompactModel and uses the trained model to classify new data.
**Deploy Simulink Model to Device**

Now that you have prepared a classification model, you can open the Simulink model, depending on which type of smartphone you have, and deploy the model to your device. Note that the Simulink model requires the `EnsembleModel.mat` file and the calibration matrix file `slexHARAndroidCalibrationMatrix.mat` or `slexHARiOSCalibrationMatrix.mat`. If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder that includes these calibration matrix files.

Type `slexHARAndroidExample` to open the Simulink model for Android deployment.

Type `slexHARiOSExample` to open the Simulink model for iOS deployment.
The two Simulink models classify human activity based on acceleration data measured by a smartphone sensor. The models include the following blocks:

- The **Accelerometer** block receives raw acceleration data from accelerometer sensors on the device.
- The **calibrate** block is a MATLAB Function block that calibrates the raw acceleration data. This block uses the calibration matrix in the `slexHARAndroidCalibrationMatrix.mat` file or the `slexHARiOSCalibrationMatrix.mat` file. If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder that includes these files.
- The display blocks **Acc X**, **Acc Y**, and **Acc Z** are connected to the **calibrate** block and display calibrated data points for each axis on the device.
- Each of the **Buffer** blocks, **X Buffer**, **Y Buffer**, and **Z Buffer**, buffers 32 samples of an accelerometer axis with 12 samples of overlap between buffered frames. After collecting 20 samples, each **Buffer** block joins the 20 samples with 12 samples from the previous frame and passes the total 32 samples to the **extractFeatures** block. Each **Buffer** block receives an input sample every 0.1 second and outputs a buffered frame including 32 samples every 2 seconds.
- The **extractFeatures** block is a MATLAB Function block that extracts 60 features from a buffered frame of 32 accelerometer samples. This function block uses DSP System Toolbox™ and Signal Processing Toolbox™.
The **predictActivity** block is a MATLAB Function block that loads the trained model from the `EnsembleModel.mat` file by using `loadCompactModel` and classifies the user activity using the extracted features. The output is an integer between 1 and 5, corresponding to Sitting, Standing, Walking, Running, and Dancing, respectively.

- The **Predicted Activity** block displays the classified user activity values on the device.
- The **Video Output** subsystem uses a multiport switch block to choose the corresponding user activity image data to display on the device. The **Convert to RGB** block decomposes the selected image into separate RGB vectors and passes the image to the **Activity Display** block.

To deploy the Simulink model to your device, follow the steps in Run Model on Android Devices or Run Model on iOS Devices. After the configuration process is complete, click **Deploy to Hardware** to create an app with the same name as the model. Run the app, place the device in the same way as described earlier for collecting the training data, and try the five activities. The app displays the classified activity accordingly.

![APP INFO](image)

To ensure the accuracy of the app, you need to place your device in the same way as described for collecting the training data. If you want to place your device in a different location or orientation, then collect the data in your own way and use your data to train the classification model.
The accuracy of the app can be different from the accuracy of the test data set (testaccuracy), depending on the device. To improve the app, you can consider using additional sensors and updating the calibration matrix. Also, you can add another output block for audio feedback to the output subsystem using Audio System Toolbox™. Use a ThingSpeak™ write block to publish classified activities and acceleration data from your device to the Internet of Things. For details, see https://thingspeak.com/.

Code Generation for Prediction and Update Using Coder Configurer

This example shows how to generate C/C++ code for the prediction of an SVM model using a coder configurer, and how to update model parameters of a deployed SVM model without having to regenerate the code. After training an SVM model, use the learnerCoderConfigurer function to create a coder configurer object, ClassificationSVMCoderConfigurer for an SVM classification model or RegressionSVMCoderConfigurer for an SVM regression model. A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of SVM model parameters using object properties.
- Generate C/C++ code for the predict and update functions of the SVM model by using generateCode. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use validatedUpdateInputs to validate and extract the model parameters to update.

This flow chart shows the code generation workflow for the predict and update functions of an SVM model using a coder configurer.

**Update Model Parameters in Generated Code**

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder
attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

**Train Model**

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```matlab
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

Mdl is a ClassificationSVM object.

**Create Coder Configurer**

Create a coder configurer for the ClassificationSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```matlab
configurer = learnerCoderConfigurer(Mdl,X(1:50,:),'NumOutputs',2);
```

configurer is a ClassificationSVMCoderConfigurer object, which is a coder configurer of a ClassificationSVM object.

**Specify Coder Attributes of Parameters**

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of X so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```matlab
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```
The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is Inf and the size is variable, meaning that X can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. X contains 34 predictors, so the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be false.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of SupportVectors so that you can update the support vectors in the generated code.

```matlab
configurer.SupportVectors.SizeVector = [250 34];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.

```matlab
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the predict and update functions of the ClassificationSVM model with default settings.

```matlab
generateCode(configurer)
```
These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

generateCode generates these files for code generation.

generateCode generates the MATLAB files required to generate code, including the two entry-point functions predict.m and update.m for the predict and update functions of the ClassificationSVM model (Mdl), respectively. Then generateCode creates a MEX function named ClassificationSVMModel for the two entry-point functions in the codegen\mex\ClassificationSVMModel folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the predict function of Mdl and the predict function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

[label, score] = predict(Mdl, X);
[label_mex, score_mex] = ClassificationSVMModel('predict', X);

Compare label and label_mex by using isequal.

isequal(label, label_mex)

ans = logical
  1

isequal returns logical 1 (true) if all the inputs are equal. The comparison confirms that the predict function of Mdl and the predict function in the MEX function return the same labels.

score_mex might include round-off differences compared with score. In this case, compare score_mex and score, allowing a small tolerance.

find(abs(score - score_mex) > 1e-8)

ans =

0x1 empty double column vector

The comparison confirms that score and score_mex are equal within the tolerance 1e–8.
Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

retrainedMdl = fitcsvm(X,Y);

Extract parameters to update by using validatedUpdateInputs. This function detects the modified model parameters in retrainedMdl and validates whether the modified parameter values satisfy the coder attributes of the parameters.

params = validatedUpdateInputs(configurer,retrainedMdl);

Update parameters in the generated code.

ClassificationSVMModel('update',params)

Verify Generated Code

Compare the outputs from the predict function of retrainedMdl and the predict function in the updated MEX function.

labels = predict(retrainedMdl,X);
label_mex = ClassificationSVMModel('predict',X);
isequal(labels,label_mex)

ans = logical
   1

find(abs(score-score_mex) > 1e-8)
ans =

0x1 empty double column vector

The comparison confirms that labels and labels_mex are equal, and the score values are equal within the tolerance.

Functions — Alphabetical List
addedvarplot

Added variable plot

Syntax

addedvarplot(X,y,num,inmodel)
addedvarplot(X,y,num,inmodel,stats)

Description

`addedvarplot(X,y,num,inmodel)` displays an added variable plot using the predictive terms in `X`, the response values in `y`, the added term in column `num` of `X`, and the model with current terms specified by `inmodel`. `X` is an `n`-by-`p` matrix of `n` observations of `p` predictive terms. `y` is vector of `n` response values. `num` is a scalar index specifying the column of `X` with the term to be added. `inmodel` is a logical vector of `p` elements specifying the columns of `X` in the current model. By default, all elements of `inmodel` are false.

**Note** `addedvarplot` automatically includes a constant term in all models. Do not enter a column of 1s directly into `X`.

`addedvarplot(X,y,num,inmodel,stats)` uses the `stats` output from the `stepwisefit` function to improve the efficiency of repeated calls to `addedvarplot`. Otherwise, this syntax is equivalent to the previous syntax.

Added variable plots are used to determine the unique effect of adding a new term to a multilinear model. The plot shows the relationship between the part of the response unexplained by terms already in the model and the part of the new term unexplained by terms already in the model. The “unexplained” parts are measured by the residuals of the respective regressions. A scatter of the residuals from the two regressions forms the added variable plot.

In addition to the scatter of residuals, the plot produced by `addedvarplot` shows 95% confidence intervals on predictions from the fitted line. The fitted line has intercept zero.
because, under typical linear model assumptions, both of the plotted variables have mean zero. The slope of the fitted line is the coefficient that the new term would have if it were added to the model with terms inmodel.

Added variable plots are sometimes known as partial regression leverage plots.

**Examples**

Load the data in hald.mat, which contains observations of the heat of reaction of various cement mixtures:

```matlab
load hald
whos
```

Name          Size    Bytes   Class   Attributes
Description   22x58   2552    char
hald          13x5     520    double
heat          13x1     104    double
ingredients   13x4     416    double

Create an added variable plot to investigate the addition of the third column of ingredients to a model consisting of the first two columns:

```matlab
inmodel = [true true false false];
addedvarplot(ingredients,heat,3,inmodel)
```
The wide scatter and the low slope of the fitted line are evidence against the statistical significance of adding the third column to the model.

stepwise | stepwisefit

Introduced before R2006a
addK

**Class:** clustering.evaluation.ClusterCriterion

**Package:** clustering.evaluation

Evaluate additional numbers of clusters

**Syntax**

eva_out = addK(eva,klist)

**Description**

eva_out = addK(eva,klist) returns a clustering evaluation object eva_out that contains the evaluation data stored in the input object eva, plus additional evaluation data for the proposed number of clusters specified in klist.

**Input Arguments**

eva — Clustering evaluation data
clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using evalclusters.

klist — Additional numbers of clusters to evaluate
vector of positive integer values

Additional numbers of clusters to evaluate, specified as a vector of positive integer values. If any values in klist overlap with clustering solutions already evaluated in the input object eva, then addK ignores the overlapping values.
Output Arguments

**eva_out — Updated clustering evaluation data**  
clustering evaluation object

Updated clustering evaluation data, returned as a clustering evaluation object. `eva_out` contains data on the proposed clustering solutions included in the input clustering evaluation object `eva`, plus data on the additional proposed numbers of clusters specified in `klist`.

For all clustering evaluation object classes, `addK` updates the `InspectedK` and `CriterionValues` properties to include the proposed clustering solutions specified in `klist` and their corresponding criterion values. `addK` might also update the `OptimalK` and `OptimalY` properties to reflect the new optimal number of clusters and optimal clustering solution.

For certain cluster evaluation objects classes, `addK` might also update the following additional property values:

- For gap evaluation objects — `LogW`, `ExpectedLogW`, `StdLogW`, and `SE`
- For silhouette evaluation objects — `ClusterSilhouettes`

Examples

**Evaluate Additional Numbers of Clusters**

Create a clustering evaluation object using `evalclusters`, then use `addK` to evaluate additional numbers of clusters.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the Calinski-Harabasz criterion to evaluate proposed solutions of one through five clusters.

```
eva = evalclusters(meas,'kmeans','calinski','klist',1:5)
```
eva = CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
    InspectedK: [1 2 3 4 5]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279]
    OptimalK: 3

The clustering evaluation object eva contains data on each proposed clustering solution. The returned value of OptimalK indicates that the optimal solution is three clusters.

Evaluate proposed solutions of 6 through 10 clusters using the same criteria. Add these evaluations to the original clustering evaluation object eva.

eva = addK(eva,6:10)

eva = CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
    InspectedK: [1 2 3 4 5 6 7 8 9 10]
    CriterionValues: [1x10 double]
    OptimalK: 3

The updated values for InspectedK and CriterionValues show that eva now evaluates proposed solutions of 1 through 10 clusters. The OptimalK value still equals 3, indicating that three clusters remain the optimal solution.

addlevels

Add levels to nominal or ordinal arrays

Note The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

B = addlevels(A,newlevels)

Description

B = addlevels(A,newlevels) adds new levels specified by newlevels to the nominal or ordinal array A. addlevels adds the new levels at the end of the list of possible levels in A, but does not modify the value of any element. B does not contain elements at the new levels.

Examples

Add Levels To A Nominal Array

Add levels for additional species to Fisher's iris data.

Create a nominal array of the existing species in Fisher's iris data.

load fisheriris
species = nominal(species);
getlevels(species)

ans = 1x3 nominal array
    setosa    versicolor    virginica
Add two additional species.

```matlab
species = addlevels(species,{'spuria','ruthenica'});
getlevels(species)
```

```
ans = 1x5 nominal array
   setosa   versicolor   virginica   spuria   ruthenica
```

Even though there are new levels, there are no elements in `species` that are in these new levels.

```matlab
sum(species=='spuria')
an = 0
sum(species=='ruthenica')
an = 0
```

### Input Arguments

**A** — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with `nominal` or `ordinal`.

**newlevels** — Levels to add

string array | cell array of character vectors | 2-D character matrix

Levels to add to the input nominal or ordinal array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: char | string | cell

### Output Arguments

**B** — Nominal or ordinal array

nominal array | ordinal array
Nominal or ordinal array, returned as a nominal or ordinal array object.

**See Also**
droplevels | mergelevels | nominal | ordinal | reorderlevels

“Add and Drop Category Levels” on page 2-24

**Introduced in R2007a**
addlistener

Class: qrandstream

Add listener for event

Syntax

\[ \text{el} = \text{addlistener}(\text{hsource},'eventname',\text{callback}) \]
\[ \text{el} = \text{addlistener}(\text{hsource},\text{property},'eventname',\text{callback}) \]

Description

\[ \text{el} = \text{addlistener}(\text{hsource},'eventname',\text{callback}) \] creates a listener for the event named eventname, the source of which is handle object hsource. If hsource is an array of source handles, the listener responds to the named event on any handle in the array. callback is a function handle that is invoked when the event is triggered.

\[ \text{el} = \text{addlistener}(\text{hsource},\text{property},'eventname',\text{callback}) \] adds a listener for a property event. eventname must be 'PreGet', 'PostGet', 'PreSet', or 'PostSet'. property must be either a property name or cell array of property names, or a meta.property or array of meta.property. The properties must belong to the class of hsource. If hsource is scalar, property can include dynamic properties.

For all forms, addlistener returns an event.listener. To remove a listener, delete the object returned by addlistener. For example, delete(el) calls the handle class delete method to remove the listener and delete it from the workspace.

anova

Class:  GeneralizedLinearMixedModel

Analysis of variance for generalized linear mixed-effects model

Syntax

stats = anova(glme)
stats = anova(glme,Name,Value)

Description

stats = anova(glme) returns a table, stats, that contains the results of $F$-tests to determine if all coefficients representing each fixed-effects term in the generalized linear mixed-effects model glme are equal to 0.

stats = anova(glme,Name,Value) returns a table, stats, using additional options specified by one or more Name,Value pair arguments. For example, you can specify the method used to compute the approximate denominator degrees of freedom for the $F$-tests.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
**DFMethod — Method for computing approximate denominator degrees of freedom**

'residual' (default) | 'none'

Method for computing approximate denominator degrees of freedom to use in the F-test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'residual'</td>
<td>The degrees of freedom are assumed to be constant and equal to (n - p), where (n) is the number of observations and (p) is the number of fixed effects.</td>
</tr>
<tr>
<td>'none'</td>
<td>All degrees of freedom are set to infinity.</td>
</tr>
</tbody>
</table>

The denominator degrees of freedom for the F-statistic correspond to the column DF2 in the output structure `stats`.

Example: 'DFMethod', 'none'

## Output Arguments

**stats — Results of F-tests for fixed-effects terms**

* table

Results of F-tests for fixed-effects terms, returned as a table with one row for each fixed-effects term in `glme` and the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Term</td>
<td>Name of the fixed-effects term</td>
</tr>
<tr>
<td>FStat</td>
<td>F-statistic for the term</td>
</tr>
<tr>
<td>DF1</td>
<td>Numerator degrees of freedom for the F-statistic</td>
</tr>
<tr>
<td>DF2</td>
<td>Denominator degrees of freedom for the F-statistic</td>
</tr>
<tr>
<td>pValue</td>
<td>(p)-value for the term</td>
</tr>
</tbody>
</table>
Each fixed-effects term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, anova performs an $F$-test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

To perform tests for the type III hypothesis, when fitting the generalized linear mixed-effects model `fitglme`, you must use the 'effects' contrasts for the 'DummyVarCoding' name-value pair argument.

**Examples**

**F-Tests for Fixed Effects**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept
grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log \mu_{ij} = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time dev}_{ij} + \beta_3 \text{temp dev}_{ij} + \beta_4 \text{supplier C}_{ij} + \beta_5 \text{supplier B}_{ij} + b_i, \]

where

- defects\(_{ij}\) is the number of defects observed in the batch produced by factory \(i\) during batch \(j\).
- \(\mu_{ij}\) is the mean number of defects corresponding to factory \(i\) (where \(i = 1, 2, ..., 20\)) during batch \(j\) (where \(j = 1, 2, ..., 5\)).
- newprocess\(_{ij}\), time dev\(_{ij}\), and temp dev\(_{ij}\) are the measurements for each variable that correspond to factory \(i\) during batch \(j\). For example, newprocess\(_{ij}\) indicates whether the batch produced by factory \(i\) during batch \(j\) used the new process.
- supplier C\(_{ij}\) and supplier B\(_{ij}\) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \(i\) during batch \(j\).
- \(b_i \sim N(0, \sigma^2_b)\) is a random-effects intercept for each factory \(i\) that accounts for factory-specific variation in quality.

\[ \text{glme} = \text{fitglme}(\text{mfr}, \text{''defects} \sim 1 + \text{newprocess} + \text{time dev} + \text{temp dev} + \text{supplier} + (1|\text{factory})\), 'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects') \]

\[ \text{glme} = \]

</tr>
<tr>
<td>'supplier'</td>
<td>0.59212</td>
<td>2</td>
<td>94</td>
<td>0.5552</td>
</tr>
</tbody>
</table>
```

The $p$-values for the intercept, `newprocess`, `time_dev`, and `temp_dev` are the same as in the coefficient table of the `glme` display. The small $p$-values for the intercept and `newprocess` indicate that these are significant predictors at the 5% significance level.

The large $p$-values for `time_dev` and `temp_dev` indicate that these are not significant predictors at this level.

The $p$-value of 0.5552 for `supplier` measures the combined significance for both coefficients representing the categorical variable `supplier`. This includes the dummy variables `supplier_C` and `supplier_B` as shown in the coefficient table of the `glme` display. The large $p$-value indicates that `supplier` is not a significant predictor at the 5% significance level.

**Tips**

- For each fixed-effects term, `anova` performs an $F$-test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

  When fitting a generalized linear mixed-effects (GLME) model using `fitglme` and one of the maximum likelihood fit methods (`'Laplace'` or `'ApproximateLaplace'`):

  - If you specify the `'CovarianceMethod'` name-value pair argument as `'conditional'`, then the $F$-tests are conditional on the estimated covariance parameters.
• If you specify the 'CovarianceMethod' name-value pair as 'JointHessian', then the $F$-tests account for the uncertainty in estimation of covariance parameters.

When fitting a GLME model using fitglme and one of the pseudo likelihood fit methods ("MPL" or "REML"), anova uses the fitted linear mixed effects model from the final pseudo likelihood iteration for inference on fixed effects.

See Also
GeneralizedLinearMixedModel | coefCI | coefTest | disp | fitglme | fixedEffects
addTerms

Class: GeneralizedLinearModel

Add terms to generalized linear model

Syntax

mdl1 = addTerms(mdl,terms)

Description

mdl1 = addTerms(mdl,terms) returns a generalized linear model the same as mdl but with additional terms.

Input Arguments

mdl

Generalized linear model, as constructed by fitglm or stepwiseglm.

terms

Terms to add to the mdl regression model. Specify as either a:

- Text representing one or more terms to add. For details, see “Wilkinson Notation” on page 32-21.
- Row or rows in the terms matrix (see modelspec in fitglm). For example, if there are three variables A, B, and C:
  
  [0 0 0] represents a constant term or intercept
  [0 1 0] represents B; equivalently, A^0 * B^1 * C^0
  [1 0 1] represents A*C
  [2 0 0] represents A^2
  [0 1 2] represents B*(C^2)
Output Arguments

mdl1

Generalized linear model, the same as mdl but with additional terms given in terms. You can set mdl1 equal to mdl to overwrite mdl.

Examples

Add a term to a generalized linear regression model

Create a model using just one predictor, then add a second.

Generate artificial data for the model, Poisson random numbers with two underlying predictors X(1) and X(2).

rng default % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

Create a generalized linear regression model of Poisson data. Use just the first predictor in the model.

mdl = fitglm(X,y,...
   'y ~ x1','distr','poisson')

mdl =
   Generalized linear regression model:
   log(y) ~ 1 + x1
   Distribution = Poisson

Estimated Coefficients:

<td>0</td>
</tr>
</tbody>
</table>
100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0

Add the second predictor to the model.

```
mdl1 = addTerms(mdl,'x2')
```

```matlab
mdl1 =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson
```

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>

**Definitions**

**Wilkinson Notation**

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>Wilkinson Notation</td>
<td>Factors in Standard Notation</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

For details, see Wilkinson and Rogers [1].

**Alternatives**

`step` adds or removes terms from a model using a greedy one-step algorithm.

**References**

**See Also**

`GeneralizedLinearModel | removeTerms | step | stepwiseglm`

**Topics**

“Generalized Linear Models” on page 12-12
addTerms

Class: LinearModel

Add terms to linear regression model

Syntax

mdl1 = addTerms(mdl,terms)

Description

mdl1 = addTerms(mdl,terms) returns a linear model mdl1 that is the same as the input model mdl, but with additional terms as specified by terms.

Input Arguments

mdl — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a LinearModel object constructed using fitlm or stepwiselm.

terms — Terms to add to regression model
formula | matrix

Terms to add to the regression model mdl, specified as one of the following:

- Formula representing one or more terms to add. For details, see Wilkinson Notation on page 32-25.
- Row or rows in the terms matrix (see the modelspec argument description in the fitting function fitlm). For example, if there are three variables A, B, and C:

  
  
  [0 0 0] represents a constant term or intercept
  [0 1 0] represents B; equivalently, A^0 * B^1 * C^0
  [1 0 1] represents A*C

  

Output Arguments

mdl1 — Regression model with additional terms
LinearModel object

Regression model with additional terms, returned as a LinearModel object. mdl1 is the same as mdl but includes the additional terms specified in terms. To overwrite mdl, set mdl1 equal to mdl.

Examples

Add Terms to Linear Regression Model

Create a model of the carsmall data without any interactions, then add an interaction term.

Load the carsmall data and make a model of the MPG as a function of weight and model year.

load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');

Add an interaction term to mdl.

terms = 'Year*Weight';
mdl1 = addTerms(mdl,terms)

mdl1 =
Linear regression model:
    MPG ~ 1 + Weight*Year + Weight^2

Estimated Coefficients:
           Estimate      SE      tStat     pValue
           _________    _____    ______    _______
Number of observations: 94, Error degrees of freedom: 87
Root Mean Squared Error: 2.76
R-squared: 0.89, Adjusted R-Squared 0.882
F-statistic vs. constant model: 117, p-value = 1.88e-39

Definitions

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>

<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.
For details, see Wilkinson and Rogers [1].

**Alternatives**

Use `stepwiselm` to select a model from a starting model, continuing until no single step is beneficial.

Use `removeTerms` to remove particular terms.

Use `step` to optimally improve the model by adding or removing terms.

“Linear Regression” on page 11-11
adtest

Anderson-Darling test

Syntax

h = adtest(x)
h = adtest(x,Name,Value)
[h,p] = adtest(__)
[h,p,adstat,cv] = adtest(__)

Description

h = adtest(x) returns a test decision for the null hypothesis that the data in vector x is from a population with a normal distribution, using the Anderson-Darling test on page 32-33. The alternative hypothesis is that x is not from a population with a normal distribution. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

h = adtest(x,Name,Value) returns a test decision for the Anderson-Darling test with additional options specified by one or more name-value pair arguments. For example, you can specify a null distribution other than normal, or select an alternative method for calculating the p-value.

[h,p] = adtest(__) also returns the p-value, p, of the Anderson-Darling test, using any of the input arguments from the previous syntaxes.

[h,p,adstat,cv] = adtest(__) also returns the test statistic, adstat, and the critical value, cv, for the Anderson-Darling test.

Examples
Anderson-Darling Test for a Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```matlab
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from a normal distribution. You do not need to specify values for the population parameters.

```matlab
[h,p,adstat,cv] = adtest(x)
```

$h = \text{logical} 0$

$p = 0.1854$

$adstat = 0.5194$

$cv = 0.7470$

The returned value of $h = 0$ indicates that $\text{adtest}$ fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test for Extreme Value Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```matlab
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from an extreme value distribution. You do not need to specify values for the population parameters.

```matlab
[h,p] = adtest(x,'Distribution','ev')
```

$h = \text{logical} 0$
The returned value of \( h = 0 \) indicates that \texttt{adtest} fails to reject the null hypothesis at the default 5% significance level.

\textbf{Anderson-Darling Test Using Specified Probability Distribution}

Load the sample data. Create a vector containing the first column of the students' exam grades data.

\begin{verbatim}
load examgrades
x = grades(:,1);
\end{verbatim}

Create a normal probability distribution object with mean \( \mu = 75 \) and standard deviation \( \sigma = 10 \).

\begin{verbatim}
dist = makedist('normal','mu',75,'sigma',10)
dist =
    NormalDistribution
    Normal distribution
    mu = 75
    sigma = 10
\end{verbatim}

Test the null hypothesis that \( x \) comes from the hypothesized normal distribution.

\begin{verbatim}
[h,p] = adtest(x,'Distribution',dist)
\end{verbatim}

\begin{verbatim}
h = logical
    0
\end{verbatim}

\begin{verbatim}
p = 0.4687
\end{verbatim}

The returned value of \( h = 0 \) indicates that \texttt{adtest} fails to reject the null hypothesis at the default 5% significance level.
**Input Arguments**

**x** — Sample data
vector

Sample data, specified as a vector. Missing observations in x, indicated by NaN, are ignored.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Alpha',0.01,'MCTol',0.01 conducts the hypothesis test at the 1% significance level, and determines the p-value, p, using a Monte Carlo simulation with a maximum Monte Carlo standard error for p of 0.01.

**Distribution — Hypothesized distribution**

'norm' (default) | 'exp' | 'ev' | 'logn' | 'weibull' | probability distribution object

Hypothesized distribution of data vector x, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'norm'</td>
<td>Normal distribution</td>
</tr>
<tr>
<td>'exp'</td>
<td>Exponential distribution</td>
</tr>
<tr>
<td>'ev'</td>
<td>Extreme value distribution</td>
</tr>
<tr>
<td>'logn'</td>
<td>Lognormal distribution</td>
</tr>
<tr>
<td>'weibull'</td>
<td>Weibull distribution</td>
</tr>
</tbody>
</table>

In this case, you do not need to specify population parameters. Instead, adtest estimates the distribution parameters from the sample data and tests x against a composite hypothesis that it comes from the selected distribution family with parameters unspecified.

Alternatively, you can specify any continuous probability distribution object for the null distribution. In this case, you must specify all the distribution parameters, and adtest...
tests x against a simple hypothesis that it comes from the given distribution with its specified parameters.

Example: 'Distribution','exp'

**Alpha — Significance level**
0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

**MCTol — Maximum Monte Carlo standard error**
positive scalar value

Maximum Monte Carlo standard error on page 32-34 for the p-value, p, specified as the comma-separated pair consisting of 'MCTol' and a positive scalar value. If you use MCTol, adtest determines p using a Monte Carlo simulation, and the name-value pair argument Asymptotic must have the value false.

Example: 'MCTol',0.01

Data Types: single | double

**Asymptotic — Method for calculating p-value**
false (default) | true

Method for calculating the p-value of the Anderson-Darling test, specified as the comma-separated pair consisting of 'Asymptotic' and either true or false. If you specify 'true', adtest estimates the p-value using the limiting distribution of the Anderson-Darling test statistic. If you specify false, adtest calculates the p-value based on an analytical formula. For sample sizes greater than 120, the limiting distribution estimate is likely to be more accurate than the small sample size approximation method.

- If you specify a distribution family with unknown parameters for the Distribution name-value pair, Asymptotic must be false.
- If you use MCTol to calculate the p-value using a Monte Carlo simulation, Asymptotic must be false.

Example: 'Asymptotic',true

Data Types: logical
Output Arguments

**h — Hypothesis test result**

\[ 1 \mid 0 \]

Hypothesis test result, returned as a logical value.

- If \( h = 1 \), this indicates the rejection of the null hypothesis at the \( \text{Alpha} \) significance level.
- If \( h = 0 \), this indicates a failure to reject the null hypothesis at the \( \text{Alpha} \) significance level.

**p — p-value**

Scalar value in the range \([0,1]\)

\( p \)-value of the Anderson-Darling test, returned as a scalar value in the range \([0,1]\). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. \( p \) is calculated using one of these methods:

- If the hypothesized distribution is a fully specified probability distribution object, \( \text{adtest} \) calculates \( p \) analytically. If 'Asymptotic' is true, \( \text{adtest} \) uses the asymptotic distribution of the test statistic. If you specify a value for 'MCTol', \( \text{adtest} \) uses a Monte Carlo simulation.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, \( \text{adtest} \) retrieves the critical value from a table and uses inverse interpolation to determine the \( p \)-value. If you specify a value for 'MCTol', \( \text{adtest} \) uses a Monte Carlo simulation.

**adstat — Test statistic**

Scalar value

Test statistic for the Anderson-Darling test, returned as a scalar value.

- If the hypothesized distribution is a fully specified probability distribution object, \( \text{adtest} \) computes \( \text{adstat} \) using specified parameters.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, \( \text{adtest} \) computes \( \text{adstat} \) using parameters estimated from the sample data.

**cv — Critical value**

Scalar value
Critical value for the Anderson-Darling test at the significance level Alpha, returned as a scalar value. `adtest` determines cv by interpolating into a table based on the specified Alpha significance level.

**Definitions**

**Anderson-Darling Test**

The Anderson-Darling test is commonly used to test whether a data sample comes from a normal distribution. However, it can be used to test for another hypothesized distribution, even if you do not fully specify the distribution parameters. Instead, the test estimates any unknown parameters from the data sample.

The test statistic belongs to the family of quadratic empirical distribution function statistics, which measure the distance between the hypothesized distribution, \( F(x) \) and the empirical cdf, \( F_n(x) \) as

\[
n \int_{-\infty}^{\infty} (F_n(x) - F(x))^2 w(x) dF(x),
\]

over the ordered sample values \( x_1 < x_2 < ... < x_n \), where \( w(x) \) is a weight function and \( n \) is the number of data points in the sample.

The weight function for the Anderson-Darling test is

\[
w(x) = \left[ F'(x)(1 - F(x)) \right]^{-1},
\]

which places greater weight on the observations in the tails of the distribution, thus making the test more sensitive to outliers and better at detecting departure from normality in the tails of the distribution.

The Anderson-Darling test statistic is

\[
A_n^2 = -n - \sum_{i=1}^{n} \frac{2i-1}{n} \left[ \ln(F(X_i)) + \ln(1 - F(X_{n+1-i})) \right],
\]
where \( \{X_1 < ... < X_n\} \) are the ordered sample data points and \( n \) is the number of data points in the sample.

In \texttt{adtest}, the decision to reject or not reject the null hypothesis is based on comparing the \( p \)-value for the hypothesis test with the specified significance level, not on comparing the test statistic with the critical value.

**Monte Carlo Standard Error**

The Monte Carlo standard error is the error due to simulating the \( p \)-value.

The Monte Carlo standard error is calculated as

\[
SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mc reps}}},
\]

where \( \hat{p} \) is the estimated \( p \)-value of the hypothesis test, and \( \text{mc reps} \) is the number of Monte Carlo replications performed.

\texttt{adtest} chooses the number of Monte Carlo replications, \( \text{mc reps} \), large enough to make the Monte Carlo standard error for \( \hat{p} \) less than the value specified for \texttt{MCTol}.

**See Also**

\texttt{jbtest} | \texttt{kstest}

**Introduced in R2013a**
andrewsplot

Andrews plot

Syntax

andrewsplot(X)
andrewsplot(X,...,'Standardize',standopt)
andrewsplot(X,...,'Quantile',alpha)
andrewsplot(X,...,'Group',group)
andrewsplot(X,...,'PropName',PropVal,...)
h = andrewsplot(X,...)

Description

andrewsplot(X) creates an Andrews plot of the multivariate data in the matrix X. The rows of X correspond to observations, the columns to variables. Andrews plots represent each observation by a function \( f(t) \) of a continuous dummy variable \( t \) over the interval \([0,1]\). \( f(t) \) is defined for the \( i \)th observation in \( X \) as

\[
f(t) = X(i,1) / \sqrt{2} + X(i,2) \sin(2\pi t) + X(i,3) \cos(2\pi t) + \ldots
\]

andrewsplot treats NaN values in X as missing values and ignores the corresponding rows.

andrewsplot(X,...,'Standardize',standopt) creates an Andrews plot where \( \text{standopt} \) is one of the following:

- 'on' — scales each column of X to have mean 0 and standard deviation 1 before making the plot.
- 'PCA' — creates an Andrews plot from the principal component scores of X, in order of decreasing eigenvalue. (See pca.)
- 'PCAStd' — creates an Andrews plot using the standardized principal component scores. (See pca.)
andrewsplot(X,...,'Quantile',alpha) plots only the median and the alpha and (1 - alpha) quantiles of f(t) at each value of t. This is useful if X contains many observations.

andrewsplot(X,...,'Group',group) plots the data in different groups with different colors. Groups are defined by group, a numeric array containing a group index for each observation. group can also be a categorical array, character matrix, string array, or cell array of character vectors containing a group name for each observation.

andrewsplot(X,...,'PropName',PropVal,...) sets optional lineseries object properties to the specified values for all lineseries objects created by andrewsplot. (See Line Properties.)

h = andrewsplot(X,...) returns a column vector of handles to the lineseries objects created by andrewsplot, one handle per row of X. If you use the 'Quantile' input parameter, h contains one handle for each of the three lineseries objects created. If you use both the 'Quantile' and the 'Group' input parameters, h contains three handles for each group.

Examples

Create Andrews Plot to Visualize Grouped Data

This example shows how to create an Andrews plot to visualize grouped sample data.

Load the sample data.

load fisheriris

Create an Andrews plot, grouping the sample data by species.

andrewsplot(meas,'group',species)
Create a second, simplified Andrews plot that only displays the median and quartiles of each group.

```matlab
andrewsplot(meas,'group',species,'quantile',.25)
```

“Grouping Variables” on page 2-57

Introduced before R2006a
anova

Class: CompactLinearModel

Analysis of variance for linear model

Syntax

tbl = anova(mdl)
tbl = anova(mdl,anovatype)
tbl = anova(mdl,anovatype,sstype)

Description

tbl = anova(mdl) returns a table with summary ANOVA statistics.
tbl = anova(mdl,anovatype) returns ANOVA statistics of the chosen type.
tbl = anova(mdl,anovatype,sstype) computes ANOVA statistics using the chosen type of sum of squares.

Input Arguments

mdl — Linear model object
LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using fitlm or stepwiselm, or a compacted CompactLinearModel object constructed using compact.

anovatype — ANOVA type
'component' (default) | 'summary'

ANOVA type, specified as one of the following:

- 'component' — tbl displays a ‘components’ ANOVA table, with sums of squares and F tests attributable to each term in the model except the constant term.
• 'summary' — tbl displays a summary ANOVA table with an $F$ test for the model as a whole.

• If there are both linear and higher-order terms, there is also an $F$ test for the higher-order terms as a group.

• If mdl is a full LinearModel object and the sample data contains replications (multiple observations sharing the same predictor values), there is also an $F$ test for lack-of-fit computed by decomposing the residual sum of squares into a sum of squares for the replicated observations and the remaining sum of squares. If mdl is a compacted CompactLinearModel object, then the ANOVA table presents, but does not decompose, the residual sum of squares.

**sstype — Sum of squares type**

'h' (default) | 1 | 2 | 3

Sum of squares type, specified as one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it.</td>
</tr>
<tr>
<td>2</td>
<td>Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question</td>
</tr>
<tr>
<td>3</td>
<td>Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable.</td>
</tr>
<tr>
<td>'h'</td>
<td>Hierarchical model. Similar to Type II, but uses both continuous and categorical factors to determine the hierarchy of terms.</td>
</tr>
</tbody>
</table>

For Type III sum of squares:
• If `mdl` is a `CompactLinearModel` object and the model is non-hierarchical, `anova` errors.

• If `mdl` is a full `LinearModel` object and the model is non-hierarchical, then `anova` refits the model using effects coding whenever it needs to compute Type III sums of squares.

• If `mdl` is either a `CompactLinearModel` or a `LinearModel` object and the model is hierarchical, `anova` computes the results without refitting the model.

`sstype` only applies if `anovatype` is 'component'.

For more information about sum of squares types, see the `sstype` argument on the `anovan` function reference page.

Data Types: char | string | single | double

### Output Arguments

**tbl — ANOVA summary statistics table**

table

ANOVA summary statistics table, returned as table

The contents of `tbl` depends on the ANOVA type specified in `anovatype`.

• If `anovatype` is 'component', then `tbl` contains:

  • Sum of squares
  • Degrees of freedom
  • Mean squares
  • $F$ statistic
  • $p$-value
  • Formula used for model

• If `anovatype` is 'summary', then `tbl` contains:

  • Total Sum of Squares
  • Model Sum of Squares
    • Linear Sum of Squares (present if model has powers or interactions)
• Nonlinear Sum of Squares (present if model has powers or interactions)
• Residual Sum of Squares
  • Lack-of-fit Sum of Squares (present if model has replicates)
  • Pure error Sum of Squares (present if model has replicates)

Examples

Component ANOVA Table for Linear Model

Create a component ANOVA table from a model of the hospital data.

Load the hospital data and make a model of the blood pressure as a function of age and gender.

```matlab
load hospital
tbl = table(hospital.Age,hospital.Sex,hospital.BloodPressure(:,2), ...  'VariableNames',{'Age','Sex','BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl,'BloodPressure ~ Sex + Age^2');

Create an ANOVA table.

tbl = anova(mdl)
tbl=4×5 table
    SumSq    DF    MeanSq     F    pValue
    ______    __    ______    _______    ________
    Age      18.705     1    18.705    0.40055     0.52831
    Sex      222.09     1    222.09     4.7558    0.031643
    Age^2    30.934     1    30.934    0.66242     0.41772
    Error    4483.1    96    46.699
```

Summary ANOVA Table for Linear Model

Create a summary ANOVA table from a model of the carsmall data.
Load the `carsmall` data and make a model of the MPG as a function of weight and model year.

```matlab
load carsmall
cars = table(MPG,Weight);
cars.Year = ordinal(Model_Year);
mdl = fitlm(cars,'MPG ~ Year + Weight^2');
```

Create a summary ANOVA table.

```matlab
tbl = anova(mdl,'summary')
```

```
tbl=7×5 table
    SumSq    DF    MeanSq     F     pValue
     ______    __    ______    ______   ______
       Total    6005.3    93    64.573
      Model      5317     4    1329.3    171.88    5.5208e-41
    . Linear      5240.3     3    1746.8    225.87    1.7302e-41
    . Nonlinear    76.688     1    76.688    9.9164     0.0022303
   Residual      688.27    89    7.7334
    . Lack of fit   663.77    86    7.7183    0.9451       0.62874
    . Pure error      24.5     3    8.1667
```

The summary ANOVA table shows tests for groups of terms. The nonlinear group consists of just the `Weight^2` term, so it has the same \( P \)-value as that term in the component ANOVA table. The \( F \) statistic comparing the residual sum of squares to a "pure error" estimate from replicated observations shows no evidence of lack of fit.

**Alternatives**

More complete ANOVA statistics are available in the `anova1`, `anova2`, and `anovan` functions.

**See Also**

`CompactLinearModel` | `LinearModel` | `table`
Topics
“ANOVA” on page 11-21
“Linear Regression” on page 11-11
**anova**

**Class:** LinearMixedModel

Analysis of variance for linear mixed-effects model

**Syntax**

```matlab
code = anova(lme)
code = anova(lme,Name,Value)
```

**Description**

`stats = anova(lme)` returns the dataset array `stats` that includes the results of the $F$-tests for each fixed-effects term in the linear mixed-effects model `lme`.

`stats = anova(lme,Name,Value)` also returns the dataset array `stats` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

- `lme` — Linear mixed-effects model
  LinearMixedModel object

  Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

32-45
DFMethod — Method for computing approximate degrees of freedom
'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom to use in the F-test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'
Default. The degrees of freedom are assumed to be constant and equal to \( n - p \), where \( n \) is the number of observations and \( p \) is the number of fixed effects.

'satterthwaite'
Satterthwaite approximation.

'none'
All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.
Example: 'DFMethod','satterthwaite'

Output Arguments

stats — Results of F-tests for fixed-effects terms

dataset array

Results of F-tests for fixed-effects terms, returned as a dataset array with the following columns.

<table>
<thead>
<tr>
<th>Term</th>
<th>Name of the fixed effects term</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fstat</td>
<td>F-statistic for the term</td>
</tr>
<tr>
<td>DF1</td>
<td>Numerator degrees of freedom for the F-statistic</td>
</tr>
<tr>
<td>DF2</td>
<td>Denominator degrees of freedom for the F-statistic</td>
</tr>
<tr>
<td>pValue</td>
<td>p-value of the test for the term</td>
</tr>
</tbody>
</table>

There is one row for each fixed-effects term. Each term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, anova performs an F-test (marginal test) to determine if all coefficients representing the fixed-effects term are 0. To perform tests for
the type III hypothesis, you must use the 'effects' contrasts while fitting the linear mixed-effects model.

**Examples**

**F-Tests for Fixed Effects**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```matlab
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts indicate that the coefficients sum to 0, and fitlme creates two contrast-coded variables in the fixed-effects design matrix, $X_1$ and $X_2$, where

\[
Shift_{Evening} = \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

and

\[
Shift_{Morning} = \begin{cases} 
1, & \text{if Morning} \\
0, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]
The model corresponds to

\[
\text{MorningShift}: QCD_{n,m} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im}, \quad m = 1, 2, \ldots, 5, \\
\text{EveningShift}: QCD_{n,m} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \epsilon_{im}, \\
\text{NightShift}: QCD_{n,m} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im},
\]

where \( b \sim N(0, \sigma_b^2) \) and \( \epsilon \sim N(0, \sigma^2) \).

\[\text{lme} = \text{fitlme(shift,}'QCD_{ev} \sim \text{Shift} + (1|\text{Operator}')',...\]
\[\text{'FitMethod','REML','DummyVarCoding','effects'})\]

\[\text{lme} = \]
Linear mixed-effects model fit by REML

Model information:

Perform an $F$-test to determine if all fixed-effects coefficients are 0.

anova(lme)

ans =

    ANOVA marginal tests: DFMethod = 'Residual'

        Term     | FStat  | DF1 | DF2  | pValue   |
    -----------|--------|-----|------|----------|
    '(Intercept)' | 15.063 | 1   | 12   | 0.0021832 |
    'Shift'      | 11.091 | 2   | 12   | 0.0018721 |

The $P$-value for the constant term, 0.0021832, is the same as in the coefficient table in the lme display. The $P$-value of 0.0018721 for Shift measures the combined significance for both coefficients representing Shift.

**ANOVA for Fixed-Effects in LME Model**

Load the sample data.

load(fullfile(matlabroot,'examples','stats','fertilizer.mat'))

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.
Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently. Use the 'effects' contrasts when fitting the data for the type III sum of squares.

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)',...
'DummyVarCoding','effects')
```

```matlab
lme =
Linear mixed-effects model fit by ML
```

Model information:
- Number of observations: 60
- Fixed effects coefficients: 20
- Random effects coefficients: 18
- Covariance parameters: 3

Formula:
```
Yield ~ 1 + Tomato*Fertilizer + (1 | Soil) + (1 | Soil:Tomato)
```

Model fit statistics:
```
AIC    BIC    LogLikelihood    Deviance
522.57 570.74    -238.29       476.57
```

Fixed effects coefficients (95% CIs):
```

Random effects covariance parameters (95% CIs):
Group: Soil (3 Levels)

Group: Soil:Tomato (15 Levels)
Perform an analysis of variance to test for the fixed-effects.

anova(lme)

ans =
  ANOVA marginal tests: DFMethod = 'Residual'

    Term              FStat   DF1  DF2    pValue
    (Intercept)      1004.2   1   40    5.9086e-30
    Tomato           7.1663   4   40   0.00018935
    Fertilizer       58.833   3   40   1.0024e-14
    Tomato:Fertilizer 1.4182  12   40    0.19804

The \( P \)-value for the constant term, 5.9086e-30, is the same as in the coefficient table in the lme display. The \( P \)-values of 0.00018935, 1.0024e-14, and 0.19804 for Tomato, Fertilizer, and Tomato:Fertilizer represent the combined significance for all tomato coefficients, fertilizer coefficients, and coefficients representing the interaction between the tomato and fertilizer, respectively. The \( P \)-value of 0.19804 indicates that the interaction between tomato and fertilizer is not significant.

**Satterthwaite Approximation for Degrees of Freedom**

Load the sample data.

load(fullfile(matlabroot,'examples','stats','weight.mat'))
weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define Subject and Program as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit the model using the 'effects' contrasts.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)',...
             'DummyVarCoding','effects')
```

```
lme =
 Linear mixed-effects model fit by ML

Model information:
  Number of observations             120
  Fixed effects coefficients           9
  Random effects coefficients         40
  Covariance parameters                4

Formula:  
  y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)

Model fit statistics:
  AIC        BIC       LogLikelihood    Deviance

Fixed effects coefficients (95% CIs):
Name               Estimate    SE         tStat    DF  pValue
'(Intercept)'     0.77122     0.24309     3.1725    111

'Program_B'       0.25061     0.08045     3.1151    111
'Program_C'       -0.14344    0.080475    -1.7824    111
'Week'            0.19881     0.033727    5.8946    111
'Program_A:Week' -0.025607    0.058417   -0.43835   111
'Program_B:Week'  0.013164    0.058417    0.22535   111
'Program_C:Week'  0.0049357   0.058417    0.084492  111

   pValue    Lower    Upper
```
The \( P \)-values 0.022863 and 4.1099e-08 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they are significant.

Perform an F-test that all fixed-effects coefficients are zero.

\[ \text{anova(lme)} \]

\[ \text{ans} = \]

\[ \text{ANOVA marginal tests: DFMethod = 'Residual'} \]

<table>
<thead>
<tr>
<th>Term</th>
<th>FStat</th>
<th>DF1</th>
<th>DF2</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>'( Intercept)'</td>
<td>10.065</td>
<td>1</td>
<td>111</td>
<td>0.0019549</td>
</tr>
<tr>
<td>'InitialWeight'</td>
<td>5.326</td>
<td>1</td>
<td>111</td>
<td>0.022863</td>
</tr>
</tbody>
</table>
The $p$-values for the constant term, initial weight, and week are the same as in the coefficient table in the previous lme output display. The $p$-value of 0.014286 for Program represents the combined significance for all program coefficients. Similarly, the $p$-value for the interaction between program and week (Program:Week) measures the combined significance for all coefficients representing this interaction.

Now, use the Satterthwaite method to compute the degrees of freedom.

```matlab
anova(lme,'DFMethod','satterthwaite')
```

```
Term                  FStat   DF1   DF2       pValue
'(Intercept)'        10.065   1   20.445      0.004695
'InitialWeight'      5.326    1     20      0.031827
'Program'            3.6798   3    19.14      0.030233
'Week'               34.747   1    20     9.1346e-06
'Program:Week'      0.066648   3    20      0.97697
```

The Satterthwaite method produces smaller denominator degrees of freedom and slightly larger $p$-values.

**Tips**

- For each fixed-effects term, anova performs an $F$-test (marginal test), that all coefficients representing the fixed-effects term are 0. To perform tests for type III hypotheses, you must set the 'DummyVarCoding' name-value pair argument to 'effects' contrasts while fitting your linear mixed-effects model.

anova1

One-way analysis of variance

Syntax

\[
p = \text{anova1}(y)
\]
\[
p = \text{anova1}(y,\text{group})
\]
\[
p = \text{anova1}(y,\text{group},\text{displayopt})
\]
\[
[p,\text{tbl}] = \text{anova1}(\text{____})
\]
\[
[p,\text{tbl},\text{stats}] = \text{anova1}(\text{____})
\]

Description

\[p = \text{anova1}(y)\] returns the \(p\)-value for a balanced one-way ANOVA on page 9-3. It also displays the standard ANOVA table (\text{tbl}) and a box plot of the columns of \(y\). \text{anova1} tests the hypothesis that the samples in \(y\) are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same.

\[p = \text{anova1}(y,\text{group})\] returns the \(p\)-value for a balanced one-way ANOVA by group. It also displays the standard ANOVA table and a box-plot on page 32-72 of the observations of \(y\) by group.

\[p = \text{anova1}(y,\text{group},\text{displayopt})\] enables the ANOVA table and box plot displays when \text{displayopt} is 'on' (default) and suppresses the displays when \text{displayopt} is 'off'.

\[p,\text{tbl} = \text{anova1}(\text{____})\] returns the ANOVA table (including column and row labels) in the cell array \text{tbl}. To copy a text version of the ANOVA table to the clipboard, select \text{Edit > Copy Text}.

\[p,\text{tbl},\text{stats} = \text{anova1}(\text{____})\] returns a structure, \text{stats}, which you can use to perform a multiple comparison test on page 9-26. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use \text{multcompare}, providing the \text{stats} structure as an input argument.
Examples

One-Way ANOVA

Create sample data matrix $y$ with columns that are constants, plus random normal disturbances with mean 0 and standard deviation 1.

```matlab
y = meshgrid(1:5);
rng default; % For reproducibility
y = y + normrnd(0,1,5,5)
y = 5x5
    1.5377  0.6923  1.6501  3.7950  5.6715
    2.8339  1.5664  6.0349  3.8759  3.7925
   -1.2588  2.3426  3.7254  5.4897  5.7172
    1.8622  5.5784  2.9369  5.4090  6.6302
    1.3188  4.7694  3.7147  5.4172  5.4889
```

Perform one-way ANOVA.

```matlab
p = anova1(y)
```
### ANOVA Table

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob&gt;F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns</td>
<td>53.7238</td>
<td>4</td>
<td>13.4309</td>
<td>6.05</td>
<td>0.0023</td>
</tr>
<tr>
<td>Error</td>
<td>44.408</td>
<td>20</td>
<td>2.2204</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>98.1318</td>
<td>24</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The ANOVA table shows the between-groups variation (Columns) and within-groups variation (Error). SS is the sum of squares, and df is the degrees of freedom. The total degrees of freedom is total number of observations minus one, which is $25 - 1 = 24$. The between-groups degrees of freedom is number of groups minus one, which is $5 - 1 = 4$. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is $24 - 4 = 20$.

MS is the mean squared error, which is $SS/df$ for each source of variation. The $F$-statistic is the ratio of the mean squared errors ($13.4309/2.2204$). The $p$-value is the probability that the test statistic can take a value greater than the value of the computed test $p = 0.0023$.
statistic, i.e., $P(F > 6.05)$. The small $p$-value of 0.0023 indicates that differences between column means are significant.

**Compare Beam Strength Using One-Way ANOVA**

Input the sample data.

```matlab
strength = [82 86 79 83 84 85 86 87 74 82 ... 78 75 76 79 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',... 'al1','al1','al1','al1','al1','al1',... 'al2','al2','al2','al2','al2','al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector alloy identifies each beam as steel ('st'), alloy 1 ('al1'), or alloy 2 ('al2'). Although alloy is sorted in this example, grouping variables do not need to be sorted.

Test the null hypothesis that the steel beams are equal in strength to the beams made of the two more expensive alloys. Turn the figure display off and return the ANOVA results in a cell array.

```matlab
[p,tbl] = anova1(strength,alloy,'off')
```

```
p = 1.5264e-04

tbl = 4x6 cell array
Columns 1 through 5
{'Source'}    {'SS'     }    {'df'}    {'MS'     }    {'F'     }
{'Groups'}    {[184.8000]}    {[ 2]}    {[ 92.4000]}    {[ 15.4000]}
{'Error' }    {[102.0000]}    {[17]}    {[  6.0000]}    {0x0 double}
{'Total' }    {[286.8000]}    {[19]}    {0x0 double}    {0x0 double}

Column 6
{'Prob>F'    }
{[1.5264e-04]}
{0x0 double}
{0x0 double}
```
The total degrees of freedom is total number of observations minus one, which is 20 – 1 = 19. The between-groups degrees of freedom is number of groups minus one, which is 3 – 1 = 2. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is 19 – 2 = 17.

MS is the mean squared error, which is SS/df for each source of variation. The F-statistic is the ratio of the mean squared errors. The p-value is the probability that the test statistic can take a value greater than or equal to the value of the test statistic. The p-value of 1.5264e-04 suggests rejection of the null hypothesis.

You can retrieve the values in the ANOVA table by indexing into the cell array. Save the F-statistic value and the p-value in the new variables Fstat and pvalue.

Fstat = tbl{2,5}
Fstat = 15.4000
pvalue = tbl{2,6}
pvalue = 1.5264e-04

**Multiple Comparisons for One-Way ANOVA**

Input the sample data.

```matlab
strength = [82 86 79 83 84 85 86 87 74 82 ...
    78 75 76 77 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',
       'al1','al1','al1','al1','al1','al1',...
       'al2','al2','al2','al2','al2','al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector alloy identifies each beam as steel (st), alloy 1 (al1), or alloy 2 (al2). Although alloy is sorted in this example, grouping variables do not need to be sorted.

Perform one-way ANOVA using anova1. Return the structure stats, which contains the statistics multcompare needs for performing “Multiple Comparisons” on page 9-26.

```matlab
[~,~,stats] = anova1(strength,alloy);
```
### ANOVA Table

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob&gt;F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Groups</td>
<td>184.8</td>
<td>2</td>
<td>92.4</td>
<td>15.4</td>
<td>0.0002</td>
</tr>
<tr>
<td>Error</td>
<td>102</td>
<td>17</td>
<td>6</td>
<td>0.0002</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>286.8</td>
<td>19</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The small $p$-value of 0.0002 suggests that the strength of the beams is not the same.

Perform a multiple comparison of the mean strength of the beams.

$[c,~,~,gnames] = \text{multcompare}(\text{stats});$
Display the comparison results with the corresponding group names.

[gnames(c(:,1)), gnames(c(:,2)), num2cell(c(:,3:6))]

ans = 3x6 cell array
Columns 1 through 5
{'st'} {'al1'} {[3.6064]} {[7]} {[10.3936]}
{'st'} {'al2'} {[1.6064]} {[5]} {[8.3936]}
{'al1'} {'al2'} {[-5.6280]} {[2]} {[1.6280]}

Column 6
{[1.6831e-04]}
The first two columns show the pair of groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for the 95% confidence intervals of the true difference of means. The sixth column shows the p-value for a hypothesis that the true difference of means for the corresponding groups is equal to zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. Because the corresponding p-values (1.6831e-04 and 0.0040, respectively) are small, those differences are significant.

The third row shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6, 1.6], so you cannot reject the hypothesis that the true difference is zero. The corresponding p-value of 0.3560 in the sixth column confirms this result.

In the figure, the blue bar represents the comparison interval for mean material strength for steel. The red bars represent the comparison intervals for the mean material strength for alloy 1 and alloy 2. Neither of the red bars overlap with the blue bar, which indicates that the mean material strength for steel is significantly different from that of alloy 1 and alloy 2. To confirm the significant difference by clicking the bars that represent alloy 1 and 2.

### Input Arguments

**y — sample data**

vector | matrix

Sample data, specified as a vector or a matrix.

- If `y` is a vector, you must specify the `group` input argument. `group` must be a categorical variable, numeric vector, logical vector, character array, string array, or cell array of character vectors, with one name for each element of `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group. Use this design when groups have different numbers of elements (unbalanced ANOVA).
• If \( y \) is a matrix and you do not specify \( \text{group} \), \( \text{anova1} \) treats each column of \( y \) as a separate group. In this design, the function evaluates whether the population means of the columns are equal. Use this design when each group has the same number of elements (balanced ANOVA).

\[
\begin{align*}
\mathbf{y} &= \begin{bmatrix}
  y_1 & y_2 & y_3 & y_4 & \cdots & y_N \\
\end{bmatrix} \\
\mathbf{g} &= \{ 'A', 'A', 'C', 'B', 'B', \ldots, 'D' \}
\end{align*}
\]

• If \( y \) is a matrix and you specify \( \text{group} \), then \( \text{group} \) must be a character array, string array, or cell array of character vectors, with one name for each column of \( y \). The \( \text{anova1} \) function treats the columns that have the same group name as part of the same group.
If `group` contains empty or NaN-valued elements, `anova1` disregards the corresponding observations in `y`.

Data Types: `single` | `double`

**group — Grouping variable**
numeric vector | logical vector | character array | string array | cell array of character vectors

Grouping variable, specified as a numeric or logical vector, character array, string array, or cell array of character vectors, containing group names.

- If `y` is a vector, `group` must be a categorical variable, numeric vector, logical vector, character array, string array, or cell array of character vectors, with one name for each element of `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group.

\[
Y = \begin{bmatrix}
Y_{11} & Y_{12} & Y_{13} & \cdots & Y_{1k} \\
Y_{21} & Y_{22} & Y_{23} & \cdots & Y_{2k} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
Y_{n1} & Y_{n2} & Y_{n3} & \cdots & Y_{nk}
\end{bmatrix}
\]

- If `y` is a matrix, then `group` must be a character array, string array, or cell array of character vectors, with one group name for each column of `y`. The `anova1` function treats the columns of `y` that have the same group name as part of the same group.

\[N \text{ is the total number of observations.}\]
If you do not want to specify group names, enter an empty array ([ ]) or omit this argument.

If group contains empty or NaN-valued elements, the corresponding observations in y are disregarded.

For more information on grouping variables, see “Grouping Variables” on page 2-57.

For example, if y is a vector, with observations categorized into groups 1, 2, and 3, then you can specify the grouping variables as follows.

Example: 'group', [1,2,1,3,1,...,3,1]

For example, if y is a matrix, with six columns categorized into groups red, white, and black, then you can specify the grouping variables as follows.

Example: 'group',{'white','red','white','black','red'}

Data Types: single | double | logical | char | string | cell

displayopt — Indicator to display ANOVA table and box plot
'on' (default) | 'off'

Indicator to display ANOVA table and box plot, specified as 'on' or 'off'. When displayopt is 'off', anova1 returns the output arguments, only. It does not display the standard ANOVA table and box-plot of the columns of y.

Example: p = anova(x,group,'off')
Output Arguments

\( p \) — \( p \)-value for the F-test
scalar value

\( p \)-value for the F-test, returned as a scalar value. \( p \)-value is the probability that the F-statistic can take a value larger than the computed test-statistic value. `anova1` tests the null hypothesis that all group means are equal to each other against the alternative hypothesis that at least one group mean is different from the others. The function derives the \( p \)-value from the cdf of the F-distribution.

A \( p \)-value that is smaller than the significance level indicates that at least one of the sample means is significantly different from the others. Common significance levels are 0.05 or 0.01.

\( tbl \) — ANOVA table

cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

<table>

Definitions

Box-Plot

`anova1` returns box plots of the observations in `y`, by group. Box plots provide a visual comparison of the group location parameters.

If `y` is a vector, then the plot shows one box for each value of `group`. If `y` is a matrix and you do not specify `group`, then the plot shows one box for each column of `y`. On each box, the central mark is the median and the edges of the box are the 25th and 75th percentiles (1st and 3rd quantiles). The whiskers extend to the most extreme data points that are not considered outliers. The outliers are plotted individually. The interval endpoints are the extremes of the notches. The extremes correspond to \( q_2 - 1.57(q_3 - q_1)/\sqrt{n} \) and \( q_2 + 1.57(q_3 - q_1)/\sqrt{n} \), where \( q_2 \) is the median (50th percentile), \( q_1 \) and \( q_3 \) are the 25th and 75th percentiles, respectively, and \( n \) is the number of observations without any NaN values.

Two medians are significantly different at the 5% significance level if their intervals do not overlap. This test is different from the F-test that ANOVA performs, but large differences in the center lines of the boxes correspond to large F-statistic values and correspondingly small p-values. For more information about box plots, see `boxplot`.

Introduced before R2006a
anova2

Two-way analysis of variance

anova2 performs two-way analysis of variance (ANOVA) with balanced designs. To perform two-way ANOVA with unbalanced designs, see anovan.

Syntax

\[ p = \text{anova2}(y,\text{reps}) \]
\[ p = \text{anova2}(y,\text{reps},\text{displayopt}) \]
\[ [p,\text{tbl}] = \text{anova2}(__) \]
\[ [p,\text{tbl},\text{stats}] = \text{anova2}(__) \]

Description

\[ p = \text{anova2}(y,\text{reps}) \] returns the \( p \)-values for a balanced two-way ANOVA for comparing the means of two or more columns and two or more rows of the observations in \( y \).

\( \text{reps} \) is the number of replicates for each combination of factor groups, which must be constant, indicating a balanced design. For unbalanced designs, use anovan. The anova2 function tests the main effects for column and row factors and their interaction effect. To test the interaction effect, \( \text{reps} \) must be greater than 1.

anova2 also displays the standard ANOVA table.

\[ p = \text{anova2}(y,\text{reps},\text{displayopt}) \] enables the ANOVA table display when \( \text{displayopt} \) is 'on' (default) and suppresses the display when \( \text{displayopt} \) is 'off'.

\[ [p,\text{tbl}] = \text{anova2}(__) \] returns the ANOVA table (including column and row labels) in cell array \( \text{tbl} \). To copy a text version of the ANOVA table to the clipboard, select Edit > Copy Text menu.

\[ [p,\text{tbl},\text{stats}] = \text{anova2}(__) \] returns a \text{stats} structure, which you can use to perform a multiple comparison test on page 9-26. A multiple comparison test enables you.
to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as input.

### Examples

**Two-Way ANOVA**

Load the sample data.

```matlab
load popcorn
popcorn
popcorn = 6×3
5.5000    4.5000    3.5000
5.5000    4.5000    4.0000
6.0000    4.0000    3.0000
6.5000    5.0000    4.0000
7.0000    5.5000    5.0000
7.0000    5.0000    4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands, Gourmet, National, and Generic, respectively. The rows are popper types, oil and air. In the study, researchers popped a batch of each brand three times with each popper, that is, the number of replications is 3. The first three rows correspond to the oil popper, and the last three rows correspond to the air popper. The response values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Save the ANOVA table in the cell array `tbl` for easy access to results.

```matlab
[p,tbl] = anova2(popcorn,3);
```
The column Prob>F shows the \( p \)-values for the three brands of popcorn (0.0000), the two popper types (0.0001), and the interaction between brand and popper type (0.7462). These values indicate that popcorn brand and popper type affect the yield of popcorn, but there is no evidence of an interaction effect of the two.

Display the cell array containing the ANOVA table.

tbl

tbl = 6x6 cell array
   Columns 1 through 5

   { 'Source' }, { 'SS' }, { 'df' }, { 'MS' }, { 'F' }, { 'Prob>F' }
   { 'Columns' }, { 15.7500 }, { 2 }, { 7.8750 }, { 56.7000 }, { 0 }
   { 'Rows' }, { 4.5 }, { 1 }, { 4.5 }, { 32.4 }, { 0.0001 }
   { 'Interaction' }, { 0.0833 }, { 2 }, { 0.04167 }, { 0.3 }, { 0.7462 }
   { 'Error' }, { 1.6667 }, { 12 }, { 0.13889 }
Store the $F$-statistic for the factors and factor interaction in separate variables.

$$F_{brands} = tbl(2,5)$$

$F_{brands} = 56.7000$

$$F_{poppertype} = tbl(3,5)$$

$F_{poppertype} = 32.4000$

$$F_{interaction} = tbl(4,5)$$

$F_{interaction} = 0.3000$

### Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```matlab
load popcorn
popcorn
```

$\text{popcorn} = 6 \times 3$

<table>
<thead>
<tr>
<th></th>
<th>5.5000</th>
<th>4.5000</th>
<th>3.5000</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5.5000</td>
<td>4.5000</td>
<td>4.0000</td>
</tr>
<tr>
<td>2</td>
<td>6.0000</td>
<td>4.0000</td>
<td>3.0000</td>
</tr>
<tr>
<td>3</td>
<td>6.5000</td>
<td>5.0000</td>
<td>4.0000</td>
</tr>
<tr>
<td>4</td>
<td>7.0000</td>
<td>5.5000</td>
<td>5.0000</td>
</tr>
</tbody>
</table>
The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix popcorn are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

\[
\text{[~,~,stats] = anova2(popcorn,3,'off')}\]

\[
\text{stats = struct with fields:}
\]
\[
\begin{align*}
\text{source: 'anova2'} \\
\text{sigmasq: 0.1389} \\
\text{colmeans: [6.2500 4.7500 4]} \\
\text{coln: 6} \\
\text{rowmeans: [4.5000 5.5000]} \\
\text{rown: 9} \\
\text{inter: 1} \\
\text{pval: 0.7462} \\
\text{df: 12}
\end{align*}
\]

The stats structure includes

- The mean squared error (sigmasq)
- The estimates of the mean yield for each popcorn brand (colmeans)
- The number of observations for each popcorn brand (coln)
- The estimate of the mean yield for each popper type (rowmeans)
- The number of observations for each popper type (rown)
- The number of interactions (inter)
- The p-value that shows the significance level of the interaction term (pval)
- The error degrees of freedom (df).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

\[
c = \text{multcompare(stats)}
\]
Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

The first two columns of \( c \) show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the \( p \)-value for a hypothesis test that the corresponding mean
difference is equal to zero. All $p$-values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

c = multcompare(stats,'Estimate','row')

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.
The small $p$-value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.
Input Arguments

**y — Sample data**

matrix

Sample data, specified as a matrix. The columns correspond to groups of one factor, and the rows correspond to the groups of the other factor and the replications. Replications are the measurements or observations for each combination of groups (levels) of the row and column factor. For example, in the following data the row factor A has three levels, column factor B has two levels, and there are two replications (reps = 2). The subscripts indicate row, column, and replication, respectively.

\[
\begin{bmatrix}
  y_{11} & y_{12} \\
  y_{12} & y_{12} \\
  y_{21} & y_{22} \\
  y_{22} & y_{22} \\
  y_{31} & y_{32} \\
  y_{32} & y_{32}
\end{bmatrix}
\]

Data Types: single | double

**reps — Number of replications**

1 (default) | an integer number

Number of replications for each combination of groups, specified as an integer number. For example, the following data has two replications (reps = 2) for each group combination of row factor A and column factor B.

\[
\begin{bmatrix}
  y_{11} & y_{12} \\
  y_{12} & y_{12} \\
  y_{21} & y_{22} \\
  y_{22} & y_{22} \\
  y_{31} & y_{32} \\
  y_{32} & y_{32}
\end{bmatrix}
\]
When `reps` is 1 (default), `anova2` returns two p-values in vector `p`:

- The p-value for the null hypothesis that all samples from factor B (i.e., all column samples in `y`) are drawn from the same population.
- The p-value for the null hypothesis, that all samples from factor A (i.e., all row samples in `y`) are drawn from the same population.

When `reps` is greater than 1, `anova2` also returns the p-value for the null hypothesis that factors A and B have no interaction (i.e., the effects due to factors A and B are additive).

Example: `p = anova(y, 3)` specifies that each combination of groups (levels) has three replications.

Data Types: `single` | `double`

`displayopt — Indicator to display the ANOVA table`
`'on' (default) | 'off'`

Indicator to display the ANOVA table as a figure, specified as `'on'` or `'off'`.

Output Arguments

`p — p-value`
scalar value

p-value for the F-test, returned as a scalar value. A small p-value indicates that the results are statistically significant. Common significance levels are 0.05 or 0.01. For example:

- A sufficiently small p-value for the null hypothesis for group means of row factor A suggests that at least one row-sample mean is significantly different from the other row-sample means; i.e., there is a main effect due to factor A.
- A sufficiently small p-value for the null hypothesis for group (level) means of column factor B suggests that at least one column-sample mean is significantly different from the other column-sample means; i.e., there is a main effect due to factor B.
- A sufficiently small p-value for combinations of groups (levels) of factors A and B suggests that there is an interaction between factors A and B.

`tbl — ANOVA table`
cell array
ANOVA table, returned as a cell array. \( \texttt{tbl} \) has six columns.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>Source of the variability.</td>

Introduced before R2006a
anovan

N-way analysis of variance

Syntax

\[ p = \text{anovan}(y,\text{group}) \]
\[ p = \text{anovan}(y,\text{group},\text{Name},\text{Value}) \]
\[ [p,\text{tbl}] = \text{anovan}(\_\_\_\_\_\_) \]
\[ [p,\text{tbl,stats}] = \text{anovan}(\_\_\_\_\_) \]
\[ [p,\text{tbl,stats,terms}] = \text{anovan}(\_\_\_\_\_) \]

Description

\[ p = \text{anovan}(y,\text{group}) \] returns a vector of \( p \)-values, one per term, for multiway \((n\)-way) analysis of variance (ANOVA) for testing the effects of multiple factors on the mean of the vector \( y \).

anovan also displays a figure showing the standard ANOVA table.

\[ p = \text{anovan}(y,\text{group},\text{Name},\text{Value}) \] returns a vector of \( p \)-values for multiway \((n\)-way) ANOVA using additional options specified by one or more Name,Value pair arguments.

For example, you can specify which predictor variable is continuous, if any, or the type of sum of squares to use.

\[ [p,\text{tbl}] = \text{anovan}(\_\_\_\_\_) \] returns the ANOVA table (including factor labels) in cell array tbl for any of the input arguments specified in the previous syntaxes. Copy a text version of the ANOVA table to the clipboard by using the Copy Text item on the Edit menu.

\[ [p,\text{tbl,stats}] = \text{anovan}(\_\_\_\_\_) \] returns a stats structure that you can use to perform a multiple comparison test on page 9-26, which enables you to determine which pairs of group means are significantly different. You can perform such a test using the multcompare function by providing the stats structure as input.
[\text{p, tbl, stats, terms}] = \text{anovan}(\_\_\_) \text{ returns the main and interaction terms used in the ANOVA computations in terms.}

**Examples**

**Three-Way ANOVA**

Load the sample data.

\[
y = [52.7 \ 57.5 \ 45.9 \ 44.5 \ 53.0 \ 57.0 \ 45.9 \ 44.0]';
y = \text{[52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]'};
g1 = [1 \ 2 \ 1 \ 2 \ 1 \ 2 \ 1 \ 2];
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g2 = {'hi' 'hi' 'lo' 'lo' 'hi' 'hi' 'lo' 'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
g3 = {'may' 'may' 'may' 'may' 'june' 'june' 'june' 'june'};
\]

\text{\text{y}} \text{ is the response vector and g1, g2, and g3 are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation y(1) is associated with level 1 of factor g1, level 'hi' of factor g2, and level 'may' of factor g3. Similarly, observation y(6) is associated with level 2 of factor g1, level 'hi' of factor g2, and level 'june' of factor g3.}

Test if the response is the same for all factor levels.

\text{p = anovan(y,\{g1, g2, g3\})}
In the ANOVA table, $X_1$, $X_2$, and $X_3$ correspond to the factors $g_1$, $g_2$, and $g_3$, respectively. The $p$-value 0.4174 indicates that the mean responses for levels 1 and 2 of the factor $g_1$ are not significantly different. Similarly, the $p$-value 0.914 indicates that the mean responses for levels 'may' and 'june', of the factor $g_3$ are not significantly different. However, the $p$-value 0.0028 is small enough to conclude that the mean responses are
significantly different for the two levels, 'hi' and 'lo' of the factor $g2$. By default, \texttt{anovan} computes $p$-values just for the three main effects.

Test the two-factor interactions. This time specify the variable names.

```matlab
p = anovan(y, [g1 g2 g3], 'model', 'interaction', 'varnames', {'g1', 'g2', 'g3'})
```

<table>
<thead>
<tr>

</tr>
<tr>
<td>Error</td>
<td>0.011</td>
<td>1</td>
<td>0.011</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>221.379</td>
<td>7</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Constrained (Type III) sums of squares.

```matlab
p = 6x1
0.0347
0.0048
0.2578
0.0158
0.1444
```
The interaction terms are represented by $g_1g_2$, $g_1g_3$, and $g_2g_3$ in the ANOVA table. The first three entries of $p$ are the $p$-values for the main effects. The last three entries are the $p$-values for the two-way interactions. The $p$-value of 0.0158 indicates that the interaction between $g_1$ and $g_2$ is significant. The $p$-values of 0.1444 and 0.5 indicate that the corresponding interactions are not significant.

**Two-Way ANOVA for Unbalanced Design**

Load the sample data.

```matlab
load carbig
```

The data has measurements on 406 cars. The variable `org` shows where the cars were made and `when` shows when in the year the cars were manufactured.

Study how the mileage depends on when and where the cars were made. Also include the two-way interactions in the model.

```matlab
p = anovan(MPG,{org when},'model',2,'varnames',{'origin','mfg date'})
```
The 'model',2 name-value pair argument represents the two-way interactions. The $p$-value for the interaction term, 0.3059, is not small, indicating little evidence that the effect of the time of manufacture (mfg date) depends on where the car was made (origin). The main effects of origin and manufacturing date, however, are significant, both $p$-values are 0.
Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```matlab
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

$y$ is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in $y$ is identified by a combination of factor levels. For example, observation $y(1)$ is associated with level 1 of factor $g1$, level 'hi' of factor $g2$, and level 'may' of factor $g3$. Similarly, observation $y(6)$ is associated with level 2 of factor $g1$, level 'hi' of factor $g2$, and level 'june' of factor $g3$.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```matlab
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```
The \( p \)-value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor g3 are not significantly different. The \( p \)-value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor g1 are significantly different. Similarly, the \( p \)-value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor g2 are significantly different.

Perform multiple comparison tests to find out which groups of the factors g1 and g2 are significantly different.

```matlab
results = multcompare(stats,'Dimension',[1 2])
```
multcompare compares the combinations of groups (levels) of the two grouping variables, g1 and g2. In the results matrix, the number 1 corresponds to the combination of level 1 of g1 and level hi of g2, the number 2 corresponds to the combination of level 2 of g1 and level hi of g2. Similarly, the number 3 corresponds to
the combination of level 1 of g1 and level lo of g2, and the number 4 corresponds to the 
combination of level 2 of g1 and level lo of g2. The last column of the matrix contains the 
p-values.

For example, the first row of the matrix shows that the combination of level 1 of g1 and 
level hi of g2 has the same mean response values as the combination of level 2 of g1 and 
level hi of g2. The p-value corresponding to this test is 0.0280, which indicates that the 
mean responses are significantly different. You can also see this result in the figure. The 
blue bar shows the comparison interval for the mean response for the combination of 
level 1 of g1 and level hi of g2. The red bars are the comparison intervals for the mean 
response for other group combinations. None of the red bars overlap with the blue bar, 
which means the mean response for the combination of level 1 of g1 and level hi of g2 is 
significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for 
the group. The bar you click on turns to blue. The bars for the groups that are 
significantly different are red. The bars for the groups that are not significantly different 
are gray. For example, if you click on the comparison interval for the combination of level 
1 of g1 and level lo of g2, the comparison interval for the combination of level 2 of g1 
and level lo of g2 overlaps, and is therefore gray. Conversely, the other comparison 
intervals are red, indicating significant difference.

Input Arguments

**y — Sample data**

c_numeric vector

Sample data, specified as a numeric vector.

Data Types: single | double

**group — Grouping variables**

cell array

Grouping variables, i.e. the factors and factor levels of the observations in y, specified as 
a cell array. Each of the cells in group contains a list of factor levels identifying the 
observations in y with respect to one of the factors. The list within each cell can be a 
categorical array, numeric vector, character matrix, string array, or single-column cell 
array of character vectors, and must have the same number of elements as y.
By default, `anovan` treats all grouping variables as fixed effects.

For example, in a study you want to investigate the effects of gender, school, and the education method on the academic success of elementary school students, then you can specify the grouping variables as follows.

Example: `{'Gender','School','Method'}`

Data Types: `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'model','interaction','sstype',2` specifies `anovan` to compute the 99% confidence bounds and p-values for the main effects and two-way interactions using type II sum of squares.

#### alpha — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level for confidence bounds, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is $100(1-\alpha)\%$.

Example: `'alpha',0.01` corresponds to 99% confidence intervals

Data Types: `single` | `double`

#### continuous — Indicator for continuous predictors

vector of indices
Indicator for continuous predictors, representing which grouping variables should be treated as continuous predictors rather than as categorical predictors, specified as the comma-separated pair consisting of 'continuous' and a vector of indices.

For example, if there are three grouping variables and second one is continuous, then you can specify as follows.

Example: 'continuous',[2]

Data Types: single | double

display — Indicator to display ANOVA table

'on' (default) | 'off'

Indicator to display ANOVA table, specified as the comma-separated pair consisting of 'display' and 'on' or 'off'. When displayopt is 'off', anovan only returns the output arguments, and does not display the standard ANOVA table as a figure.

Example: 'display','off'

model — Type of the model

'linear' (default) | 'interaction' | 'full' | integer value | terms matrix

Type of the model, specified as the comma-separated pair consisting of 'model' and one of the following:

- 'linear' — The default 'linear' model computes only the p-values for the null hypotheses on the N main effects.
- 'interaction' — The 'interaction' model computes the p-values for null hypotheses on the N main effects and the two-factor interactions.
- 'full' — The 'full' model computes the p-values for null hypotheses on the N main effects and interactions at all levels.
- An integer — For an integer value of k, (k ≤ N) for model type, anovan computes all interaction levels through the kth level. For example, the value 3 means main effects plus two- and three-factor interactions. The values k = 1 and k = 2 are equivalent to the 'linear' and 'interaction' specifications, respectively. The value k = N is equivalent to the 'full' specification.
- Terms matrix — A matrix of term definitions having the same form as the input to the x2fx function. All entries must be 0 or 1 (no higher powers).
For more precise control over the main and interaction terms that \texttt{anovan} computes, you can specify a matrix containing one row for each main or interaction term to include in the ANOVA model. Each row defines one term using a vector of \( N \) zeros and ones. The table below illustrates the coding for a 3-factor ANOVA for factors \( A \), \( B \), and \( C \).

<table>
<thead>
<tr>
<th>Matrix Row</th>
<th>ANOVA Term</th>
</tr>
</thead>
<tbody>
<tr>
<td>([1 0 0])</td>
<td>Main term ( A )</td>
</tr>
<tr>
<td>([0 1 0])</td>
<td>Main term ( B )</td>
</tr>
<tr>
<td>([0 0 1])</td>
<td>Main term ( C )</td>
</tr>
<tr>
<td>([1 1 0])</td>
<td>Interaction term ( AB )</td>
</tr>
<tr>
<td>([1 0 1])</td>
<td>Interaction term ( AC )</td>
</tr>
<tr>
<td>([0 1 1])</td>
<td>Interaction term ( BC )</td>
</tr>
<tr>
<td>([1 1 1])</td>
<td>Interaction term ( ABC )</td>
</tr>
</tbody>
</table>

For example, if there are three factors \( A \), \( B \), and \( C \), and \texttt{'model'}, \([0 1 0;0 0 1;0 1 1]\), then \texttt{anovan} tests for the main effects \( B \) and \( C \), and the interaction effect \( BC \), respectively.

A simple way to generate the terms matrix is to modify the \texttt{terms} output, which codes the terms in the current model using the format described above. If \texttt{anovan} returns \([0 1 0;0 0 1;0 1 1]\) for \texttt{terms}, for example, and there is no significant interaction \( BC \), then you can recompute ANOVA on just the main effects \( B \) and \( C \) by specifying \([0 1 0;0 0 1]\) for \texttt{model}.

Example: \texttt{'model'}, \([0 1 0;0 0 1;0 1 1]\)
Example: \texttt{'model'}, \texttt{'interaction'}

\textbf{Data Types:} char | string | single | double

\textbf{\textit{nested} — Nesting relationships}
matrix of 0’s and 1’s

Nesting relationships among the grouping variables, specified as the comma-separated pair consisting of \texttt{'nested'} and a matrix \( M \) of 0’s and 1’s, i.e.\( M(i,j) = 1 \) if variable \( i \) is nested in variable \( j \).

For example, if there are two grouping variables District and School, where School is nested in District, then you can express this relationship as follows.
Example: 'nested', [0 0; 1 0]
Data Types: single | double

**random — Indicator for random variables**
vector of indices

Indicator for random variables, representing which grouping variables are random, specified as the comma-separated pair consisting of 'random' and a vector of indices. By default, anovan treats all grouping variables as fixed.

anovan treats an interaction term as random if any of the variables in the interaction term is random.

Example: 'random', [3]
Data Types: single | double

**sstype — Type of sum of squares**
3 (default) | 1 | 2 | 'h'

Type of sum squares, specified as the comma-separated pair consisting of 'sstype' and the following:

- 1 — Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it.
- 2 — Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question.
- 3 — Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable.
- 'h' — Hierarchical model. Similar to type 2, but with continuous as well as categorical factors used to determine the hierarchy of terms.

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of sstype only influences computations on unbalanced data.

Suppose you are fitting a model with two factors and their interaction, and that the terms appear in the order A, B, AB. Let R(·) represent the residual sum of squares for a model, so for example R(A, B, AB) is the residual sum of squares fitting the whole model, R(A) is
the residual sum of squares fitting just the main effect of A, and \( R(1) \) is the residual sum of squares fitting just the mean. The three types of sums of squares are as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Type 1 Sum of Squares</th>
<th>Type 2 Sum of Squares</th>
<th>Type 3 Sum of Squares</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>( R(1) - R(A) )</td>
<td>( R(B) - R(A, B) )</td>
<td>( R(B, AB) - R(A, B, AB) )</td>
</tr>
<tr>
<td>B</td>
<td>( R(A) - R(A, B) )</td>
<td>( R(A) - R(A, B) )</td>
<td>( R(A, AB) - R(A, B, AB) )</td>
</tr>
<tr>
<td>AB</td>
<td>( R(A, B) - R(A, B, AB) )</td>
<td>( R(A, B) - R(A, B, AB) )</td>
<td>( R(A, B) - R(A, B, AB) )</td>
</tr>
</tbody>
</table>

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting \( R(B, AB) \), the array of \( AB \) effects is constrained to sum to 0 over \( A \) for each value of \( B \), and over \( B \) for each value of \( A \).

Example: 'sstype','h'

Data Types: single | double | char | string

**varnames — Names of grouping variables**

X1, X2, ..., XN (default) | character matrix | string array | cell array of character vectors

Names of grouping variables, specified as the comma-separating pair consisting of 'varnames' and a character matrix, a string array, or a cell array of character vectors.

Example: 'varnames',{'Gender','City'}

Data Types: char | string | cell

## Output Arguments

**p — p-values**

vector

\( p \)-values, returned as a vector.

Output vector \( p \) contains \( p \)-values for the null hypotheses on the \( N \) main effects and any interaction terms specified. Element \( p(1) \) contains the \( p \)-value for the null hypotheses that samples at all levels of factor \( A \) are drawn from the same population; element \( p(2) \) contains the \( p \)-value for the null hypotheses that samples at all levels of factor \( B \) are drawn from the same population; and so on.
For example, if there are three factors \( A, B, \) and \( C, \) and 'model', \([0\ 1\ 0;0\ 0\ 1;0\ 1\ 1]\), then the output vector \( p \) contains the \( p \)-values for the null hypotheses on the main effects \( B \) and \( C \) and the interaction effect \( BC \), respectively.

A sufficiently small \( p \)-value corresponding to a factor suggests that at least one group mean is significantly different from the other group means; that is, there is a main effect due to that factor. It is common to declare a result significant if the \( p \)-value is less than 0.05 or 0.01.

**tbl — ANOVA table**
cell array

ANOVA table, returned as a cell array. The ANOVA table has seven columns:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>Source of the variability.</td>
</tr>
<tr>
<td>SS</td>
<td>Sum of squares due to each source.</td>
</tr>
<tr>
<td>df</td>
<td>Degrees of freedom associated with each source.</td>
</tr>
<tr>
<td>MS</td>
<td>Mean squares for each source, which is the ratio SS/df.</td>
</tr>
<tr>
<td>Singular?</td>
<td>Indication of whether the term is singular.</td>
</tr>
<tr>
<td>( F )</td>
<td>( F )-statistic, which is the ratio of the mean squares.</td>
</tr>
<tr>
<td>Prob&gt;F</td>
<td>The ( p )-values, which is the probability that the ( F )-statistic can take a value larger than a computed test-statistic value. \textit{anovan} derives these probabilities from the cdf of ( F )-distribution.</td>
</tr>
</tbody>
</table>

The ANOVA table also contains the following columns if at least one of the grouping variables is specified as random using the name-value pair argument random:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Type of each source; 'fixed' for a fixed effect or 'random' for a random effect.</td>
</tr>
<tr>
<td>Column name</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>Expected MS</td>
<td>Text representation of the expected value for the mean square. $Q(\text{source})$ represents a quadratic function of source and $V(\text{source})$ represents the variance of source.</td>
</tr>
<tr>
<td>MS denom</td>
<td>Denominator of the $F$-statistic.</td>
</tr>
<tr>
<td>d.f. denom</td>
<td>Degrees of freedom for the denominator of the $F$-statistic.</td>
</tr>
<tr>
<td>Denom. defn.</td>
<td>Text representation of the denominator of the $F$-statistic. MS(source) represents the mean square of source.</td>
</tr>
<tr>
<td>Var. est.</td>
<td>Variance component estimate.</td>
</tr>
<tr>
<td>Var. lower bnd</td>
<td>Lower bound of the 95% confidence interval for the variance component estimate.</td>
</tr>
<tr>
<td>Var. upper bnd</td>
<td>Upper bound of the 95% confidence interval for the variance component estimate.</td>
</tr>
</tbody>
</table>

**stats — Statistics**

*structure*

Statistics to use in a multiple comparison test on page 9-26 using the `multcompare` function, returned as a structure.

`anovan` evaluates the hypothesis that the different groups (levels) of a factor (or more generally, a term) have the same effect, against the alternative that they do not all have the same effect. Sometimes it is preferable to perform a test to determine which pairs of levels are significantly different, and which are not. Use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

The `stats` structure contains the fields listed below, in addition to a number of other fields required for doing multiple comparisons using the `multcompare` function:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coeffs</td>
<td>Estimated coefficients</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>coeffnames</td>
<td>Name of term for each coefficient</td>
</tr>
<tr>
<td>vars</td>
<td>Matrix of grouping variable values for each term</td>
</tr>
<tr>
<td>resid</td>
<td>Residuals from the fitted model</td>
</tr>
</tbody>
</table>

The `stats` structure also contains the following fields if at least one of the grouping variables is specified as random using the name-value pair argument `random`:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ems</td>
<td>Expected mean squares</td>
</tr>
<tr>
<td>denom</td>
<td>Denominator definition</td>
</tr>
<tr>
<td>rtnames</td>
<td>Names of random terms</td>
</tr>
<tr>
<td>varest</td>
<td>Variance component estimates (one per random term)</td>
</tr>
<tr>
<td>varci</td>
<td>Confidence intervals for variance components</td>
</tr>
</tbody>
</table>

**terms — Main and interaction terms**

Matrix

Main and interaction terms, returned as a matrix. The terms are encoded in the output matrix `terms` using the same format described above for input `model`. When you specify `model` itself in this format, the matrix returned in `terms` is identical.

Introduced before R2006a
anova

Class: RepeatedMeasuresModel

Analysis of variance for between-subject effects

Syntax

anovatbl = anova(rm)
anovatbl = anova(rm,'WithinModel',WM)

Description

anovatbl = anova(rm) returns the analysis of variance results for the repeated measures model rm.

anovatbl = anova(rm,'WithinModel',WM) returns the analysis of variance results it performs using the response or responses specified by the within-subject model WM.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

WM — Within-subject model
'separatemeans' (default) | 'orthogonalcontrasts' | character vector or string scalar defining a model specification | r-by-nc matrix specifying nc contrasts

Within-subject model, specified as one of the following:

• 'separatemeans' — The response is the average of the repeated measures (average across the within-subject model).
• 'orthogonalcontrasts' — This is valid when the within-subject model has a single numeric factor $T$. Responses are the average, the slope of centered $T$, and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where $p$ is the number of rows in the within-subject model. anova multiplies $Y$, the response you use in the repeated measures model rm by the orthogonal contrasts, and uses the columns of the resulting product matrix as the responses.

anova computes the orthogonal contrasts for $T$ using the $Q$ factor of a QR factorization on page 32-111 of the Vandermonde matrix on page 32-111.

• A character vector or string scalar that defines a model specification in the within-subject factors. Responses are defined by the terms in that model. anova multiplies $Y$, the response matrix you use in the repeated measures model rm by the terms of the model, and uses the columns of the result as the responses.

For example, if there is a Time factor and 'Time' is the model specification, then anova uses two terms, the constant and the uncentered Time term. The default is '1' to perform on the average response.

• An $r$-by-$nc$ matrix, $C$, specifying $nc$ contrasts among the $r$ repeated measures. If $Y$ represents the matrix of repeated measures you use in the repeated measures model rm, then the output tbl contains a separate analysis of variance for each column of $Y*C$.

The anova table contains a separate univariate analysis of variance results for each response.

Example: 'WithinModel','Time'
Example: 'WithinModel','orthogonalcontrasts'

Output Arguments

anova — Results of analysis of variance table

Results of analysis of variance for between-subject effects, returned as a table. This includes all terms on the between-subjects model and the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Within</td>
<td>Within-subject factors</td>
</tr>
</tbody>
</table>
### Column Name | Definition
--- | ---
Between | Between-subject factors
SumSq | Sum of squares
DF | Degrees of freedom
MeanSq | Mean squared error
F | $F$-statistic
pValue | $p$-value corresponding to the $F$-statistic

### Examples

**Analysis of Variance for Average Response**

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```matlab
t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4),... 'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4],'VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform analysis of variance.

```matlab
anova(rm)
```

```
ans=3×7 table
     Within    Between    SumSq    DF     MeanSq     F     pValue
          ____    ______    ______    ___    _______    ______    ___________
```

32-107
There are 150 observations and 3 species. The degrees of freedom for species is 3 - 1 = 2, and for error it is 150 - 3 = 147. The small $p$-value of 1.1517e-61 indicates that the measurements differ significantly according to species.

### Panel Data

Load the sample panel data.

```matlab
load(fullfile(matlabroot,'examples','stats','panelData.mat'));
```

The dataset array, `panelData`, contains yearly observations on eight cities for 6 years. The first variable, `Growth`, measures economic growth (the response variable). The second and third variables are city and year indicators, respectively. The last variable, `Employ`, measures employment (the predictor variable). This is simulated data.

Store the data in a table array and define city as a nominal variable.

```matlab
t = table(panelData.Growth,panelData.City,panelData.Year,...
    'VariableNames',{'Growth','City','Year'});
```

Convert the data in a proper format to do repeated measures analysis.

```matlab
t = unstack(t,'Growth','Year','NewDataVariableNames',
    {'year1','year2','year3','year4','year5','year6'});
```

Add the mean employment level over the years as a predictor variable to the table `t`.

```matlab
t(:,8) = table(grpstats(panelData.Employ,panelData.City));
t.Properties.VariableNames{'Var8'} = 'meanEmploy';
```

Define the within-subjects variable.

```matlab
Year = [1 2 3 4 5 6]';
```

Fit a repeated measures model, where the growth figures over the 6 years are the responses and the mean employment is the predictor variable.
```matlab
rm = fitrm(t,'year1-year6 ~ meanEmploy','WithinDesign',Year);

Perform analysis of variance.

anovatbl = anova(rm,'WithinModel',Year)
```

```
anovatbl=3x7 table
Within       Between        SumSq       DF      MeanSq         F         pValue
_________    __________    __________    __    __________    ________    _________
Contrast1    constant          588.17    1         588.17    0.038495      0.85093
Contrast1    meanEmploy    3.7064e+05    1     3.7064e+05      24.258    0.0026428
Contrast1    Error              91675    6          15279
```

**Longitudinal Data**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','longitudinalData.mat'))
```

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of `Y` corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```matlab
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']
```

Store the data in a proper table array format to do repeated measures analysis.

```matlab
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```matlab
Time = [0 2 4 6 8]
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable.

```matlab
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```
Perform analysis of variance.

\[
\text{anova} = \text{anova(rm)}
\]

\[
\begin{array}{cccccc}
\text{Within} & \text{Between} & \text{SumSq} & \text{DF} & \text{MeanSq} & \text{F} & \text{pValue} \\
\hline
\text{Constant} & \text{constant} & 54702 & 1 & 54702 & 1079.2 & 1.1897e-14 \\
\text{Constant} & \text{Gender} & 2251.7 & 1 & 2251.7 & 44.425 & 1.0693e-05 \\
\text{Constant} & \text{Error} & 709.6 & 14 & 50.685 & & \\
\end{array}
\]

There are 2 genders and 16 observations, so the degrees of freedom for gender is \((2 - 1) = 1\) and for error it is \((16 - 2) \times (2 - 1) = 14\). The small \textit{p}-value of 1.0693e-05 indicates that there is a significant effect of gender on blood pressure.

Repeat analysis of variance using orthogonal contrasts.

\[
\text{anova} = \text{anova(rm,'WithinModel','orthogonalcontrasts')}
\]

\[
\begin{array}{cccccc}
\text{Within} & \text{Between} & \text{SumSq} & \text{DF} & \text{MeanSq} & \text{F} & \text{pValue} \\

\]
Definitions

**Vandermonde Matrix**

Vandermonde matrix is the matrix where columns are the powers of the vector $a$, that is, $V(i,j) = a(i)^{(n-j)}$, where $n$ is the length of $a$.

**QR Factorization**

QR factorization of an $m$-by-$n$ matrix $A$ is the factorization that matrix into the product $A = Q^*R$, where $R$ is an $m$-by-$n$ upper triangular matrix and $Q$ is an $m$-by-$m$ unitary matrix.

“Model Specification for Repeated Measures Models” on page 9-78
ansaribradley

Ansari-Bradley test

Syntax

h = ansaribradley(x,y)
h = ansaribradley(x,y,Name,Value)
[h,p] = ansaribradley(__)
[h,p,stats] = ansaribradley(__)

Description

h = ansaribradley(x,y) returns a test decision for the null hypothesis that the data in vectors x and y comes from the same distribution, using the Ansari-Bradley test on page 32-117. The alternative hypothesis is that the data in x and y comes from distributions with the same median and shape but different dispersions (e.g., variances). The result h is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

h = ansaribradley(x,y,Name,Value) returns a test decision for the Ansari-Bradley test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level, conduct a one-sided test, or use a normal approximation to calculate the value of the test statistic.

[h,p] = ansaribradley(__) also returns the p-value, p, of the test, using any of the input arguments in the previous syntaxes.

[h,p,stats] = ansaribradley(__) also returns the structure stats containing information about the test statistic.

Examples
Ansari-Bradley Test for Equal Variances

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```matlab
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances.

```matlab
[h,p,stats] = ansaribradley(x,y)
```

```matlab
h = 0
p = 0.8426
stats = struct with fields:
    W: 526.9000
    Wstar: 0.1986
```

The returned value of \( h = 0 \) indicates that `ansaribradley` does not reject the null hypothesis at the default 5% significance level.

Ansari-Bradley One-Sided Hypothesis Test

Load the sample data. Create data vectors of miles per gallon (MPG) measurements for the model years 1982 and 1976.

```matlab
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances, against the alternative hypothesis that the variance of cars from 1982 is greater than that of cars from 1976.

```matlab
[h,p,stats] = ansaribradley(x,y,'Tail','right')
```

```matlab
h = 0
```
\[ p = 0.5787 \]

\[
\text{stats} = \text{struct with fields:}
\begin{align*}
W & : 526.9000 \\
W_{\text{star}} & : 0.1986
\end{align*}
\]

The returned value of \( h = 0 \) indicates that \texttt{ansaribradley} does not reject the null hypothesis that the variance in miles per gallon is the same for the two model years, when the alternative is that the variance of cars from 1982 is greater than that of cars from 1976.

### Input Arguments

\[ x \rightarrow \text{Sample data} \]

- **vector** | **matrix** | **multidimensional array**

Sample data, specified as a vector, matrix, or multidimensional array.

- If \( x \) and \( y \) are specified as vectors, they do not need to be the same length.
- If \( x \) and \( y \) are specified as matrices, they must have the same number of columns. \texttt{ansaribradley} performs separate tests along each column and returns a vector of results.
- If \( x \) and \( y \) are specified as multidimensional arrays on page 32-117, \texttt{ansaribradley} works along the first nonsingleton dimension on page 32-118. \( x \) and \( y \) must have the same size along all remaining dimensions.

Data Types: \texttt{single} | \texttt{double}

\[ y \rightarrow \text{Sample data} \]

- **vector** | **matrix** | **multidimensional array**

Sample data, specified as a vector, matrix, or multidimensional array.

- If \( x \) and \( y \) are specified as vectors, they do not need to be the same length.
- If \( x \) and \( y \) are specified as matrices, they must have the same number of columns. \texttt{ansaribradley} performs separate tests along each column and returns a vector of results.
• If x and y are specified as multidimensional arrays on page 32-117, ansaribradley works along the first nonsingleton dimension on page 32-118. x and y must have the same size along all remaining dimensions.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Tail','right','Alpha',0.01 specifies a right-tailed hypothesis test at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

**Dim — Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column means, while 'Dim',2 tests the row means.

Example: 'Dim',2

Data Types: single | double

**Tail — Type of alternative hypothesis**

'both' (default) | 'left' | 'right'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.
Test the alternative hypothesis that the dispersion parameters of \( x \) and \( y \) are not equal.

Test the alternative hypothesis that the dispersion parameter of \( x \) is greater than that of \( y \).

Test the alternative hypothesis that the dispersion parameter of \( x \) is less than that of \( y \).

Example: 'Tail','right'

**Method — Computation method**

'exact' | 'approximate'

Computation method for the test statistic, specified as the comma-separated pair consisting of 'Method' and one of the following.

'exact' Compute \( p \) using an exact calculation of the distribution of the test statistic \( W \). This is the default if \( n \), the total number of rows in \( x \) and \( y \), is 25 or less. Note that \( n \) is computed before any NaN values (representing missing data) are removed.

'approximate' Compute \( p \) using a normal approximation for the statistic \( W^* \). This is the default if \( n \), the total number of rows in \( x \) and \( y \), is greater than 25.

Example: 'Method','exact'

**Output Arguments**

\( h \) — Hypothesis test result

\[ 1 \mid 0 \]

Hypothesis test result, returned as \( 1 \) or \( 0 \).

- If \( h = 1 \), this indicates the rejection of the null hypothesis at the \( \alpha \) significance level.
- If \( h = 0 \), this indicates a failure to reject the null hypothesis at the \( \alpha \) significance level.

\( p \) — \( p \)-value

Scalar value in the range \([0,1]\)
p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

**stats — Test statistics**

*structure*

Test statistics for the Ansari-Bradley test, returned as a structure containing:

- **W** — Value of the test statistic, which is the sum of the Ansari-Bradley ranks for the x sample.
- **Wstar** — Approximate normal statistic $W^*$. 

**Definitions**

**Ansari-Bradley Test**

The Ansari-Bradley test is a nonparametric alternative to the two-sample $F$-test of equal variances. It does not require the assumption that $x$ and $y$ come from normal distributions. The dispersion of a distribution is generally measured by its variance or standard deviation, but the Ansari-Bradley test can be used with samples from distributions that do not have finite variances.

This test requires that the samples have equal medians. Under that assumption, and if the distributions of the samples are continuous and identical, the test is independent of the distributions. If the samples do not have the same medians, the results can be misleading. In that case, Ansari and Bradley recommend subtracting the median, but then the distribution of the resulting test under the null hypothesis is no longer independent of the common distribution of $x$ and $y$. If you want to perform the tests with medians subtracted, you should subtract the medians from $x$ and $y$ before calling `ansaribradley`.

**Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if $x$ is a 1-by-3-by-4 array, then $x$ is a three-dimensional array.
First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if \( x \) is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of \( x \).

Introduced before R2006a
**aoctool**

Interactive analysis of covariance

**Syntax**

```
aoctool(x,y,group)
aoctool(x,y,group,alpha)
aoctool(x,y,group,alpha,xname,yname,gname)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)
```

```
h = aoctool(...)  
[h,atab,ctab] = aoctool(...)  
[h,atab,ctab,stats] = aoctool(...)  
```

**Description**

**aoctool(x,y,group)** fits a separate line to the column vectors, x and y, for each group defined by the values in the array group. group may be a categorical variable, numeric vector, character array, string array, or cell array of character vectors. These types of models are known as one-way analysis of covariance (ANOCOVA) models. The output consists of three figures:

- An interactive graph of the data and prediction curves
- An ANOVA table
- A table of parameter estimates

You can use the figures to change models and to test different parts of the model. More information about interactive use of the aoctool function appears in “Analysis of Covariance Tool” on page 9-58.

**aoctool(x,y,group,alpha)** determines the confidence levels of the prediction intervals. The confidence level is $100(1-\alpha)\%$. The default value of alpha is 0.05.

**aoctool(x,y,group,alpha,xname,yname,gname)** specifies the name to use for the x, y, and g variables in the graph and tables. If you enter simple variable names for the
x, y, and g arguments, the aoctool function uses those names. If you enter an expression for one of these arguments, you can specify a name to use in place of that expression by supplying these arguments. For example, if you enter m(:,2) as the x argument, you might choose to enter 'Col 2' as the xname argument.

aoctool(x,y,group,alpha,xname,yname,gname,displayopt) enables the graph and table displays when displayopt is 'on' (default) and suppresses those displays when displayopt is 'off'.

aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model) specifies the initial model to fit. The value of model can be any of the following:

• 'same mean' — Fit a single mean, ignoring grouping
• 'separate means' — Fit a separate mean to each group
• 'same line' — Fit a single line, ignoring grouping
• 'parallel lines' — Fit a separate line to each group, but constrain the lines to be parallel
• 'separate lines' — Fit a separate line to each group, with no constraints

h = aoctool(...) returns a vector of handles to the line objects in the plot.

[h,atab,ctab] = aoctool(...) returns cell arrays containing the entries in ANOVA table (atab) and the table of coefficient estimates (ctab). (You can copy a text version of either table to the clipboard by using the Copy Text item on the Edit menu.)

[h,atab,ctab,stats] = aoctool(...) returns a stats structure that you can use to perform a follow-up multiple comparison test. The ANOVA table output includes tests of the hypotheses that the slopes or intercepts are all the same, against a general alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of values are significantly different, and which are not. You can use the multcompare function to perform such tests by supplying the stats structure as input. You can test either the slopes, the intercepts, or population marginal means (the heights of the curves at the mean x value).

**Examples**

This example illustrates how to fit different models non-interactively. After loading the smaller car data set and fitting a separate-slopes model, you can examine the coefficient estimates.
load carsmall
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
    '','','', 'off','separate lines');
c(:,1:2)
ans =
    'Term'       'Estimate'
    'Intercept'  [45.97983716833132]
    ' 70'        [-8.58050531454973]
    ' 76'        [-3.89017396094922]
    ' 82'        [12.47067927549897]
    'Slope'      [-0.00780212907455]
    ' 70'        [ 0.00195840368824]
    ' 76'        [ 0.00113831038418]
    ' 82'        [-0.00309671407243]

Roughly speaking, the lines relating MPG to Weight have an intercept close to 45.98 and a slope close to -0.0078. Each group's coefficients are offset from these values somewhat. For instance, the intercept for the cars made in 1970 is 45.98-8.58 = 37.40.

Next, try a fit using parallel lines. (The ANOVA table shows that the parallel-lines fit is significantly worse than the separate-lines fit.)

[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
    '','','', 'off','parallel lines');
c(:,1:2)
ans =
    'Term'       'Estimate'
    'Intercept'  [43.38984085130596]
    ' 70'        [-3.27948192983761]
    ' 76'        [-1.35036234809006]
    ' 82'        [ 4.62984427792768]
    'Slope'      [-0.00664751826198]

Again, there are different intercepts for each group, but this time the slopes are constrained to be the same.

Introduced before R2006a
append

Class: TreeBagger

Append new trees to ensemble

Syntax

B = append(B,other)

Description

B = append(B,other) appends the trees from the other ensemble to those in B. This method checks for consistency of the X and Y properties of the two ensembles, as well as consistency of their compact objects and out-of-bag indices, before appending the trees. The output ensemble B takes training parameters such as FBoot, Prior, Cost, and other from the B input. There is no attempt to check if these training parameters are consistent between the two objects.

See Also

CompactTreeBagger.combine
**barttest**

Bartlett’s test

**Syntax**

\[
\text{ndim} = \text{barttest}(x,\alpha) \\
[\text{ndim}, \text{prob}, \text{chisquare}] = \text{barttest}(x,\alpha)
\]

**Description**

\[
\text{ndim} = \text{barttest}(x,\alpha)
\]

returns the number of dimensions necessary to explain the nonrandom variation in the data matrix \(x\) at the \(\alpha\) significance level.

\[
[\text{ndim}, \text{prob}, \text{chisquare}] = \text{barttest}(x,\alpha)
\]

also returns the significance values for the hypothesis tests \(\text{prob}\), and the \(\chi^2\) values associated with the tests \(\text{chisquare}\).

**Examples**

**Determine Dimensions Needed to Explain Nonrandom Data Variation**

Generate a 20-by-6 matrix of random numbers from a multivariate normal distribution with mean \(\mu = [0 0]\) and covariance \(\Sigma = [1 0.99; 0.99 1]\).

\[
\begin{align*}
\text{rng default} & \quad \% \text{for reproducibility} \\
\mu &= [0 \ 0]; \\
\sigma &= [1 \ 0.99; \ 0.99 \ 1]; \\
X &= \text{mvnrnd}(\mu,\sigma,20); \quad \% \text{columns 1 and 2} \\
X(:,3:4) &= \text{mvnrnd}(\mu,\sigma,20); \quad \% \text{columns 3 and 4} \\
X(:,5:6) &= \text{mvnrnd}(\mu,\sigma,20); \quad \% \text{columns 5 and 6}
\end{align*}
\]

Determine the number of dimensions necessary to explain the nonrandom variation in data matrix \(X\). Report the significance values for the hypothesis tests.

\[
[\text{ndim}, \text{prob}] = \text{barttest}(X,0.05)
\]
ndim = 3
prob = 5x1

0.0000
0.0000
0.0000
0.5148
0.3370

The returned value of ndim indicates that three dimensions are necessary to explain the nonrandom variation in X.

**Input Arguments**

x — Input data
matrix of scalar values

Input data, specified as a matrix of scalar values.

Data Types: single | double

alpha — Significance level
0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1).

Example: 0.1

Data Types: single | double

**Output Arguments**

ndim — Number of dimensions
positive integer value

Number of dimensions, returned as a positive integer value. The dimension is determined by a series of hypothesis tests. The test for ndim = 1 tests the hypothesis that the variances of the data values along each principal component are equal, the test for ndim
= 2 tests the hypothesis that the variances along the second through last components are equal, and so on. The null hypothesis is that the number of dimensions is equal to the number of the largest unequal eigenvalues of the covariance matrix of $x$.

**prob — Significance value**

vector of scalar values in the range $(0, 1)$

Significance value for the hypothesis tests, returned as a vector of scalar values in the range $(0, 1)$. Each element in prob corresponds to an element of chisquare.

**chisquare — Test statistics**

vector of scalar values

Test statistics for each dimension’s hypothesis test, returned as a vector of scalar values.

**See Also**

*Introduced before R2006a*
BayesianOptimization

Bayesian optimization results

Description

A BayesianOptimization object contains the results of a Bayesian optimization. It is the output of bayesopt or a fit function that accepts the OptimizeHyperparameters name-value pair such as fitcdiscr. In addition, a BayesianOptimization object contains data for each iteration of bayesopt that can be accessed by a plot function or an output function.

Creation

Create a BayesianOptimization object using the bayesopt function or a fit function with the OptimizeHyperparameters name-value pair.

Properties

Problem Definition Properties

ObjectiveFcn — ObjectiveFcn argument used by bayesopt
function handle

This property is read-only.

ObjectiveFcn argument used by bayesopt, returned as a function handle.

• If you call bayesopt directly, ObjectiveFcn is the bayesopt objective function argument.

• If you call a fit function containing the 'OptimizeHyperparameters' name-value pair argument, ObjectiveFcn is a function handle that returns the misclassification rate for classification or returns the logarithm of one plus the cross-validation loss for regression, measured by five-fold cross-validation.
Data Types: function_handle

VariableDescriptions — VariableDescriptions argument that bayesopt used
vector of optimizableVariable objects

This property is read-only.

VariableDescriptions argument that bayesopt used, returned as a vector of optimizableVariable objects.

- If you called bayesopt directly, VariableDescriptions is the bayesopt variable description argument.
- If you called a fit function with the OptimizeHyperparameters name-value pair, VariableDescriptions is the vector of hyperparameters.

Options — Options that bayesopt used
structure

This property is read-only.

Options that bayesopt used, returned as a structure.

- If you called bayesopt directly, Options is the options used in bayesopt, which are the name-value pairs See bayesopt “Input Arguments” on page 32-157.
- If you called a fit function with the OptimizeHyperparameters name-value pair, Options are the default bayesopt options, modified by the HyperparameterOptimizationOptions name-value pair.

Options is a read-only structure containing the following fields.

Data Types: struct

**Solution Properties**

**MinObjective — Minimum observed value of objective function**

real scalar

This property is read-only.

Minimum observed value of objective function, returned as a real scalar. When there are coupled constraints or evaluation errors, this value is the minimum over all observed points that are feasible according to the final constraint and Error models.

Data Types: double

**XAtMinObjective — Observed point with minimum objective function value**

1-by-D table

This property is read-only.

Observed point with minimum objective function value, returned as a 1-by-D table, where D is the number of variables.

Data Types: table

**MinEstimatedObjective — Minimum estimated value of objective function**

real scalar

This property is read-only.

Minimum estimated value of objective function, returned as a real scalar.  
MinEstimatedObjective uses the final objective model.

MinEstimatedObjective is the same as the CriterionValue result of bestPoint with default criterion.
Data Types: double

**XAtMinEstimatedObjective** — Point with minimum estimated objective function value
1-by-D table

This property is read-only.

Point with minimum estimated objective function value, returned as a 1-by-D table, where D is the number of variables. `XAtMinEstimatedObjective` uses the final objective model.

Data Types: table

**NumObjectiveEvaluations** — Number of objective function evaluations
positive integer

This property is read-only.

Number of objective function evaluations, returned as a positive integer. This includes the initial evaluations to form a posterior model as well as evaluation during the optimization iterations.

Data Types: double

**TotalElapsedTime** — Total elapsed time of optimization in seconds
positive scalar

This property is read-only.

Total elapsed time of optimization in seconds, returned as a positive scalar.

Data Types: double

**NextPoint** — Next point to evaluate if optimization continues
1-by-D table

This property is read-only.

Next point to evaluate if optimization continues, returned as a 1-by-D table, where D is the number of variables.

Data Types: table
Trace Properties

**XTrace — Points where the objective function was evaluated**

T-by-D table

This property is read-only.

Points where the objective function was evaluated, returned as a T-by-D table, where T is the number of evaluation points and D is the number of variables.

Data Types: table

**ObjectiveTrace — Objective function values**

column vector of length T

This property is read-only.

Objective function values, returned as a column vector of length T, where T is the number of evaluation points. ObjectiveTrace contains the history of objective function evaluations.

Data Types: double

**ObjectiveEvaluationTimeTrace — Objective function evaluation times**

column vector of length T

This property is read-only.

Objective function evaluation times, returned as a column vector of length T, where T is the number of evaluation points. ObjectiveEvaluationTimeTrace includes the time in evaluating coupled constraints, because the objective function computes these constraints.

Data Types: double

**IterationTimeTrace — Iteration times**

column vector of length T

This property is read-only.

Iteration times, returned as a column vector of length T, where T is the number of evaluation points. IterationTimeTrace includes both objective function evaluation time and other overhead.
Data Types: double

**ConstraintsTrace — Coupled constraint values**
T-by-K array

This property is read-only.

Coupled constraint values, returned as a T-by-K array, where T is the number of evaluation points and K is the number of coupled constraints.

Data Types: double

**ErrorTrace — Error indications**
column vector of length T of -1 or 1 entries

This property is read-only.

Error indications, returned as a column vector of length T of -1 or 1 entries, where T is the number of evaluation points. Each 1 entry indicates that the objective function errored or returned NaN on the corresponding point in XTrace. Each -1 entry indicates that the objective function value was computed.

Data Types: double

**FeasibilityTrace — Feasibility indications**
logical column vector of length T

This property is read-only.

Feasibility indications, returned as a logical column vector of length T, where T is the number of evaluation points. Each 1 entry indicates that the final constraint model predicts feasibility at the corresponding point in XTrace.

Data Types: logical

**FeasibilityProbabilityTrace — Probability that evaluation point is feasible**
column vector of length T

This property is read-only.

Probability that evaluation point is feasible, returned as a column vector of length T, where T is the number of evaluation points. The probabilities come from the final constraint model, including the error constraint model, on the corresponding points in XTrace.
Data Types: double

**IndexOfMinimumTrace** — Which evaluation gave minimum feasible objective
column vector of integer indices of length T

This property is read-only.

Which evaluation gave minimum feasible objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points. Feasibility is determined with respect to the constraint models that existed at each iteration, including the error constraint model.

Data Types: double

**ObjectiveMinimumTrace** — Minimum observed objective
column vector of length T

This property is read-only.

Minimum observed objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points.

Data Types: double

**EstimatedObjectiveMinimumTrace** — Minimum estimated objective
column vector of length T

This property is read-only.

Minimum estimated objective, returned as a column vector of integer indices of length T, where T is the number of evaluation points. The estimated objective at each iteration is determined with respect to the objective model that existed at that iteration.

Data Types: double

**UserDataTrace** — Auxiliary data from the objective function
cell array of length T

This property is read-only.

Auxiliary data from the objective function, returned as a cell array of length T, where T is the number of evaluation points. Each entry in the cell array is the UserData returned in the third output of the objective function.
Data Types: cell

Object Functions

- `bestPoint` - Best point in a Bayesian optimization according to a criterion.
- `plot` - Plot Bayesian optimization results.
- `predictConstraints` - Predict coupled constraint violations at a set of points.
- `predictError` - Predict error value at a set of points.
- `predictObjective` - Predict objective function at a set of points.
- `predictObjectiveEvaluationTime` - Predict objective function run times at a set of points.
- `resume` - Resume a Bayesian optimization.

Examples

Create a BayesianOptimization Object Using `bayesopt`

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'. Set options give no iterative display.

```matlab
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
```
results = bayesopt(fun,[num,dst], 'Verbose', 0, ...
  'AcquisitionFunctionName','expected-improvement-plus')
results =

Topics
“Bayesian Optimization Workflow” on page 10-30

Introduced in R2016b
bayesopt

Select optimal machine learning hyperparameters using Bayesian optimization

Syntax

results = bayesopt(fun,vars)
results = bayesopt(fun,vars,Name,Value)

Description

results = bayesopt(fun,vars) attempts to find values of vars that minimize fun(vars).

results = bayesopt(fun,vars,Name,Value) modifies the optimization process according to the Name,Value arguments.

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a BayesianOptimization object by using bayesopt to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the ionosphere data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have bayesopt minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, set the partition, and set the AcquisitionFunctionName option to 'expected-improvement-plus'. Set options give no iterative display.
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
results =

Bayesian Optimization with Coupled Constraints

A coupled constraint is one that can be evaluated only by evaluating the objective function. In this case, the objective function is the cross-validated loss of an SVM model. The coupled constraint is that the number of support vectors is no more than 100. The model details are in “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-55.

Create the data for classification.

```matlab
rng default
grnpop = mvnrnd([1,0],eye(2),10);  
redpop = mvnrnd([0,1],eye(2),10);  
redpts = zeros(100,2);            
grnpts = redpts;                  
for i = 1:100                    
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);  
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);  
end

cdata = [grnpts;redpts];         
grp = ones(200,1);                
grp(101:200) = -1;                
c = cvpartition(200,'KFold',10);  
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');  
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
```

The objective function is the cross-validation loss of the SVM model for partition c. The coupled constraint is the number of support vectors minus 100.5. This ensures that 100...
support vectors give a negative constraint value, but 101 support vectors give a positive value. The model has 200 data points, so the coupled constraint values range from -99.5 (there is always at least one support vector) to 99.5. Positive values mean the constraint is not satisfied.

```matlab
function [objective,constraint] = mysvmfun(x,cdata,grp,c)
    SVMMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',... 
                      'BoxConstraint',x.box,... 
                      'KernelScale',x.sigma);
    cvModel = crossval(SVMMModel,'CVPartition',c);
    objective = kfoldLoss(cvModel);
    constraint = sum(SVMMModel.IsSupportVector)-100.5;

    fun = @(x)mysvmfun(x,cdata,grp,c); 

    Set the NumCoupledConstraints to 1 so the optimizer knows that there is a coupled constraint. Set options to plot the constraint model.

    results = bayesopt(fun,[sigma,box],'IsObjectiveDeterministic',true,... 
                      'NumCoupledConstraints',1,'PlotFcn',... 
                      {@plotMinObjective,@plotConstraintModels},... 
                      'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```
Min objective vs. Number of function evaluations

- Min observed objective
- Estimated min objective
Constraint 1 model
Most points lead to an infeasible number of support vectors.

**Parallel Bayesian Optimization**

Improve the speed of a Bayesian optimization by using parallel objective function evaluation.
Prepare variables and the objective function for Bayesian optimization.

The objective function is the cross-validation error rate for the ionosphere data, a binary classification problem. Use `fitcsvm` as the classifier, with `BoxConstraint` and `KernelScale` as the parameters to optimize.

```matlab
load ionosphere
box = optimizableVariable('box',[1e-4,1e3],'Transform','log');
kern = optimizableVariable('kern',[1e-4,1e3],'Transform','log');
vars = [box,kern];
fun = @(vars)kfoldLoss(fitcsvm(X,Y,'BoxConstraint',vars.box,'KernelScale',vars.kern,...
    'Kfold',5));
```

Search for the parameters that give the lowest cross-validation error by using parallel Bayesian optimization.

```matlab
results = bayesopt(fun,vars,'UseParallel',true);
```

\[
\text{ans} = 0.0011
\]

\[
\text{Mdl.KernelParameters.Scale}
\]

\[
\text{ans} = 0.0120
\]

**Input Arguments**

fun — Objective function
function handle | \texttt{parallel.pool.Constant} whose Value is a function handle
Objective function, specified as a function handle or, when the UseParallel name-value pair is true, a parallel.pool.Constant whose Value is a function handle. Typically, fun returns a measure of loss (such as a misclassification error) for a machine learning model that has tunable hyperparameters to control its training. fun has these signatures:

```matlab
objective = fun(x)
% or
[objective, constraints] = fun(x)
% or
[objective, constraints, UserData] = fun(x)
```

fun accepts `x`, a 1-by-`D` table of variable values, and returns `objective`, a real scalar representing the objective function value `fun(x)`.

Optionally, fun also returns:

- `constraints`, a real vector of coupled constraint violations. For a definition, see “Coupled Constraints” on page 32-169. `constraint(j) > 0` means constraint `j` is violated. `constraint(j) < 0` means constraint `j` is satisfied.
- `UserData`, an entity of any type (such as a scalar, matrix, structure, or object). For an example of a custom plot function that uses `UserData`, see “Create a Custom Plot Function” on page 10-16.

For details about using `parallel.pool.Constant` with `bayesopt`, see “Placing the Objective Function on Workers” on page 10-10.

Example: `@objfun`

Data Types: `function_handle`

`vars — Variable descriptions`  
vector of `optimizableVariable` objects defining the hyperparameters to be tuned

Variable descriptions, specified as a vector of `optimizableVariable` objects defining the hyperparameters to be tuned.

Example: `[X1,X2]`, where `X1` and `X2` are `optimizableVariable` objects

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: results = bayesopt(fun, vars, 'AcquisitionFunctionName', 'expected-improvement-plus')

**Algorithm Control**

**AcquisitionFunctionName** — Function to choose next evaluation point

String. Function to choose next evaluation point, specified as one of the listed choices. For algorithm descriptions, see “Acquisition Function Types” on page 10-4.

Example: 'AcquisitionFunctionName', 'expected-improvement-per-second-plus'

**IsObjectiveDeterministic** — Specify deterministic objective function

Logical. Specify deterministic objective function, specified as false or true. If fun is stochastic (that is, fun(x) can return different values for the same x), then set IsObjectiveDeterministic to false. In this case, bayesopt estimates a noise level during optimization.

Example: 'IsObjectiveDeterministic', true

**ExplorationRatio** — Propensity to explore

Scalar. Propensity to explore, specified as a positive real. Applies to the 'expected-improvement-plus' and 'expected-improvement-per-second-plus' acquisition functions. See “Plus” on page 10-6.

Example: 'ExplorationRatio', 0.2

**GPActiveSetSize** — Fit Gaussian Process model to GPActiveSetSize or fewer points

Positive integer. Specify the number of points to use to fit the Gaussian Process model.
Fit Gaussian Process model to `GPActiveSetSize` or fewer points, specified as a positive integer. When `bayesopt` has visited more than `GPActiveSetSize` points, subsequent iterations that use a GP model fit the model to `GPActiveSetSize` points. `bayesopt` chooses points uniformly at random without replacement among visited points. Using fewer points leads to faster GP model fitting, at the expense of possibly less accurate fitting.

Example: `'GPActiveSetSize',80`

Data Types: `double`

**UseParallel — Compute in parallel**

`false` (default) | `true`

Compute in parallel, specified as `false` (do not compute in parallel) or `true` (compute in parallel). `bayesopt` performs parallel objective function evaluations concurrently on parallel workers. For algorithmic details, see “Parallel Bayesian Optimization” on page 10-9.

Example: `'UseParallel',true`

Data Types: `logical`

**ParallelMethod — Imputation method for parallel worker objective function values**

`'clipped-model-prediction'` (default) | `'model-prediction'` | `'max-observed'` | `'min-observed'`

Imputation method for parallel worker objective function values, specified as `'clipped-model-prediction'`, `'model-prediction'`, `'max-observed'`, or `'min-observed'`. To generate a new point to evaluate, `bayesopt` fits a Gaussian process to all points, including the points being evaluated on workers. To fit the process, `bayesopt` imputes objective function values for the points that are currently on workers. `ParallelMethod` specifies the method used for imputation.

- `'clipped-model-prediction'` — Impute the maximum of these quantities:
  - Mean Gaussian process prediction at the point \( x \)
  - Minimum observed objective function among feasible points visited
  - Minimum model prediction among all feasible points
- `'model-prediction'` — Impute the mean Gaussian process prediction at the point \( x \).
• 'max-observed' — Impute the maximum observed objective function value among feasible points.
• 'min-observed' — Impute the minimum observed objective function value among feasible points.

Example: 'ParallelMethod','max-observed'

**MinWorkerUtilization — Tolerance on number of active parallel workers**

floor(0.8*Nworkers) (default) | positive integer

Tolerance on the number of active parallel workers, specified as a positive integer. After bayesopt assigns a point to evaluate, and before it computes a new point to assign, it checks whether fewer than MinWorkerUtilization workers are active. If so, bayesopt assigns random points within bounds to all available workers. Otherwise, bayesopt calculates the best point for one worker. bayesopt creates random points much faster than fitted points, so this behavior leads to higher utilization of workers, at the cost of possibly poorer points. For details, see “Parallel Bayesian Optimization” on page 10-9.

Example: 'MinWorkerUtilization',3

Data Types: double

**Starting and Stopping**

**MaxObjectiveEvaluations — Objective function evaluation limit**

30 (default) | positive integer

Objective function evaluation limit, specified as a positive integer.

Example: 'MaxObjectiveEvaluations',60

Data Types: double

**MaxTime — Time limit**

Inf (default) | positive real

Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc.

Run time can exceed MaxTime because bayesopt does not interrupt function evaluations.

Example: 'MaxTime',3600
Data Types: double

**NumSeedPoints — Number of initial evaluation points**
4 (default) | positive integer

Number of initial evaluation points, specified as a positive integer. `bayesopt` chooses these points randomly within the variable bounds, according to the setting of the `Transform` setting for each variable (uniform for 'none', logarithmically spaced for 'log').

Example: 'NumSeedPoints',10

Data Types: double

**Constraints**

**XConstraintFcn — Deterministic constraints on variables**
[] (default) | function handle

Deterministic constraints on variables, specified as a function handle.

For details, see “Deterministic Constraints — XConstraintFcn” on page 10-45.

Example: 'XConstraintFcn',@xconstraint

Data Types: function_handle

**ConditionalVariableFcn — Conditional variable constraints**
[] (default) | function handle

Conditional variable constraints, specified as a function handle.

For details, see “Conditional Constraints — ConditionalVariableFcn” on page 10-46.

Example: 'ConditionalVariableFcn',@condfun

Data Types: function_handle

**NumCoupledConstraints — Number of coupled constraints**
0 (default) | positive integer

Number of coupled constraints, specified as a positive integer. For details, see “Coupled Constraints” on page 10-48.

**Note** `NumCoupledConstraints` is required when you have coupled constraints.
Example: 'NumCoupledConstraints',3
Data Types: double

AreCoupledConstraintsDeterministic — Indication of whether coupled constraints are deterministic
true for all coupled constraints (default) | logical vector

Indication of whether coupled constraints are deterministic, specified as a logical vector of length NumCoupledConstraints. For details, see “Coupled Constraints” on page 10-48.

Example: 'AreCoupledConstraintsDeterministic',[true,false,true]
Data Types: logical

Reports, Plots, and Halting

Verbose — Command-line display level
1 (default) | 0 | 2

Command-line display level, specified as 0, 1, or 2.

- 0 — No command-line display.
- 1 — At each iteration, display the iteration number, result report (see the next paragraph), objective function model, objective function evaluation time, best (lowest) observed objective function value, best (lowest) estimated objective function value, and the observed constraint values (if any). When optimizing in parallel, the display also includes a column showing the number of active workers, counted after assigning a job to the next worker.

The result report for each iteration is one of the following:

- **Accept** — The objective function returns a finite value, and all constraints are satisfied.
- **Best** — Constraints are satisfied, and the objective function returns the lowest value among feasible points.
- **Error** — The objective function returns a value that is not a finite real scalar.
- **Infeas** — At least one constraint is violated.
- **2** — Same as 1, adding diagnostic information such as time to select the next point, model fitting time, indication that "plus" acquisition functions declare overexploiting,
and parallel workers are being assigned to random points due to low parallel utilization.

Example: 'Verbose',2

Data Types: double

**OutputFcn — Function called after each iteration**

 `{}` (default) | function handle | cell array of function handles

Function called after each iteration, specified as a function handle or cell array of function handles. An output function can halt the solver, and can perform arbitrary calculations, including creating variables or plotting. Specify several output functions using a cell array of function handles.

There are two built-in output functions:

- @assignInBase — Constructs a BayesianOptimization instance at each iteration and assigns it to a variable in the base workspace. Choose a variable name using the SaveVariableName name-value pair.
- @saveToFile — Constructs a BayesianOptimization instance at each iteration and saves it to a file in the current folder. Choose a file name using the SaveFileName name-value pair.

You can write your own output functions. For details, see “Bayesian Optimization Output Functions” on page 10-23.

Example: 'OutputFcn',{@saveToFile @myOutputFunction}

Data Types: cell | function_handle

**SaveFileName — File name for the @saveToFile output function**

'BayesoptResults.mat' (default) | character vector | string scalar

File name for the @saveToFile output function, specified as a character vector or string scalar. The file name can include a path, such as '
../optimizations/ September2.mat'.

Example: 'SaveFileName','September2.mat'

Data Types: char | string

**SaveVariableName — Variable name for the @assignInBase output function**

'BayesoptResults' (default) | character vector | string scalar
Variable name for the @assignInBase output function, specified as a character vector or string scalar.
Example: 'SaveVariableName','September2Results'
Data Types: char | string

PlotFcn — Plot function called after each iteration
[@plotObjectiveModel,@plotMinObjective] (default) | 'all' | function handle | cell array of function handles

Plot function called after each iteration, specified as 'all', a function handle, or a cell array of function handles. A plot function can halt the solver, and can perform arbitrary calculations, including creating variables, in addition to plotting.

Specify no plot function as [].

'all' calls all built-in plot functions. Specify several plot functions using a cell array of function handles.

The built-in plot functions appear in the following tables.

<table>
<thead>
<tr>
<th>Model Plots — Apply When D ≤ 2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@plotAcquisitionFunction</td>
<td>Plot the acquisition function surface.</td>
</tr>
</tbody>
</table>
| @plotConstraintModels         | Plot each constraint model surface. Negative values indicate feasible points. Also plot a $P(\text{feasible})$ surface. Also plot the error model, if it exists, which ranges from −1 to 1. Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: \[
\text{Plotted error} = 2 \times \text{Probability(error)} - 1.\] |
| @plotObjectiveEvaluationTimeModel | Plot the objective function evaluation time model surface. |
## Model Plots — Apply When $D \leq 2$

<table>
<thead>
<tr>
<th>Description</th>
<th>@plotObjectiveModel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot the fun model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean.</td>
<td></td>
</tr>
</tbody>
</table>

## Trace Plots — Apply to All $D$

<table>
<thead>
<tr>
<th>Description</th>
<th>@plotObjective</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot each observed function value versus the number of function evaluations.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>@plotObjectiveEvaluationTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot each observed function evaluation run time versus the number of function evaluations.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>@plotMinObjective</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot the minimum observed and estimated function values versus the number of function evaluations.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Description</th>
<th>@plotElapsedTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.</td>
<td></td>
</tr>
</tbody>
</table>

You can write your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-14.

### Note

When there are coupled constraints, iterative display and plot functions can give counterintuitive results such as:

- A *minimum objective* plot can increase.
- The optimization can declare a problem infeasible even when it showed an earlier feasible point.

The reason for this behavior is that the decision about whether a point is feasible can change as the optimization progresses. *bayesopt* determines feasibility with respect to its constraint model, and this model changes as *bayesopt* evaluates points. So a “minimum objective” plot can increase when the minimal point is later deemed infeasible, and the iterative display can show a feasible point that is later deemed infeasible.
Example: 'PlotFcnc','all'
Data Types: char | string | cell | function_handle

Initialization

**InitialX — Initial evaluation points**
NumSeedPoints-by-D random initial points within bounds (default) | N-by-D table

Initial evaluation points, specified as an N-by-D table, where N is the number of evaluation points, and D is the number of variables.

**Note** If only InitialX is provided, it is interpreted as initial points to evaluate. The objective function is evaluated at InitialX.

If any other initialization parameters are also provided, InitialX is interpreted as prior function evaluation data. The objective function is not evaluated. Any missing values are set to NaN.

Data Types: table

**InitialObjective — Objective values corresponding to InitialX**
[] (default) | length-N vector

Objective values corresponding to InitialX, specified as a length-N vector, where N is the number of evaluation points.

Example: 'InitialObjective',[17;-3;-12.5]

Data Types: double

**InitialConstraintViolations — Constraint violations of coupled constraints**
[] (default) | N-by-K matrix

Constraint violations of coupled constraints, specified as an N-by-K matrix, where N is the number of evaluation points and K is the number of coupled constraints. For details, see “Coupled Constraints” on page 10-48.

Data Types: double

**InitialErrorValues — Errors for InitialX**
[] (default) | length-N vector with entries -1 or 1
Errors for InitialX, specified as a length-N vector with entries -1 or 1, where N is the number of evaluation points. Specify -1 for no error, and 1 for an error.

Example: ' InitialErrorValues', [-1, -1, -1, -1, 1]

Data Types: double

InitialUserData — Initial data corresponding to InitialX

[ ] (default) | length-N cell vector

Initial data corresponding to InitialX, specified as a length-N cell vector, where N is the number of evaluation points.

Example: ' InitialUserData', {2, 3, -1}

Data Types: cell

InitialObjectiveEvaluationTimes — Evaluation times of objective function at InitialX

[ ] (default) | length-N vector

Evaluation times of objective function at InitialX, specified as a length-N vector, where N is the number of evaluation points. Time is measured in seconds.

Data Types: double

InitialIterationTimes — Times for the first N iterations

{} (default) | length-N vector

Times for the first N iterations, specified as a length-N vector, where N is the number of evaluation points. Time is measured in seconds.

Data Types: double

Output Arguments

results — Bayesian optimization results
BayesianOptimization object

Bayesian optimization results, returned as a BayesianOptimization object.
Definitions

Coupled Constraints

Coupled constraints are those constraints whose value comes from the objective function calculation. See “Coupled Constraints” on page 10-48.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel',true name-value pair argument in the call to this function.

Introduced in R2016b
**bbdesign**

Box-Behnken design

**Syntax**

```plaintext
dBB = bbdesign(n)
[dBB,blocks] = bbdesign(n)
[...] = bbdesign(n,param,val)
```

**Description**

`dBB = bbdesign(n)` generates a Box-Behnken design for `n` factors. `n` must be an integer 3 or larger. The output matrix `dBB` is `m`-by-`n`, where `m` is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

`[dBB,blocks] = bbdesign(n)` requests a blocked design. The output `blocks` is an `m`-by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = bbdesign(n,param,val)` specifies one or more optional parameter/value pairs for the design. The following table lists valid parameter/value pairs.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'center'</td>
<td>Number of center points.</td>
<td>Integer. The default depends on <code>n</code>.</td>
</tr>
<tr>
<td>'blocksize'</td>
<td>Maximum number of points per block.</td>
<td>Integer. The default is Inf.</td>
</tr>
</tbody>
</table>

**Examples**

The following creates a 3-factor Box-Behnken design:
dBB = bbdesign(3)
dBB =
   -1   -1    0
   -1    1    0
    1   -1    0
    1    1    0
   -1    0   -1
   -1    0    1
    1    0   -1
    1    0    1
    0   -1   -1
    0   -1    1
    0    1   -1
    0    1    1
    0    0    0
    0    0    0
    0    0    0

The center point is run 3 times to allow for a more uniform estimate of the prediction variance over the entire design space.

Visualize the design as follows:

plot3(dBB(:,1),dBB(:,2),dBB(:,3),'ro',
     'MarkerFaceColor','b')
X = [1 -1 -1 -1 -1 -1 -1 1 1 1 -1 -1; ...
     1 1 1 -1 1 1 1 -1 1 1 -1 -1];
Y = [-1 -1 -1 -1 -1 -1 -1 1 1 1 -1 -1; ...
     1 -1 1 1 -1 1 1 -1 1 1 -1 -1];
Z = [1 1 1 -1 -1 -1 -1 -1 1 1 1 1; ...
     1 1 1 1 -1 -1 -1 1 1 1 1 1;]
line(X,Y,Z,'Color','b')
axis square equal

Introduced before R2006a
bestPoint

Best point in a Bayesian optimization according to a criterion

Syntax

\[
x = \text{bestPoint} \left( \text{results} \right) \\
x = \text{bestPoint} \left( \text{results}, \text{Name}, \text{Value} \right) \\
\left[ x, \text{CriterionValue} \right] = \text{bestPoint}(\_\_) \\
\left[ x, \text{CriterionValue}, \text{iteration} \right] = \text{bestPoint}(\_\_) \\
\]

Description

\( x = \text{bestPoint} \left( \text{results} \right) \) returns the best feasible point in the Bayesian model \( \text{results} \) according to the default criterion 'min-visited-upper-confidence-interval'.

\( x = \text{bestPoint} \left( \text{results}, \text{Name}, \text{Value} \right) \) modifies the best point using name-value pairs.

\( \left[ x, \text{CriterionValue} \right] = \text{bestPoint}(\_\_), \) for any previous syntax, also returns the value of the criterion at \( x \).

\( \left[ x, \text{CriterionValue}, \text{iteration} \right] = \text{bestPoint}(\_\_) \) also returns the iteration number at which the best point was returned. Applies when the Criterion name-value pair is 'min-observed', 'min-visited-mean', or the default 'min-visited-upper-confidence-interval'.

Examples

Best Point of an Optimized KNN Classifier

This example shows how to obtain the best point of an optimized classifier.
Optimize a KNN classifier for the *ionosphere* data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions 'chebychev', 'euclidean', and 'minkowski'.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to 'expected-improvement-plus'.

```matlab
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```
Obtain the best point according to the default 'min-visited-upper-confidence-interval' criterion.

\[
x = \text{bestPoint}\left(\text{results}\right)
\]

\[
x = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}
\]

The lowest estimated cross-validation loss occurs for ten nearest neighbors and 'chebychev' distance.
Careful examination of the objective function model plot shows a point with one nearest neighbor and 'chebychev' distance that has a lower objective function value. Find this point using a different criterion.

\[ x = \text{bestPoint}(\text{results},'\text{Criterion}', '\text{min-observed}') \]

\[
\begin{array}{|c|c|}
\hline
n & dst \\
\hline
1 & chebychev \\
\hline
\end{array}
\]

Also find the minimum observed objective function value, and the iteration number at which it was observed.

\[ [x,\text{CriterionValue},\text{iteration}] = \text{bestPoint}(\text{results},'\text{Criterion}', '\text{min-observed}') \]

\[
\begin{array}{|c|c|}
\hline
n & dst \\
\hline
1 & chebychev \\
\hline
\end{array}
\]

CriterionValue = 0.1197

iteration = 11

**Input Arguments**

- **results** — Bayesian optimization results
  - BayesianOptimization object

  Bayesian optimization results, specified as a BayesianOptimization object.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.
Example: x = bestPoint(results,'Criterion','min-observed')

**Criterion — Best point criterion**

<table>
<thead>
<tr>
<th>Criterion Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'min-observed'</td>
<td>x is the feasible point with minimum observed objective.</td>
</tr>
<tr>
<td>'min-mean'</td>
<td>x is the feasible point where the objective model mean is minimized.</td>
</tr>
<tr>
<td>'min-upper-confidence-interval'</td>
<td>x is the feasible point minimizing an upper confidence interval of the objective model. See ( \alpha ).</td>
</tr>
<tr>
<td>'min-visited-mean'</td>
<td>x is the feasible point where the objective model mean is minimized among the visited points.</td>
</tr>
<tr>
<td>'min-visited-upper-confidence-interval'</td>
<td>x is the feasible point minimizing an upper confidence interval of the objective model among the visited points. See ( \alpha ).</td>
</tr>
</tbody>
</table>

Example: 'Criterion','min-visited-mean'

**alpha — Probability that modeled objective mean exceeds CriterionValue**

\( \theta \cdot 0.01 \) (default) | scalar between \( \theta \) and 1

Probability that the modeled objective mean exceeds CriterionValue, specified as the comma-separated pair consisting of 'alpha' and a scalar between \( \theta \) and 1. \( \alpha \) relates to the 'min-upper-confidence-interval' and 'min-visited-upper-confidence-interval' Criterion values. The definition for the upper confidence interval is the value \( Y \) where

\[
P(\text{mean}_Q(\text{fun}(x)) > Y) = \alpha,
\]

where \( \text{fun} \) is the objective function, and the mean is calculated with respect to the posterior distribution \( Q \).

Example: 'alpha',0.05

Data Types: double
Output Arguments

\textbf{x — Best point}
1-by-D table

Best point, returned as a 1-by-D table, where D is the number of variables. The meaning of “best” is with respect to \texttt{Criterion}.

\textbf{CriterionValue — Value of criterion}
real scalar

Value of criterion, returned as a real scalar. The value depends on the setting of the \texttt{Criterion} name-value pair, which has a default value of 'min-visited-upper-confidence-interval'.

<table>
<thead>
<tr>
<th>Criterion Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'min-observed'</td>
<td>Minimum observed objective.</td>
</tr>
<tr>
<td>'min-mean'</td>
<td>Minimum of model mean.</td>
</tr>
<tr>
<td>'min-upper-confidence-interval'</td>
<td>Value ( Y ) satisfying the equation ( P(\text{mean}(\text{fun}(x)) &gt; Y) = \alpha ).</td>
</tr>
<tr>
<td>'min-visited-mean'</td>
<td>Minimum of observed model mean.</td>
</tr>
<tr>
<td>'min-visited-upper-confidence-interval'</td>
<td>Value ( Y ) satisfying the equation ( P(\text{mean}(\text{fun}(x)) &gt; Y) = \alpha ) among observed points.</td>
</tr>
</tbody>
</table>

\textbf{iteration — Iteration number at which best point was observed}
positive integer

Iteration number at which best point was observed, returned as a positive integer. The best point is defined by \texttt{CriterionValue}.

\textbf{See Also}
BayesianOptimization | bayesopt

\textbf{Introduced in R2016b}
betacdf

Beta cumulative distribution function

Syntax

p = betacdf(x,a,b)
p = betacdf(x,a,b,'upper')

Description

p = betacdf(x,a,b) returns the beta cdf at each of the values in x using the corresponding parameters in a and b. x, a, and b can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in a and b must all be positive, and the values in x must lie on the interval [0,1].

p = betacdf(x,a,b,'upper') returns the complement of the beta cdf at each of the values in x, using an algorithm that more accurately computes the extreme upper tail probabilities.

The beta cdf for a given value x and given pair of parameters a and b is

\[ p = F(x | a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1}(1-t)^{b-1} dt \]

where \( B(\cdot) \) is the Beta function.

Examples

Compute Beta Distribution CDF

Compute the cdf for a beta distribution with parameters \( a = 2 \) and \( b = 2 \).
\[ x = 0.1:0.2:0.9; \\
\text{a} = 2; \\
\text{b} = 2; \\
p = \text{betacdf}(x, \text{a}, \text{b}) \\
p = \text{1x5} \\
\begin{array}{cccccc}
0.0280 & 0.2160 & 0.5000 & 0.7840 & 0.9720 \\
\end{array} \\
\]

\[ \text{a} = [1 \ 2 \ 3]; \\
p = \text{betacdf}(0.5, \text{a}, \text{a}) \\
p = \text{1x3} \\
\begin{array}{ccc}
0.5000 & 0.5000 & 0.5000 \\
\end{array} \]

### Topics

“Beta Distribution” on page B-4
Introduced before R2006a
**betafit**

Beta parameter estimates

**Syntax**

`phat = betafit(data)`  
`[phat,pci] = betafit(data,alpha)`

**Description**

`phat = betafit(data)` computes the maximum likelihood estimates of the beta distribution parameters \( a \) and \( b \) from the data in the vector `data` and returns a column vector containing the \( a \) and \( b \) estimates, where the beta cdf is given by

\[
F(x | a,b) = \frac{1}{B(a,b)} \int_0^x t^{a-1}(1-t)^{b-1} dt
\]

and \( B(\cdot) \) is the Beta function. The elements of `data` must lie in the open interval (0, 1), where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betafit` maximizes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at `1-eps/2`, respectively.

`[phat,pci] = betafit(data,alpha)` returns confidence intervals on the \( a \) and \( b \) parameters in the 2-by-2 matrix `pci`. The first column of the matrix contains the lower and upper confidence bounds for parameter \( a \), and the second column contains the confidence bounds for parameter \( b \). The optional input argument `alpha` is a value in the range \([0, 1]\) specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals. The confidence intervals are based on a normal approximation for the distribution of the logs of the parameter estimates.
Examples

This example generates 100 beta distributed observations. The true $a$ and $b$ parameters are 4 and 3, respectively. Compare these to the values returned in $p$ by the beta fit. Note that the columns of $ci$ both bracket the true parameters.

```matlab
data = betarnd(4,3,100,1);
[p,ci] = betafit(data,0.01)
p =
   5.5328    3.8097
ci =
   3.6538    2.6197
   8.3781    5.5402
```

Topics
“Beta Distribution” on page B-4

Introduced before R2006a
betainv

Beta inverse cumulative distribution function

Syntax

\[ X = \text{betainv}(P,A,B) \]

Description

\[ X = \text{betainv}(P,A,B) \] computes the inverse of the beta cdf with parameters specified by \( A \) and \( B \) for the corresponding probabilities in \( P \). \( P, A, \) and \( B \) can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in \( A \) and \( B \) must all be positive, and the values in \( P \) must lie on the interval \([0, 1]\).

The inverse beta cdf for a given probability \( p \) and a given pair of parameters \( a \) and \( b \) is

\[
x = F^{-1}(p \mid a,b) = \{ x : F(x \mid a,b) = p \}
\]

where

\[
p = F(x \mid a,b) = \frac{1}{B(a,b)} \int_{0}^{x} t^{a-1}(1-t)^{b-1} dt
\]

and \( B(\cdot) \) is the Beta function. Each element of output \( X \) is the value whose cumulative probability under the beta cdf defined by the corresponding parameters in \( A \) and \( B \) is specified by the corresponding value in \( P \).

Examples

\[
p = [0.01 \ 0.5 \ 0.99];
x = \text{betainv}(p,10,5)
\]
According to this result, for a beta cdf with $a = 10$ and $b = 5$, a value less than or equal to 0.3726 occurs with probability 0.01. Similarly, values less than or equal to 0.6742 and 0.8981 occur with respective probabilities 0.5 and 0.99.

**Algorithms**

The betainv function uses Newton's method with modifications to constrain steps to the allowable range for $x$, i.e., [0 1].

**betalike**

Beta negative log-likelihood

**Syntax**

```matlab
nlogL = betalike(params,data)
[nlogL,AVAR] = betalike(params,data)
```

**Description**

`nlogL = betalike(params,data)` returns the negative of the beta log-likelihood function for the beta parameters `a` and `b` specified in vector `params` and the observations specified in the column vector `data`.

The elements of `data` must lie in the open interval `(0, 1)`, where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betalike` computes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at `1-eps/2`, respectively.

`[nlogL,AVAR] = betalike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`betalike` is a utility function for maximum likelihood estimation of the beta distribution. The likelihood assumes that all the elements in the data sample are mutually independent. Since `betalike` returns the negative beta log-likelihood function, minimizing `betalike` using `fminsearch` is the same as maximizing the likelihood.
Examples

This example continues the betafit example, which calculates estimates of the beta parameters for some randomly generated beta distributed data.

\[
\begin{align*}
\text{r} &= \text{betarnd}(4,3,100,1); \\
[n\text{logl},AVAR] &= \text{betalike(betafit(r),r)} \\
n\text{logl} &= \\
-27.5996 \\
\end{align*}
\]

\[
\begin{align*}
AVAR &= \\
0.2783 & 0.1316 \\
0.1316 & 0.0867
\end{align*}
\]

**betapdf**

Beta probability density function

**Syntax**

\[ Y = \text{betapdf}(X, A, B) \]

**Description**

\[ Y = \text{betapdf}(X, A, B) \] computes the beta pdf at each of the values in \( X \) using the corresponding parameters in \( A \) and \( B \). \( X, A, \) and \( B \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The parameters in \( A \) and \( B \) must all be positive, and the values in \( X \) must lie on the interval \([0, 1]\).

The beta probability density function for a given value \( x \) and given pair of parameters \( a \) and \( b \) is

\[
y = f(x \mid a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{[0,1]}(x)
\]

where \( B(\cdot) \) is the Beta function. The uniform distribution on \((0, 1)\) is a degenerate case of the beta pdf where \( a = 1 \) and \( b = 1 \).

A **likelihood function** is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of \( x \).

**Examples**

\[
a = [0.5 \; 1; \; 2 \; 4]
a =
\begin{bmatrix}
0.5000 & 1.0000 \\
2.0000 & 4.0000
\end{bmatrix}
\]

32-189
y = betapdf(0.5,a,a)
y =
  0.6366  1.0000
  1.5000  2.1875

**betarnd**

Beta random numbers

**Syntax**

\[
R = \text{betarnd}(A,B)
\]

\[
R = \text{betarnd}(A,B,m,n,...)
\]

\[
R = \text{betarnd}(A,B,[m,n,...])
\]

**Description**

\( R = \text{betarnd}(A,B) \) generates random numbers from the beta distribution with parameters specified by \( A \) and \( B \). \( A \) and \( B \) can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \( R \). A scalar input for \( A \) or \( B \) is expanded to a constant array with the same dimensions as the other input.

\( R = \text{betarnd}(A,B,m,n,...) \) or \( R = \text{betarnd}(A,B,[m,n,...]) \) generates an \( m \)-by-\( n \)-by-... array containing random numbers from the beta distribution with parameters \( A \) and \( B \). \( A \) and \( B \) can each be scalars or arrays of the same size as \( R \).

**Examples**

\[
a = [1 1; 2 2];
b = [1 2; 1 2];
\]

\[
r = \text{betarnd}(a,b)
\]

\[
r =
\begin{array}{cc}
0.6987 & 0.6139 \\
0.9102 & 0.8067
\end{array}
\]

\[
r = \text{betarnd}(10,10,[1 5])
\]

\[
r =
\begin{array}{cccccc}
0.5974 & 0.4777 & 0.5538 & 0.5465 & 0.6327
\end{array}
\]

\[
r = \text{betarnd}(4,2,2,3)
\]
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

betastat
Beta mean and variance

Syntax

[M,V] = betastat(A,B)

Description

[M,V] = betastat(A,B), with A>0 and B>0, returns the mean of and variance for the beta distribution with parameters specified by A and B. A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V. A scalar input for A or B is expanded to a constant array with the same dimensions as the other input.

The mean of the beta distribution with parameters a and b is \( a / (a + b) \) and the variance is

\[
\frac{ab}{(a + b + 1)(a + b)^2}
\]

Examples

If parameters a and b are equal, the mean is 1/2.

a = 1:6;
[m,v] = betastat(a,a)
m =
   0.5000  0.5000  0.5000  0.5000  0.5000  0.5000
v =
   0.0833  0.0500  0.0357  0.0278  0.0227  0.0192

32-193

binocdf

Binomial cumulative distribution function

Syntax

\[ y = \text{binocdf}(x,N,p) \]
\[ y = \text{binocdf}(x,N,p,'upper') \]

Description

\( y = \text{binocdf}(x,N,p) \) computes a binomial cdf at each of the values in \( x \) using the corresponding number of trials in \( N \) and probability of success for each trial in \( p \). \( x, N, \) and \( p \) can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The values in \( N \) must all be positive integers, the values in \( x \) must lie on the interval \([0, N]\), and the values in \( p \) must lie on the interval \([0, 1]\).

\( y = \text{binocdf}(x,N,p,'upper') \) returns the complement of the binomial cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

The binomial cdf for a given value \( x \) and a given pair of parameters \( n \) and \( p \) is

\[
y = F(x \mid n,p) = \sum_{i=0}^{x} \binom{n}{i} p^{i} (1-p)^{n-i} I_{(0,1,...,n)}(i).
\]

The result, \( y \), is the probability of observing up to \( x \) successes in \( n \) independent trials, where the probability of success in any given trial is \( p \). The indicator function \( I_{(0,1,...,n)}(i) \) ensures that \( x \) only adopts values of \( 0,1,...,n \).

Examples
Compute Binomial CDF

If a baseball team plays 162 games in a season and has a 50-50 chance of winning any game, then the probability of that team winning more than 100 games in a season is:

\[ 1 - \text{binocdf}(100, 162, 0.5) \]

\[ \text{ans} = 0.0010 \]

The result is \( 0.001 \) (i.e., \( 1 - 0.999 \)). If a team wins 100 or more games in a season, this result suggests that it is likely that the team's true probability of winning any game is greater than 0.5.

**binofit**

Binomial parameter estimates

**Syntax**

```matlab
phat = binofit(x,n)
[phat,pci] = binofit(x,n)
[phat,pci] = binofit(x,n,alpha)
```

**Description**

`phat = binofit(x,n)` returns a maximum likelihood estimate of the probability of success in a given binomial trial based on the number of successes, `x`, observed in `n` independent trials. If `x = (x(1), x(2), ... x(k))` is a vector, `binofit` returns a vector of the same size as `x` whose `i`th entry is the parameter estimate for `x(i)`. All `k` estimates are independent of each other. If `n = (n(1), n(2), ..., n(k))` is a vector of the same size as `x`, the binomial fit, `binofit`, returns a vector whose `i`th entry is the parameter estimate based on the number of successes `x(i)` in `n(i)` independent trials. A scalar value for `x` or `n` is expanded to the same size as the other input.

`[phat,pci] = binofit(x,n)` returns the probability estimate, `phat`, and the 95% confidence intervals, `pci`. `binofit` uses the Clopper-Pearson method to calculate confidence intervals.

`[phat,pci] = binofit(x,n,alpha)` returns the \(100(1 - \alpha)\)% confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

**Note** `binofit` behaves differently than other Statistics and Machine Learning Toolbox functions that compute parameter estimates, in that it returns independent estimates for each entry of `x`. By comparison, `expfit` returns a single parameter estimate based on all the entries of `x`.

Unlike most other distribution fitting functions, the `binofit` function treats its input `x` vector as a collection of measurements from separate samples. If you want to treat `x` as a
single sample and compute a single parameter estimate for it, you can use 
\text{binofit}(\text{sum}(x),\text{sum}(n)) \text{ when } n \text{ is a vector, and } \text{binofit}(\text{sum}(X),N*\text{length}(X)) \text{ when } n \text{ is a scalar.}

\section*{Examples}

This example generates a binomial sample of 100 elements, where the probability of 
success in a given trial is 0.6, and then estimates this probability from the outcomes in 
the sample.

\begin{verbatim}
   r = binornd(100,0.6);
   [phat,pci] = binofit(r,100)
   phat =
      0.5800
   pci =
      0.4771   0.6780
\end{verbatim}

The 95\% confidence interval,pci, contains the true value, 0.6.

Topics

“Binomial Distribution” on page B-9

Introduced before R2006a
**binoinv**

Binomial inverse cumulative distribution function

**Syntax**

\[ X = \text{binoinv}(Y,N,P) \]

**Description**

\[ X = \text{binoinv}(Y,N,P) \] returns the smallest integer \( X \) such that the binomial cdf evaluated at \( X \) is equal to or exceeds \( Y \). You can think of \( Y \) as the probability of observing \( X \) successes in \( N \) independent trials where \( P \) is the probability of success in each trial. Each \( X \) is a positive integer less than or equal to \( N \).

\( Y \), \( N \), and \( P \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in \( N \) must be positive integers, and the values in both \( P \) and \( Y \) must lie on the interval \([0 1]\).

**Examples**

If a baseball team has a 50-50 chance of winning any game, what is a reasonable range of games this team might win over a season of 162 games?

\[
\text{binoinv}([0.05 \ 0.95],162,0.5)
\]

\[
\text{ans} = \\
71 \quad 91
\]

This result means that in 90% of baseball seasons, a .500 team should win between 71 and 91 games.

binopdf

Binomial probability density function

Syntax

\( Y = \text{binopdf}(X,N,P) \)

Description

\( Y = \text{binopdf}(X,N,P) \) computes the binomial pdf at each of the values in \( X \) using the corresponding number of trials in \( N \) and probability of success for each trial in \( P \). \( Y, N, \) and \( P \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs.

The parameters in \( N \) must be positive integers, and the values in \( P \) must lie on the interval \([0, 1]\).

The binomial probability density function for a given value \( x \) and given pair of parameters \( n \) and \( p \) is

\[
y = f(x | n, p) = \binom{n}{x} p^x q^{(n-x)} I_{(0,1,\ldots,n)}(x)
\]

where \( q = 1 - p \). The result, \( y \), is the probability of observing \( x \) successes in \( n \) independent trials, where the probability of success in any given trial is \( p \). The indicator function \( I_{(0,1,\ldots,n)}(x) \) ensures that \( x \) only adopts values of 0, 1, \ldots, \( n \).

Examples

A Quality Assurance inspector tests 200 circuit boards a day. If 2% of the boards have defects, what is the probability that the inspector will find no defective boards on any given day?
What is the most likely number of defective boards the inspector will find?

```
defects=0:200;
y = binopdf(defects,200,.02);
[x,i]=max(y);
defects(i)
ans =
   4
```

binornd

Binomial random numbers

Syntax

R = binornd(N,P)
R = binornd(N,P,m,n,...)
R = binornd(N,P,[m,n,...])

Description

R = binornd(N,P) generates random numbers from the binomial distribution with parameters specified by the number of trials, N, and probability of success for each trial, P. N and P can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for N or P is expanded to a constant array with the same dimensions as the other input.

R = binornd(N,P,m,n,...) or R = binornd(N,P,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the binomial distribution with parameters N and P. N and P can each be scalars or arrays of the same size as R.

Examples

n = 10:10:60;

r1 = binornd(n,1./n)
r1 =
   2 1 0 1 1 2

r2 = binornd(n,1./n,[1 6])
r2 =
   0 1 2 1 3 1

r3 = binornd(n,1./n,1,6)
r3 =
   0 1 1 1 0 3
Algorithms

The binornd function uses the direct method using the definition of the binomial distribution as a sum of Bernoulli random variables.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

binostat

Binomial mean and variance

Syntax

\[ [M, V] = \text{binostat}(N, P) \]

Description

\[ [M, V] = \text{binostat}(N, P) \]
returns the mean of and variance for the binomial distribution with parameters specified by the number of trials, \( N \), and probability of success for each trial, \( P \). \( N \) and \( P \) can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \( M \) and \( V \). A scalar input for \( N \) or \( P \) is expanded to a constant array with the same dimensions as the other input.

The mean of the binomial distribution with parameters \( n \) and \( p \) is \( np \). The variance is \( npq \), where \( q = 1 - p \).

Examples

\( n = \logspace(1,5,5) \)
\( n = \)
\begin{align*}
&10 & 100 & 1000 & 10000 & 100000 \\
\end{align*}
\[ [m, v] = \text{binostat}(n, 1./n) \]
\( m = \)
\begin{align*}
&1 & 1 & 1 & 1 & 1 \\
\end{align*}
\( v = \)
\begin{align*}
&0.9000 & 0.9900 & 0.9990 & 0.9999 & 1.0000 \\
\end{align*}
\[ [m, v] = \text{binostat}(n, 1/2) \]
\( m = \)
\begin{align*}
&5 & 50 & 500 & 5000 & 50000 \\
\end{align*}
\( v = \)
\begin{align*}
&1.0e+04 * \\
&0.0003 & 0.0025 & 0.0250 & 0.2500 & 2.5000 \\

binScatterPlot

Scatter plot of bins for tall arrays

Syntax

binScatterPlot(X,Y)
binScatterPlot(X,Y,nbins)
binScatterPlot(X,Y,Xedges,Yedges)
binScatterPlot(X,Y,Name,Value)
h = binScatterPlot(__)

Description

binScatterPlot(X,Y) creates a binned scatter plot of the data in X and Y. The binScatterPlot function uses an automatic binning algorithm that returns bins with a uniform area, chosen to cover the range of elements in X and Y and reveal the underlying shape of the distribution.

binScatterPlot(X,Y,nbins) specifies the number of bins to use in each dimension.

binScatterPlot(X,Y,Xedges,Yedges) specifies the edges of the bins in each dimension using the vectors Xedges and Yedges.

binScatterPlot(X,Y,Name,Value) specifies additional options with one or more name-value pair arguments using any of the previous syntaxes. For example, you can specify 'Color' and a valid color option to change the color theme of the plot, or 'Gamma' with a positive scalar to adjust the level of detail.

h = binScatterPlot(__) returns a Histogram2 object. Use this object to inspect properties of the plot.

Examples
Binned Scatter Plot of Normally-Distributed Random Data

Create two tall vectors of random data. Create a binned scatter plot for the data.

\[ X = \text{tall}(\text{randn}(1e5,1)); \]

Starting parallel pool (parpool) using the 'local' profile ... connected to 12 workers.

\[ Y = \text{tall}(\text{randn}(1e5,1)); \]
\[ \text{binScatterPlot}(X,Y) \]
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.49 sec

The resulting figure contains a slider to adjust the level of detail in the image.

**Specify Number of Scatter Plot Bins**

Specify a scalar value as the third input argument to use the same number of bins in each dimension, or a two-element vector to use a different number of bins in each dimension.

Plot a binned scatter plot of random data sorted into 100 bins in each dimension.

```matlab
X = tall(randn(1e5,1));
Y = tall(randn(1e5,1));
binScatterPlot(X,Y,100)
```
Use 20 bins in the x-dimension and continue to use 100 bins in the y-dimension.

`binScatterPlot(X,Y,[20 100])`
Specify Bin Edges for Scatter Plot

Plot a binned scatter plot of random data with specific bin edges. Use bin edges of `Inf` and `-Inf` to capture outliers.
Create a binned scatter plot with 100 bin edges between [-2 2] in each dimension. The data outside the specified bin edges is not included in the plot.

\[
X = \text{tall}(\text{randn}(1\text{e5},1));
\]

Starting parallel pool (parpool) using the 'local' profile ... connected to 12 workers.

\[
Y = \text{tall}(\text{randn}(1\text{e5},1));
\]

Xedges = linspace(-2,2);
Yedges = linspace(-2,2);
binScatterPlot(X,Y,Xedges,Yedges)

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 1.5 sec
Use coarse bins extending to infinity on the edges of the plot to capture outliers.

\[
\text{Xedges} = [-\infty \ \text{linspace}(-2,2) \ \infty]; \\
\text{Yedges} = [-\infty \ \text{linspace}(-2,2) \ \infty]; \\
\text{binScatterPlot}(X,Y,\text{Xedges},\text{Yedges})
\]
\begin{verbatim}
X = tall(randn(1e5,1));

Starting parallel pool (parpool) using the 'local' profile ... connected to 12 workers.

Y = tall(randn(1e5,1));
binScatterPlot(X,Y,'Color','c')
\end{verbatim}

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 3 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.5 sec
Input Arguments

X,Y — Data to distribute among bins (as separate arguments)
tall vectors | tall matrices | tall multidimensional arrays

Data to distribute among bins, specified as separate arguments of tall vectors, matrices, or multidimensional arrays. X and Y must be the same size. If X and Y are not vectors, then binScatterPlot treats them as single column vectors, X(:) and Y(:).

Corresponding elements in X and Y specify the x and y coordinates of 2-D data points, [X(k),Y(k)]. The underlying data types of X and Y can be different, but binScatterPlot concatenates these inputs into a single N-by-2 tall matrix of the dominant underlying data type.

binScatterPlot ignores all NaN values. Similarly, binScatterPlot ignores Inf and -Inf values, unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Note If X or Y contain integers of type int64 or uint64 that are larger than flintmax, then it is recommended that you explicitly specify the bin edges. binScatterPlot automatically bins the input data using double precision, which lacks integer precision for numbers greater than flintmax.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

nbins — Number of bins in each dimension
scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify nbins, then binScatterPlot automatically calculates how many bins to use based on the values in X and Y.

- If nbins is a scalar, then binScatterPlot uses that many bins in each dimension.
- If nbins is a vector, then nbins(1) specifies the number of bins in the x-dimension and nbins(2) specifies the number of bins in the y-dimension.

Example: binScatterPlot(X,Y,20) uses 20 bins in each dimension.
Example: binScatterPlot(X,Y,[10 20]) uses 10 bins in the x-dimension and 20 bins in the y-dimension.
**Xedges — Bin edges in x-dimension**
vector

Bin edges in x-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the x-dimension, and `Xedges(end)` is the outer edge of the last bin.

The value `\[X(k),Y(k)\]` is in the `(i,j)`th bin if `Xedges(i) \leq X(k) < Xedges(i+1)` and `Yedges(j) \leq Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `\[X(k),Y(k)\]` falls into the `i`th bin in the last row if `Xedges(end-1) \leq X(k) \leq Xedges(end)` and `Yedges(i) \leq Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Yedges — Bin edges in y-dimension**
vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value `\[X(k),Y(k)\]` is in the `(i,j)`th bin if `Xedges(i) \leq X(k) < Xedges(i+1)` and `Yedges(j) \leq Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `\[X(k),Y(k)\]` falls into the `i`th bin in the last row if `Xedges(end-1) \leq X(k) \leq Xedges(end)` and `Yedges(i) \leq Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])`

**BinMethod — Binning algorithm**

'auto' (default) | 'scott' | 'integers'

Binning algorithm, specified as the comma-separated pair consisting of `BinMethod` and one of these values.
Value | Description
--- | ---
'auto' | The default 'auto' algorithm uses a maximum of 100 bins and chooses a bin width to cover the data range and reveal the shape of the underlying distribution.
'scott' | Scott’s rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5*\text{std}(X)*\text{numel}(X)^{(-1/4)}, \ 3.5*\text{std}(Y)*\text{numel}(Y)^{(-1/4)}]$. 
'integers' | The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins ($2^{16}$). If the data range is greater than 65536, then the integer rule uses wider bins instead.

**Note** The BinMethod property of the resulting Histogram2 object always has a value of 'manual'.

**BinWidth — Width of bins in each dimension**

*scalar | vector*

Width of bins in each dimension, specified as the comma-separated pair consisting of 'BinWidth' and a scalar or two-element vector of positive integers, [xWidth yWidth]. A scalar value indicates the same bin width for each dimension.

If you specify BinWidth, then binScatterPlot can use a maximum of 1024 bins ($2^{10}$) along each dimension. If instead the specified bin width requires more bins, then binScatterPlot uses a larger bin width corresponding to the maximum number of bins.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])` uses bins with size 5 in the x-dimension and size 10 in the y-dimension.
**Color — Plot color theme**
'b' (default) | 'y' | 'm' | 'c' | 'r' | 'g' | 'k'

Plot color theme, specified as the comma-separated pair consisting of 'Color' and one of these options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'b'</td>
<td>Blue</td>
</tr>
<tr>
<td>'m'</td>
<td>Magenta</td>
</tr>
<tr>
<td>'c'</td>
<td>Cyan</td>
</tr>
<tr>
<td>'r'</td>
<td>Red</td>
</tr>
<tr>
<td>'g'</td>
<td>Green</td>
</tr>
<tr>
<td>'y'</td>
<td>Yellow</td>
</tr>
<tr>
<td>'k'</td>
<td>Black</td>
</tr>
</tbody>
</table>

**Gamma — Gamma correction**
1 (default) | positive scalar

Gamma correction, specified as the comma-separated pair consisting of 'Gamma' and a positive scalar. Use this option to adjust the brightness and color intensity to affect the amount of detail in the image.

- gamma < 1 — As gamma decreases, the shading of bins with smaller bin counts becomes progressively darker, including more detail in the image.
- gamma > 1 — As gamma increases, the shading of bins with smaller bin counts becomes progressively lighter, removing detail from the image.
- The default value of 1 does not apply any correction to the display.

**XBinLimits — Bin limits in x-dimension**
vector

Bin limits in x-dimension, specified as the comma-separated pair consisting of 'XBinLimits' and a two-element vector, [xbmin,xbmax]. The vector indicates the first and last bin edges in the x-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax).
YBinLimits — Bin limits in y-dimension

vector

Bin limits in y-dimension, specified as the comma-separated pair consisting of 'YBinLimits' and a two-element vector, [ybmin, ybmax]. The vector indicates the first and last bin edges in the y-dimension.

binScatterPlot only plots data that falls within the bin limits inclusively, Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax).

Output Arguments

h — Binned scatter plot

histogram2 object

Binned scatter plot, returned as a histogram2 object. For more information, see Histogram2.

Introduced in R2016b
biplot

Biplot

Syntax

biplot(coefs)

\[ h = \text{biplot}(\text{coefs},'\text{Name}',\text{Value}) \]

Description

\[ \text{biplot}(\text{coefs}) \] creates a biplot of the coefficients in the matrix \( \text{coefs} \). The biplot is 2-D if \( \text{coefs} \) has two columns or 3-D if it has three columns. \( \text{coefs} \) usually contains principal component coefficients created with \text{pca}, \text{pcacov}, or factor loadings estimated with \text{factoran}. The axes in the biplot represent the principal components or latent factors (columns of \( \text{coefs} \)), and the observed variables (rows of \( \text{coefs} \)) are represented as vectors.

A biplot allows you to visualize the magnitude and sign of each variable's contribution to the first two or three principal components, and how each observation is represented in terms of those components.

\[ \text{biplot} \] imposes a sign convention, forcing the element with largest magnitude in each column of \( \text{coefs} \) to be positive. This flips some of the vectors in \( \text{coefs} \) to the opposite direction, but often makes the plot easier to read. Interpretation of the plot is unaffected, because changing the sign of a coefficient vector does not change its meaning.

\[ \text{biplot} \] scales the scores so that they fit on the plot: It divides each score by the maximum absolute value of all scores, and multiplies by the maximum coefficient length of \( \text{coefs} \). Then \text{biplot} changes the sign of score coordinates according to the sign convention for the \( \text{coefs} \).

\[ h = \text{biplot}(\text{coefs},'\text{Name}',\text{Value}) \] specifies one or more name/value input pairs and returns a column vector of handles to the graphics objects created by \text{biplot}. The \( h \) contains, in order, handles corresponding to variables (line handles, followed by marker handles, followed by text handles), to observations (if present, marker handles followed by text handles), and to the axis lines.
Input Arguments

Name-Value Pair Arguments

Scores

Plots both coefs and the scores in the matrix scores in the biplot. scores usually contains principal component scores created with pca or factor scores estimated with factoran. Each observation (row of scores) is represented as a point in the biplot.

VarLabels

Labels each vector (variable) with the text in the character array, string array or cell array varlabels.

ObsLabels

Uses the text in the character array, string array or cell array obslabels as observation names when displaying data cursors.

Positive

• true — restricts the biplot to the positive quadrant (in 2-D) or octant (in 3-D).
• false — makes the biplot over the range +/- max(coefs(:)) for all coordinates.

Default: false

PropertyName

Specifies optional property name/value pairs for all Primitive Line graphics objects created by biplot.

Examples

Biplot of Coefficients and Scores

Load the sample data.

load carsmall

load carsmall
Define the variable matrix and delete the rows with missing values.

```matlab
x = [Acceleration Displacement Horsepower MPG Weight];
x = x(all(~isnan(x),2),:);
```

Perform a principal component analysis of the data.

```matlab
[coefs,score] = pca(zscore(x));
```

View the data and the original variables in the space of the first three principal components.

```matlab
vbls = {'Accel','Disp','HP','MPG','Wgt'};
biplot(coefs(:,1:3),'Scores',score(:,1:3),'Varlabels',vbls);
```

factoran | nnmf | pca | pcacov | rotatefactors

Introduced before R2006a
**bootci**

Bootstrap confidence interval

**Syntax**

```matlab
ci = bootci(nboot,bootfun,...)  
ci = bootci(nboot,{bootfun,...},'alpha',alpha)  
ci = bootci(nboot,{bootfun,...},...,'type',type)  
ci = bootci(nboot,{bootfun,...},...,'type','student','nbootstd',nbootstd)  
ci = bootci(nboot,{bootfun,...},...,'type','student','stderr',stderr)  
ci = bootci(nboot,{bootfun,...},...,'Weights',weights)  
ci = bootci(nboot,{bootfun,...},...,'Options',options)  
[ci,bootstat] = bootci(...)```

**Description**

`ci = bootci(nboot,bootfun,...)` computes the 95% bootstrap confidence interval of the statistic computed by the function `bootfun`. `nboot` is a positive integer indicating the number of bootstrap samples used in the computation. `bootfun` is a function handle specified with @. The third and later input arguments to `bootci` are data (scalars, column vectors, or matrices) that are used to create inputs to `bootfun`. `bootci` creates each bootstrap sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `bootfun` unchanged.

If `bootfun` returns a scalar, `ci` is a vector containing the lower and upper bounds of the confidence interval. If `bootfun` returns a vector of length `m`, `ci` is an array of size 2-by-`m`, where `ci(1,:)` are lower bounds and `ci(2,:)` are upper bounds. If `bootfun` returns an array of size `m`-by-`n`-by-`p`-by-..., `ci` is an array of size 2-by-`m`-by-`n`-by-`p`-by-..., where `ci(1,:,:,:)` is an array of lower bounds and `ci(2,:,:,:)` is an array of upper bounds.

`ci = bootci(nboot,{bootfun,...},'alpha',alpha)` computes the 100*(1-alpha) bootstrap confidence interval of the statistic defined by the function `bootfun`. 

32-225
bootfun and the data that bootci passes to it are contained in a single cell array. alpha is a scalar between 0 and 1. The default value of alpha is 0.05.

\[
\text{ci} = \text{bootci}(nboot,\{\text{bootfun},\ldots\},\ldots,'\text{type}',\text{type})
\]
computes the bootstrap confidence interval of the statistic defined by the function bootfun. type is the confidence interval type, chosen from among the following:

- 'norm' or 'normal' — Normal approximated interval with bootstrapped bias and standard error.
- 'per' or 'percentile' — Basic percentile method.
- 'cper' or 'corrected percentile' — Bias corrected percentile method.
- 'bca' — Bias corrected and accelerated percentile method. This is the default.
- 'stud' or 'student' — Studentized confidence interval.

\[
\text{ci} = \text{bootci}(nboot,\{\text{bootfun},\ldots\},\ldots,'\text{type}','\text{student}',\text{nbootstd},\text{nbootstd})
\]
computes the studentized bootstrap confidence interval of the statistic defined by the function bootfun. The standard error of the bootstrap statistics is estimated using bootstrap, with nbootstd bootstrap data samples. nbootstd is a positive integer value. The default value of nbootstd is 100.

\[
\text{ci} = \text{bootci}(nboot,\{\text{bootfun},\ldots\},\ldots,'\text{type}','\text{student}',\text{stderr},\text{stderr})
\]
computes the studentized bootstrap confidence interval of statistics defined by the function bootfun. The standard error of the bootstrap statistics is evaluated by the function stderr. stderr is a function handle. stderr takes the same arguments as bootfun and returns the standard error of the statistic computed by bootfun.

\[
\text{ci} = \text{bootci}(nboot,\{\text{bootfun},\ldots\},\ldots,'\text{Weights}',\text{weights})
\]
specifies observation weights. weights must be a vector of non-negative numbers with at least one positive element. The number of elements in weights must be equal to the number of rows in non-scalar input arguments to bootfun. To obtain one bootstrap replicate, bootstrp samples N out of N with replacement using these weights as multinominal sampling probabilities.

\[
\text{ci} = \text{bootci}(nboot,\{\text{bootfun},\ldots\},\ldots,'\text{Options}',\text{options})
\]
specifies options that govern the computation of bootstrap iterations. One option requests that bootci perform bootstrap iterations using multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to be used in bootstrap resampling. This argument is a struct that you can create with a call to statset. You can
retrieve values of the individual fields with a call to statget. Applicable statset parameters are:

- 'UseParallel' — If true and if a parpool of the Parallel Computing Toolbox is open, compute bootstrap iterations in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.
- UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- Streams — A RandStream object or cell array of such objects. If you do not specify Streams, bootci uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
  - You have an open Parallel pool
  - UseParallel is true
  - UseSubstreams is false

In that case, use a cell array the same size as the Parallel pool.

[ci,bootstat] = bootci(...) also returns the bootstrapped statistic computed for each of the nboot bootstrap replicate samples. Each row of bootstat contains the results of applying bootfun to one bootstrap sample. If bootfun returns a matrix or array, then this output is converted to a row vector for storage in bootstat.

**Examples**

Compute the confidence interval for the capability index in statistical process control:

```matlab
y = normrnd(1,1,30,1); % Simulated process data
LSL = -3; USL = 3;     % Process specifications
capable = @(x)(USL-LSL)/(6* std(x)); % Process capability
ci = bootci(2000,capable,y) % BCa confidence interval
    ci =
         0.8122
         1.2657

sci = bootci(2000,{capable,y},'type','student') % Studentized ci
    sci =
         0.7739
         1.2707
```
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

bootstrap | jackknife | parfor | randsample | statget | statset

Introduced in R2006a
**bootstrap**

Bootstrap sampling

**Syntax**

```plaintext
bootstat = bootstrp(nboot,bootfun,d1,...)
[bootstat,bootsam] = bootstrp(...)
bootstat = bootstrp(...,'Name',Value)
```

**Description**

`bootstat = bootstrp(nboot,bootfun,d1,...)` draws `nboot` bootstrap data samples, computes statistics on each sample using `bootfun`, and returns the results in the matrix `bootstat`. `nboot` must be a positive integer. `bootfun` is a function handle specified with @. Each row of `bootstat` contains the results of applying `bootfun` to one bootstrap sample. If `bootfun` returns a matrix or array, then this output is converted to a row vector for storage in `bootstat`.

The third and later input arguments (d1,...) are data (scalars, column vectors, or matrices) used to create inputs to `bootfun`. `bootstrp` creates each bootstrap sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). `bootfun` accepts scalar data unchanged.

`[bootstat,bootsam] = bootstrp(...)` returns an n-by-nboot matrix of bootstrap indices, `bootsam`. Each column in `bootsam` contains indices of the values that were drawn from the original data sets to constitute the corresponding bootstrap sample. For example, if d1,... each contain 16 values, and nboot = 4, then `bootsam` is a 16-by-4 matrix. The first column contains the indices of the 16 values drawn from d1,..., for the first of the four bootstrap samples, the second column contains the indices for the second of the four bootstrap samples, and so on. (The bootstrap indices are the same for all input data sets.) To get the output samples `bootsam` without applying a function, set `bootfun` to empty ([]).

`bootstat = bootstrp(...,'Name',Value)` uses additional arguments specified by one or more `Name`, `Value` pair arguments. The name-value pairs must appear after the data arguments. The available name-value pairs:
'Weights' — Observation weights. The weights value must be a vector of nonnegative numbers with at least one positive element. The number of elements in weights must be equal to the number of rows in non-scalar input arguments to bootstrap. To obtain one bootstrap replicate, bootstrap samples $N$ out of $N$ with replacement using these weights as multinomial sampling probabilities.

'Options' — The value is a structure that contains options specifying whether to compute bootstrap iterations in parallel, and specifying how to use random numbers during the bootstrap sampling. Create the options structure with statset. Applicable statset parameters are:

- 'UseParallel' — If true Parallel Computing Toolbox is installed, compute bootstrap iterations in parallel. If the Parallel Computing Toolbox is not installed, computation occurs in serial mode. Default is false, meaning serial computation.
- UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- Streams — A RandStream object or cell array of such objects. If you do not specify Streams, bootstrap uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
  - You have an open Parallel pool
  - UseParallel is true
  - UseSubstreams is false

In that case, use a cell array the same size as the Parallel pool.

Examples

Bootstrapping a Correlation Coefficient Standard Error

This example shows how to compute a correlation coefficient standard error using bootstrap resampling of the sample data.

Load a data set containing the LSAT scores and law-school GPA for 15 students. These 15 data points are resampled to create 1000 different data sets, and the correlation between the two variables is computed for each data set.
load lawdata
rng default  % For reproducibility
[bootstat,bootsam] = bootstrp(1000,@corr,lsat,gpa);

Display the first 5 bootstrapped correlation coefficients.

bootstat(1:5,:)

ans = 5×1
    0.9874
    0.4918
    0.5459
    0.8458
    0.8959

Display the indices of the data selected for the first 5 bootstrap samples.

bootsam(:,1:5)

ans = 15×5
     13     3    11     8    12
     14     7     1     7     4
     2    14     5    10     8
     14    12     1    11    11
     10    15     2    12    14
     2    10    13     5    15
     5     1    11    11     9
     9    13     5    10     3
    15    15    15     3     3
    15    11     1     2     4
    :

figure
histogram(bootstat)
The histogram shows the variation of the correlation coefficient across all the bootstrap samples. The sample minimum is positive, indicating that the relationship between LSAT score and GPA is not accidental.

Finally, compute a bootstrap standard of error for the estimated correlation coefficient.

```
se = std(bootstat)
se = 0.1285
```
**Estimate the Density of Bootstrapped Statistic**

This example shows how to estimate the kernel density of bootstrapped means.

Compute a sample of 100 bootstrapped means of random samples taken from the vector Y.

```matlab
rng default;  % For reproducibility
y = exprnd(5,100,1);
m = bootstrp(100,@mean,y);

Plot an estimate of the density of these bootstrapped means.

```matlab
figure;
[fi,xi] = ksdensity(m);
plot(xi,fi);
```
Bootstrapping Multiple Statistics

This example shows how to compute and plot the means and standard deviations of bootstrapped 100 samples from a data vector.

Compute a sample of 100 bootstrapped means and standard deviations of random samples taken from the vector y.

```matlab
rng('default') % For reproducibility
y = exprnd(5,100,1);
stats = bootstrp(100,@(x)[mean(x) std(x)],y);
```
Plot the bootstrap estimate pairs.

```matlab
plot(stats(:,1),stats(:,2), 'o')
```

**Bootstrapping a Regression Model**

This example shows how to estimate the standard errors for a coefficient vector in a linear regression by bootstrapping the residuals.

Load the sample data.

```matlab
load hald
```
Perform a linear regression and compute the residuals.

\[
x = [\text{ones(size(heat))}, \text{ingredients}];
\]
\[
y = \text{heat};
\]
\[
b = \text{regress}(y,x);
\]
\[
yfit = x*b;
\]
\[
resid = y - yfit;
\]

Estimate the standard errors by bootstrapping the residuals.

\[
se = \text{std} \left( \text{bootstrp} \left(1000, @(bootr) \text{regress}(yfit+bootr,x), resid\right) \right)
\]

\[
se = 1\times5
\]
\[
\begin{align*}
56.1752 & & 0.5940 & & 0.5815 & & 0.5989 & & 0.5691 \\
\end{align*}
\]

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', `statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

RandStream | bootci | histogram | ksdensity | parfor | random | randsample | statget | statset
Introduced before R2006a
boxplot

Box plot

Syntax

boxplot(x)
boxplot(x,g)
boxplot(ax,___)
boxplot(___,Name,Value)

Description

boxplot(x) creates a box plot of the data in x. If x is a vector, boxplot plots one box. If x is a matrix, boxplot plots one box for each column of x.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+' symbol.

boxplot(x,g) creates a box plot using one or more grouping variables contained in g. boxplot produces a separate box for each set of x values that share the same g value or values.

boxplot(ax,___) creates a box plot using the axes specified by the axes graphic object ax, using any of the previous syntaxes.

boxplot(___,Name,Value) creates a box plot with additional options specified by one or more Name,Value pair arguments. For example, you can specify the box style or order.

Examples
Create a Box Plot

Load the sample data.

load carsmall

Create a box plot of the miles per gallon (MPG) measurements. Add a title and label the axes.

boxplot(MPG)
xlabel('All Vehicles')
ylabel('Miles per Gallon (MPG)')
title('Miles per Gallon for All Vehicles')
The boxplot shows that the median miles per gallon for all vehicles in the sample data is approximately 24. The minimum value is about 9, and the maximum value is about 44.

**Create Box Plots for Grouped Data**

Load the sample data.

```matlab
load carsmall
```

Create a box plot of the miles per gallon (MPG) measurements from the sample data, grouped by the vehicles' country of origin (Origin). Add a title and label the axes.

```matlab
boxplot(MPG,Origin)
title('Miles per Gallon by Vehicle Origin')
xlabel('Country of Origin')
ylabel('Miles per Gallon (MPG)')
```
Each box visually represents the MPG data for cars from the specified country. Italy's "box" appears as a single line because the sample data contains only one observation for this group.

**Create Notched Box Plots**

Generate two sets of sample data. The first sample, $x_1$, contains random numbers generated from a normal distribution with $\mu = 5$ and $\sigma = 1$. The second sample, $x_2$, contains random numbers generated from a normal distribution with $\mu = 6$ and $\sigma = 1$. 

32-241
rng default  % For reproducibility
x1 = normrnd(5,1,100,1);
x2 = normrnd(6,1,100,1);

Create notched box plots of x1 and x2. Label each box with its corresponding mu value.

figure
boxplot([x1,x2],'Notch','on','Labels',{'mu = 5','mu = 6'})
title('Compare Random Data from Different Distributions')

The boxplot shows that the difference between the medians of the two groups is approximately 1. Since the notches in the box plot do not overlap, you can conclude, with 95% confidence, that the true medians do differ.
The following figure shows the box plot for the same data with the maximum whisker length specified as 1.0 times the interquartile range. Data points beyond the whiskers are displayed using +.

```matlab
figure
boxplot([x1,x2],'Notch','on','Labels',{'mu = 5','mu = 6'},'Whisker',1)
title('Compare Random Data from Different Distributions')
```

With the smaller whiskers, `boxplot` displays more data points as outliers.
Create Compact Box Plots

Create a 100-by-25 matrix of random numbers generated from a standard normal distribution to use as sample data.

```matlab
rng default  % For reproducibility
x = randn(100,25);
```

Create two box plots for the data in `x` on the same figure. Use the default formatting for the top plot, and compact formatting for the bottom plot.

```matlab
figure
subplot(2,1,1)
boxplot(x)

subplot(2,1,2)
boxplot(x,'PlotStyle','compact')
```
Each plot presents the same data, but the compact formatting may improve readability for plots with many boxes.

**Input Arguments**

- **x — Input data**
  numeric vector | numeric matrix

Input data, specified as a numeric vector or numeric matrix. If x is a vector, boxplot plots one box. If x is a matrix, boxplot plots one box for each column of x.
On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the '+ ' symbol.

Data Types: single | double

**g — Grouping variables**

numeric vector | character array | string array | cell array | categorical array

Grouping variables, specified as a numeric vector, character array, string array, cell array, or categorical array. You can specify multiple grouping variables in g by using a cell array of these variable types or a matrix. If you specify multiple grouping variables, they must all be the same length.

If x is a vector, then the grouping variables must contain one row for each element of x. If x is a matrix, then the grouping variables must contain one row for each column of x. Groups that contain a missing value (NaN), an empty character vector, an empty or <missing> string, or an <undefined> value in a grouping variable are omitted, and are not counted in the number of groups considered by other parameters.

By default, boxplot sorts character and string grouping variables in the order they initially appear in the data, categorical grouping variables by the order of their levels, and numeric grouping variables in numeric order. To control the order of groups, do one of the following:

- Use categorical variables in g and specify the order of their levels.
- Use the 'GroupOrder' name-value pair argument.
- Pre-sort your data.

Data Types: single | double | char | string | cell | categorical

**ax — Axes on which to plot**

axes graphic object

Axes on which to plot, specified as an axes graphic object. If you do not specify ax, then boxplot creates the plot using the current axis. For more information on creating an axes graphic object, see axes and Axes.
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Notch','on','Labels','{mu = 5','mu = 6'} creates a notched box plot and labels the two boxes mu = 5 and mu = 6, from left to right.

**Box Appearance**

**BoxStyle — Box style**

'outline' | 'filled'

Box style, specified as the comma-separated pair consisting of 'BoxStyle' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'outline'</td>
<td>Plot boxes using an unfilled box with dashed whiskers. This is the default if 'PlotStyle' is 'traditional'.</td>
</tr>
<tr>
<td>'filled'</td>
<td>Plot boxes using a narrow filled box with lines for whiskers. This is the default if 'PlotStyle' is 'compact'.</td>
</tr>
</tbody>
</table>

Example: 'BoxStyle','filled'

**Colors — Box colors**

RGB triplet | character vector or string scalar of color names

Box colors, specified as the comma-separated pair consisting of 'Colors' and an RGB triplet, character vector, or string scalar. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range [0,1].

The following table lists the available color characters and their equivalent RGB triplet values.
You can specify multiple colors either as a character vector or string scalar of color names (for example, 'rgbm') or a three-column matrix of RGB values. The sequence is replicated or truncated as required, so for example, 'rb' gives boxes that alternate red and blue.

If you do not specify the name-value pair 'ColorGroup', then boxplot uses the same color scheme for all boxes. If you do specify 'ColorGroup', then the default is a modified hsv colormap.

Example: 'Colors','rgbm'

**MedianStyle — Median style**

'line' | 'target'

Median style, specified as the comma-separated pair consisting of 'MedianStyle' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'line'</td>
<td>Draw a line to represent the median in each box. This is the default when 'PlotStyle' is 'traditional'.</td>
</tr>
<tr>
<td>'target'</td>
<td>Draw a black dot inside a white circle to represent the median in each box. This is the default when 'PlotStyle' is 'compact'.</td>
</tr>
</tbody>
</table>
Notch — Marker for comparison intervals
'off' (default) | 'on' | 'marker'

Marker for comparison intervals, specified as the comma-separated pair consisting of 'Notch' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'off'</td>
<td>Omit comparison intervals from box display.</td>
</tr>
<tr>
<td>'on'</td>
<td>If 'PlotStyle' is 'traditional', draw comparison intervals using notches. If 'PlotStyle' is 'compact', draw comparison intervals using triangular markers.</td>
</tr>
<tr>
<td>'marker'</td>
<td>Draw comparison intervals using triangular markers.</td>
</tr>
</tbody>
</table>

Two medians are significantly different at the 5% significance level if their intervals do not overlap. boxplot represents interval endpoints using the extremes of the notches or the centers of the triangular markers. The notch extremes correspond to \( q_2 - 1.57(q_3 - q_1)/\sqrt{n} \) and \( q_2 + 1.57(q_3 - q_1)/\sqrt{n} \), where \( q_2 \) is the median (50th percentile), \( q_1 \) and \( q_3 \) are the 25th and 75th percentiles, respectively, and \( n \) is the number of observations without any NaN values. If the sample size is small, the notches might extend beyond the end of the box.

Example: 'Notch','on'

OutlierSize — Marker size for outliers
positive numeric value

Marker size for outliers, specified as the comma-separated pair consisting of 'OutlierSize' and a positive numeric value. The specified value represents the marker size in points.

If 'PlotStyle' is 'traditional', then the default value for OutlierSize is 6. If 'PlotStyle' is 'compact', then the default value for OutlierSize is 4.

Example: 'OutlierSize',8

Data Types: single | double

PlotStyle — Plot style
'traditional' (default) | 'compact'
Plot style, specified as the comma-separated pair consisting of 'PlotStyle' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'traditional'</td>
<td>Plot boxes using a traditional box style.</td>
</tr>
<tr>
<td>'compact'</td>
<td>Plot boxes using a smaller box style designed for plots with many groups. This style changes the defaults for some other parameters.</td>
</tr>
</tbody>
</table>

Example: 'PlotStyle','compact'

Symbol — Symbol and color for outliers

Symbol and color for outliers, specified as the comma-separated pair consisting of 'Symbol' and a line specification. See the LineSpec parameter in plot for available line specifications.

If 'PlotStyle' is 'traditional', then the default value is 'r+', which plots each outlier using a red '+' symbol.

If 'PlotStyle' is 'compact', then the default value is 'o', which plots each outlier using an 'o' symbol in the same color as the corresponding box.

If you omit the symbol, then the outliers appear invisible. If you omit the color, then the outliers appear in the same color as the box.

Example: 'kx'

Widths — Box width

Box width, specified as the comma-separated pair consisting of 'Widths' and a numeric scalar or numeric vector. If the number of boxes is not equal to the number of width values specified, then the list of values is replicated or truncated as necessary.

This name-value pair argument does not alter the spacing between boxes. Therefore, if you specify a large value for 'Widths', the boxes might overlap.

The default box width is equal to half of the minimum separation between boxes, which is 0.5 when the 'Positions' name-value pair argument takes its default value.
Example: 'Widths', 0.3
Data Types: single | double

**Group Appearance**

**ColorGroup — Grouping variable for box color change**

[] (default) | numeric vector | character array | string array | cell array | categorical array

Grouping variable for box color change, specified as the comma-separated pair consisting of 'ColorGroup' and a grouping variable. The grouping variable is a numeric vector, character array, string array, cell array, or categorical array. The box color changes when the specified grouping variable changes. The default value [] indicates that the box color does not change based on the group.

Data Types: single | double | char | string | cell | categorical

**FactorDirection — Order of factors on plot**

'data' (default) | 'list' | 'auto'

Order of factors on plot, specified as the comma-separated pair consisting of 'FactorDirection' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'data'</td>
<td>Factors appear with the first value next to the plot origin.</td>
</tr>
<tr>
<td>'list'</td>
<td>Factors appear left-to-right if on the x-axis, or top-to-bottom if on the y-axis.</td>
</tr>
<tr>
<td>'auto'</td>
<td>If the grouping variables are numeric, then boxplot uses 'data'. If the grouping variables are character arrays, string arrays, cell arrays, or categorical arrays, then boxplot uses 'list'.</td>
</tr>
</tbody>
</table>

**FullFactors — Plot all group factors**

'off' (default) | 'on'

Plot all group factors, specified as the comma-separated pair consisting of 'FullFactors' and either 'off' or 'on'. If 'off', then boxplot plots one box for each unique row of grouping variables. If 'on', then boxplot plots one box for each
possible combination of grouping variable values, including combinations that do not appear in the data.

Example: 'FullFactors','on'

**FactorGap** — Distance between different grouping factors

[] | positive numeric value | vector of positive numeric values | 'auto'

Distance between different grouping factors, specified as the comma-separated pair consisting of 'FactorGap' and a positive numeric value, a vector of positive numeric values, or 'auto'. If you specify a vector, then the vector length must be less than or equal to the number of grouping variables.

'FactorGap' represents the distance of the gap between different factors of a grouping variable, expressed as a percentage of the width of the plot. For example, if you specify [3,1], then the gap is three percent of the width of the plot between groups with different values of the first grouping variable, and one percent between groups with the same value of the first grouping variable but different values for the second.

If you specify 'auto', then boxplot selects a gap distance automatically. The value [] indicates no change in gap size between different factors.

If 'PlotStyle' is 'traditional', then the default value for FactorGap is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.

Example: 'FactorGap', [3,1]

Data Types: single | double | char | string

**FactorSeparator** — Separation between grouping factors

[] | positive integer | vector of positive integers | 'auto'

Separation between grouping factors, specified as the comma-separated pair consisting of 'FactorSeparator' and a positive integer or a vector of positive integers, or 'auto'. If you specify a vector, then the length of the vector should be less than or equal to the number of grouping variables. The integer values must be in the range [1,G], where G is the number of grouping variables.

'FactorSeparator' specifies which factors should have their values separated by a grid line. For example, [1,2] adds a separator line when the first or second grouping variable changes value.

If 'PlotStyle' is 'traditional', then the default value for FactorSeparator is []. If 'PlotStyle' is 'compact', then the default value is 'auto'.
Example: 'FactorSeparator',[1,2]
Data Types: single | double | char | string

**GroupOrder** — Plotting order of groups

[
] (default) | string array | cell array

Plotting order of groups, specified as the comma-separated pair consisting of 'GroupOrder' and a string array or cell array containing the names of the grouping variables. If you have multiple grouping variables, separate values with a comma. You can also use categorical arrays as grouping variables to control the order of the boxes. The default value [] does not reorder the boxes.

Data Types: string | cell

**Data Limits and Maximum Distances**

**DataLim** — Extreme data limits

[-Inf,Inf] (default) | two-element numeric vector

Extreme data limits, specified as the comma-separated pair consisting of 'DataLim' and a two-element numeric vector containing the lower and upper limits, respectively. The values specified for 'DataLim' are used by 'ExtremeMode' to determine which data points are extreme.

Data Types: single | double

**ExtremeMode** — Handling method for extreme data

'clip' (default) | 'compress'

Handling method for extreme data, specified as the comma-separated pair consisting of 'ExtremeMode' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'clip'</td>
<td>If any data values fall outside the limits specified by 'DataLim', then boxplot displays these values at DataLim on the plot.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'compress'</td>
<td>If 'ExtremeMode' is 'compress', boxplot displays extreme data points with the box.</td>
</tr>
<tr>
<td>Name</td>
<td>Value</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'compress'</td>
<td>If any data values fall outside the limits specified by 'DataLim', then boxplot displays these values evenly distributed in a region just outside DataLim, retaining the relative order of the points.</td>
</tr>
</tbody>
</table>

If any data points lie outside the limit specified by 'DataLim', then the limit is marked with a dotted line. If any data points are compressed, then two gray lines mark the compression region. Values at –Inf or Inf can be clipped or compressed, but NaN values do not appear on the plot. Box notches are drawn to scale and may extend beyond the bounds if the median is inside the limit. Box notches are not drawn if the median is outside the limits.

Example: 'ExtremeMode','compress'

**Jitter — Maximum outlier displacement distance**

numeric value

Maximum outlier displacement distance, specified as the comma-separated pair consisting of 'Jitter' and a numeric value. Jitter is the maximum distance to displace outliers along the factor axis by a uniform random amount, in order to make duplicate points visible. If you specify 'Jitter' equal to 1, then the jitter regions just touch between the closest adjacent groups.

If 'PlotStyle' is 'traditional', then the default value for Jitter is 0. If 'PlotStyle' is 'compact', then the default value is 0.5.

Example: 'Jitter',1

Data Types: single | double

**Whisker — Maximum whisker length**

1.5 (default) | positive numeric value

Maximum whisker length, specified as the comma-separated pair consisting of 'Whisker' and a positive numeric value.

boxplot draws points as outliers if they are greater than \( q_3 + w \times (q_3 - q_1) \) or less than \( q_1 - w \times (q_3 - q_1) \), where \( w \) is the maximum whisker length, and \( q_1 \) and \( q_3 \) are the 25th and 75th percentiles of the sample data, respectively.
The default value for 'Whisker' corresponds to approximately +/-2.7σ and 99.3 percent coverage if the data are normally distributed. The plotted whisker extends to the adjacent value, which is the most extreme data value that is not an outlier.

Specify 'Whisker' as 0 to give no whiskers and to make every point outside of $q_1$ and $q_3$ an outlier.

Example: 'Whisker',0

Data Types: single | double

**Plot Appearance**

**Labels — Box labels**

character array | string array | cell array | numeric vector | numeric matrix

Box labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, cell array, or numeric vector containing the box label names. Specify one label per x value or one label per group. To specify multiple label variables, use a numeric matrix or a cell array containing any of the accepted data types.

To remove labels from a plot, use the following command: `set(gca,'XTickLabel',{});`.

Data Types: char | string | cell | single | double

**LabelOrientation — Label orientation**

'inline' | 'horizontal'

Label orientation, specified as the comma-separated pair consisting of 'LabelOrientation' and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'inline'</td>
<td>Rotate box labels to be vertical. This is the default when 'PlotStyle' is 'compact'.</td>
</tr>
<tr>
<td>'horizontal'</td>
<td>Leave box labels horizontal. This is the default when 'PlotStyle' is 'traditional'.</td>
</tr>
</tbody>
</table>

If the labels are on the y axis, then both settings leave the labels horizontal.

Example: 'LabelOrientation','inline'

32-255
**LabelVerbosity — Labels to display on plot**

'all' | 'minor' | 'majorminor'

Labels to display on plot, specified as the comma-separated pair consisting of LabelVerbosity and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'all'</td>
<td>Display a label for every factor. This is the default when 'PlotStyle' is 'traditional'.</td>
</tr>
<tr>
<td>'minor'</td>
<td>Display a label for a factor only when that factor has a different value from the previous group.</td>
</tr>
<tr>
<td>'majorminor'</td>
<td>Display a label for a factor when that factor or any factor major to it has a different value from the previous group. This is the default when 'PlotStyle' is 'compact'.</td>
</tr>
</tbody>
</table>

Example: 'LabelVerbosity','minor'

**Orientation — Plot orientation**

'vertical' (default) | 'horizontal'

Plot orientation, specified as the comma-separated pair consisting of Orientation and one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'vertical'</td>
<td>Plot x on the y-axis.</td>
</tr>
<tr>
<td>'horizontal'</td>
<td>Plot x on the x-axis.</td>
</tr>
</tbody>
</table>

Example: 'horizontal'

**Positions — Box positions**

numeric vector

Box positions, specified as the comma-separated pair consisting of 'Positions' and a numeric vector containing one entry for each group or x value. The default is 1:NumGroups, where NumGroups is the number of groups.

Data Types: single | double
Tips

- `boxplot` creates a visual representation of the data, but does not return numeric values. To calculate the relevant summary statistics for the sample data, use the following functions:
  - `min` — Find the minimum value in the sample data.
  - `max` — Find the maximum value in the sample data.
  - `median` — Find the median value in the sample data.
  - `quantile` — Find the quantile values in the sample data.
  - `grpstats` — Calculate summary statistics for the sample data, organized by group.
- You can see data values and group names using the data cursor (MATLAB) in the figure window. The cursor shows the original values of any points affected by the `datalim` parameter. You can label the group to which an outlier belongs using the `gname` function.
- To modify graphics properties of a box plot component, use `findobj` with the `Tag` property to find the component's handle. `Tag` values for box plot components depend on parameter settings, and are listed in the following table.

<table>
<thead>
<tr>
<th>Parameter Settings</th>
<th>Tag Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>All settings</td>
<td>• 'Box'</td>
</tr>
<tr>
<td></td>
<td>• 'Outliers'</td>
</tr>
<tr>

Introduced before R2006a
boundary

Piecewise distribution boundaries

Syntax

[p, q] = boundary(pd)
[p, q] = boundary(pd, j)

Description

[p, q] = boundary(pd) returns the boundary points between segments in pd, the piecewise distribution. p is a vector of the cumulative probabilities at the boundaries, and q is a vector of the corresponding quantiles.

[p, q] = boundary(pd, j) returns boundary values of the jth boundary.

Examples

Boundaries in paretotails Object

Generate a sample data set and create a paretotails object by fitting a piecewise distribution with Pareto tails to the generated data. Find the boundary points between segments in a paretotails object by using the object function boundary.

Generate a sample data set containing 20% outliers.

rng('default');  % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];

Create a paretotails object by fitting a piecewise distribution to x. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a
fitted object consists of the empirical distribution for the middle 80\% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10\% of the data set.

\[
\text{pd} = \text{paretotails}(x,0.1,0.9)
\]

\[
\text{pd} =
\]

\[
\text{Piecewise distribution with 3 segments}
\]

\[
-\text{Inf} < x < -1.33251 \ (0 < p < 0.1): \text{lower tail, GPD(-0.0063504,0.567017)}
\]

\[
-1.33251 < x < 1.80149 \ (0.1 < p < 0.9): \text{interpolated empirical cdf}
\]

\[
1.80149 < x < \text{Inf} \ (0.9 < p < 1): \text{upper tail, GPD(0.24874,3.00974)}
\]

Return the boundary values between the piecewise segments by using the \text{boundary} function.

\[
[p,q] = \text{boundary}(\text{pd})
\]

\[
p = 2\times1
\]

\[
0.1000
\]

\[
0.9000
\]

\[
q = 2\times1
\]

\[
-1.3325
\]

\[
1.8015
\]

The values in \text{p} are the cumulative probabilities at the boundaries, and the values in \text{q} are the corresponding quantiles.

Plot the \text{cdf} of the \text{paretotails} object and mark the boundary points on the figure.

\[
\text{xi} = \text{sort}(x);
\text{plot(xi,cdf(pd,xi))}
\text{hold on}
\text{plot(q,p,'ro')}
\text{legend('Pareto Tails Object','Boundary Points','Location','best')}
\text{hold off}
\]
Input Arguments

**pd** — Piecewise distribution with Pareto tails
daretails object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

**j** — Boundary index
positive integer

Boundary index indicating which boundary to return, specified as a positive integer.
Data Types: single | double

Output Arguments

p — Cumulative probability at boundary
numeric vector of range (0, 1) values

Cumulative probability at each boundary, returned as a numeric vector of range (0, 1) values.

q — Quantile at boundary
numeric vector

Quantile at each boundary, returned as a numeric vector.

Introduced in R2007a
CalinskiHarabaszEvaluation

Package: clustering.evaluation

Superclasses:
Calinski-Harabasz criterion clustering evaluation object

Description

CalinskiHarabaszEvaluation is an object consisting of sample data, clustering data, and Calinski-Harabasz criterion values used to evaluate the optimal number of clusters. Create a Calinski-Harabasz criterion clustering evaluation object using evalclusters.

Construction

eva = evalclusters(x,clust,'CalinskiHarabasz') creates a Calinski-Harabasz criterion clustering evaluation object.

eva = evalclusters(x,clust,'CalinskiHarabasz',Name,Value) creates a Calinski-Harabasz criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data
matrix

Input data, specified as an N-by-P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm
'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.
'kmeans' Cluster the data in x using the \texttt{kmeans} clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.

'linkage' Cluster the data in x using the \texttt{clusterdata} agglomerative clustering algorithm, with 'Linkage' set to 'ward'.

'gmdistribution' Cluster the data in x using the \texttt{gmdistribution} Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If \texttt{criterion} is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form \texttt{C = clustfun(DATA,K)}, where \texttt{DATA} is the data to be clustered, and \texttt{K} is the number of clusters. The output of \texttt{clustfun} must be one of the following:

- A vector of integers representing the cluster index for each observation in \texttt{DATA}. There must be \texttt{K} unique values in this vector.
- A numeric \texttt{n-by-K} matrix of score for \texttt{n} observations and \texttt{K} classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If \texttt{criterion} is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify \texttt{clust} as a \texttt{n-by-K} matrix containing the proposed clustering solutions. \texttt{n} is the number of observations in the sample data, and \texttt{K} is the number of proposed clustering solutions. Column \texttt{j} contains the cluster indices for each of the \texttt{N} points in the \texttt{j}th clustering solution.

Data Types: \texttt{single} | \texttt{double} | \texttt{char} | \texttt{string} | \texttt{function_handle}

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: 'KList',[1:6] specifies to test 1, 2, 3, 4, 5, and 6 clusters to find the optimal number.

**KList — List of number of clusters to evaluate**

\texttt{vector}
List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when clust is a clustering algorithm name or a function handle. When criterion is 'gap', clust must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]

Data Types: single | double

**Properties**

**ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

**CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

**CriterionValues**

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

**Distance**

Distance metric used for clustering data, stored as a valid distance metric name.

**InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

**Missing**

Logical flag for excluded data, stored as a column vector of logical values. If Missing equals true, then the corresponding value in the data matrix x is not used in the clustering solution.
**NumObservations**

Number of observations in the data matrix $X$, minus the number of missing (NaN) values in $X$, stored as a positive integer value.

**OptimalK**

Optimal number of clusters, stored as a positive integer value.

**OptimalY**

Optimal clustering solution corresponding to $OptimalK$, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, $OptimalY$ is empty.

**X**

Data used for clustering, stored as a matrix of numerical values.

**Methods**

**Inherited Methods**

- addK: Evaluate additional numbers of clusters
- plot: Plot clustering evaluation object criterion values
- compact: Compact clustering evaluation object

**Examples**

**Evaluate the Clustering Solution Using Calinski-Harabasz Criterion**

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```matlab
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using \texttt{kmeans}.

```matlab
rng('default'); \% For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])
```

```matlab
eva =
    CalinskiHarabaszEvaluation with properties:
        NumObservations: 150
            InspectedK: [1 2 3 4 5 6]
            CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
            OptimalK: 3
```

The \texttt{OptimalK} value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```matlab
figure;
plot(eva);
```
The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```matlab
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
figure;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rgb','xod');
```
The plot shows cluster 3 in the lower-left corner, completely separated from the other two clusters. Cluster 3 contains flowers with the smallest petal widths and lengths. Cluster 1 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Cluster 2 is near the center of the plot, and contains flowers with measurements between these two extremes.
Definitions

Calinski-Harabasz Criterion

The Calinski-Harabasz criterion is sometimes called the variance ratio criterion (VRC). The Calinski-Harabasz index is defined as

\[ VRC_k = \frac{SS_B}{SS_W} \times \frac{(N - k)}{(k - 1)}, \]

where \( SS_B \) is the overall between-cluster variance, \( SS_W \) is the overall within-cluster variance, \( k \) is the number of clusters, and \( N \) is the number of observations.

The overall between-cluster variance \( SS_B \) is defined as

\[ SS_B = \sum_{i=1}^{k} n_i \|m_i - m\|^2, \]

where \( k \) is the number of clusters, \( n_i \) is the number of observations in cluster \( i \), \( m_i \) is the centroid of cluster \( i \), \( m \) is the overall mean of the sample data, and \( \|m_i - m\| \) is the \( L^2 \) norm (Euclidean distance) between the two vectors.

The overall within-cluster variance \( SS_W \) is defined as

\[ SS_W = \sum_{i=1}^{k} \sum_{x \in c_i} \|x - m_i\|^2, \]

where \( k \) is the number of clusters, \( x \) is a data point, \( c_i \) is the \( i \)th cluster, \( m_i \) is the centroid of cluster \( i \), and \( \|x - m_i\| \) is the \( L^2 \) norm (Euclidean distance) between the two vectors.

Well-defined clusters have a large between-cluster variance (\( SS_B \)) and a small within-cluster variance (\( SS_W \)). The larger the \( VRC_k \) ratio, the better the data partition. To determine the optimal number of clusters, maximize \( VRC_k \) with respect to \( k \). The optimal number of clusters is the solution with the highest Calinski-Harabasz index value.
The Calinski-Harabasz criterion is best suited for $k$-means clustering solutions with squared Euclidean distances.

Property Attributes (MATLAB)
candexch

$D$-optimal design from candidate set using row exchanges

Syntax

```matlab
rlist = candexch(C,nrows)
rlist = candexch(C,nrows,Name,Value)
```

Description

$rlist = candexch(C,nrows)$ uses a row-exchange algorithm to select a $D$-optimal design from the candidate set $C$.

$rlist = candexch(C,nrows,Name,Value)$ generates a $D$-optimal design with additional options specified by one or more Name,Value pair arguments.

Input Arguments

C

N-by-P matrix containing the values of P model terms at each of N points.

Default:

nrows

The desired number of rows in the design.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as

```
Name1,Value1,...,NameN,ValueN.
```

32-272
display

When 'on', displays iteration number. Disable the display by setting to 'off'.

**Default:** 'on', except when the UseParallel option is true

init

n rows-by-P matrix giving an initial design.

**Default:** A random subset of the rows of C

maxiter

Maximum number of iterations, a positive integer.

**Default:** 10

options

A structure that specifies whether to run in parallel, and specifies the random stream or streams. This option requires Parallel Computing Toolbox.

Create the options structure with statset. Option fields:

- **UseParallel** — Set to true to compute in parallel. Default is false.
- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- **Streams** — A RandStream object or cell array of such objects. If you do not specify Streams, candexch uses the default stream or streams. If you choose to specify Streams, use a single object except in the case

  - You have an open Parallel pool
  - UseParallel is true
  - UseSubstreams is false

  In that case, use a cell array the same size as the Parallel pool.

**Default:** []
An nobs-by-p matrix of factor settings, specifying a set of nobs fixed design points to include in the design. candexch finds nrows additional rows to add to the start design. The parameter provides the same functionality as the daugment function, using a row-exchange algorithm rather than a coordinate-exchange algorithm.

**Default**: []

**tries**

Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first.

**Default**: 1

### Output Arguments

**rlist**

Vector of length nrows listing the selected rows.

### Examples

This example shows how to generate a D-optimal design when there is a restriction on the candidate set, so the rowexch function isn't appropriate.

```matlab
F = (fullfact([5 5 5])-1)/4; % factor settings in unit cube
T = sum(F,2)<=1.51;         % find rows matching a restriction
F = F(T,:);                 % take only those rows
C = [ones(size(F,1),1) F F.^2];
    % compute model terms including
    % a constant and all squared terms
R = candexch(C,12);         % find a D-optimal 12-point subset
X = F(R,:);                 % get factor settings
```
Algorithms

candexch selects a starting design $X$ at random, and uses a row-exchange algorithm to iteratively replace rows of $X$ by rows of $C$ in an attempt to improve the determinant of $X'*X$.

Alternatives

The `rowexch` function also generates $D$-optimal designs using a row-exchange algorithm, but it automatically generates a candidate set that is appropriate for a specified model. The `daugment` function augments a set of fixed design points using a coordinate-exchange algorithm; the 'start' parameter provides the same functionality using the row exchange algorithm.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Topics

“Specify Candidate Sets” on page 27-22
“D-Optimal Designs” on page 27-16

Introduced before R2006a
candgen

Candidate set generation

Syntax

dC = candgen(nfactors,'model')
[dC,C] = candgen(nfactors,'model')
[...] = candgen(nfactors,'model','Name',value)

Description

dC = candgen(nfactors,'model') generates a candidate set dC of treatments
appropriate for estimating the parameters in the model with nfactors factors. dC has
nfactors columns and one row for each candidate treatment. model is one of the
following:

• 'linear' — Constant and linear terms. This is the default.
• 'interaction' — Constant, linear, and interaction terms
• 'quadratic' — Constant, linear, interaction, and squared terms
• 'purequadratic' — Constant, linear, and squared terms

Alternatively, model can be a matrix specifying polynomial terms of arbitrary order. In
this case, model should have one column for each factor and one row for each term in the
model. The entries in any row of model are powers for the factors in the columns. For
example, if a model has factors X1, X2, and X3, then a row [0 1 2] in model specifies
the term (X1.^0).*(X2.^1).*(X3.^2). A row of all zeros in model specifies a
constant term, which can be omitted.

[dC,C] = candgen(nfactors,'model') also returns the design matrix C evaluated at
the treatments in dC. The order of the columns of C for a full quadratic model with n
terms is:

1   The constant term
2   The linear terms in order 1, 2, ..., n
The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., (n – 1, n)
The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Pass C to candexch to generate a D-optimal design using a coordinate-exchange algorithm.

 [...] = candgen(nfactors,'model','Name',value) specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify Name inside single quotes.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>bounds</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>categorical</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>levels</td>
<td>Vector of number of levels for each factor.</td>
</tr>
</tbody>
</table>

**Note** The rowexch function automatically generates a candidate set using candgen, and then creates a D-optimal design from that candidate set using candexch. Call candexch separately to specify your own candidate set to the row-exchange algorithm.

**Examples**

The following example uses rowexch to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1    1
    0    0
    1    1
    1    0
    1    1
```

The same thing can be done using candgen and candexch in sequence:
candgen

\[
\begin{bmatrix}
-1 & -1 \\
0 & -1 \\
1 & -1 \\
-1 & 0 \\
0 & 0 \\
1 & 0 \\
-1 & 1 \\
0 & 1 \\
1 & 1 
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & -1 & -1 & 1 & 1 \\
1 & 0 & -1 & 0 & 1 \\
1 & 1 & -1 & 1 & 1 \\
1 & -1 & 0 & 1 & 0 \\
1 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 1 & 0 \\
1 & -1 & 1 & 1 & 1 \\
1 & 0 & 1 & 0 & 1 \\
1 & 1 & 1 & 1 & 1 
\end{bmatrix}
\]

\[
\begin{bmatrix}
2 \\
1 \\
7 \\
3 \\
4 
\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & -1 \\
-1 & -1 \\
-1 & 1 \\
1 & -1 \\
-1 & 0 
\end{bmatrix}
\]

canoncorr

Canonical correlation

Syntax

[A,B] = canoncorr(X,Y)
[A,B,r] = canoncorr(X,Y)
[A,B,r,U,V] = canoncorr(X,Y)
[A,B,r,U,V,stats] = canoncorr(X,Y)

Description

[A,B] = canoncorr(X,Y) computes the sample canonical coefficients for the n-by-d1 and n-by-d2 data matrices X and Y. X and Y must have the same number of observations (rows) but can have different numbers of variables (columns). A and B are d1-by-d and d2-by-d matrices, where d = min(rank(X), rank(Y)). The jth columns of A and B contain the canonical coefficients, i.e., the linear combination of variables making up the jth canonical variable for X and Y, respectively. Columns of A and B are scaled to make the covariance matrices of the canonical variables the identity matrix (see U and V below). If X or Y is less than full rank, canoncorr gives a warning and returns zeros in the rows of A or B corresponding to dependent columns of X or Y.

[A,B,r] = canoncorr(X,Y) also returns a 1-by-d vector containing the sample canonical correlations. The jth element of r is the correlation between the jth columns of U and V (see below).

[A,B,r,U,V] = canoncorr(X,Y) also returns the canonical variables, scores. U and V are n-by-d matrices computed as

\[ U = (X - \text{repmat} (\text{mean}(X), N, 1)) \ast A \]
\[ V = (Y - \text{repmat} (\text{mean}(Y), N, 1)) \ast B \]

[A,B,r,U,V,stats] = canoncorr(X,Y) also returns a structure stats containing information relating to the sequence of d null hypotheses \( H_0^{(k)} \), that the (k+1)st through dth correlations are all zero, for k = 0:(d-1). stats contains seven fields, each a 1-by-
A d vector with elements corresponding to the values of k, as described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wilks</td>
<td>Wilks' lambda (likelihood ratio) statistic</td>
</tr>
<tr>
<td>df1</td>
<td>Degrees of freedom for the chi-squared statistic, and the numerator degrees of freedom for the $F$ statistic</td>
</tr>
<tr>
<td>df2</td>
<td>Denominator degrees of freedom for the $F$ statistic</td>
</tr>
<tr>
<td>F</td>
<td>Rao's approximate $F$ statistic for $H_0^{(k)}$</td>
</tr>
<tr>
<td>pF</td>
<td>Right-tail significance level for $F$</td>
</tr>
<tr>
<td>chisq</td>
<td>Bartlett's approximate chi-squared statistic for $H_0^{(k)}$ with Lawley's modification</td>
</tr>
<tr>
<td>pChisq</td>
<td>Right-tail significance level for chisq</td>
</tr>
</tbody>
</table>

`stats` has two other fields (dfe and p) which are equal to df1 and pChisq, respectively, and exist for historical reasons.

**Examples**

**Compute Sample Canonical Correlation**

Load the sample data.

```matlab
load carbig;
X = [Displacement Horsepower Weight Acceleration MPG];
nans = sum(isnan(X),2) > 0;

Compute the sample canonical correlation.

```matlab
[A,B,r,U,V] = canoncorr(X(~nans,1:3),X(~nans,4:5));
```

Plot the canonical variables scores.

```matlab
plot(U(:,1),V(:,1),'.'
xlabel('0.0025*Disp+0.020*HP-0.000025*Wgt')
ylabel('-0.17*Accel-0.092*MPG')
```

manova1 | pca
Introduced before R2006a
capability

Process capability indices

Syntax

\[ S = \text{capability}(\text{data}, \text{specs}) \]

Description

\( S = \text{capability}(\text{data}, \text{specs}) \) estimates capability indices for measurements in \( \text{data} \) given the specifications in \( \text{specs} \). \( \text{data} \) can be either a vector or a matrix of measurements. If \( \text{data} \) is a matrix, indices are computed for the columns. \( \text{specs} \) can be either a two-element vector of the form \([L,U]\) containing lower and upper specification limits, or (if \( \text{data} \) is a matrix) a two-row matrix with the same number of columns as \( \text{data} \). If there is no lower bound, use \(-\text{Inf}\) as the first element of \( \text{specs} \). If there is no upper bound, use \text{Inf} as the second element of \( \text{specs} \).

The output \( S \) is a structure with the following fields:

- \( \mu \) — Sample mean
- \( \sigma \) — Sample standard deviation
- \( P \) — Estimated probability of being within limits
- \( P_{L} \) — Estimated probability of being below \( L \)
- \( P_{U} \) — Estimated probability of being above \( U \)
- \( C_{p} \) — \( (U-L)/(6*\sigma) \)
- \( C_{pL} \) — \( (\mu-L)/(3*\sigma) \)
- \( C_{pu} \) — \( (U-\mu)/(3*\sigma) \)
- \( C_{pk} \) — \( \min(C_{pL},C_{pu}) \)

Indices are computed under the assumption that data values are independent samples from a normal population with constant mean and variance.
Indices divide a “specification width” (between specification limits) by a “process width” (between control limits). Higher ratios indicate a process with fewer measurements outside of specification.

Examples

Compute Capability Indices

Simulate a sample from a process with a mean of 3 and a standard deviation of 0.005.

```matlab
rng default; % for reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```matlab
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
   mu: 3.0006
   sigma: 0.0058
   P: 0.9129
   Pl: 0.0339
   Pu: 0.0532
   Cp: 0.5735
   Cpl: 0.6088
   Cpu: 0.5382
   Cpk: 0.5382
```

Visualize the specification and process widths.

```matlab
capaplot(data,[2.99 3.01]);
grid on
```
References

See Also

*capaplot* | *histfit*
Introduced in R2006b
capaplot

Process capability plot

Syntax

```
p = capaplot(data,specs)
[p,h] = capaplot(data,specs)
```

Description

```
p = capaplot(data,specs) estimates the mean of and variance for the observations in input vector data, and plots the pdf of the resulting T distribution. The observations in data are assumed to be normally distributed. The output, p, is the probability that a new observation from the estimated distribution will fall within the range specified by the two-element vector specs. The portion of the distribution between the lower and upper bounds specified in specs is shaded in the plot.
```

```
[p,h] = capaplot(data,specs) additionally returns handles to the plot elements in h.
```

capaplot treats NaN values in data as missing, and ignores them.

Examples

Create a Process Capability Plot

Randomly generate sample data from a normal process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.
\[ S = \text{capability}(\text{data}, [2.99 \ 3.01]) \]

\[ S = \text{struct with fields:} \]
\[ \quad \text{mu: 3.0006} \]
\[ \quad \text{sigma: 0.0058} \]
\[ \quad P: 0.9129 \]
\[ \quad Pl: 0.0339 \]
\[ \quad Pu: 0.0532 \]
\[ \quad Cp: 0.5735 \]
\[ \quad Cpl: 0.6088 \]
\[ \quad Cpu: 0.5382 \]
\[ \quad Cpk: 0.5382 \]

Visualize the specification and process widths.

\[ \text{capaplot}(\text{data}, [2.99 \ 3.01]); \]
\[ \text{grid on} \]

caseread

Read case names from file

Syntax

names = caseread('filename')
names = caseread

Description

names = caseread('filename') reads the contents of *filename* and returns a character array of names. *filename* is the name of a file in the current folder, or the complete path name of any file elsewhere. *caseread* treats each line as a separate case.

names = caseread displays the **Select File to Open** dialog box for interactive selection of the input file.

Examples

Read the file months.dat created using the *casewrite* function.

type months.dat

January
February
March
April
May

names = caseread('months.dat')
names =
January
February
March
April
May

Introduced before R2006a
casewrite

Write case names to file

Syntax

casewrite(strmat,'filename')
casewrite(strmat)

Description

casewrite(strmat,'filename') writes the contents of the character array or string
array strmat to filename. Each row of strmat represents one case name. filename is
the name of a file in the current folder, or the complete path name of any file elsewhere.
casewrite writes each name to a separate line in filename.

casewrite(strmat) displays the Select File to Write dialog box for interactive
specification of the output file.

Examples

strmat = char('January','February',...              
        'March','April','May')
strmat =
January
February
March
April
May

casewrite(strmat,'months.dat')

Introduced before R2006a
DaviesBouldinEvaluation

Package: clustering.evaluation

Superclasses:
Davies-Bouldin criterion clustering evaluation object

Description

DaviesBouldinEvaluation is an object consisting of sample data, clustering data, and Davies-Bouldin criterion values used to evaluate the optimal number of clusters. Create a Davies-Bouldin criterion clustering evaluation object using evalclusters.

Construction

eva = evalclusters(x, clust, 'DaviesBouldin') creates a Davies-Bouldin criterion clustering evaluation object.

eva = evalclusters(x, clust, 'DaviesBouldin', Name, Value) creates a Davies-Bouldin criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data
matrix

Input data, specified as an N-by-P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm
'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.
Cluster the data in x using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.

Cluster the data in x using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.

Cluster the data in x using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where DATA is the data to be clustered, and K is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in DATA. There must be K unique values in this vector.
- A numeric n-by-K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify clust as a n-by-K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the jth clustering solution.

Data Types: single | double | char | string | function_handle

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'KList',[1:5] specifies to test 1, 2, 3, 4, and 5 clusters to find the optimal number.

**KList — List of number of clusters to evaluate**

vector
List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when clust is a clustering algorithm name or a function handle. When criterion is 'gap', clust must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]
Data Types: single | double

Properties

**ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

**CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

**CriterionValues**

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

**InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

**Missing**

Logical flag for excluded data, stored as a column vector of logical values. If Missing equals true, then the corresponding value in the data matrix x is not used in the clustering solution.

**NumObservations**

Number of observations in the data matrix X, minus the number of missing (NaN) values in X, stored as a positive integer value.
OptimalK
Optimal number of clusters, stored as a positive integer value.

OptimalY
Optimal clustering solution corresponding to OptimalK, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, OptimalY is empty.

X
Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK Evaluate additional numbers of clusters
plot Plot clustering evaluation object criterion values
compact Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Davies-Bouldin Criterion
Evaluate the optimal number of clusters using the Davies-Bouldin clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];
mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];
mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];
N = 200;
X = [mvnrnd(mu1,sigma1,N);...
    mvnrnd(mu2,sigma2,N);...
    mvnrnd(mu3,sigma3,N)];

Evaluate the optimal number of clusters using the Davies-Bouldin criterion. Cluster the data using kmeans.

E = evalclusters(X,'kmeans','DaviesBouldin','klist',[1:6])

E =
    DaviesBouldinEvaluation with properties:

    NumObservations: 600
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 0.4663 0.4454 0.8316 1.0444 0.9236]
    OptimalK: 3

The OptimalK value indicates that, based on the Davies-Bouldin criterion, the optimal number of clusters is three.

Plot the Davies-Bouldin criterion values for each number of clusters tested.

figure;
plot(E)
The plot shows that the lowest Davies-Bouldin value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```matlab
figure;
gscatter(X(:,1),X(:,2),E.OptimalY,'rgb','xod')
```
The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

**Definitions**

**Davies-Bouldin Criterion**

The Davies-Bouldin criterion is based on a ratio of within-cluster and between-cluster distances. The Davies-Bouldin index is defined as
\[ DB = \frac{1}{k} \sum_{i=1}^{k} \max_{j \neq i} \{ D_{i,j} \}, \]

where \( D_{i,j} \) is the within-to-between cluster distance ratio for the \( i \)th and \( j \)th clusters. In mathematical terms,

\[ D_{i,j} = \frac{\bar{d}_i + \bar{d}_j}{d_{i,j}}. \]

\( \bar{d}_i \) is the average distance between each point in the \( i \)th cluster and the centroid of the \( i \)th cluster. \( \bar{d}_j \) is the average distance between each point in the \( j \)th cluster and the centroid of the \( j \)th cluster. \( d_{i,j} \) is the Euclidean distance between the centroids of the \( i \)th and \( j \)th clusters.

The maximum value of \( D_{i,j} \) represents the worst-case within-to-between cluster ratio for cluster \( i \). The optimal clustering solution has the smallest Davies-Bouldin index value.

Class Attributes (MATLAB)

Property Attributes (MATLAB)
cat

Class: dataset

Concatenate dataset arrays

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

\[ ds = \text{cat}(\text{dim}, \, ds_1, \, ds_2, \, ...) \]

Description

\[ ds = \text{cat}(\text{dim}, \, ds_1, \, ds_2, \, ...) \] concatenates the dataset arrays \( ds_1, \, ds_2, \, ... \) along dimension \( \text{dim} \) by calling the \text{dataset/horzcat} or \text{dataset/vertcat} method. \( \text{dim} \) must be 1 or 2.

See Also
horzcat | vertcat
catsplit

Class: classregtree

(Removed) Categorical splits used for branches in decision tree

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

```
v=catsplit(t)
v=catsplit(t,j)
```

**Description**

```
v=catsplit(t) returns an n-by-2 cell array v. Each row in v gives left and right values for a categorical split. For each branch node j based on a categorical predictor variable z, the left child is chosen if z is in v(j,1) and the right child is chosen if z is in v(j,2). The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running cuttype and selecting 'categorical' cuts from top to bottom.
```

```
v=catsplit(t,j) takes an array j of rows and returns the splits for the specified rows.
```

cdf

Cumulative distribution function for Gaussian mixture distribution

Syntax

\[ y = \text{cdf}(gm,X) \]

Description

\[ y = \text{cdf}(gm,X) \] returns the cumulative distribution function (cdf) of the Gaussian mixture distribution \( gm \), evaluated at the values in \( X \).

Examples

Compute cdf Values

Create a \textit{gmdistribution} object and compute its cdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

\[
\begin{align*}
\text{mu} &= \begin{bmatrix} 1 & 2; \end{bmatrix} -3 -5]; \\
\text{sigma} &= \begin{bmatrix} 1 & 1; \end{bmatrix}; \quad \% \text{ shared diagonal covariance matrix}
\end{align*}
\]

Create a \textit{gmdistribution} object by using the \textit{gmdistribution} function. By default, the function creates an equal proportion mixture.

\[
\begin{align*}
gm &= \text{gmdistribution(mu,sigma)} \\
gm &= \text{Gaussian mixture distribution with 2 components in 2 dimensions} \\
\text{Component 1:} \\
\text{Mixing proportion: 0.500000} \\
\text{Mean: 1 2} \\
\end{align*}
\]
Component 2:
Mixing proportion: 0.500000
Mean:    -3   -5

Compute the cdf values of gm.

\[
X = \begin{bmatrix}
0 & 0;1 & 2;3 & 3;5 & 3
\end{bmatrix};
\]
cdf(gm,X)

ans = 4×1

0.5011
0.6250
0.9111
0.9207

Plot cdf

Create a gmdistribution object and plot its cdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

\[
p = \begin{bmatrix}0.4 & 0.6;\end{bmatrix}; \quad \text{Mixing proportions}
\]
\[
mu = \begin{bmatrix}1 & 2; -3 & -5;\end{bmatrix}; \quad \text{Means}
\]
\[
sigma = \text{cat}(3,\begin{bmatrix}2 & 0.5;\end{bmatrix},\begin{bmatrix}1 & 1;\end{bmatrix}); \quad \text{Covariances 1-by-2-by-2 array}
\]

\[
sigma =
\]
\[
sigma(:,:,1) =
\begin{bmatrix}2.0000 & 0.5000\end{bmatrix}
\]
\[
sigma(:,:,2) =
\begin{bmatrix}1 & 1\end{bmatrix}
\]

The cat function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal. The \text{sigma}(1,:,i) \text{ contains the diagonal elements of the covariance matrix of component i.}
Create a `gmdistribution` object by using the `gmdistribution` function.

```matlab
gm = gmdistribution(mu,sigma,p)
```

```matlab
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.400000
Mean: 1 2

Component 2:
Mixing proportion: 0.600000
Mean: -3 -5
```

Plot the cdf of the Gaussian mixture distribution by using `ezsurf`.

```matlab
ezsurf(@(x,y)cdf(gm,[x y]),[-10 10],[-10 10])
```
Input Arguments

**gm — Gaussian mixture distribution**

*gm* is a `gmdistribution` object.

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the
distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

**X** — Values at which to evaluate cdf

*n-by-m* numeric matrix

Values at which to evaluate the cdf, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

Data Types: `single` | `double`

### Output Arguments

**y** — cdf values

*n*-by-1 numeric vector

cdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

### Introduced in R2007b
**ccdesign**

Central composite design

**Syntax**

\[
dCC = \text{ccdesign}(n) \\
[dCC, blocks] = \text{ccdesign}(n) \\
[...] = \text{ccdesign}(n,'Name',value)
\]

**Description**

\(dCC = \text{ccdesign}(n)\) generates a central composite design for \(n\) factors. \(n\) must be an integer 2 or larger. The output matrix \(dCC\) is \(m\)-by-\(n\), where \(m\) is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between -1 and 1.

\([dCC, blocks] = \text{ccdesign}(n)\) requests a blocked design. The output \(blocks\) is an \(m\)-by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

\([...] = \text{ccdesign}(n,'Name',value)\) specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify \(Name\) in single quotes.

<table>

</tbody>
</table>

**Examples**

**Two-Factor Central Composite Design**

Create a 2-factor central composite design.

```matlab
dCC = ccdesign(2,'type','circumscribed')
dCC = 16×2
```
The center point is run 8 times to reduce the correlations among the coefficient estimates.

Visualize the design.

```matlab
plot(dCC(:,1),dCC(:,2),'ro','MarkerFaceColor','b')
X = [1 -1 -1 -1; 1 1 1 -1];
Y = [-1 -1 1 -1; 1 -1 1 1];
line(X,Y,'Color','b')
axis square equal
```

bbdesign

Introduced before R2006a
cdf

Package: prob

Cumulative distribution function

Syntax

\[
\begin{align*}
  y &= \text{cdf}('\text{name}',x,A) \\
  y &= \text{cdf}('\text{name}',x,A,B) \\
  y &= \text{cdf}('\text{name}',x,A,B,C) \\
  y &= \text{cdf}('\text{name}',x,A,B,C,D) \\
  y &= \text{cdf}(pd,x) \\
  y &= \text{cdf}(\_\_,'upper')
\end{align*}
\]

Description

\[
\begin{align*}
  y &= \text{cdf}('\text{name}',x,A) \text{ returns the cumulative distribution function (cdf) for the one-} \\
  \text{parameter distribution family specified by 'name' and the distribution parameter A,} \\
  \text{evaluated at the values in } x. \\
  y &= \text{cdf}('\text{name}',x,A,B) \text{ returns the cdf for the two-parameter distribution family} \\
  \text{specified by 'name' and the distribution parameters A and B, evaluated at the values in } x. \\
  y &= \text{cdf}('\text{name}',x,A,B,C) \text{ returns the cdf for the three-parameter distribution family} \\
  \text{specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in } x. \\
  y &= \text{cdf}('\text{name}',x,A,B,C,D) \text{ returns the cdf for the four-parameter distribution} \\
  \text{family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at} \\
  \text{the values in } x. \\
  y &= \text{cdf}(pd,x) \text{ returns the cdf of the probability distribution object } pd, \text{ evaluated at the} \\
  \text{values in } x.
\end{align*}
\]
\[ y = \text{cdf}(\_\_\_, 'upper') \] returns the complement of the cdf using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input arguments in the previous syntaxes.

## Examples

### Compute Normal Distribution cdf

Create a standard normal distribution object with the mean, \( \mu \), equal to 0 and the standard deviation, \( \sigma \), equal to 1.

\[
\text{mu} = 0;  \\
\text{sigma} = 1;  \\
\text{pd} = \text{makedist('Normal', 'mu', mu, 'sigma', sigma)};
\]

Define the input vector \( x \) to contain the values at which to calculate the cdf.

\[
x = [-2, -1, 0, 1, 2];
\]

Compute the cdf values for the standard normal distribution at the values in \( x \).

\[
y = \text{cdf(pd, x)}
\]

\[
y = 1\times5
\]

\[
0.0228  \quad 0.1587  \quad 0.5000  \quad 0.8413  \quad 0.9772
\]

Each value in \( y \) corresponds to a value in the input vector \( x \). For example, at the value \( x \) equal to 1, the corresponding cdf value \( y \) is equal to 0.8413.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the cdf function, and specify a standard normal distribution using the same parameter values for \( \mu \) and \( \sigma \).

\[
y2 = \text{cdf('Normal', x, mu, sigma)}
\]

\[
y2 = 1\times5
\]

\[
0.0228  \quad 0.1587  \quad 0.5000  \quad 0.8413  \quad 0.9772
\]
The cdf values are the same as those computed using the probability distribution object.

**Compute Poisson Distribution cdf**

Create a Poisson distribution object with the rate parameter, $\lambda$, equal to 2.

```matlab
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector $x$ to contain the values at which to calculate the cdf.

```matlab
x = [0,1,2,3,4];
```

Compute the cdf values for the Poisson distribution at the values in $x$.

```matlab
y = cdf(pd,x)
y = 1×5
    0.1353    0.4060    0.6767    0.8571    0.9473
```

Each value in $y$ corresponds to a value in the input vector $x$. For example, at the value $x$ equal to 3, the corresponding cdf value $y$ is equal to 0.8571.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a Poisson distribution using the same value for the rate parameter, $\lambda$.

```matlab
y2 = cdf('Poisson',x,lambda)
y2 = 1×5
    0.1353    0.4060    0.6767    0.8571    0.9473
```

The cdf values are the same as those computed using the probability distribution object.
Plot Standard Normal Distribution cdf

Create a standard normal distribution object.

\[ \text{pd} = \text{makedist('Normal')} \]

\[ \text{pd} = \]
\[ \text{NormalDistribution} \]
\[ \text{Normal distribution} \]
\[ \mu = 0 \]
\[ \sigma = 1 \]

Specify the \( x \) values and compute the cdf.

\[ x = -3:.1:3; \]
\[ \text{cdf} \_\text{normal} = \text{cdf(pd,x)}; \]

Plot the cdf of the standard normal distribution.

\[ \text{plot}(x,\text{cdf} \_\text{normal},'\text{LineWidth}',2) \]
Create three gamma distribution objects. The first uses the default parameter values. The second specifies $a = 1$ and $b = 2$. The third specifies $a = 2$ and $b = 1$. 

```matlab
pd_gamma = makedist('Gamma')
```

```
Gamma distribution
a = 1
b = 1
```

**Plot Gamma Distribution cdf**

Create three gamma distribution objects. The first uses the default parameter values. The second specifies $a = 1$ and $b = 2$. The third specifies $a = 2$ and $b = 1$. 

```matlab
pd_gamma = makedist('Gamma')
```

```
Gamma distribution
a = 1
b = 1
```
pd_12 = makedist('Gamma','a',1,'b',2)

pd_12 =
    GammaDistribution
    Gamma distribution
    a = 1
    b = 2

pd_21 = makedist('Gamma','a',2,'b',1)

pd_21 =
    GammaDistribution
    Gamma distribution
    a = 2
    b = 1

Specify the x values and compute the cdf for each distribution.

x = 0:.1:5;
cdf_gamma = cdf(pd_gamma,x);
cdf_12 = cdf(pd_12,x);
cdf_21 = cdf(pd_21,x);

Create a plot to visualize how the cdf of the gamma distribution changes when you specify different values for the shape parameters a and b.

figure;
J = plot(x,cdf_gamma);
hold on;
K = plot(x,cdf_12,'r--');
L = plot(x,cdf_21,'k-.');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K L],'a = 1, b = 1','a = 1, b = 2','a = 2, b = 1','Location','southeast');
hold off;
Fit Pareto Tails to t Distribution and Compute the cdf

Fit Pareto tails to a $t$ distribution at cumulative probabilities 0.1 and 0.9.

t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)

p = 2×1

0.1000
0.9000
q = 2×1
   -1.8487
    2.0766

Compute the cdf at the values in q.

cdf(obj,q)

ans = 2×1
   0.1000
   0.9000

**Input Arguments**

'name' — Probability distribution name
character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

**x — Values at which to evaluate cdf**

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Example: `[0.1, 0.25, 0.5, 0.75, 0.9]`

Data Types: `single` | `double`

**A — First probability distribution parameter**

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

**B — Second probability distribution parameter**

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs.
Data Types: single | double

**C — Third probability distribution parameter**

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x, A, B, C, and D are arrays, then the array sizes must be the same. In this case, cdf expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**D — Fourth probability distribution parameter**

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x, A, B, C, and D are arrays, then the array sizes must be the same. In this case, cdf expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**pd — Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td><strong>Distribution Fitter</strong></td>
<td>Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
</tbody>
</table>
paretotails | Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

\( y \) — cdf values
scalar value | array of scalar values

cdf values, returned as a scalar value or an array of scalar values. \( y \) is the same size as \( x \) after any necessary scalar expansion. Each element in \( y \) is the cdf value of the distribution, specified by the corresponding elements in the distribution parameters (\( A, B, C, \) and \( D \)) or the probability distribution object (\( pd \)), evaluated at the corresponding element in \( x \).

Alternative Functionality

- \( \text{cdf} \) is a generic function that accepts either a distribution by its name ‘name’ or a probability distribution object \( pd \). It is faster to use a distribution-specific function, such as \( \text{normcdf} \) for the normal distribution and \( \text{binocdf} \) for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-16.
- Use the Probability Distribution Function app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the -args value of codegen.

• Code generation does not support the probability distribution object (pd) input argument.

Introduced before R2006a
**cdfplot**

Empirical cumulative distribution function (cdf) plot

**Syntax**

```matlab
cdfplot(x)
h = cdfplot(x)
[h,stats] = cdfplot(x)
```

**Description**

cdfplot(x) creates an empirical cumulative distribution function (cdf) plot for the data in x. For a value \( t \) in x, the empirical cdf \( F(t) \) is the proportion of the values in x less than or equal to \( t \).

\( h = \text{cdfplot}(x) \) returns a handle of the empirical cdf plot line object. Use \( h \) to query or modify properties of the object after you create it. For a list of properties, see Line Properties.

\( [h,\text{stats}] = \text{cdfplot}(x) \) also returns a structure including summary statistics for the data in x.

**Examples**

**Compare Empirical cdf to Theoretical cdf**

Plot the empirical cdf of a sample data set and compare it to the theoretical cdf of the underlying distribution of the sample data set. In practice, a theoretical cdf can be unknown.

Generate a random sample data set from the extreme value distribution with a location parameter of 0 and a scale parameter of 3.
rng('default')  % For reproducibility
y = evrnd(0,3,100,1);

Plot the empirical cdf of the sample data set and the theoretical cdf on the same figure.

cdfplot(y)
hold on
x = linspace(min(y),max(y));
plot(x,evcdf(x,0,3))
legend('Empirical CDF','Theoretical CDF','Location','best')
hold off

The plot shows the similarity between the empirical cdf and the theoretical cdf.
Alternatively, you can use the `ecdf` function. The `ecdf` function also plots the 95% confidence intervals estimated by using Greenwood's Formula. For details, see “Greenwood’s Formula” on page 32-1374.

```matlab
ecdf(y,'Bounds','on')
hold on
plot(x,ecdf(x,0,3))
grid on
title('Empirical CDF')
legend('Empirical CDF','Lower Confidence Bound','Upper Confidence Bound','Theoretical CDF','Location','best')
hold off
```
**Test for Standard Normal Distribution**

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the `examgrades` data set. Create a vector containing the first column of the exam grade data.

```matlab
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

```matlab
x = (test1-75)/10;
h = kstest(x)
```

```matlab
h = logical
0
```

The returned value of \( h = 0 \) indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```matlab
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```
The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

**Input Arguments**

\( x \) — Input data  
numeric vector

Input data, specified as a numeric vector.

Data Types: `single` | `double`
Output Arguments

**h** — Handle of plot line object

chart line object

Handle of the empirical cdf plot line object, returned as a chart line object. Use **h** to query or modify properties of the object after you create it. For a list of properties, see Line Properties.

**stats** — Summary statistics

structure

Summary statistics for the data in **x**, returned as a structure with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>Minimum value</td>
</tr>
<tr>
<td>max</td>
<td>Maximum value</td>
</tr>
<tr>
<td>mean</td>
<td>Sample mean</td>
</tr>
<tr>
<td>median</td>
<td>Sample median (50th percentile)</td>
</tr>
<tr>
<td>std</td>
<td>Sample standard deviation</td>
</tr>
</tbody>
</table>

Tips

- **cdfplot** is useful for examining the distribution of a sample data set. You can overlay a theoretical cdf on the same plot of **cdfplot** to compare the empirical distribution of the sample to the theoretical distribution. For an example, see “Compare Empirical cdf to Theoretical cdf” on page 32-329.

- The **kstest**, **kstest2**, and **lillietest** functions compute test statistics derived from an empirical cdf. **cdfplot** is useful in helping you to understand the output from these functions. For an example, see “Test for Standard Normal Distribution” on page 32-331.
Alternative Functionality

You can use the `ecdf` function to find the empirical cdf values and create an empirical cdf plot. The `ecdf` function enables you to indicate censored data and compute the confidence bounds for the estimated cdf values.

Introduced before R2006a
cell2dataset

Convert cell array to dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

ds = cell2dataset(C)
ds = cell2dataset(C,Name,Value)

Description

ds = cell2dataset(C) converts a cell array to a dataset array.

ds = cell2dataset(C,Name,Value) performs the conversion using additional options specified by one or more Name,Value pair arguments.

Examples

Convert Cell Array to Dataset Array

Convert a cell array to a dataset array using the default options.

Create a cell array to convert.

C = {'Name','Gender','SystolicBP','DiastolicBP';
     'CLARK','M',124,93;
     'BROWN','F',122,80;
     'MARTIN','M',130,92}

C = 4x4 cell array
     {'Name'} {'Gender'} {'SystolicBP'} {'DiastolicBP'}
Convert the cell array to a dataset array.

ds = cell2dataset(C)

```
ds =
    Name    Gender   SystolicBP   DiastolicBP
    'CLARK' 'M'      124          93
    'BROWN' 'F'      122          80
    'MARTIN' 'M'     130          92
```

The first row of C become the variable names in the output dataset array, ds.

### Create a Dataset Array with Multicolumn Variables

Convert a cell array to a dataset array containing multicolumn variables.

Create a cell array to convert.

```
C = {'Name', 'Gender', 'SystolicBP', 'DiastolicBP';
    'CLARK', 'M', 124, 93;
    'BROWN', 'F', 122, 80;
    'MARTIN', 'M', 130, 92}
```

Convert the cell array to a dataset array, combining the systolic and diastolic blood pressure measurements into one variable named BloodPressure.

```
ds = cell2dataset(C, 'NumCols', [1,1,2]);
ds.Properties.VarNames{3} = 'BloodPressure';
ds
```

```
d =
    Name    Gender   SystolicBP   BloodPressure
    'CLARK' 'M'      124          124
    'BROWN' 'F'      122          122
    'MARTIN' 'M'     130          130
```
The output dataset array has three observations and three variables.

### Input Arguments

**C** — Input cell array

cell array

Input cell array to convert to a dataset array, specified as an M-by-N cell array. Each column of C becomes a variable in the output dataset array, ds. By default, `cell2dataset` assumes that the first row of C contains variable names.

Data Types: `cell` | `string`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'ReadVarNames',false,'ReadObsNames',true specifies that the first row of the cell array does not contain variable names, but the first column contains observation names.

#### ReadVarNames — Indicator for whether or not to read variable names

type: `true` (default) | `false`

Indicator for whether or not to read variable names from the first row of the input cell array, specified as the comma-separated pair consisting of 'ReadVarNames' and either `true` or `false`. The default value is `true`, unless variable names are specified using the name-value pair argument `VarNames`. When `ReadVarNames` is `false`, `cell2dataset` creates default variable names if you do not provide any.

Example: 'ReadVarNames',false
VarNames — Variable names for output dataset array
string array | cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors. You must provide a variable name for each variable in ds. The names must be valid MATLAB identifiers, and must be unique.

Example: 'VarNames',{'myVar1','myVar2','myVar3'}

ReadObsNames — Indicator for whether or not to read observation names
false (default) | true

Indicator for whether or not to read observation names from the input cell array, specified as the comma-separated pair consisting of 'ReadObsNames' and either true or false. When ReadObsNames has the value true, cell2dataset creates observation names in ds using the first column of C, and sets ds.Properties.DimNames equal to {C{1,1},'Variables'}.

Example: 'ReadObsNames',true

ObsNames — Observation names for output dataset array
string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable
vector of nonnegative integers

Number of columns for each variable in ds, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, cell2dataset combines multiple columns in C into a single variable in ds. The vector you assign to NumCols must sum to size(C,2), or size(C,1) of ReadObsNames is equal to true.

For example, to convert a cell array with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].
Output Arguments

ds — Output dataset array
dataset array

Output dataset array, returned by default with a variable for each column of C, an observation for each row of C (except for the first row), and variable names corresponding to the first row of C.

- If you set ReadVarNames equal to false (or specify VarNames), then there is an observation in ds for each row of C, and cell2dataset creates default variable names (or uses the names in VarNames).
- If you set ReadObsNames equal to true, then cell2dataset uses the first column of C as observation names.
- If you specify NumCols, then the number of variables in ds is equal to the length of the specified vector of column numbers.

“Dataset Arrays” on page 2-137

Introduced in R2012b
cellstr

Class: dataset

Create cell array of character vectors from dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

B = cellstr(A)
B = cellstr(A,VARS)

Description

B = cellstr(A) returns the contents of the dataset A, converted to a cell array of character vectors. The variables in the dataset must support the conversion and must have compatible sizes.

B = cellstr(A,VARS) returns the contents of the dataset variables specified by VARS. VARS is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

dataset.double | dataset.replacedata
chi2cdf

Chi-square cumulative distribution function

Syntax

\[ p = \text{chi2cdf}(x, v) \]
\[ p = \text{chi2cdf}(x, v, 'upper') \]

Description

\( p = \text{chi2cdf}(x, v) \) computes the chi-square cdf at each of the values in \( x \) using the corresponding degrees of freedom in \( v \). \( x \) and \( v \) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The degrees of freedom parameters in \( v \) must be positive, and the values in \( x \) must lie on the interval \([0, \infty]\).

\( p = \text{chi2cdf}(x, v, 'upper') \) returns the complement of the chi-square cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

The \( \chi^2 \) cdf for a given value \( x \) and degrees-of-freedom \( \nu \) is

\[
p = F(x \mid \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt
\]

where \( \Gamma(\cdot) \) is the Gamma function.

The chi-square density function with \( \nu \) degrees-of-freedom is the same as the gamma density function with parameters \( \nu/2 \) and 2.

Examples
Compute Chi-Square CDF

\[
\text{probability} = \text{chi2cdf}(5,1:5)
\]
\[
\text{probability} = \begin{bmatrix}
0.9747 & 0.9179 & 0.8282 & 0.7127 & 0.5841 \\
\end{bmatrix}
\]

\[
\text{probability} = \text{chi2cdf}(1:5,1:5)
\]
\[
\text{probability} = \begin{bmatrix}
0.6827 & 0.6321 & 0.6084 & 0.5940 & 0.5841 \\
\end{bmatrix}
\]

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

cdf | chi2inv | chi2pdf | chi2rnd | chi2stat

Topics
“Chi-Square Distribution” on page B-28
Introduced before R2006a
Chi-square goodness-of-fit test

Syntax

h = chi2gof(x)
h = chi2gof(x,Name,Value)
[h,p] = chi2gof(___)
[h,p,stats] = chi2gof(___)
**Test for Normal Distribution**

Create a standard normal probability distribution object. Generate a data vector \( x \) using random numbers from the distribution.

```matlab
pd = makedist('Normal');
rng default;  % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in \( x \) comes from a population with a normal distribution.

```matlab
h = chi2gof(x)
```

\( h = 0 \)

The returned value \( h = 0 \) indicates that \( \text{chi2gof} \) does not reject the null hypothesis at the default 5% significance level.

**Test Hypothesis at Different Significance Level**

Create a standard normal probability distribution object. Generate a data vector \( x \) using random numbers from the distribution.

```matlab
pd = makedist('Normal');
rng default;  % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in \( x \) comes from a population with a normal distribution at the 1% significance level.

```matlab
[h,p] = chi2gof(x,'Alpha',0.01)
```

\( h = 0 \)

\( p = 0.3775 \)

The returned value \( h = 0 \) indicates that \( \text{chi2gof} \) does not reject the null hypothesis at the 1% significance level.
Test for Weibull Distribution Using Probability Distribution Object

Load the light bulb lifetime sample data.

```matlab
load lightbulb
```

Create a vector from the first column of the data matrix, which contains the lifetime in hours of the light bulbs.

```matlab
x = lightbulb(:,1);
```

Test the null hypothesis that the data in `x` comes from a population with a Weibull distribution. Use `fitdist` to create a probability distribution object with A and B parameters estimated from the data.

```matlab
pd = fitdist(x,'Weibull');
```

```matlab
h = chi2gof(x,'CDF',pd)
```

```matlab
h = 1
```

The returned value `h = 1` indicates that `chi2gof` rejects the null hypothesis at the default 5% significance level.

Test for Poisson Distribution

Create six bins, numbered 0 through 5, to use for data pooling.

```matlab
bins = 0:5;
```

Create a vector containing the observed counts for each bin and compute the total number of observations.

```matlab
obsCounts = [6 16 10 12 4 2];
n = sum(obsCounts);
```

Fit a Poisson probability distribution object to the data and compute the expected count for each bin. Use the transpose operator `.'` to transform `bins` and `obsCounts` from row vectors to column vectors.

```matlab
pd = fitdist(bins','Poisson','Frequency',obsCounts');
```

```matlab
expCounts = n * pdf(pd,bins);
```
Test the null hypothesis that the data in obsCounts comes from a Poisson distribution with a lambda parameter equal to lambdaHat.

\[ h, p, st = \text{chi2gof}(\text{bins}, 'Ctrs', \text{bins}, ... \]
\[ 'Frequency', \text{obsCounts}, ... \]
\[ 'Expected', \text{expCounts}, ... \]
\[ 'NParams', 1) \]

\[ h = 0 \]

\[ p = 0.4654 \]

st = struct with fields:
  chi2stat: 2.5550
  df: 3
  edges: [-0.5000 0.5000 1.5000 2.5000 3.5000 5.5000]
  0: [6 16 10 12 6]

The returned value \( h = 0 \) indicates that \text{chi2gof} does not reject the null hypothesis at the default 5% significance level. The vector E contains the expected counts for each bin under the null hypothesis, and O contains the observed counts for each bin.

**Test for Normal Distribution Using Function Handle**

Use the probability distribution function \text{normcdf} as a function handle in the chi-square goodness-of-fit test (\text{chi2gof}).

Test the null hypothesis that the sample data in the input vector x comes from a normal distribution with parameters \( \mu \) and \( \sigma \) equal to the mean (\text{mean}) and standard deviation (\text{std}) of the sample data, respectively.

\[ \text{rng('default')} \ % \text{For reproducibility} \]
\[ x = \text{normrnd}(50,5,100,1); \]
\[ h = \text{chi2gof}(x, 'cdf', \{@\text{normcdf}, \text{mean}(x), \text{std}(x)\}) \]

\[ h = 0 \]

The returned result \( h = 0 \) indicates that \text{chi2gof} does not reject the null hypothesis at the default 5% significance level.
Input Arguments

\[ \text{x} \quad \text{— Sample data} \]

vector

Sample data for the hypothesis test, specified as a vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:

`'NBins',8,'Alpha',0.01` pools the data into eight bins and conducts the hypothesis test at the 1% significance level.

**NBins — Number of bins**

10 (default) | positive integer value

Number of bins to use for the data pooling, specified as the comma-separated pair consisting of 'NBins' and a positive integer value. If you specify a value for NBins, do not specify a value for Ctrs or Edges.

Example: `NBins',8`

Data Types: `single` | `double`

**Ctrs — Bin centers**

vector

Bin centers, specified as the comma-separated pair consisting of 'Ctrs' and a vector of center values for each bin. If you specify a value for Ctrs, do not specify a value for NBins or Edges.

Example: `Ctrs',[1 2 3 4 5]`

Data Types: `single` | `double`

**Edges — Bin edges**

vector
Bin edges, specified as the comma-separated pair consisting of 'Edges' and a vector of edge values for each bin. If you specify a value for Edges, do not specify a value for NBins or Ctrs.

Example: 'Edges',[-2.5 -1.5 -0.5 0.5 1.5 2.5]

Data Types: single | double

CDF — cdf of hypothesized distribution

The cdf of the hypothesized distribution, specified as the comma-separated pair consisting of 'CDF' and a probability distribution object, function handle, or cell array.

- If CDF is a probability distribution object, the degrees of freedom account for whether you estimate the parameters using fitdist or specify them using makedist.
- If CDF is a function handle, the distribution function must take x as its only argument.
- If CDF is a cell array, the first element must be a function handle, and the remaining elements must be parameter values, one per cell. The function must take x as its first argument, and the other parameters in the array as later arguments.

If you specify a value for CDF, do not specify a value for Expected.

Example: 'CDF',pd_object

Data Types: single | double

Expected — Expected counts

Expected counts for each bin, specified as the comma-separated pair of 'Expected' and a vector of nonnegative values. If Expected depends on estimated parameters, use NParams to ensure that chi2gof correctly calculates the degrees of freedom. If you specify a value for Expected, do not specify a value for CDF.

Data Types: single | double

NParams — Number of estimated parameters

Number of estimated parameters used to describe the null distribution, specified as the comma-separated pair consisting of 'NParams' and a positive integer value. This value
adjusts the degrees of freedom of the test based on the number of estimated parameters used to compute the cdf or expected counts.

The default value for NParams depends on how you specify the null distribution:

- If you specify CDF as a probability distribution object, NParams is equal to the number of estimated parameters used to create the object.
- If you specify CDF as a function name or handle, the default value of NParams is 0.
- If you specify CDF as a cell array, the default value of NParams is the number of parameters in the array.
- If you specify Expected, the default value of NParams is 0.

Example: 'NParams',1
Data Types: single | double

EMin — Minimum expected count per bin

5 (default) | nonnegative integer value

Minimum expected count per bin, specified as the comma-separated pair consisting of 'EMin' and a nonnegative integer value. If the bin at the extreme end of either tail has an expected value less than EMin, it is combined with a neighboring bin until the count in each extreme bin is at least 5. If any interior bins have a count less than 5, chi2gof displays a warning, but does not combine the interior bins. In that case, you should use fewer bins, or provide bin centers or edges, to increase the expected counts in all bins. Specify EMin as 0 to prevent the combining of bins.

Example: 'EMin',0
Data Types: single | double

Frequency — Frequency

vector of nonnegative integer values

Frequency of data values, specified as the comma-separated pair consisting of 'Frequency' and a vector of nonnegative integer values that is the same length as the vector x.

Example: 'Frequency',[20 16 13 10 8]
Data Types: single | double

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)
Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: single | double

Output Arguments

h — Hypothesis test result
1 | 0

Hypothesis test result, returned as 1 or 0.

- If h = 1, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If h = 0, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics
structure

Test statistics, returned as a structure containing the following:

- chi2stat — Value of the test statistic.
- df — Degrees of freedom of the test.
- edges — Vector of bin edges after pooling.
- O — Vector of observed counts for each bin.
- E — Vector of expected counts for each bin.
Definitions

Chi-Square Goodness-of-Fit Test

The chi-square goodness-of-fit test determines if a data sample comes from a specified probability distribution, with parameters estimated from the data.

The test groups the data into bins, calculating the observed and expected counts for those bins, and computing the chi-square test statistic

$$\chi^2 = \sum_{i=1}^{N} \frac{(O_i - E_i)^2}{E_i},$$

where $O_i$ are the observed counts and $E_i$ are the expected counts based on the hypothesized distribution. The test statistic has an approximate chi-square distribution when the counts are sufficiently large.

Algorithms

chi2gof compares the value of the test statistic to a chi-square distribution with degrees of freedom equal to $nbins - 1 - nparams$, where $nbins$ is the number of bins used for the data pooling and $nparams$ is the number of estimated parameters used to determine the expected counts. If there are not enough degrees of freedom to conduct the test, chi2gof returns the $p$-value as NaN.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“Chi-Square Distribution” on page B-28

Introduced before R2006a
chi2inv

Chi-square inverse cumulative distribution function

**Syntax**

\[ X = \text{chi2inv}(P,V) \]

**Description**

\[ X = \text{chi2inv}(P,V) \] computes the inverse of the chi-square cdf with degrees of freedom specified by \( V \) for the corresponding probabilities in \( P \). \( P \) and \( V \) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The degrees of freedom parameters in \( V \) must be positive, and the values in \( P \) must lie in the interval \([0, 1]\).

The inverse chi-square cdf for a given probability \( p \) and \( v \) degrees of freedom is

\[ x = F^{-1}(p \mid v) = \{ x : F(x \mid v) = p \} \]

where

\[ p = F(x \mid v) = \int_0^x \frac{t^{(v-2)/2}e^{-t/2}}{2^{v/2}\Gamma(v/2)} dt \]

and \( \Gamma(\cdot) \) is the Gamma function. Each element of output \( X \) is the value whose cumulative probability under the chi-square cdf defined by the corresponding degrees of freedom parameter in \( V \) is specified by the corresponding value in \( P \).

**Examples**

Find a value that exceeds 95% of the samples from a chi-square distribution with 10 degrees of freedom.
\[ x = \text{chi2inv}(0.95, 10) \]
\[ x = 18.3070 \]

You would observe values greater than 18.3 only 5% of the time by chance.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**See Also**

**Topics**

“Chi-Square Distribution” on page B-28

**Introduced before R2006a**
chi2pdf

Chi-square probability density function

Syntax

Y = chi2pdf(X,V)

Description

Y = chi2pdf(X,V) computes the chi-square pdf at each of the values in X using the corresponding degrees of freedom in V. X and V can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of the output Y. A scalar input is expanded to a constant array with the same dimensions as the other input. The degrees of freedom parameters in V must be positive, and the values in X must lie on the interval [0 Inf].

The chi-square pdf for a given value x and ν degrees of freedom is

\[ y = f(x | ν) = \frac{x^{(ν-2)/2}e^{-x/2}}{2^{ν/2} Γ(ν / 2)} \]

where Γ(·) is the Gamma function.

If x is standard normal, then x² is distributed chi-square with one degree of freedom. If \( x_1, x_2, ..., x_n \) are \( n \) independent standard normal observations, then the sum of the squares of the \( x \)'s is distributed chi-square with \( n \) degrees of freedom (and is equivalent to the gamma density function with parameters \( ν/2 \) and 2).

Examples

nu = 1:6;
x = nu;
y = chi2pdf(x,nu)
\begin{align*}
y &= 0.2420 \quad 0.1839 \quad 0.1542 \quad 0.1353 \quad 0.1220 \quad 0.1120 \\
\end{align*}

The mean of the chi-square distribution is the value of the degrees of freedom parameter, \( \nu \). The above example shows that the probability density of the mean falls as \( \nu \) increases.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

**Topics**

“Chi-Square Distribution” on page B-28

**Introduced before R2006a**
**chi2rnd**

Chi-square random numbers

**Syntax**

\[
R = \text{chi2rnd}(V)
\]

\[
R = \text{chi2rnd}(V,m,n,...)
\]

\[
R = \text{chi2rnd}(V,[m,n,...])
\]

**Description**

\(R = \text{chi2rnd}(V)\) generates random numbers from the chi-square distribution with degrees of freedom parameters specified by \(V\). \(V\) can be a vector, a matrix, or a multidimensional array. \(R\) is the same size as \(V\). The degrees of freedom parameters in \(V\) must be positive.

\(R = \text{chi2rnd}(V,m,n,...)\) or \(R = \text{chi2rnd}(V,[m,n,...])\) generates an \(m\)-by-\(n\)-by-... array containing random numbers from the chi-square distribution with degrees of freedom parameter \(V\). \(V\) can be a scalar or an array of the same size as \(R\).

**Examples**

Note that the first and third commands are the same, but are different from the second command.

\[
r = \text{chi2rnd}(1:6)
\]

\[
r =
\begin{bmatrix}
0.0037 & 3.0377 & 7.8142 & 0.9021 & 3.2019 & 9.0729 \\
\end{bmatrix}
\]

\[
r = \text{chi2rnd}(6,[1 6])
\]

\[
r =
\begin{bmatrix}
\end{bmatrix}
\]

\[
r = \text{chi2rnd}(1:6,1,6)
\]

\[
r =
\begin{bmatrix}
0.7638 & 6.0955 & 0.8273 & 3.2506 & 1.5469 & 10.9197 \\
\end{bmatrix}
\]
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

• The output is nonscalar.
• An input parameter is invalid for the distribution.

Introduced before R2006a
**chi2stat**

Chi-square mean and variance

**Syntax**

\[
[M,V] = \text{chi2stat}(NU)
\]

**Description**

\[
[M,V] = \text{chi2stat}(NU)
\]

returns the mean of and variance for the chi-square distribution with degrees of freedom parameters specified by \(NU\). \(NU\) can be a vector, a matrix, or a multidimensional array. The degrees of freedom parameters in \(NU\) must be positive.

The mean of the chi-square distribution is \(\nu\), the degrees of freedom parameter, and the variance is \(2\nu\).

**Examples**

\[
u = 1:10;
\]

\[
u = \nu^\prime * \nu;
\]

\[
[M,V] = \text{chi2stat}(nu)
\]

\[
m =
\]

\[
\begin{array}{cccccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
2 & 4 & 6 & 8 & 10 & 12 & 14 & 16 & 18 & 20 \\
3 & 6 & 9 & 12 & 15 & 18 & 21 & 24 & 27 & 30 \\
4 & 8 & 12 & 16 & 20 & 24 & 28 & 32 & 36 & 40 \\
5 & 10 & 15 & 20 & 25 & 30 & 35 & 40 & 45 & 50 \\
6 & 12 & 18 & 24 & 30 & 36 & 42 & 48 & 54 & 60 \\
7 & 14 & 21 & 28 & 35 & 42 & 49 & 56 & 63 & 70 \\
8 & 16 & 24 & 32 & 40 & 48 & 56 & 64 & 72 & 80 \\
9 & 18 & 27 & 36 & 45 & 54 & 63 & 72 & 81 & 90 \\
10 & 20 & 30 & 40 & 50 & 60 & 70 & 80 & 90 & 100 \\
\end{array}
\]

\[
v =
\]

\[
\begin{array}{cccccccccc}
2 & 4 & 6 & 8 & 10 & 12 & 14 & 16 & 18 & 20 \\
\end{array}
\]

Introduced before R2006a
children

Class: classregtree

(Removed) Child nodes

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

C = children(t)
C = children(t,nodes)

Description

C = children(t) returns an n-by-2 array C containing the numbers of the child nodes for each node in the tree t, where n is the number of nodes. Leaf nodes have child node 0.

C = children(t,nodes) takes a vector nodes of node numbers and returns the children for the specified nodes.

References

See Also
classregtree | numnodes | parent
cholcov

Cholesky-like covariance decomposition

Syntax

T = cholcov(SIGMA)
[T,num] = cholcov(SIGMA)
[T,num] = cholcov(SIGMA,0)

Description

T = cholcov(SIGMA) computes T such that SIGMA = T' * T. SIGMA must be square, symmetric, and positive semi-definite. If SIGMA is positive definite, then T is the square, upper triangular Cholesky factor. If SIGMA is not positive definite, T is computed from an eigenvalue decomposition of SIGMA. T is not necessarily triangular or square in this case. Any eigenvectors whose corresponding eigenvalue is close to zero (within a small tolerance) are omitted. If any remaining eigenvalues are negative, T is empty.

[T,num] = cholcov(SIGMA) returns the number num of negative eigenvalues of SIGMA, and T is empty if num is positive. If num is zero, SIGMA is positive semi-definite. If SIGMA is not square and symmetric, num is NaN and T is empty.

[T,num] = cholcov(SIGMA,0) returns num equal to zero if SIGMA is positive definite, and T is the Cholesky factor. If SIGMA is not positive definite, num is a positive integer and T is empty. [...] = cholcov(SIGMA,1) is equivalent to [...] = cholcov(SIGMA).

Examples

The following 4-by-4 covariance matrix is rank-deficient:

C1 = [2 1 1 2;1 2 1 2;1 1 2 2;2 2 2 3]
C1 =
   2 1 1 2
   1 2 1 2
   1 1 2 2
   2 2 2 3
rank(C1)
ans =
    3

Use cholcov to factor C1:

T = cholcov(C1)
T =
    -0.2113    0.7887   -0.5774         0
     0.7887   -0.2113   -0.5774         0
    1.1547    1.1547    1.1547    1.7321

C2 = T'*T
C2 =
    2.0000    1.0000    1.0000    2.0000
     1.0000    2.0000    1.0000    2.0000
     1.0000    1.0000    2.0000    2.0000
    2.0000    2.0000    2.0000    3.0000

Use T to generate random data with the specified covariance:

C3 = cov(randn(1e6,3)*T)
C3 =
    1.9973    0.9982    0.9995    1.9975
    0.9982    1.9962    0.9969    1.9956
    0.9995    0.9969    1.9980    1.9972
    1.9975    1.9956    1.9972    2.9951

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

classcount

Class: classregtree

(Removed) Class counts

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[ P = \text{classcount}(t) \]
\[ P = \text{classcount}(t, \text{nodes}) \]

**Description**

\[ P = \text{classcount}(t) \text{ returns an } n\text{-by-}m \text{ array } P \text{ of class counts for the nodes in the classification tree } t, \text{ where } n \text{ is the number of nodes and } m \text{ is the number of classes. For any node number } i, \text{ the class counts } P(i,:) \text{ are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node } i. \]

\[ P = \text{classcount}(t, \text{nodes}) \text{ takes a vector } \text{nodes} \text{ of node numbers and returns the class counts for the specified nodes.} \]

**ClassificationBaggedEnsemble**

**Package:** classreg.learning.classif  
**Superclasses:**
Classification ensemble grown by resampling

**Description**

ClassificationBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

**Construction**

Create a bagged classification ensemble object using `fitcensemble`.

**Properties**

**CategoricalPredictors**

Categorical predictor indices, specified as a vector of positive integers. **CategoricalPredictors** contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

**ClassNames**

List of the elements in Y with duplicates removed. **ClassNames** can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. **ClassNames** has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)
CombineWeights
Character vector describing how ens combines weak learner weights, either 'WeightedSum' or 'WeightedAverage'.

ExpandedPredictorNames
Expanded predictor names, stored as a cell array of character vectors.
If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

FitInfo
Numeric array of fit information. The FitInfoDescription property describes the content of this array.

FitInfoDescription
Character vector describing the meaning of the FitInfo array.

FResample
Numeric scalar between 0 and 1. FResample is the fraction of training data fitcensemble resampled at random for every weak learner when constructing the ensemble.

HyperparameterOptimizationResults
Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair is nonempty at creation. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)
Method
Character vector describing the method that creates ens.

ModelParameters
Parameters used in training ens.

NumTrained
Number of trained weak learners in ens, a scalar.

PredictorNames
Cell array of names for the predictor variables, in the order in which they appear in X.

ReasonForTermination
Character vector describing the reason fitensemble stopped adding weak learners to the ensemble.

Replace
Logical value indicating if the ensemble was trained with replacement (true) or without replacement (false).

ResponseName
Character vector with the name of the response variable Y.

ScoreTransform
Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see fitctree.

Add or change a ScoreTransform function using dot notation:

ens.ScoreTransform = 'function'

or

ens.ScoreTransform = @function
Trained
Trained learners, a cell array of compact classification models.

TrainedWeights
Numeric vector of trained weights for the weak learners in ens. TrainedWeights has \( T \) elements, where \( T \) is the number of weak learners in learners.

UseObsForLearner
Logical matrix of size \( N \)-by-\( \text{NumTrained} \), where \( N \) is the number of observations in the training data and \( \text{NumTrained} \) is the number of trained weak learners. UseObsForLearner(\( I,J \)) is true if observation \( I \) was used for training learner \( J \), and is false otherwise.

W
Scaled weights, a vector with length \( n \), the number of rows in \( X \). The sum of the elements of \( W \) is 1.

X
Matrix of predictor values that trained the ensemble. Each column of \( X \) represents one variable, and each row represents one observation.

Y
A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as \( X \). Each row of \( Y \) represents the classification of the corresponding row of \( X \).
Methods

- `oobEdge` Out-of-bag classification edge
- `oobLoss` Out-of-bag classification error
- `oobMargin` Out-of-bag classification margins
- `oobPermutedPredictorImportance` Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees
- `oobPredict` Predict out-of-bag response of ensemble

Inherited Methods

- `compact` Compact classification ensemble
- `crossval` Cross validate ensemble
- `resubEdge` Classification edge by resubstitution
- `resubLoss` Classification error by resubstitution
- `resubMargin` Classification margins by resubstitution
- `resubPredict` Predict ensemble response by resubstitution
- `resume` Resume training ensemble

- `edge` Classification edge
- `loss` Classification error
- `margin` Classification margins
- `predict` Predict labels using ensemble of classification models
- `predictorImportance` Estimates of predictor importance
- `removeLearners` Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

Train Bagged Ensemble of Classification Trees

Load the ionosphere data set.

load ionosphere

Train a bagged ensemble of 100 classification trees using all measurements.

rng(1) % For reproducibility
Mdl = fitcensemble(X,Y,'Method','bag')

Mdl =
    classreg.learning.classif.ClassificationBaggedEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'    'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    NumTrained: 100
    Method: 'Bag'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of
                        iterations.'
    FitInfo: []
    FitInfoDescription: 'None'
    FResample: 1
    Replace: 1
    UseObsForLearner: [351x100 logical]

Properties, Methods

Mdl is a ClassificationBaggedEnsemble model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained
classification trees (CompactClassificationTree model objects) that compose the
ensemble.

Plot a graph of the first trained classification tree.

view(Mdl.Trained{1}, 'Mode', 'graph')
By default, fitcensemble grows deep decision trees for bagged ensembles.

Estimate the in-sample misclassification rate.

\[ L = \text{resubLoss}(Mdl) \]

\[ L = 0 \]

L is 0, which indicates that Mdl is perfect at classifying the training data.
Tip

For a bagged ensemble of classification trees, the Trained property of ens stores a cell vector of ens.NumTrained CompactClassificationTree model objects. For a textual or graphical display of tree \( t \) in the cell vector, enter

\[
\text{view(ens.Trained}\{t\})
\]

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the predict function supports code generation.
- When you train an ensemble by using fitcensemble, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of CompactClassificationDiscriminant and CompactClassificationTree.

For more information, see “Introduction to Code Generation” on page 31-2.

“Framework for Ensemble Learning” on page 18-40

Introduced in R2011a
ClassificationECOC class

Superclasses:
Multiclass model for support vector machines or other classifiers

Description

ClassificationECOC is an error-correcting output codes (ECOC) classifier for multiclass learning by reduction to multiple binary classifiers such as support vector machines (SVMs). Train a ClassificationECOC classifier using fitcecoc and the training data.

Trained ClassificationECOC classifiers store the training data, parameter values, prior probabilities, and coding matrices. You can use these classifiers to:

• Estimate resubstitution predictions. For details, see resubPredict.
• Predict labels or posterior probabilities for new data. For details, see predict.

Construction

Create a ClassificationECOC object by using fitcecoc.

Properties

BinaryLearners — Trained binary learners
cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. BinaryLearners has as many elements as classes in Y.

The software trained BinaryLearner{j} according to the binary problem specified by CodingMatrix(:,j). For example, for multiclass learning using SVM learners, each element of BinaryLearners is a CompactClassificationSVM classifier.

Data Types: cell
BinaryLoss — Binary learner loss function
character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets BinaryLoss to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the BinaryLoss name-value pair argument of predict or loss.

Data Types: char

BinaryY — Binary learner class labels
numeric matrix

Binary learner class labels, specified as a numeric matrix. BinaryY is a NumObservations-by-L matrix, where L is the number of binary learners (size(CodingMatrix,2)).

Elements of BinaryY are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observation k to a dichotomous class corresponding to the value of BinaryY(k,j).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner j assigns observation k to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner j removes observation k from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner j assigns observation k to a positive class.</td>
</tr>
</tbody>
</table>

Data Types: double

CategoricalPredictors — Categorical predictor indices
vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).
Data Types: `single` | `double`

**ClassNames — Unique class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

**CodingMatrix — Class-assignment codes**
numeric matrix

Class-assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a $K$-by-$L$ matrix, where $K$ is the number of classes and $L$ is the number of binary learners.

Elements of `CodingMatrix` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes the meaning of `CodingMatrix(i,j)`, that is, the class that learner $j$ assigns to observations in class $i$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner $j$ assigns observations in class $i$ to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner $j$ removes observations in class $i$ from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner $j$ assigns observations in class $i$ to a positive class.</td>
</tr>
</tbody>
</table>

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

**CodingName — Coding design name**
character vector

Coding design name, specified as a character vector. For more details, see “Coding Design” on page 32-392.

Data Types: `char`
**Cost — Misclassification costs**

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has `K` rows and columns, where `K` is the number of classes.

`Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: double

**ExpandedPredictorNames — Expanded predictor names**

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: cell

**HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters**

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: table
**LearnerWeights — Binary learner weights**

numeric row vector

Binary learner weights, specified as a numeric row vector. `LearnerWeights` has length equal to the number of binary learners (`size(CodingMatrix,2)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner `j` used to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence.

Data Types: `double` | `single`

**ModelParameters — Parameter values**

object

Parameter values, e.g., the name-value pair argument values, used to train the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation. For example, list the templates containing parameters the binary learners using `Mdl.ModelParameters.BinaryLearner`.

**NumObservations — Number of observations**

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

**PredictorNames — Predictor names**

cell array of character vectors

Predictor names in order of their appearance in the predictor data `X`, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

**Prior — Prior class probabilities**

numeric vector
This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as there are classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

`ResponseName` — Response variable name
character vector

Response variable name, specified as a character vector.

Data Types: `char`

`ScoreTransform` — Score transformation function to apply to predicted scores
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to `function`, for example, use dot notation.

- For a built-in function, enter this code and replace `function` with a value in the table.

```
Mdl.ScoreTransform = 'function';
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log\left(\frac{x}{1-x}\right) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------</td>
</tr>
</tbody>
</table>
| 'sign'           | -1 for \( x < 0 \)  
                      | 0 for \( x = 0 \)  
                      | 1 for \( x > 0 \)  |
| 'symmetric'      | \( 2x - 1 \)                                       |
| 'symmetricismax' | Sets the score for the class with the largest     
                      | score to 1, and sets the scores for all other     
                      | classes to \(-1\)                                     |
| 'symmetriclogit' | \( \frac{2}{1 + e^{-x}} - 1 \)                   |

- For a MATLAB function or a function that you define, enter its function handle.

```matlab
Mdl.ScoreTransform = @function;
```

*function* must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

**W — Observation weights**

numeric vector

Observation weights used to train the classifier, specified as a numeric vector. \( W \) has \( \text{NumObservations} \) elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: single | double

**X — Unstandardized predictor data used to train the classifier**

numeric matrix

Unstandardized predictor data used to train the classifier, specified as a numeric matrix. \( X \) is a \( \text{NumObservations} \)-by-\( p \) matrix, where \( p \) is the number of predictors.

Each row of \( X \) corresponds to one observation, and each column corresponds to one variable.

Data Types: single | double
Y — Observed class labels
categorical array | character array | logical vector | numeric vector | cell array of
class labels

treated as character vectors.

Observed class labels used to train the classifier, specified as a categorical or character
array, logical or numeric vector, or cell array of character vectors. Y has
NumObservations elements, and is the same data type as the input argument Y of
fitcecoc. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of Tbl or
X.

Methods

compact Compact multiclass, error-correcting output codes model
crossval Cross-validate multiclass, error-correcting output codes model
resubEdge Classification edge by resubstitution for multiclass, error-correcting output
codes model
resubLoss Classification loss by resubstitution for multiclass, error-correcting output
codes model
resubMargin Classification margins by resubstitution for multiclass, error-correcting
output codes model
resubPredict Predict resubstitution responses for multiclass, error-correcting output
codes model
Inherited Methods

discardSupportVectors  Discard support vectors of linear support vector machine binary learners
edge                 Classification edge for multiclass, error-correcting output codes model
loss                 Classification loss for multiclass, error-correcting output codes model
margin               Classification margins for multiclass, error-correcting output codes model
predict              Predict labels using multiclass, error-correcting output codes model
selectModels         Choose subset of regularized linear classification models

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Multiclass Model Using SVM Learners

Train an error-correcting output codes (ECOC) multiclass model using support vector machine (SVM) binary learners.

Load Fisher's iris data set.

load fisheriris
X = meas;
Y = species;

Train an ECOC multiclass model using the default options.

Mdl = fitcecoc(X,Y)
Mdl is a ClassificationECOC model. By default, fitcecoc uses SVM binary learners, and uses a one-versus-one coding design. You can access Mdl properties using dot notation.

Display the coding design matrix.

Mdl.ClassNames

ans = 3x1 cell array
    {'setosa' }    
    {'versicolor'}
    {'virginica' }

CodingMat = Mdl.CodingMatrix

CodingMat = 3×3
     1   1   0
    -1   0   1
     0  -1  -1

A one-versus-one coding design on three classes yields three binary learners. Columns of CodingMat correspond to learners, and rows correspond to classes. The class order corresponds to the order in Mdl.ClassNames. For example, CodingMat(:,1) is [1; -1; 0] and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Since 'setosa' corresponds to 1, it is the positive class, and since 'versicolor' corresponds to -1, it is the negative class.

You can access each binary learner using cell indexing and dot notation.

Mdl.BinaryLearners{1} % The first binary learner
ans =
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: [-1 1]
    ScoreTransform: 'none'
    Beta: [4x1 double]
    Bias: 1.4505
    KernelParameters: [1x1 struct]

Properties, Methods

Compute the in-sample classification error.

isLoss = resubLoss(Mdl)

isLoss = 0.0067

The classification error is small, but the classifier might have been overfit. You can cross-validate the classifier using crossval.

**Inspect Binary Learner Properties of ECOC Classifiers**

Access properties of binary learners, such as estimated parameters, using dot notation.

Load Fisher's iris data set. Use the petal dimensions as predictors.

load fisheriris
X = meas(:,3:4);
Y = species;

Train an ECOC classifier using the SVM binary learners and the default coding design (one-versus-one). Standardize the predictors and save the support vectors.

t = templateSVM('Standardize',1,'SaveSupportVectors',true);
predictorNames = {'petalLength','petalWidth'};
responseName = 'irisSpecies';
classNames = {'setosa','versicolor','virginica'}; % Specify class order
Mdl = fitcecoc(X,Y,'Learners',t,'ResponseName',responseName,...
               'PredictorNames',predictorNames,'ClassNames',classNames)
Mdl = ClassificationECOC
    PredictorNames: {'petalLength' 'petalWidth'}
    ResponseName: 'irisSpecies'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
    CodingName: 'onevsone'

Properties, Methods

t is a template object that contains options for SVM classification. All properties are empty ([]), except for Method, SaveSupportVectors, StandardizeData, and Type. The function fitcecoc uses the default values of the empty properties. Mdl is a ClassificationECOC classifier. You can access properties of Mdl using dot notation.

Display the class names and the coding design matrix.

Mdl.ClassNames
ans = 3x1 cell array
     {'setosa'   }
     {'versicolor'}
     {'virginica'}

Mdl.CodingMatrix
ans = 3×3
     1     1     0
    -1     0     1
    0    -1    -1

L = size(Mdl.CodingMatrix,2); % Number of SVMs

The columns correspond to SVM binary learners, and the rows correspond to the distinct classes. The row order corresponds to the order of the ClassNames property of Mdl. For each column:
• A 1 indicates that fitcecoc trained the SVM using observations in the corresponding class as members of the positive group.
• A -1 indicates that fitcecoc trained the SVM using observations in the corresponding class as members of the negative group.
• A 0 indicates that the SVM did not use observations in the corresponding class.

For example, fitcecoc assigns all observations to 'setosa' or 'versicolor', but not 'virginica', in the first SVM.

You can access properties of the SVMs using cell subscripting and dot notation. Store the standardized support vectors of each SVM. Unstandardize the support vectors.

```matlab
sv = cell(L,1); % Preallocate for support vector indices
for j = 1:L
    SVM = Mdl.BinaryLearners{j};
    sv{j} = SVM.SupportVectors;
    sv{j} = bsxfun(@plus,bsxfun(@times,sv{j},SVM.Sigma),SVM.Mu);
end
```

sv is a cell array of matrices containing the unstandardized support vectors for the SVMs.

Plot the data, and identify the support vectors.

```matlab
figure
h = zeros(3 + L,1); % Preallocate for handles
h(1:3) = gscatter(X(:,1),X(:,2),Y);
hold on
markers = {'ko','ro','bo'};
for j = 1:L
    svs = sv{j};
    h(j + 3) = plot(svs(:,1),svs(:,2),markers{j},...
                    'MarkerSize',10 + (j - 1)*3);
end
title('Fisher''s Iris -- ECOC Support Vectors')
xlabel(predictorNames{1})
ylabel(predictorNames{2})
legend(h,[classNames,{'Support vectors - SVM 1',...
                  'Support vectors - SVM 2','Support vectors - SVM 3'}],...
                  'Location','Best')
hold off
```
You can pass `Mdl` to:

- `predict` to classify new observations.
- `resubLoss` to estimate the in-sample classification error.
- `crossval` to perform 10-fold cross-validation.

**Cross-Validate ECOC Classifier**

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`. 

32-389
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility

Create an SVM template, and standardize the predictors.

t = templateSVM('Standardize',1)

is a SVM template. Most of the template object's properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.
Md1 = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});

Md1 is a ClassificationECOC classifier. You can access its properties using dot notation.

Cross-validate Md1 using 10-fold cross-validation.

CVMd1 = crossval(Md1);

CVMd1 is a ClassificationPartitionedECOC cross-validated ECOC classifier.

Estimate the classification error.

loss = kfoldLoss(CVMd1)

loss = 0.0400

The classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Definitions

Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classifiers.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Suppose that:

• There are three classes.
• The coding design is one-versus-one.
• The decoding scheme uses loss \( g \).
• The learners are SVMs.

To build this classification model, ECOC follows these steps.
1 A one-versus-one coding design is

<table>
<thead>
<tr>
<th></th>
<th>Learner 1</th>
<th>Learner 2</th>
<th>Learner 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class 1</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Class 2</td>
<td>-1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Class 3</td>
<td>0</td>
<td>-1</td>
<td>-1</td>
</tr>
</tbody>
</table>

Learner 1 trains on observations having Class 1 and Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly. Let $M$ be the coding design matrix with elements $m_{kl}$, and $s_l$ be the predicted classification score for the positive class of learner $l$.

2 A new observation is assigned to the class ($\hat{k}$) that minimizes the aggregation of the losses for the $L$ binary learners. That is,

$$
\hat{k} = \arg\min_k \sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l).
$$

ECOC models can improve classification accuracy, even compared to other multiclass models [2].

**Coding Design**

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design (adopted by the software), for a particular column (or binary learner):

- Rows containing a 1 indicate to the binary learner to group all observations in the corresponding classes into a positive class.
- Rows containing a -1 indicate to the binary learner to group all observations in the corresponding classes into a negative class.
Rows containing a 0 indicate to the binary learner to ignore all observations in the corresponding classes.

Coding matrices with large, minimal, pair-wise row distances based on the Hamming measure are desirable. For details on the pair-wise row distance, see “Random Coding Design Matrices” on page 32-1795 and [4].

This table describes popular coding designs. For the example, suppose $K$ (the number of distinct classes) is 3.

<table>
<thead>
<tr>
<th>Coding Design</th>
<th>Description</th>
<th>Number of Learners</th>
<th>Minimal Pair-Wise Row Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>one-versus-all (OVA)</td>
<td>For each binary learner, one class is positive and the rest are negative.</td>
<td>$K$</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>This design exhausts all combinations of positive class assignments.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>one-versus-one (OVO)</td>
<td>For each binary learner, one class is positive, another is negative, and the</td>
<td>$K(K - 1)/2$</td>
<td>1</td>

</tr>
<tr>
<td>sparse random</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1795.</td>
<td>Random, but approximately $15 \log_2 K$</td>
<td>Variable</td>
</tr>
</tbody>
</table>

This plot compares the number of binary learners for the coding designs with increasing $K$. 

---

32-395
**Algorithms**

**Random Coding Design Matrices**

For a given number of classes, for example, $K$, the software generates random coding design matrices as follows.

1. The software generates one of the following:
   a. Dense random — The software assigns a 1 or -1 with equal probability to each element of the $K$-by-$L_d$ coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$. 

\[ \text{Number of binary learners (log10-scale)} \]
\[ \text{K} \]

---

32-396
b Sparse random — The software assigns a 1 to each element of the $K$-by-$L_s$ coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s = \lceil 15 \log_2 K \rceil$.

2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.

3 For distinct columns $u$ and $v$, if $u = v$ or $u = -v$, then the software removes $v$ from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$
\Delta(k_1,k_2) = 0.5 \sum_{l=1}^{L} \left| m_{k_1,l} - m_{k_2,l} \right|,
$$

where $m_{k,l}$ is an element of coding design matrix $j$.

**Support Vector Storage**

For linear, SVM binary learners, and for efficiency, fitcecoc empties the properties Alpha, SupportVectorLabels, and SupportVectors. fitcecoc lists Beta, rather than Alpha, in the model display.

To store Alpha, SupportVectorLabels, and SupportVectors, pass a linear, SVM template that specifies storing support vectors to fitcecoc. For example, enter:

```matlab
t = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

**Alternatives**

You can use these alternative algorithms to train a multiclass model:

- Classification ensembles—see fitcensemble and ClassificationEnsemble
- Classification trees—see fitctree and ClassificationTree
Discriminant analysis classifiers—see `fitcdiscr` and `ClassificationDiscriminant`

k-nearest neighbor classifiers—see `fitcknn` and `ClassificationKNN`

Naive Bayes classifiers—see `fitcnb` and `ClassificationNaiveBayes`

References

ExtendedCapabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.
  - You cannot fit posterior probabilities by using the 'FitPosterior' name-value pair argument.
  - All binary learners must be either SVM classifiers or linear classification models.
  For the 'Learners' name-value pair argument, you can specify:
    - 'svm' or 'linear'
    - An SVM template object or a cell vector of such objects (see `templateSVM`)
    - A linear classification model template object or a cell vector of such objects (see `templateLinear`)
Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-554 of the ClassificationSVM class and “Code Generation” on page 32-442 of the ClassificationLinear class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2014b
**ClassificationDiscriminant class**

**Superclasses:**

Discriminant analysis classification

**Description**

A `ClassificationDiscriminant` object encapsulates a discriminant analysis classifier, which is a Gaussian mixture model for data generation. A `ClassificationDiscriminant` object can predict responses for new data using the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

**Construction**

Create a `ClassificationDiscriminant` object by using `fitcdiscr`.

**Properties**

**BetweenSigma**

p-by-p matrix, the between-class covariance, where p is the number of predictors.

**CategoricalPredictors**

Categorical predictor indices, which is always empty ([ ]).

**ClassNames**

List of the elements in the training data Y with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)
**Coeffs**

k-by-k structure of coefficient matrices, where k is the number of classes. \(\text{Coeffs}(i,j)\) contains coefficients of the linear or quadratic boundaries between classes i and j. Fields in \(\text{Coeffs}(i,j)\):

- **DiscrimType**
- **Class1** — ClassNames(i)
- **Class2** — ClassNames(j)
- **Const** — A scalar
- **Linear** — A vector with p components, where p is the number of columns in X
- **Quadratic** — p-by-p matrix, exists for quadratic DiscrimType

The equation of the boundary between class i and class j is

\[
\text{Const} + \text{Linear} \ast x + x' \ast \text{Quadratic} \ast x = 0,
\]

where \(x\) is a column vector of length p.

If `fitcdiscr` had the FillCoeffs name-value pair set to 'off' when constructing the classifier, \(\text{Coeffs}\) is empty ([]).

**Cost**

Square matrix, where \(\text{Cost}(i,j)\) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of \(\text{Cost}\) corresponds to the order of the classes in ClassNames. The number of rows and columns in \(\text{Cost}\) is the number of unique classes in the response.

Change a \(\text{Cost}\) matrix using dot notation: \(\text{obj.Cost} = \text{costMatrix}\).

**Delta**

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of \(\text{obj}\) has magnitude smaller than \(\text{Delta}\), \(\text{obj}\) sets this coefficient to 0, and so you can eliminate the corresponding predictor from the model. Set \(\text{Delta}\) to a higher value to eliminate more predictors.

\(\text{Delta}\) must be 0 for quadratic discriminant models.
Change Delta using dot notation: \( \text{obj.Delta} = \text{newDelta} \).

**DeltaPredictor**

Row vector of length equal to the number of predictors in \( \text{obj} \). If \( \text{DeltaPredictor}(i) < \text{Delta} \) then coefficient \( i \) of the model is 0.

If \( \text{obj} \) is a quadratic discriminant model, all elements of \( \text{DeltaPredictor} \) are 0.

**DiscrimType**

Character vector specifying the discriminant type. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Change DiscrimType using dot notation: \( \text{obj.DiscrimType} = \text{newDiscrimType} \).

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

**Gamma**

Value of the Gamma regularization parameter, a scalar from 0 to 1. Change Gamma using dot notation: \( \text{obj.Gamma} = \text{newGamma} \).

- If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.
- If you set a value between MinGamma and 1 for linear discriminant, the discriminant sets its type to 'linear'.
- You cannot set values below the value of the MinGamma property.
- For quadratic discriminant, you can set either 0 (for DiscrimType 'quadratic') or 1 (for DiscrimType 'diagQuadratic').

**HyperparameterOptimizationResults**

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values.
Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

**LogDetSigma**

Logarithm of the determinant of the within-class covariance matrix. The type of `LogDetSigma` depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length $K$ for quadratic discriminant analysis, where $K$ is the number of classes

**MinGamma**

Nonnegative scalar, the minimal value of the Gamma parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, `MinGamma` is 0.

**ModelParameters**

Parameters used in training `obj`.

**Mu**

Class means, specified as a $K$-by-$p$ matrix of scalar values class means of size. $K$ is the number of classes, and $p$ is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

**NumObservations**

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data $X$ when there are missing values in $X$ or response $Y$. 
**PredictorNames**

Cell array of names for the predictor variables, in the order in which they appear in the training data \( X \).

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of \( \text{Prior} \) corresponds to the order of the classes in \( \text{ClassNames} \).

Add or change a \( \text{Prior} \) vector using dot notation: \( \text{obj.Prior} = \text{priorVector} \).

**ResponseName**

Character vector describing the response variable \( Y \).

**ScoreTransform**

Character vector representing a built-in transformation function, or a function handle for transforming scores. 'none' means no transformation; equivalently, 'none' means \( @(x)x \). For a list of built-in transformation functions and the syntax of custom transformation functions, see \( \text{fitcdiscr} \).

Implement dot notation to add or change a \( \text{ScoreTransform} \) function using one of the following:

- \( \text{cobj.ScoreTransform} = 'function' \)
- \( \text{cobj.ScoreTransform} = @function \)

**Sigma**

Within-class covariance matrix or matrices. The dimensions depend on \( \text{DiscrimType} \):

- 'linear' (default) — Matrix of size \( p \)-by-\( p \), where \( p \) is the number of predictors
- 'quadratic' — Array of size \( p \)-by-\( p \)-by-\( K \), where \( K \) is the number of classes
- 'diagLinear' — Row vector of length \( p \)
- 'diagQuadratic' — Array of size 1-by-\( p \)-by-\( K \)
- 'pseudoLinear' — Matrix of size \( p \)-by-\( p \)
- 'pseudoQuadratic' — Array of size \( p \)-by-\( p \)-by-\( K \)
Scaled weights, a vector with length n, the number of rows in X.

Matrix of predictor values. Each column of X represents one predictor (variable), and each row represents one observation.

X centered

X data with class means subtracted. If Y(i) is of class j,

\[ X_{\text{centered}}(i,:) = X(i,:) - \text{Mu}(j,:), \]

where Mu is the class mean property.

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Methods

- compact: Compact discriminant analysis classifier
- crossval: Cross-validated discriminant analysis classifier
- cvshrink: Cross-validate regularization of linear discriminant
- resubEdge: Classification edge by resubstitution
- resubLoss: Classification error by resubstitution
- resubMargin: Classification margins by resubstitution
- resubPredict: Predict resubstitution response of classifier

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

load fisheriris

Train a discriminant analysis model using the entire data set.

Mdl = fitcdiscr(meas,species)

Mdl =
    ClassificationDiscriminant
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'setosa'  'versicolor'  'virginica'}
        ScoreTransform: 'none'
        NumObservations: 150
        DiscrimType: 'linear'
        Mu: [3x4 double]
        Coeffs: [3x3 struct]
Properties, Methods

Mdl is a ClassificationDiscriminant model. To access its properties, use dot notation. For example, display the group means for each predictor.

Mdl.Mu
ans = 3×4

<p>| | | | |</p>

</tbody>
</table>

To predict labels for new observations, pass Mdl and predictor data to predict.

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class \( (Y) \) generates data \( (X) \) using a multivariate normal distribution. That is, the model assumes \( X \) has a Gaussian mixture distribution (gmdistribution).
- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
- For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

\[
\hat{y} = \arg\min_{y=1,...,K} \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]

where
• $\hat{y}$ is the predicted classification.
• $K$ is the number of classes.
• $\hat{P}(k \mid x)$ is the posterior probability on page 20-7 of class $k$ for observation $x$.
• $C(y \mid k)$ is the cost on page 20-8 of classifying an observation as $y$ when its true class is $k$.

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.

**Regularization**

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$, that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let $\Sigma$ represent the covariance matrix of the data $X$, and let $\hat{X}$ be the centered data (the data $X$ minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T \ast \hat{X}).$$

The regularized covariance matrix $\hat{\Sigma}$ is

$$\hat{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$  

Whenever $\gamma \geq \text{MinGamma}$, $\hat{\Sigma}$ is nonsingular.

Let $\mu_k$ be the mean vector for those elements of $X$ in class $k$, and let $\mu_0$ be the global mean vector (the mean of the rows of $X$). Let $C$ be the correlation matrix of the data $X$, and let $\hat{C}$ be the regularized correlation matrix:

$$\hat{C} = (1 - \gamma)C + \gamma I,$$

where $I$ is the identity matrix.
The linear term in the regularized discriminant analysis classifier for a data point $x$ is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[ (x - \mu_0)^T D_{-1/2} \right] \left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter $\delta$ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller in magnitude than the threshold $\delta$. Therefore, for class $k$, if component $j$ is thresholded to zero, component $j$ of $x$ does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes $k$ have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor $i$.

**References**

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train a discriminant analysis model by using fitcdiscr or create a compact discriminant analysis model by using makecdiscr, the following restrictions apply.
• The class labels input argument value (Y) cannot be a categorical array.
• The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
• The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics
“Discriminant Analysis Classification” on page 20-2

Introduced in R2011b
ClassificationEnsemble

**Package:** classreg.learning.classif

**Superclasses:**

Ensemble classifier

**Description**

ClassificationEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners. It stores data used for training, can compute resubstitution predictions, and can resume training if desired.

**Construction**

Create a classification ensemble object using `fitcensemble`.

**Properties**

**CategoricalPredictors**

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty `[]`.

**ClassNames**

List of the elements in Y with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)
**CombineWeights**

Character vector describing how ens combines weak learner weights, either 'WeightedSum' or 'WeightedAverage'.

**Cost**

Square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \) (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of \( \text{Cost} \) corresponds to the order of the classes in \( \text{ClassNames} \). The number of rows and columns in \( \text{Cost} \) is the number of unique classes in the response. This property is read-only.

**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then \( \text{ExpandedPredictorNames} \) includes the names that describe the expanded variables. Otherwise, \( \text{ExpandedPredictorNames} \) is the same as \( \text{PredictorNames} \).

**FitInfo**

Numeric array of fit information. The \( \text{FitInfoDescription} \) property describes the content of this array.

**FitInfoDescription**

Character vector describing the meaning of the \( \text{FitInfo} \) array.

**HyperparameterOptimizationResults**

Description of the cross-validation optimization of hyperparameters, stored as a \( \text{BayesianOptimization} \) object or a table of hyperparameters and associated values. Nonempty when the \( \text{OptimizeHyperparameters} \) name-value pair is nonempty at creation. Value depends on the setting of the \( \text{HyperparameterOptimizationOptions} \) name-value pair at creation:

- 'bayesopt' (default) — Object of class \( \text{BayesianOptimization} \)
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)
LearnerNames
Cell array of character vectors with names of weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, LearnerNames is {'Tree'}.  

Method
Character vector describing the method that creates ens.

ModelParameters
Parameters used in training ens.

NumObservations
Numeric scalar containing the number of observations in the training data.

NumTrained
Number of trained weak learners in ens, a scalar.

PredictorNames
Cell array of names for the predictor variables, in the order in which they appear in X.

Prior
Numeric vector of prior probabilities for each class. The order of the elements of Prior corresponds to the order of the classes in ClassNames. The number of elements of Prior is the number of unique classes in the response. This property is read-only.

ReasonForTermination
Character vector describing the reason fitcensemble stopped adding weak learners to the ensemble.

ResponseName
Character vector with the name of the response variable Y.

ScoreTransform
Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means
@(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```matlab
ens.ScoreTransform = 'function'
```

or

```matlab
ens.ScoreTransform = @function
```

**Trained**

A cell vector of trained classification models.

- If `Method` is `'LogitBoost'` or `'GentleBoost'`, then `ClassificationEnsemble` stores trained learner $j$ in the `CompactRegressionLearner` property of the object stored in `Trained{j}`. That is, to access trained learner $j$, use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

**TrainedWeights**

Numeric vector of trained weights for the weak learners in `ens`. `TrainedWeights` has $T$ elements, where $T$ is the number of weak learners in `learners`.

**UsePredForLearner**

Logical matrix of size $P$-by-$NumTrained$, where $P$ is the number of predictors (columns) in the training data $X$. `UsePredForLearner(i,j)` is `true` when learner $j$ uses predictor $i$, and is `false` otherwise. For each learner, the predictors have the same order as the columns in the training data $X$.

If the ensemble is not of type `Subspace`, all entries in `UsePredForLearner` are `true`.

**W**

Scaled weights, a vector with length $n$, the number of rows in $X$. The sum of the elements of $W$ is 1.
Matrix of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

Methods

compact Compact classification ensemble
crossval Cross validate ensemble
resubEdge Classification edge by resubstitution
resubLoss Classification error by resubstitution
resubMargin Classification margins by resubstitution
resubPredict Predict ensemble response by resubstitution
resume Resume training ensemble

Inherited Methods

dge Classification edge
dloss Classification error
dmargins Classification margins
dpredict Predict labels using ensemble of classification models
dpredictorImportance Estimates of predictor importance
dremoveLearners Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

Train Boosted Classification Ensemble

Load the ionosphere data set.

load ionosphere

Train a boosted ensemble of 100 classification trees using all measurements and the AdaBoostM1 method.

Mdl = fitcensemble(X,Y,'Method','AdaBoostM1')

Mdl =
    classreg.learning.classif.ClassificationEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    NumTrained: 100
    Method: 'AdaBoostM1'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of
    iterations of the boosting algorithm.'
    FitInfo: [100x1 double]
    FitInfoDescription: {2x1 cell}

Properties, Methods

Mdl is a ClassificationEnsemble model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

view(Mdl.Trained{1},'Mode','graph')
By default, fitcensemble grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of $X$.

```
predMeanX = predict(Mdl,mean(X))
predMeanX = 1x1 cell array
   {'g'}
```
Tip

For an ensemble of classification trees, the Trained property of ens stores an ens.NumTrained-by-1 cell vector of compact classification models. For a textual or graphical display of tree t in the cell vector, enter:

- \text{view(ens.Trained\{t\}.CompactRegressionLearner)} for ensembles aggregated using LogitBoost or GentleBoost.
- \text{view(ens.Trained\{t\})} for all other aggregation methods.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train an ensemble by using fitcensemble, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of ClassificationKNN, CompactClassificationDiscriminant, and CompactClassificationTree.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a
ClassificationKNN

$k$-nearest neighbor classification

Description

ClassificationKNN is a nearest-neighbor classification model in which you can alter both the distance metric and the number of nearest neighbors. Because a ClassificationKNN classifier stores training data, you can use the model to compute resubstitution predictions. Alternatively, use the model to classify new observations using the predict method.

Creation

Create a ClassificationKNN model using fitcknn.

Properties

KNN Properties

BreakTies — Tie-breaking algorithm
'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by predict when multiple classes have the same smallest cost, specified as one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the $k$ nearest neighbors. BreakTies applies when IncludeTies is false.

Distance — Distance metric
'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | function handle | ...

Distance metric, specified as a character vector or a function handle. The values allowed depend on the NSMethod property.

<table>
<thead>
<tr>
<th>NSMethod</th>
<th>Distance Metric Allowed</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exhaustive'</td>
<td>Any distance metric of ExhaustiveSearcher</td>
</tr>
<tr>
<td>'kdtree'</td>
<td>'cityblock', 'chebychev', 'euclidean', or 'minkowski'</td>
</tr>
</tbody>
</table>

The following table lists the ExhaustiveSearcher distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix $C$. The default value of $C$ is the sample covariance matrix of $X$, as computed by nancov($X$). To specify a different value for $C$, set the DistParameter property of mdl using dot notation.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, set the DistParameter property of mdl using dot notation.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, S = nanstd(X). To specify another value for S, set the DistParameter property of mdl using dot notation.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>@distfun</td>
<td>Distance function handle. distfun has the form function D2 = distfun(ZI,ZJ) % calculation of distance ... where • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:) .</td>
</tr>
</tbody>
</table>

For more information, see “Distance Metrics” on page 18-16.

Change Distance using dot notation: mdl.Distance = newDistance.

If NSMethod is 'kdtree', you can use dot notation to change Distance only for the metrics 'cityblock', 'chebychev', 'euclidean', and 'minkowski'.

Data Types: char | function_handle

**DistanceWeight — Distance weighting function**

'equal' | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'equal'</td>
<td>No weighting</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>'inverse'</td>
<td>Weight is 1/distance</td>
</tr>
<tr>
<td>'squaredinverse'</td>
<td>Weight is 1/distance$^2$</td>
</tr>
<tr>
<td>@fcn</td>
<td>$fcn$ is a function that accepts a matrix of nonnegative distances and returns a matrix of the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(–2).</td>
</tr>
</tbody>
</table>

Change `DistanceWeight` using dot notation: `mdl.DistanceWeight = newDistanceWeight.`

Data Types: char | function_handle

**DistParameter — Parameter for distance metric**

positive definite covariance matrix | positive scalar | vector of positive scale values

Parameter for the distance metric, specified as one of the values described in this table.

<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mahalanobis'</td>
<td>Positive definite covariance matrix $C$</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance exponent, a positive scalar</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Vector of positive scale values with length equal to the number of columns of $X$</td>
</tr>
</tbody>
</table>

For any other distance metric, the value of `DistParameter` must be `[]`.

You can alter `DistParameter` using dot notation: `mdl.DistParameter = newDistParameter`. However, if `Distance` is 'mahalanobis' or 'seuclidean', then you cannot alter `DistParameter`.

Data Types: single | double

**IncludeTies — Tie inclusion flag**

false (default) | true

Tie inclusion flag indicating whether `predict` includes all the neighbors whose distance values are equal to the $k$th smallest distance, specified as false or true. If `IncludeTies` is true, `predict` includes all of these neighbors. Otherwise, `predict` uses exactly $k$ neighbors (see the `BreakTies` property).
Change IncludeTies using dot notation: `mdl.IncludeTies = newIncludeTies`.

Data Types: `logical`

**NSMethod — Nearest neighbor search method**

`'kdtree'` | `'exhaustive'`

This property is read-only.

Nearest neighbor search method, specified as either `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors.
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default value is `'kdtree'` when `X` has 10 or fewer columns, `X` is not sparse, and the distance metric is a `'kdtree'` type. Otherwise, the default value is `'exhaustive'`.

**NumNeighbors — Number of nearest neighbors**

Positive integer value

Number of nearest neighbors in `X` used to classify each point during prediction, specified as a positive integer value.

Data Types: `single` | `double`

**Other Classification Properties**

**CategoricalPredictors — Categorical predictor indices**

`[]` | vector of positive integers

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `double`
ClassNames — Names of classes in training data Y

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Names of the classes in the training data Y with duplicates removed, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as Y. (The software treats string arrays as cell arrays of character vectors.)

Data Types: categorical | char | logical | single | double | cell

Cost — Cost of misclassification

square matrix

Cost of the misclassification of a point, specified as a square matrix. Cost(i,j) is the cost of classifying a point into class j if its true class is i (that is, the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns in Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response.

By default, Cost(i,j) = 1 if i ~= j, and Cost(i,j) = 0 if i = j. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Data Types: single | double

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors. Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

Data Types: cell

ModelParameters — Parameters used in training ClassificationKNN

structure
This property is read-only.

Parameters used in training the ClassificationKNN model, specified as a structure.

Data Types: struct

**Mu — Predictor means**

numeric vector

This property is read-only.

Predictor means, specified as a numeric vector of length numel(PredictorNames).

If you do not standardize mdl when training the model using fitcknn, then Mu is empty ([]).

Data Types: single | double

**NumObservations — Number of observations**

positive integer scalar

This property is read-only.

Number of observations used in training the ClassificationKNN model, specified as a positive integer scalar. This number can be less than the number of rows in the training data because rows containing NaN values are not part of the fit.

Data Types: double

**PredictorNames — Predictor variable names**

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The variable names are in the same order in which they appear in the training data X.

Data Types: cell

**Prior — Prior probabilities for each class**

numeric vector

Prior probabilities for each class, specified as a numeric vector. The order of the elements in Prior corresponds to the order of the classes in ClassNames.
Add or change a Prior vector using dot notation: `mdl.Prior = priorVector`.

Data Types: `single` | `double`

**ResponseName — Response variable name**

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

**RowsUsed — Rows used in fitting**

`[]` | logical vector

This property is read-only.

Rows of the original data `X` used in fitting the `ClassificationKNN` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

**ScoreTransform — Score transformation**

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as either a character vector or a function handle.

This table summarizes the available character vectors.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'doublelogit'</code></td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td><code>'invlogit'</code></td>
<td>$\log(x/(1-x))$</td>
</tr>
<tr>
<td><code>'ismax'</code></td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td><code>'logit'</code></td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td><code>'none' or 'identity'</code></td>
<td>$x$ (no transformation)</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for x &lt; 0</td>
</tr>
<tr>
<td></td>
<td>0 for x = 0</td>
</tr>
<tr>
<td></td>
<td>1 for x &gt; 0</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>2x - 1</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>2/(1 + e^{-x}) - 1</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Change `ScoreTransform` using dot notation: `mdl.ScoreTransform = newScoreTransform`.

Data Types: `char` | `function_handle`

**Sigma — Predictor standard deviations**

numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector of length `numel(PredictorNames)`.

If you do not standardize the predictor variables during training, then `Sigma` is empty (`[]`).

Data Types: `single` | `double`

**W — Observation weights**

vector of nonnegative values

This property is read-only.

Observation weights, specified as a vector of nonnegative values with the same number of rows as `Y`. Each entry in `W` specifies the relative importance of the corresponding observation in `Y`.

Data Types: `single` | `double`
**X — Unstandardized predictor data**
numeric matrix

This property is read-only.

Unstandardized predictor data, specified as a numeric matrix. Each column of X represents one predictor (variable), and each row represents one observation.

Data Types: single | double

**Y — Class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each value in Y is the observed class label for the corresponding row in X.

Y has the same data type as the data in Y used for training the model. (The software treats string arrays as cell arrays of character vectors.)

Data Types: single | double | logical | char | cell | categorical

**Hyperparameter Optimization Properties**

**HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters**
BayesianOptimization object | table

This property is read-only.

Cross-validation optimization of hyperparameters, specified as a BayesianOptimization object or a table of hyperparameters and associated values. This property is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty when you create the model using fitcknn. The value depends on the setting of the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model:

- 'bayesopt' (default) — Object of class BayesianOptimization
• 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

### Object Functions

- **compareHoldout**  
  Compare accuracies of two classification models using new data
- **crossval**  
  Cross-validated k-nearest neighbor classifier
- **edge**  
  Edge of k-nearest neighbor classifier
- **loss**  
  Loss of k-nearest neighbor classifier
- **margin**  
  Margin of k-nearest neighbor classifier
- **predict**  
  Predict labels using k-nearest neighbor classification model
- **resubEdge**  
  Edge of k-nearest neighbor classifier by resubstitution
- **resubLoss**  
  Loss of k-nearest neighbor classifier by resubstitution
- **resubMargin**  
  Margin of k-nearest neighbor classifier by resubstitution
- **resubPredict**  
  Predict resubstitution response of k-nearest neighbor classifier

### Examples

#### Train k-Nearest Neighbor Classifier

Train a $k$-nearest neighbor classifier for Fisher's iris data, where $k$, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```matlab
load fisheriris
X = meas;
Y = species;
```

$X$ is a numeric matrix that contains four petal measurements for 150 irises. $Y$ is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```matlab
Mdl = 
    ClassificationKNN
    ResponseName: 'Y'
    CategoricalPredictors: []
```
Mdl is a trained ClassificationKNN classifier, and some of its properties appear in the Command Window.

To access the properties of Mdl, use dot notation.

Mdl.ClassNames
ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

Mdl.Prior
ans = 1x3
    0.3333    0.3333    0.3333

Mdl.Prior contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in fitcknn. The order of the class prior probabilities corresponds to the order of the classes in Mdl.ClassNames. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

Mdl.Prior = [0.5 0.2 0.3];

You can pass Mdl to predict to label new measurements or crossval to cross-validate the classifier.
Tips

- The **compact** function reduces the size of most classification models by removing the training data properties and any other properties that are not required to predict the labels of new observations. Because $k$-nearest neighbor classification models require all of the training data to predict labels, you cannot reduce the size of a **ClassificationKNN** model.

Alternative Functionality

**knnsearch** finds the $k$-nearest neighbors of points. **rangesearch** finds all the points within a fixed distance. You can use these functions for classification, as shown in “Classify Query Data” on page 18-24. If you want to perform classification, then using **ClassificationKNN** models can be more convenient because you can train a classifier in one step (using **fitcknn**) and classify in other steps (using **predict**). Alternatively, you can train a $k$-nearest neighbor classification model using one of the cross-validation options in the call to **fitcknn**. In this case, **fitcknn** returns a **ClassificationPartitionedModel** cross-validated model object.

Extended Capabilities

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The **predict** function supports code generation.
- When you train a $k$-nearest neighbor classification model by using **fitcknn**, the following restrictions apply.
  - The class labels input argument value (Y) cannot be a categorical array.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To
dummy-code variables that you want treated as categorical, preprocess the categorical data by using `dummyvar` before fitting the model.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
- The value of the 'Distance' name-value pair argument cannot be a custom distance function.
- The value of the 'DistanceWeight' name-value pair argument can be a custom distance weight function, but it cannot be an anonymous function.
- The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a
ClassificationLinear class

Linear model for binary classification of high-dimensional data

Description

ClassificationLinear is a trained linear model object for binary classification; the linear model is a support vector machine (SVM) or logistic regression model. fitclinear fits a ClassificationLinear model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The classification loss plus the regularization term compose the objective function.

Unlike other classification models, and for economical memory usage, ClassificationLinear model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, prior-class probabilities, and the regularization strength.

You can use trained ClassificationLinear models to predict labels or classification scores for new data. For details, see predict.

Construction

Create a ClassificationLinear object by using fitclinear.

Properties

Linear Classification Properties

Lambda — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.
Data Types: `double` | `single`

**Learner — Linear classification model type**

'logistic' | 'svm'

Linear classification model type, specified as 'logistic' or 'svm'.

In this table, \( f(x) = x\beta + b \).

- \( \beta \) is a vector of \( p \) coefficients.
- \( x \) is an observation from \( p \) predictor variables.
- \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Algorithm</th>
<th>Loss Function</th>
<th>FittedLoss Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'logistic'</td>
<td>Logistic regression</td>
<td>Deviance (logistic): [ \ell[y, f(x)] = \log[1 + \exp(-yf(x))] ]</td>
<td>'logit'</td>
</tr>
<tr>
<td>'svm'</td>
<td>Support vector machine</td>
<td>Hinge: [ \ell[y, f(x)] = \max[0, 1 - yf(x)] ]</td>
<td>'hinge'</td>
</tr>
</tbody>
</table>

**Beta — Linear coefficient estimates**

numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: `double`

**Bias — Estimated bias term**

numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: `double`

**FittedLoss — Loss function used to fit linear model**

' hinge' | 'logit'

Loss function used to fit the linear model, specified as 'hinge' or 'logit'.
Value | Algorithm | Loss Function | Learner Value
--- | --- | --- | ---
'hinge' | Support vector machine | Hinge: $\ell(y, f(x)) = \max(0, 1 - yf(x))$ | 'svm'
'logit' | Logistic regression | Deviance (logistic): $\ell(y, f(x)) = \log\{1 + \exp[-yf(x)]\}$ | 'logistic'

**Regularization — Complexity penalty type**
'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and a regularization value from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'lasso (L1)'</td>
<td>Lasso ($L_1$) penalty: $\lambda \sum_{j=1}^{p}</td>
</tr>
<tr>
<td>'ridge (L2)'</td>
<td>Ridge ($L_2$) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$</td>
</tr>
</tbody>
</table>

$\lambda$ specifies the regularization term strength (see Lambda).

The software excludes the bias term ($\beta_0$) from the regularization penalty.

**Other Classification Properties**

*CategoricalPredictors — Indices of categorical predictors*
[]

Indices of categorical predictors, whose value is always empty ([]) because a ClassificationLinear model does not support categorical predictors.

*ClassNames — Unique class labels*
categorical array | character array | logical vector | numeric vector | cell array of character vectors
Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as the class labels Y. (The software treats string arrays as cell arrays of character vectors.) ClassNames also determines the class order.

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has $K$ rows and columns, where $K$ is the number of classes.

Cost($i,j$) is the cost of classifying a point into class $j$ if its true class is $i$. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

Data Types: double

ModelParameters — Parameters used for training model

structure

Parameters used for training the ClassificationLinear model, specified as a structure.

Access fields of ModelParameters using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using Mdl.ModelParameters.BetaTolerance.

Data Types: struct

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data $X$, specified as a cell array of character vectors. The length of PredictorNames is equal to the number of columns in $X$.

Data Types: cell

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors
Expanded predictor names, specified as a cell array of character vectors.

Because a ClassificationLinear model does not support categorical predictors, ExpandedPredictorNames and PredictorNames are equal.

Data Types: cell

Prior — Prior class probabilities
numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. Prior has as many elements as classes in ClassNames, and the order of the elements corresponds to the elements of ClassNames.

Data Types: double

ScoreTransform — Score transformation function
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is \( f(x) = x\beta + b \), where \( \beta \) and \( b \) correspond to Mdl.Beta and Mdl.Bias, respectively.

To change the score transformation function to, for example, function, use dot notation.

- For a built-in function, enter this code and replace function with a value in the table.

\[
\text{Mdl.ScoreTransform} = 'function';
\]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( 1/(1 + e^{-2x}) )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( 1/(1 + e^{-x}) )</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>(x) (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>(-1) for (x &lt; 0) (0) for (x = 0) (1) for (x &gt; 0)</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>(2x - 1)</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>(2/(1 + e^{-x}) - 1)</td>
</tr>
</tbody>
</table>

- For a MATLAB function, or a function that you define, enter its function handle.

    ```matlab
    Mdl.ScoreTransform = @function;
    ```

    *function* must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

    Data Types: **char | function_handle**

**ResponseName — Response variable name**

character vector

Response variable name, specified as a character vector.

Data Types: **char**

### Methods

- **edge** Classification edge for linear classification models
- **loss** Classification loss for linear classification models
- **margin** Classification margins for linear classification models
- **predict** Predict labels for linear classification models
- **selectModels** Choose subset of regularized, binary linear classification models
Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

rng(1); % For reproducibility
[Mdl,FitInfo] = fitclinear(X,Ystats)

Mdl =
    ClassificationLinear
        ResponseName: 'Y'
        ClassNames: [0 1]
        ScoreTransform: 'none'
            Beta: [34023x1 double]
            Bias: -1.0059
            Lambda: 3.1674e-05
            Learner: 'svm'
Properties, Methods

FitInfo = struct with fields:
    Lambda: 3.1674e-05
    Objective: 5.3783e-04
    PassLimit: 10
    NumPasses: 10
    BatchLimit: []
    NumIterations: 238561
    GradientNorm: NaN
    GradientTolerance: 0
    RelativeChangeInBeta: 0.0562
    BetaTolerance: 1.0000e-04
    DeltaGradient: 1.4582
    DeltaGradientTolerance: 1
    TerminationCode: 0
    TerminationStatus: {'Iteration limit exceeded.'}
    Alpha: [31572x1 double]
    History: []
    FitTime: 0.1901
    Solver: {'dual'}

Mdl is a ClassificationLinear model. You can pass Mdl and the training or new data to loss to inspect the in-sample classification error. Or, you can pass Mdl and new predictor data to predict to predict class labels for new observations.

FitInfo is a structure array containing, among other things, the termination status (TerminationStatus) and how long the solver took to fit the model to the data (FitTime). It is good practice to use FitInfo to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like DeltaGradient.

**Predict Class Labels Using Linear Classification Model**

Load the NLP data set.

load nlpdata
n = size(X,1); % Number of observations
Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

\[ Y_{stats} = Y == 'stats'; \]

Hold out 5% of the data.

\[ \text{rng}(1); \quad \% \text{For reproducibility} \]
\[ \text{cvp} = \text{cvpartition}(n,'Holdout',0.05) \]

\[ \text{cvp} = \]
Hold-out cross validation partition
NumObservations: 31572
NumTestSets: 1
  TrainSize: 29994
  TestSize: 1578

\text{cvp} \text{ is a CVPartition object that defines the random partition of } n \text{ data into training and test sets.}

Train a binary, linear classification model using the training set that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. For faster training time, orient the predictor data matrix so that the observations are in columns.

\[ \text{idxTrain} = \text{training}(\text{cvp}); \quad \% \text{Extract training set indices} \]
\[ X = X'; \]
\[ \text{Mdl} = \text{fitclinear}(X(:,\text{idxTrain}),Y_{stats}(\text{idxTrain}),'ObservationsIn','columns'); \]

Predict observations and classification error for the hold out sample.

\[ \text{idxTest} = \text{test}(\text{cvp}); \quad \% \text{Extract test set indices} \]
\[ \text{labels} = \text{predict}(	ext{Mdl},X(:,\text{idxTest}),'ObservationsIn','columns'); \]
\[ L = \text{loss}(	ext{Mdl},X(:,\text{idxTest}),Y_{stats}(\text{idxTest}),'ObservationsIn','columns') \]

\[ L = 7.1753 \times 10^{-4} \]

\text{Mdl} misclassifies fewer than 1% of the out-of-sample observations.
**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train a linear classification model by using fitlinear, the following restrictions apply.
  - The predictor data input argument value (X) must be a full, numeric matrix.
  - The class labels input argument value (Y) cannot be a categorical array.
  - The value of the 'ClassNames' name-value pair argument or property cannot be a categorical array.
  - You can specify only one regularization strength, either 'auto' or a nonnegative scalar for the 'Lambda' name-value pair argument.
  - The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

ClassificationPartitionedLinear | ClassificationPartitionedLinearECOC |
fitlearn | predict

*Introduced in R2016a*
ClassificationNaiveBayes class

Superclasses:
Naive Bayes classification

Description
ClassificationNaiveBayes is a naive Bayes classifier for multiclass learning. Use fitcnb and the training data to train a ClassificationNaiveBayes classifier.

Trained ClassificationNaiveBayes classifiers store the training data, parameter values, data distribution, and prior probabilities. You can use these classifiers to:

- Estimate resubstitution predictions. For details, see resubPredict.
- Predict labels or posterior probabilities for new data. For details, see predict.

Construction
Create a ClassificationNaiveBayes object by using fitcnb.

Properties
CategoricalPredictors — Indices of categorical predictors
vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

CategoricalLevels — Multivariate multinomial levels
cell vector of numeric vectors
Multivariate multinomial levels, specified as a cell vector of numeric vectors. 
\texttt{CategoricalLevels} has length equal to the number of predictors (\texttt{size(X,2)}).

The cells of \texttt{CategoricalLevels} correspond to predictors that you specified as 'mvmn' 
(i.e., having a multivariate multinomial distribution) during training. Cells that do not 
correspond to a multivariate multinomial distribution are empty ([]).

If predictor \( j \) is multivariate multinomial, then \texttt{CategoricalLevels}\{\( j \)\} is a list of all
distinct values of predictor \( j \) in the sample (\texttt{NaNs} removed from \texttt{unique(X(:,j))}).

Data Types: cell

\textbf{ClassNames — Distinct class names}

categorical array | character array | logical vector | numeric vector | cell array of 
character vectors

Distinct class names, specified as a categorical or character array, logical or numeric 
vector, or cell vector of character vectors.

\texttt{ClassNames} is the same data type as \( Y \), and has \( K \) elements or rows for character arrays. 
(The software treats string arrays as cell arrays of character vectors.)

Data Types: categorical | char | logical | single | double | cell

\textbf{Cost — Misclassification cost}

square matrix

Misclassification cost, specified as a \( K \)-by-\( K \) square matrix.

The value of \texttt{Cost(i,j)} is the cost of classifying a point into class \( j \) if its true class is \( i \). 
The order of the rows and columns of \texttt{Cost} correspond to the order of the classes in 
\texttt{ClassNames}.

The value of \texttt{Cost} does not influence training. You can reset \texttt{Cost} after training \texttt{Mdl} 
using dot notation, e.g., \texttt{Mdl.Cost} = [0 0.5; 1 0];.

Data Types: double | single

\textbf{DistributionNames — Predictor distributions}

'normal' (default) | 'kernel' | 'mn' | 'mvmn' | cell array of character vectors

Predictor distributions \texttt{fitcnb} uses to model the predictors, specified as a character 
vector or cell array of character vectors.
This table summarizes the available distributions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'kernel'</td>
<td>Kernel smoothing density estimate.</td>
</tr>
<tr>
<td>'mn'</td>
<td>Multinomial bag-of-tokens model on page 32-454. Indicates that all predictors have this distribution.</td>
</tr>
<tr>
<td>'mvmn'</td>
<td>Multivariate multinomial distribution.</td>
</tr>
<tr>
<td>'normal'</td>
<td>Normal (Gaussian) distribution.</td>
</tr>
</tbody>
</table>

If `Distribution` is a 1-by-`P` cell array of character vectors, then the software models feature `j` using the distribution in element `j` of the cell array.

Data Types: `char` | `cell`

**DistributionParameters — Distribution parameter estimates**

cell array

Distribution parameter estimates, specified as a cell array. `DistributionParameters` is a `K`-by-`D` cell array, where cell `(k,d)` contains the distribution parameter estimates for instances of predictor `d` in class `k`. The order of the rows corresponds to the order of the classes in the property `ClassNames`, and the order of the predictors corresponds to the order of the columns of `X`.

If class `k` has no observations for predictor `j`, then `Distribution{k,j}` is empty ([``]).

The elements of `DistributionParameters` depends on the distributions of the predictors. This table describes the values in `DistributionParameters{k,j}`.

<table>
<thead>
<tr>
<th>Distribution of Predictor <code>j</code></th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kernel</code></td>
<td>A <code>KernelDistribution</code> model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use <code>Mdl.DistributionParameters{3,2}.BandWidth</code>.</td>
</tr>
<tr>
<td><strong>Distribution of Predictor j</strong></td>
<td><strong>Value</strong></td>
</tr>
<tr>
<td>--------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>mn</td>
<td>A scalar representing the probability that token $j$ appears in class $k$. For details, see &quot;Algorithms&quot; on page 32-455.</td>
</tr>
<tr>
<td>mvmn</td>
<td>A numeric vector containing the probabilities for each possible level of predictor $j$ in class $k$. The software orders the probabilities by the sorted order of all unique levels of predictor $j$ (stored in the property CategoricalLevels). For more details, see &quot;Algorithms&quot; on page 32-455.</td>
</tr>
<tr>
<td>normal</td>
<td>A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation.</td>
</tr>
</tbody>
</table>

**Data Types:** cell

**ExpandedPredictorNames — Expanded predictor names**
cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

**Data Types:** cell

**HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters**
BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair is nonempty at creation. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair at creation:

- 'bayesopt' (default) — Object of class BayesianOptimization
• 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: table

**Kernel — Kernel smoother types**

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. *Kernel* has length equal to the number of predictors (size(X,2)). *Kernel{j}* corresponds to predictor *j*, and contains a character vector describing the type of kernel smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Kernel</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'box'</td>
<td>Box (uniform)</td>
<td>$f(x) = 0.5I{</td>
</tr>
<tr>
<td>'epanechnikov'</td>
<td>Epanechnikov</td>
<td>$f(x) = 0.75(1-x^2)I{</td>
</tr>
<tr>
<td>'normal'</td>
<td>Gaussian</td>
<td>$f(x) = \frac{1}{\sqrt{2\pi}}\exp\left(-0.5x^2\right)$</td>
</tr>
<tr>
<td>'triangle'</td>
<td>Triangular</td>
<td>$f(x) = (1-</td>
</tr>
</tbody>
</table>

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Data Types: char | cell

**ModelParameters — Parameter values used to train**

Object

Parameter values used to train the classifier (such as the name-value pair argument values), specified as an object. This table summarizes the properties of ModelParameters. The properties correspond to the name-value pair argument values set for training the classifier.
<table>
<thead>
<tr>
<th>Property</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>DistributionNames</td>
<td>Data distribution or distributions. This is the same value as the property DistributionNames.</td>
</tr>
<tr>
<td>Kernel</td>
<td>Kernel smoother type. This is the same as the property Kernel.</td>
</tr>
<tr>
<td>Method</td>
<td>Training method. For naive Bayes, the value is 'NaiveBayes'.</td>
</tr>
<tr>
<td>Support</td>
<td>Kernel-smoothing density support. This is the same as the property Support.</td>
</tr>
<tr>
<td>Type</td>
<td>Learning type. For classification, the value is 'classification'.</td>
</tr>
<tr>
<td>Width</td>
<td>Kernel smoothing window width. This is the same as the property Width.</td>
</tr>
</tbody>
</table>

Access fields of ModelParameters using dot notation. For example, access the kernel support using Mdl.ModelParameters.Support.

**NumObservations — Number of training observations**

numeric scalar

Number of training observations, specified as a numeric scalar.

If X or Y contain missing values, then NumObservations might be less than the length of Y.

Data Types: double

**PredictorNames — Predictor names**

cell array of character vectors

Predictor names, specified as a cell array of character vectors. The order of the elements in PredictorNames corresponds to the order in X.

Data Types: cell

**Prior — Class prior probabilities**

numeric vector
Class prior probabilities, specified as a numeric row vector. `Prior` is a 1-by-$K$ vector, and the order of its elements correspond to the elements of `ClassNames`.

`fitcnb` normalizes the prior probabilities you set using the name-value pair parameter 'Prior' so that \( \text{sum}(\text{Prior}) = 1 \).

The value of `Prior` does not change the best-fitting model. Therefore, you can reset `Prior` after training `Mdl` using dot notation, e.g., `Mdl.Prior = [0.2 0.8];`.

Data Types: `double` | `single`

**ResponseName — Response name**
character vector

Response name, specified as a character vector.

Data Types: `char`

**ScoreTransform — Classification score transformation function**
'`doublelogit'` | '`invlogit'` | 'ismax' | 'logit' | 'none' | function handle | ...

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., `function`, use dot notation.

- For a built-in function, enter this code and replace `function` with a value in the table.

  `Mdl.ScoreTransform = 'function';`

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>

### Value Description

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'sign'               | -1 for $x < 0$
|                      | 0 for $x = 0$
|                      | 1 for $x > 0$                                    |
| 'symmetric'          | $2x - 1$                                         |
| 'symmetricismax'     | Sets the score for the class with the largest  |
|                      | score to 1, and sets the scores for all other  |
|                      | classes to $-1$                                 |
| 'symmetriclogit'     | $2/(1 + e^{-x}) - 1$                             |

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

*function* should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Data Types:** char | function_handle

---

**Support — Kernel smoother density support**

- **cell vector**

Kernel smoother density support, specified as a cell vector. `Support` has length equal to the number of predictors (`size(X,2)`). The cells represent the regions to apply the kernel density.

This table describes the supported options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-by-2 numeric row vector</td>
<td>For example, [L, U], where L and U are the finite lower and upper bounds, respectively, for the density support.</td>
</tr>
<tr>
<td>'positive'</td>
<td>The density support is all positive real values.</td>
</tr>
<tr>
<td>'unbounded'</td>
<td>The density support is all real values.</td>
</tr>
</tbody>
</table>

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

**W — Observation weights**

- **numeric vector**
Observation weights, specified as a numeric vector.

The length of \( W \) is \( \text{NumObservations} \).

`fitcnb` normalizes the value you set for the name-value pair parameter 'Weights' so that the weights within a particular class sum to the prior probability for that class.

Data Types: `double`

**Width — Kernel smoother window width**

numeric matrix

Kernel smoother window width, specified as a numeric matrix. \( \text{Width} \) is a \( K \)-by-\( P \) matrix, where \( K \) is the number of classes in the data, and \( P \) is the number of predictors (\( \text{size}(X,2) \)).

\( \text{Width}(k,j) \) is the kernel smoother window width for the kernel smoothing density of predictor \( j \) within class \( k \). NaNs in column \( j \) indicate that the software did not fit predictor \( j \) using a kernel density.

**X — Unstandardized predictor data**

numeric matrix

Unstandardized predictor data, specified as a numeric matrix. \( X \) has \( \text{NumObservations} \) rows and \( P \) columns.

Each row of \( X \) corresponds to one observation, and each column corresponds to one variable.

The software excludes rows removed due to missing values from \( X \).

Data Types: `double`

**Y — Observed class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. \( Y \) is the same data type as the input argument \( Y \) of `fitcnb`. (The software treats string arrays as cell arrays of character vectors.)

Each row of \( Y \) represents the observed classification of the corresponding row of \( X \).

The software excludes elements removed due to missing values from \( Y \).
Data Types: categorical | char | logical | single | double | cell

Methods

- compact: Compact naive Bayes classifier
- crossval: Cross-validated naive Bayes classifier
- resubEdge: Classification edge for naive Bayes classifiers by resubstitution
- resubLoss: Classification loss for naive Bayes classifiers by resubstitution
- resubMargin: Classification margins for naive Bayes classifiers by resubstitution
- resubPredict: Predict naive Bayes classifier resubstitution response

Inherited Methods

- edge: Classification edge for naive Bayes classifiers
- logP: Log unconditional probability density for naive Bayes classifier
- loss: Classification error for naive Bayes classifier
- margin: Classification margins for naive Bayes classifiers
- predict: Predict labels using naive Bayes classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train a Naive Bayes Classifier

Construct a naive Bayes classifier for Fisher's iris data. Also, specify prior probabilities after training.

Load Fisher's iris data.
load fisheriris
X = meas;
Y = species;

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a naive Bayes classifier.

Mdl = fitcnb(X,Y)

Mdl = ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal' 'normal' 'normal' 'normal'}
    DistributionParameters: {3x4 cell}

Properties, Methods

Mdl is a trained ClassificationNaiveBayes classifier, and some of its properties display in the Command Window. By default, the software treats each predictor as independent, and fits them using normal distributions.

To access the properties of Mdl, use dot notation.

Mdl.ClassNames

ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

Mdl.Prior

ans = 1x3
    0.3333    0.3333    0.3333
Mdl.Prior contains the class prior probabilities, which are settable using the name-value pair argument 'Prior' in fitcnb. The order of the class prior probabilities corresponds to the order of the classes in Mdl.ClassNames. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

Mdl.Prior = [0.5 0.2 0.3];

You can pass Mdl to e.g., predict to label new measurements, or crossval to cross validate the classifier.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor \( j \) is the nonnegative number of occurrences of token \( j \) in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

1. Estimates the densities of the predictors within each class.
2. Models posterior probabilities according to Bayes rule. That is, for all \( k = 1,...,K \),
\[
\hat{P}(Y = k \mid X_1,...,X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P(X_j \mid Y = k)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P(X_j \mid Y = k)},
\]

where:

- \( Y \) is the random variable corresponding to the class index of an observation.
- \( X_1,...,X_P \) are the random predictors of an observation.
- \( \pi(Y = k) \) is the prior probability that a class index is \( k \).

3. Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

\[
\hat{P}(Y = k \mid X_1,...,X_P) \propto \pi(Y = k) P_{mn}(X_1,...,X_P \mid Y = k),
\]

where \( P_{mn}(X_1,...,X_P \mid Y = k) \) is the probability mass function of a multinomial distribution.

**Algorithms**

- If you specify 'DistributionNames','mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1956. The software stores the probability that token \( j \) appears in class \( k \) in the property DistributionParameters\{\( k,j \} \). Using additive smoothing [2], the estimated probability is

\[
P(token \mid class \, k) = \frac{1 + c_{jk}}{P + c_k},
\]

where:
• \[ c_{j|k} = \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}; \] which is the weighted number of occurrences of token \( j \) in class \( k \).

• \( n_k \) is the number of observations in class \( k \).

• \( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.

• \[ c_k = \sum_{j=1}^{P} c_{j|k}; \] which is the total weighted number of occurrences of all tokens in class \( k \).

• If you specify 'DistributionNames','mvmn' when training \( \text{Mdl} \) using \( \text{fitcnb} \), then:

1. For each predictor, the software collects a list of the unique levels, stores the sorted list in \( \text{CategoricalLevels} \), and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.

2. For predictor \( j \) in class \( k \), the software counts instances of each categorical level using the list stored in \( \text{CategoricalLevels}\{j\} \).

3. The software stores the probability that predictor \( j \), in class \( k \), has level \( L \) in the property \( \text{DistributionParameters}\{k,j\} \), for all levels in \( \text{CategoricalLevels}\{j\} \). Using additive smoothing [2], the estimated probability is

\[
P(\text{predictor } j = L | \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},
\]

where:
\[ m_{j|k}(L) = \frac{\sum_{i:y_i \in \text{class } k} I\{x_{ij} = L\}w_i}{n_k} \]

which is the weighted number of observations for which predictor \( j \) equals \( L \) in class \( k \).

\( n_k \) is the number of observations in class \( k \).

\[ I\{x_{ij} = L\} = 1 \text{ if } x_{ij} = L, \ 0 \text{ otherwise.} \]

\( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.

\( m_j \) is the number of distinct levels in predictor \( j \).

\( m_k \) is the weighted number of observations in class \( k \).

ClassificationPartitionedECOC

Cross-validated multiclass ECOC model for support vector machines (SVMs) and other classifiers

Description

ClassificationPartitionedECOC is a set of error-correcting output codes (ECOC) models trained on cross-validated folds. Estimate the quality of the cross-validated classification by using one or more “kfold” functions: kfoldPredict, kfoldLoss, kfoldMargin, kfoldEdge, and kfoldfun.

Every “kfold” method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (roughly 4/5 of the data), and the validation fold contains the other group (roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1 The software trains the first model (stored in CVMdl.Trained{1}) by using the observations in the last four groups and reserves the observations in the first group for validation.
2 The software trains the second model (stored in CVMdl.Trained{2}) by using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using kfoldPredict, the software computes predictions for the observations in group i by using the ith model. In short, the software estimates a response for every observation by using the model trained without that observation.

Creation

You can create a ClassificationPartitionedECOC model in two ways:

• Create a cross-validated ECOC model from an ECOC model by using the crossval object function.
• Create a cross-validated ECOC model by using the fitcecoc function and specifying one of the name-value pair arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Properties

Cross-Validation Properties

**CrossValidatedModel** — Cross-validated model name
character vector

Cross-validated model name, specified as a character vector.

For example, 'ECOC' specifies a cross-validated ECOC model.

Data Types: char

**KFold** — Number of cross-validated folds
positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

**ModelParameters** — Cross-validation parameter values
object

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the ECOC classifier. **ModelParameters** does not contain estimated parameters.

You can access the properties of **ModelParameters** using dot notation.

**NumObservations** — Number of observations
positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

**Partition** — Data partition
cvpartition model
Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

**Trained — Compact classifiers trained on cross-validation folds**
cell array of CompactClassificationECOC models

Compact classifiers trained on cross-validation folds, specified as a cell array of CompactClassificationECOC models. Trained has \( k \) cells, where \( k \) is the number of folds.

Data Types: cell

**W — Observation weights**
numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. \( W \) has NumObservations elements.

The software normalizes the weights used for training so that nansum(\( W \)) is 1.

Data Types: single | double

**X — Unstandardized predictor data**
numeric matrix

Unstandardized predictor data used to cross-validate the classifier, specified as a numeric matrix. \( X \) is a NumObservations-by-\( p \) matrix, where \( p \) is the number of predictors.

Each row of \( X \) corresponds to one observation, and each column corresponds to one variable.

Data Types: single | double

**Y — Observed class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. \( Y \) has NumObservations elements and has the same data type as the input argument \( Y \) that you pass to fitcecoc to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of \( Y \) represents the observed classification of the corresponding row of \( X \).
Data Types: categorical | char | logical | single | double | cell

**ECOC Properties**

**BinaryLoss — Binary learner loss function**

'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets BinaryLoss to 'hamming'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of kfoldPredict or kfoldLoss.

Data Types: char

**BinaryY — Binary learner class labels**

numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then BinaryY is a NumObservations-by-L matrix, where L is the number of binary learners (size(CodingMatrix,2)).

  The elements of BinaryY are −1, 0, or 1, and the values correspond to dichotomous class assignments. This table describes how learner j assigns observation k to a dichotomous class corresponding to the value of BinaryY(k,j).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>−1</td>
<td>Learner j assigns observation k to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner j removes observation k from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner j assigns observation k to a positive class.</td>
</tr>
</tbody>
</table>

- If the coding matrix varies across folds, then BinaryY is empty ([]).
Data Types: double

**CodingMatrix — Codes specifying class assignments**
numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then CodingMatrix is a $K$-by-$L$ matrix, where $K$ is the number of classes and $L$ is the number of binary learners.

  The elements of CodingMatrix are $-1$, $0$, or $1$, and the values correspond to dichotomous class assignments. This table describes how learner $j$ assigns observations in class $i$ to a dichotomous class corresponding to the value of CodingMatrix($i,j$).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-1$</td>
<td>Learner $j$ assigns observations in class $i$ to a negative class.</td>
</tr>
<tr>
<td>$0$</td>
<td>Before training, learner $j$ removes observations in class $i$ from the data set.</td>
</tr>
<tr>
<td>$1$</td>
<td>Learner $j$ assigns observations in class $i$ to a positive class.</td>
</tr>
</tbody>
</table>

- If the coding matrix varies across folds, then CodingMatrix is empty ([]). You can obtain the coding matrix for each fold by using the Trained property. For example, CVMdl.Trained{1}.CodingMatrix is the coding matrix in the first fold of the cross-validated ECOC model CVMdl.

Data Types: double | single | int8  | int16 | int32 | int64

**Other Classification Properties**

**CategoricalPredictors — Categorical predictor indices**
vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).
Data Types: single | double

**ClassNames — Unique class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as the class labels Y. (The software treats string arrays as cell arrays of character vectors.) ClassNames also determines the class order.

Data Types: categorical | char | logical | single | double | cell

**Cost — Misclassification costs**
square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has K rows and columns, where K is the number of classes.

Cost(i,j) is the cost of classifying a point into class j if its true class is i. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

fitcecoc incorporates misclassification costs differently among different types of binary learners.

Data Types: double

**PredictorNames — Predictor names**
cell array of character vectors

Predictor names in order of their appearance in the predictor data X, specified as a cell array of character vectors. The length of PredictorNames is equal to the number of columns in X.

Data Types: cell

**Prior — Prior class probabilities**
numeric vector

This property is read-only.
Prior class probabilities, specified as a numeric vector. **Prior** has as many elements as there are classes in **ClassNames**, and the order of the elements corresponds to the elements of **ClassNames**.

**fitcecoc** incorporates misclassification costs differently among different types of binary learners.

Data Types: double

**ResponseName — Response variable name**
character vector

Response variable name, specified as a character vector.

Data Types: char

**ScoreTransform — Score transformation function to apply to predicted scores**
'**doublelogit**' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value in the table.

\[
\text{Mdl.ScoreTransform} = 'function';
\]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none'</td>
<td>or 'identity'</td>
</tr>
</tbody>
</table>
| 'sign'           | -1 for \( x < 0 \)  
                  | 0 for \( x = 0 \)  
<pre><code>              | 1 for \( x &gt; 0 \)  |
</code></pre>
<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>'symmetric'</td>
<td>$2x - 1$</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>$2/(1 + e^{-x}) - 1$</td>
</tr>
</tbody>
</table>

- For a MATLAB function or a function that you define, enter its function handle.

```
Md1.ScoreTransform = @function;
```

*function* must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

**Object Functions**

- `kfoldEdge` Classification edge for cross-validated ECOC model
- `kfoldLoss` Classification loss for cross-validated ECOC model
- `kfoldMargin` Classification margins for cross-validated ECOC model
- `kfoldPredict` Classify observations in cross-validated ECOC model
- `kfoldfun` Cross-validate function using cross-validated ECOC model

**Examples**

**Cross-Validate ECOC Classifier**

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',1)
```
t =
Fit template for classification SVM.

Version: 2
Method: 'SVM'
Type: 'classification'

t is an SVM template. Most of the template object's properties are empty. When training
the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});

Mdl is a ClassificationECOC classifier. You can access its properties using dot
notation.

Cross-validate Mdl using 10-fold cross-validation.

CVMdl = crossval(Mdl);
CVMdl is a ClassificationPartitionedECOC cross-validated ECOC classifier.

Estimate the classification error.

\[
\text{loss} = \text{kfoldLoss(CVMdl)}
\]

\[
\text{loss} = 0.0400
\]

The classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

### Train ECOC Classifiers Using Ensembles and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. Estimate the classification error using 10-fold cross-validation.

Load and inspect the arrhythmia data set.

```
load arrhythmia
[n,p] = size(X)

n = 452
p = 279

isLabels = unique(Y);
nLabels = numel(isLabels)
nLabels = 13

tabulate(categorical(Y))
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>245</td>
<td>54.20%</td>
</tr>
<tr>
<td>2</td>
<td>44</td>
<td>9.73%</td>
</tr>
<tr>
<td>3</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>4</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>5</td>
<td>13</td>
<td>2.88%</td>
</tr>
<tr>
<td>6</td>
<td>25</td>
<td>5.53%</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>0.66%</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>0.44%</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>1.99%</td>
</tr>
<tr>
<td>10</td>
<td>50</td>
<td>11.06%</td>
</tr>
</tbody>
</table>
The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```matlab
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. (The number of workers depends on your system configuration.) Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```matlab
pool = parpool; % Invoke workers
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','Options',options);
```

Mdl is a ClassificationECOC model.

Cross-validate the ECOC classifier using 10-fold cross-validation.

```matlab
CVMdl = crossval(Mdl,'Options',options);
```

Warning: One or more folds do not contain points from all the groups.

CVMdl is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those
folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```matlab
goofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```

Introduced in R2014b
ClassificationPartitionedEnsemble

Package: classreg.learning.partition
Superclasses:

Cross-validated classification ensemble

Description

ClassificationPartitionedEnsemble is a set of classification ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: kfoldPredict, kfoldLoss, kfoldMargin, kfoldEdge, and kfoldfun.

Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in Trained{1} was trained on X and Y with the first 1/5 excluded, the second model stored in Trained{2} was trained on X and Y with the second 1/5 excluded, and so on. When you call kfoldPredict, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model, and so on. In short, response for every observation is computed by kfoldPredict using the model trained without this observation.

Construction

cvens = crossval(ens) creates a cross-validated ensemble from ens, a classification ensemble. For syntax details, see the crossval method reference page.

cvens = fitcensemble(X,Y,Name,Value) creates a cross-validated ensemble when Name is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the fitcensemble function reference page.
Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

ClassNames

List of the elements in Y with duplicates removed. ClassNames can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. ClassNames has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

Combiner

Cell array of combiners across all folds.

Cost

Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response. This property is read-only.

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated ensemble, a positive integer.

ModelParameters

Object holding parameters of cvens.

NumObservations

Number of data points used in training the ensemble, a positive integer.
**NTrainedPerFold**

Number of data points used in training each fold of the ensemble, a positive integer.

**Partition**

Partition of class `cvpartition` used in creating the cross-validated ensemble.

**PredictorNames**

Cell array of names for the predictor variables, in the order in which they appear in `X`.

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

**ResponseName**

Name of the response variable `Y`, a character vector.

**ScoreTransform**

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```matlab
ens.ScoreTransform = 'function'
```

or

```matlab
ens.ScoreTransform = @function
```

**Trainable**

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.
**Trained**

Cell array of compact ensembles trained on cross-validation folds.

**W**

Scaled weights, a vector with length \( n \), the number of rows in \( X \).

**X**

A matrix of predictor values. Each column of \( X \) represents one variable, and each row represents one observation.

**Y**

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of \( Y \) is the response to the data in the corresponding row of \( X \).

**Methods**

- `kfoldEdge` Classification edge for observations not used for training
- `kfoldLoss` Classification loss for observations not used for training
- `resume` Resume training learners on cross-validation folds

**Inherited Methods**

- `kfoldEdge` Classification edge for observations not used for training
- `kfoldfun` Cross validate function
- `kfoldLoss` Classification loss for observations not used for training
- `kfoldMargin` Classification margins for observations not used for training
- `kfoldPredict` Predict response for observations not used for training

**Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

Evaluate K-Fold Cross-Validation Error for Classification Ensemble

Evaluate the k-fold cross-validation error for a classification ensemble that models the Fisher iris data.

Load the sample data set.

```matlab
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```matlab
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
t
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Create a cross-validated ensemble from `ens` and find the k-fold cross-validation error.

```matlab
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 0.0467
```

ClassificationPartitionedKernel

Cross-validated, binary kernel classification model

Description

ClassificationPartitionedKernel is a binary kernel classification model, trained on cross-validated folds. You can estimate the quality of classification, or how well the kernel classification model generalizes, using one or more “kfold“ functions: kfoldPredict, kfoldLoss, kfoldMargin, and kfoldEdge.

Every “kfold“ method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1. The software trains the first model (stored in CVMdl.Trained{1}) by using the observations in the last four groups and reserves the observations in the first group for validation.
2. The software trains the second model (stored in CVMdl.Trained{2}) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
3. The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using kfoldPredict, the software computes predictions for the observations in group $i$ by using the $i$th model. In short, the software estimates a response for every observation by using the model trained without that observation.

**Note** ClassificationPartitionedKernel model objects do not store the predictor data set.
Creation

You can create a `ClassificationPartitionedKernel` model by training a classification kernel model using `fitckernel` and specifying one of these name-value pair arguments: 'Crossval', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Properties

Cross-Validation Properties

`CrossValidatedModel` — Cross-validated model name
cell character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'Kernel' specifies a cross-validated kernel model.

Data Types: `char`

`KFold` — Number of cross-validated folds
positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: `double`

`ModelParameters` — Cross-validation parameter values
object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the kernel classifier. `ModelParameters` does not contain estimated parameters.

You can access the properties of `ModelParameters` using dot notation.
**NumObservations — Number of observations**
positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

**Partition — Data partition**
cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

**Trained — Kernel classifiers trained on cross-validation folds**
cell array of ClassificationKernel models

This property is read-only.

Kernel classifiers trained on cross-validation folds, specified as a cell array of ClassificationKernel models. Trained has k cells, where k is the number of folds.

Data Types: cell

**W — Observation weights**
numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.

The software normalizes the weights used for training so that nansum(W) is 1.

Data Types: single | double

**Y — Observed class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.
Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has NumObservations elements and has the same data type as the input argument Y that you pass to fitckernel to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X.

Data Types: categorical | char | logical | single | double | cell

**Other Classification Properties**

**CategoricalPredictors — Categorical predictor indices**

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. Because ClassificationKernel models can be trained on numeric predictor data only, this property is empty ([]).

**ClassNames — Unique class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as the observed class labels property Y and determines the class order.

Data Types: categorical | char | logical | single | double | cell

**Cost — Misclassification costs**

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has K rows and columns, where K is the number of classes.
Cost(i,j) is the cost of classifying a point into class j if its true class is i. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

Data Types: double

PredictorNames — Predictor names  
{'x1', 'x2', ...}

This property is read-only.

Predictor names in order of their appearance in the predictor data X, specified as a cell array of character vectors of the form {'x1', 'x2',...}. The length of PredictorNames is equal to the number of columns in X.

Data Types: cell

Prior — Prior class probabilities  
numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. Prior has as many elements as there are classes in ClassNames, and the order of the elements corresponds to the elements of ClassNames.

Data Types: double

ResponseName — Response variable name  
'Y'

This property is read-only.

Response variable name, specified as 'Y'. Because ClassificationKernel models cannot be trained on tabular data, this property is always 'Y'.

Data Types: char

ScoreTransform — Score transformation function  
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For a kernel classification model Mdl, and before the score transformation, the predicted classification score for the observation x (row vector) is \( f(x) = T(x)\beta + b \).
• \( T(\cdot) \) is a transformation of an observation for feature expansion.
• \( \beta \) is the estimated column vector of coefficients.
• \( b \) is the estimated scalar bias.

To change the CVMdl score transformation function to \( function \), for example, use dot notation.

• For a built-in function, enter this code and replace \( function \) with a value from the table.

\[
\text{CVMdl.ScoreTransform} = 'function';
\]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log\left(\frac{x}{1-x}\right) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>(-1 ) for ( x &lt; 0 ) \n0 for ( x = 0 ) \n1 for ( x &gt; 0 )</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>( 2x - 1 )</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^x} - 1 )</td>
</tr>
</tbody>
</table>

• For a MATLAB function or a function that you define, enter its function handle.

\[
\text{CVMdl.ScoreTransform} = @function;
\]

\( function \) must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle
Object Functions

- **kfoldEdge**  Classification edge for cross-validated kernel classification model
- **kfoldLoss**  Classification loss for cross-validated kernel classification model
- **kfoldMargin**  Classification margins for cross-validated kernel classification model
- **kfoldPredict**  Classify observations in cross-validated kernel classification model

Examples

Cross-Validate Kernel Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```matlab
load ionosphere
rng('default') % For reproducibility

Cross-validate a binary kernel classification model. By default, the software uses 10-fold cross-validation.

```matlab
CVMdl = fitckernel(X,Y,'CrossVal','on')
```

```matlab
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
```

```
numel(CVMdl.Trained)
```

```matlab
ans = 10
```
CVMdl is a ClassificationPartitionedKernel model. Because fitckernel implements 10-fold cross-validation, CVMdl contains 10 ClassificationKernel models that the software trains on training-fold (in-fold) observations.

Estimate the cross-validated classification error.

```matlab
kfoldLoss(CVMdl)
ans = 0.0940
```

The classification error rate is approximately 9%.

ClassificationPartitionedKernelECOC

Cross-validated kernel error-correcting output codes (ECOC) model for multiclass classification

Description

ClassificationPartitionedKernelECOC is an error-correcting output codes (ECOC) model composed of kernel classification models, trained on cross-validated folds. Estimate the quality of the classification by cross-validation using one or more “kfold” functions: kfoldPredict, kfoldLoss, kfoldMargin, and kfoldEdge.

Every “kfold” method uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1. The software trains the first model (stored in CVMdl.Trained{1}) by using the observations in the last four groups and reserves the observations in the first group for validation.
2. The software trains the second model (stored in CVMdl.Trained{2}) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
3. The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by using kfoldPredict, the software computes predictions for the observations in group i by using the ith model. In short, the software estimates a response for every observation by using the model trained without that observation.

Note ClassificationPartitionedKernelECOC model objects do not store the predictor data set.
Creation

You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners' - Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

For more details, see fitcecoc.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name
character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'KernelECOC' specifies a cross-validated kernel ECOC model.

Data Types: char

KFold — Number of cross-validated folds
positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: double

ModelParameters — Cross-validation parameter values
object

This property is read-only.
Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the ECOC classifier. ModelParameters does not contain estimated parameters.

You can access the properties of ModelParameters using dot notation.

**NumObservations — Number of observations**

positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

**Partition — Data partition**

cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

**Trained — Compact classifiers trained on cross-validation folds**

cell array of CompactClassificationECOC models

This property is read-only.

Compact classifiers trained on cross-validation folds, specified as a cell array of CompactClassificationECOC models. Trained has \( k \) cells, where \( k \) is the number of folds.

Data Types: cell

**W — Observation weights**

numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. \( W \) has NumObservations elements.

The software normalizes the weights used for training so that \( \text{nansum}(W) = 1 \).
Data Types: single | double

Y — Observed class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y has NumObservations elements and has the same data type as the input argument Y that you pass to fitcecoc to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X.

Data Types: categorical | char | logical | single | double | cell

ECOC Properties

BinaryLoss — Binary learner loss function
'binodeviance' | 'exponential' | 'hamming' | 'hinge' | 'linear' | 'logit' | 'quadratic'

This property is read-only.

Binary learner loss function, specified as a character vector representing the loss function name.

By default, if all binary learners are kernel classification models using SVM, then BinaryLoss is 'hinge'. If all binary learners are kernel classification models using logistic regression, then BinaryLoss is 'quadratic'. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the 'BinaryLoss' name-value pair argument of kfoldPredict or kfoldLoss.

Data Types: char

BinaryY — Binary learner class labels
numeric matrix | []

This property is read-only.
Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across all folds, then `BinaryY` is a
  `NumObservations`-by-`L` matrix, where `L` is the number of binary learners
  (size(`CodingMatrix`,2)).

The elements of `BinaryY` are –1, 0, or 1, and the values correspond to dichotomous
class assignments. This table describes how learner `j` assigns observation `k` to a
dichotomous class corresponding to the value of `BinaryY(k,j)`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>–1</td>
<td>Learner <code>j</code> assigns observation <code>k</code> to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner <code>j</code> removes observation <code>k</code> from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner <code>j</code> assigns observation <code>k</code> to a positive class.</td>
</tr>
</tbody>
</table>

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: `double`

**CodingMatrix — Codes specifying class assignments**

numeric matrix | []

This property is read-only.

Codes specifying class assignments for the binary learners, specified as a numeric matrix
or [].

- If the coding matrix is the same across all folds, then `CodingMatrix` is a `K`-by-`L`
  matrix, where `K` is the number of classes and `L` is the number of binary learners.

The elements of `CodingMatrix` are –1, 0, or 1, and the values correspond to
dichotomous class assignments. This table describes how learner `j` assigns
observations in class `i` to a dichotomous class corresponding to the value of
`CodingMatrix(i,j)`.
Value | Dichotomous Class Assignment
--- | ---
-1 | Learner \( j \) assigns observations in class \( i \) to a negative class.
0 | Before training, learner \( j \) removes observations in class \( i \) from the data set.
1 | Learner \( j \) assigns observations in class \( i \) to a positive class.

- If the coding matrix varies across folds, then `CodingMatrix` is empty (`[]`). You can obtain the coding matrix for each fold by using the `Trained` property. For example, `CVMdl.Trained{1}.CodingMatrix` is the coding matrix in the first fold of the cross-validated ECOC model `CVMdl`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

**Other Classification Properties**

**CategoricalPredictors** — Categorical predictor indices

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. Because `ClassificationKernel` models can be trained on numeric predictor data only, this property is empty (`[]`).

**ClassNames** — Unique class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the observed class labels property `Y` and determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`
**Cost — Misclassification costs**
square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has K rows and columns, where K is the number of classes.

Cost(i,j) is the cost of classifying a point into class j if its true class is i. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

Data Types: double

**PredictorNames — Predictor names**
{'}x1','x2',...'}

This property is read-only.

Predictor names in order of their appearance in the predictor data X, specified as a cell array of character vectors of the form {'}x1','x2',...'}. The length of PredictorNames is equal to the number of columns in X.

Data Types: cell

**Prior — Prior class probabilities**
numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. Prior has as many elements as there are classes in ClassNames, and the order of the elements corresponds to the elements of ClassNames.

Data Types: double

**ResponseName — Response variable name**
'{Y}'

This property is read-only.

Response variable name, specified as '{Y}'. Because ClassificationKernel models cannot be trained on tabular data, this property is always '{Y}'

Data Types: char
ScoreTransform — Score transformation function
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ... 

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For a kernel classification model Mdl, and before the score transformation, the predicted classification score for the observation \( x \) (row vector) is \( f(x) = T(x)\beta + b \).

- \( T(\cdot) \) is a transformation of an observation for feature expansion.
- \( \beta \) is the estimated column vector of coefficients.
- \( b \) is the estimated scalar bias.

To change the CVMdl score transformation function to \( \text{function} \), for example, use dot notation.

- For a built-in function, enter this code and replace \( \text{function} \) with a value from the table.

\[
\text{CVMdl.ScoreTransform} = '\text{function}';
\]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'           | -1 for \( x < 0 \)  
0 for \( x = 0 \)  
1 for \( x > 0 \) |
<p>| 'symmetric'      | ( 2x - 1 )                                    |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to (-1) |</p>
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'symmetriclogit'</td>
<td>(\frac{2}{1 + e^{-x}} - 1)</td>
</tr>
</tbody>
</table>

- For a MATLAB function or a function that you define, enter its function handle.

```matlab
CVMdl.ScoreTransform = @function;
```

*function* must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

## Object Functions

- `kfoldEdge`  
  Classification edge for cross-validated kernel ECOC model
- `kfoldLoss`  
  Classification loss for cross-validated kernel ECOC model
- `kfoldMargin`  
  Classification margins for cross-validated kernel ECOC model
- `kfoldPredict`  
  Classify observations in cross-validated kernel ECOC model

## Examples

### Cross-Validate Multiclass Kernel Classification Model

Create a cross-validated, multiclass kernel ECOC classification model using `fitcecoc`.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate a multiclass kernel ECOC classification model that can identify the species of a flower based on the flower's measurements.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

`CVMdl = `  
`classreg.learning.partition.ClassificationPartitionedKernelECOC`
CrossValidatedModel: 'KernelECOC'
ResponseName: 'Y'
NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
ClassNames: {'setosa' 'versicolor' 'virginica'}
ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC cross-validated model. fitcecoc implements 10-fold cross-validation by default. Therefore, CVMdl.Trained contains a 10-by-1 cell array of ten CompactClassificationECOC models, one for each fold. Each compact ECOC model is composed of binary kernel classification models.

Estimate the classification error by passing CVMdl to kfoldLoss.

error = kfoldLoss(CVMdl)
error = 0.0333

The estimated classification error is about 3% misclassified observations.

To change default options when training ECOC models composed of kernel classification models, create a kernel classification model template using templateKernel, and then pass the template to fitcecoc.

ClassificationPartitionedLinear

**Package:** classreg.learning.partition  
**Superclasses:**

Cross-validated linear model for binary classification of high-dimensional data

**Description**

ClassificationPartitionedLinear is a set of linear classification models trained on cross-validated folds. To obtain a cross-validated, linear classification model, use fitclinear and specify one of the cross-validation options. You can estimate the quality of classification, or how well the linear classification model generalizes, using one or more of these “kfold” methods: kfoldPredict, kfoldLoss, kfoldMargin, and kfoldEdge.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1. The software trains the first model (stored in CVMdl.Trained{1}) using the observations in the last four groups and reserves the observations in the first group for validation.

2. The software trains the second model, which is stored in CVMdl.Trained{2}, using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.

3. The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling kfoldPredict, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.
**Note** ClassificationPartitionedLinear model objects do not store the predictor data set.

**Construction**

CVMdl = fitclinear(X,Y,Name,Value) creates a cross-validated, linear classification model when Name is either 'CrossVal', 'CVPartition', 'Holdout', or 'KFold'. For more details, see fitclinear.

**Properties**

**Cross-Validation Properties**

**CrossValidatedModel** — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, 'Linear' specifies a cross-validated linear model for binary classification or regression.

Data Types: char

**KFold** — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

**ModelParameters** — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. ModelParameters does not contain estimated parameters.

Access properties of ModelParameters using dot notation.

**NumObservations** — Number of observations

positive numeric scalar
Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

**Partition — Data partition**

cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

**Trained — Linear classification models trained on cross-validation folds**

cell array of ClassificationLinear model objects

Linear classification models trained on cross-validation folds, specified as a cell array of ClassificationLinear models. Trained has \( k \) cells, where \( k \) is the number of folds.

Data Types: cell

**W — Observation weights**

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. \( W \) has NumObservations elements.

The software normalizes \( W \) so that the weights for observations within a particular class sum up to the prior probability of that class.

Data Types: single | double

**Y — Observed class labels**

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. \( Y \) has NumObservations elements, and is the same data type as the input argument \( Y \) that you passed to fitclinear to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of \( Y \) represents the observed classification of the corresponding observation in the predictor data.

Data Types: categorical | char | logical | single | double | cell
Other Classification Properties

**CategoricalPredictors — Categorical predictor indices**
vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

**ClassNames — Unique class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. ClassNames has the same data type as the class labels Y. (The software treats string arrays as cell arrays of character vectors.) ClassNames also determines the class order.

Data Types: categorical | char | logical | single | double | cell

**Cost — Misclassification costs**
square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. Cost has K rows and columns, where K is the number of classes.

Cost(i,j) is the cost of classifying a point into class j if its true class is i. The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames.

Data Types: double

**PredictorNames — Predictor names**
cell array of character vectors

Predictor names in their order of appearance in predictor data used to train CVMdl, specified as a cell array of character vectors. PredictorNames has length equal to the number of predictor variables in the predictor data.

Data Types: cell
Prior — Prior class probabilities
numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. Prior has as many elements as there are classes in ClassNames, and the order of the elements corresponds to the elements of ClassNames.

fitcecoc incorporates misclassification costs differently among different types of binary learners.

Data Types: double

ResponseName — Response variable name
character vector

Response variable name, specified as a character vector.

Data Types: char

ScoreTransform — Score transformation function
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation $x$ (row vector) is $f(x) = x\beta + b$, where $\beta$ and $b$ correspond to Mdl.Beta and Mdl.Bias, respectively.

To change the score transformation function to, for example, function, use dot notation.

- For a built-in function, enter this code and replace function with a value in the table.

  ```matlab
  Mdl.ScoreTransform = 'function';
  ```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>(-1) for ( x &lt; 0 ) \ns( 0 ) for ( x = 0 ) \ns( 1 ) for ( x &gt; 0 )</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>( 2x - 1 )</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{-x}} - 1 )</td>
</tr>
</tbody>
</table>

- For a MATLAB function, or a function that you define, enter its function handle.

  ```matlab
  Mdl.ScoreTransform = @function;
  
  function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.
  ```

Data Types: char | function_handle

**Methods**

- `kfoldEdge` Classification edge for observations not used for training
- `kfoldLoss` Classification loss for observations not used in training
- `kfoldMargin` Classification margins for observations not used in training
- `kfoldPredict` Predict labels for observations not used for training

**Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

Create Cross-Validated Binary Linear Classification Model

Load the NLP data set.

```
load nlpdata
```

*X* is a sparse matrix of predictor data, and *Y* is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on')
```

```
CVMdl = 
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

*CVMdl* is a *ClassificationPartitionedLinear* cross-validated model. Because *fitclinear* implements 10-fold cross-validation by default, *CVMdl.Trained* contains ten *ClassificationLinear* models that contain the results of training linear classification models for each of the folds.
Estimate labels for out-of-fold observations and estimate the generalization error by passing CVMdl to kfoldPredict and kfoldLoss, respectively.

```matlab
oofLabels = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)
```

```matlab
g = 7.6017e-04
```

The estimated generalization error is less than 0.1% misclassified observations.

**Find Good Lasso Penalty Using Cross-Validation**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```matlab
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

```matlab
Lambda = logspace(-6,-0.5,11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```matlab
X = X';
 rng(10); % For reproducibility
 CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
```
CVMdl = classificationLinear

numCLModels = numel(CVMdl.Trained)

CVMdl is a ClassificationPartitionedLinear model. Because fitclinear
implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models
that the software trains on each fold.

Display the first trained linear classification model.

Mdl1 = CVMdl.Trained{1}

Mdl1 =

ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
  ScoreTransform: 'logit'
  Beta: [34023×11 double]
  Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.0071 0.0251 0.0891 0.3162]
  Learner: 'logistic'
Mdl1 is a ClassificationLinear model object. fitclinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

```MATLAB
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```MATLAB
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  'Learner','logistic','Solver','sparsa','Regularization','lasso',...  'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```MATLAB
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```
Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

idxFinal = 7;

Select the model from Mdl with the chosen regularization strength.

MdlFinal = selectModels(Mdl,idxFinal);

MdlFinal is a ClassificationLinear model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to predict.

ClassificationPartitionedLinearECOC

Package: classreg.learning.partition
Superclasses:

Cross-validated linear error-correcting output codes model for multiclass classification of high-dimensional data

Description

ClassificationPartitionedLinearECOC is a set of error-correcting output codes (ECOC) models composed of linear classification models, trained on cross-validated folds. Estimate the quality of classification by cross-validation using one or more “kfold” functions: kfoldPredict, kfoldLoss, kfoldMargin, and kfoldEdge.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equal-sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows.

1 The software trains the first model (stored in CVMdl.Trained{1}) using the observations in the last four groups and reserves the observations in the first group for validation.
2 The software trains the second model (stored in CVMdl.Trained{2}) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
3 The software proceeds in a similar fashion for the third, fourth, and fifth models.

If you validate by calling kfoldPredict, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note ClassificationPartitionedLinearECOC model objects do not store the predictor data set.
Construction

CVMdl = fitcecoc(X,Y,'Learners',t,Name,Value) returns a cross-validated, linear ECOC model when:

- t is 'Linear' or a template object returned by templateLinear.
- Name is one of 'CrossVal', 'CVPartition', 'Holdout', or 'KFold'.

For more details, see fitcecoc.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name
character vector

Cross-validated model name, specified as a character vector.

For example, 'ECOC' specifies a cross-validated ECOC model.

Data Types: char

KFold — Number of cross-validated folds
positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: double

ModelParameters — Cross-validation parameter values
object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the ECOC classifier, specified as an object. ModelParameters does not contain estimated parameters.

Access properties of ModelParameters using dot notation.

NumObservations — Number of observations
positive numeric scalar
Number of observations in the training data, specified as a positive numeric scalar.
Data Types: double

**Partition — Data partition**
cvpartition model

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

**Trained — Compact classifiers trained on cross-validation folds**
cell array of CompactClassificationECOC models

Compact classifiers trained on cross-validation folds, specified as a cell array of CompactClassificationECOC models. Trained has \( k \) cells, where \( k \) is the number of folds.
Data Types: cell

**W — Observation weights**
numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. \( W \) has \( \text{NumObservations} \) elements.

The software normalizes the weights used for training so that \( \text{nansum}(W) = 1 \).
Data Types: single | double

**Y — Observed class labels**
categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Observed class labels used to cross-validate the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. \( Y \) has \( \text{NumObservations} \) elements, and is the same data type as the input argument \( Y \) that you passed to \texttt{fitcecoc} to cross-validate the model. (The software treats string arrays as cell arrays of character vectors.)

Each row of \( Y \) represents the observed classification of the observation in the predictor data.
Data Types: char | cell | categorical | logical | single | double
**ECOC Properties**

**BinaryLoss — Binary learner loss function**

Character vector representing the loss function name.

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to 'hamming'. To potentially increase accuracy, set a different binary loss function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: `char`

**BinaryY — Binary learner class labels**

Numeric matrix | []

Binary learner class labels, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then `BinaryY` is a `NumObservations`-by-`L` matrix, where `L` is the number of binary learners (`size(CodingMatrix,2)`).

  Elements of `BinaryY` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner <code>j</code> assigns observation <code>k</code> to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner <code>j</code> removes observation <code>k</code> from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner <code>j</code> assigns observation <code>k</code> to a positive class.</td>
</tr>
</tbody>
</table>

- If the coding matrix varies across folds, then `BinaryY` is empty ([]).

Data Types: `double`

**CodingMatrix — Codes specifying class assignments**

Numeric matrix | []

Codes specifying class assignments for the binary learners, specified as a numeric matrix or [].

- If the coding matrix is the same across folds, then CodingMatrix is a K-by-L matrix. K is the number of classes and L is the number of binary learners.

  Elements of CodingMatrix are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes how learner j assigns observations in class i to a dichotomous class corresponding to the value of CodingMatrix(i,j).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner j assigns observations in class i to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner j removes observations in class i from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner j assigns observations in class i to a positive class.</td>
</tr>
</tbody>
</table>

- If the coding matrix varies across folds, then CodingMatrix is empty ([]). Obtain the coding matrix for each fold using the Trained property. For example, CVMdl.Trained{1}.CodingMatrix is the coding matrix in the first fold of the cross-validated ECOC model CVMdl.

Data Types: double | single | int8 | int16 | int32 | int64

Other Classification Properties

CategoricalPredictors — Categorical predictor indices

vector of positive integers | []

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors
Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

**Cost — Misclassification costs**

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has `K` rows and columns, where `K` is the number of classes.

`Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

**PredictorNames — Predictor names**

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMdl`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

**Prior — Prior class probabilities**

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as there are classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.
Data Types: double

ResponseName — Response variable name
character vector

Response variable name, specified as a character vector.
Data Types: char

ScoreTransform — Score transformation function
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For linear classification models and before transformation, the predicted classification score for the observation x (row vector) is \( f(x) = x\beta + b \), where \( \beta \) and \( b \) correspond to Mdl.Beta and Mdl.Bias, respectively.

To change the score transformation function to, for example, \( \text{function} \), use dot notation.

- For a built-in function, enter this code and replace \( \text{function} \) with a value in the table.

\[
\text{Mdl.ScoreTransform} = '\text{function}';
\]

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'           | -1 for \( x < 0 \) 
|                  | 0 for \( x = 0 \) 
|                  | 1 for \( x > 0 \)                               |
| 'symmetric'      | \( 2x - 1 \)                                    |
### Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1.</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>(2/(1 + e^{-x}) - 1)</td>
</tr>
</tbody>
</table>

- For a MATLAB function, or a function that you define, enter its function handle.

```matlab
Mdl.ScoreTransform = @function;
```

*function* must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: `char` | `function_handle`

### Methods

- `kfoldEdge` Classification edge for observations not used for training
- `kfoldLoss` Classification loss for observations not used in training
- `kfoldMargin` Classification margins for observations not used in training
- `kfoldPredict` Predict labels for observations not used for training

### Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

### Examples

**Create Cross-Validated Multiclass Linear Classification Model**

Load the NLP data set.

```matlab
load nlpdata
```

\(X\) is a sparse matrix of predictor data, and \(Y\) is a categorical vector of class labels.
Cross-validate a multiclass, linear classification model that can identify which MATLAB® toolbox a documentation web page is from based on counts of words on the page.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','linear','CrossVal','on')
```

CVMdl = classreg.learning.partition.ClassificationPartitionedLinearECOC

```
CrossValidatedModel: 'LinearECOC'
ResponseName: 'Y'
NumObservations: 31572
KFold: 10
Partition: [1x1 cvpartition]
ClassNames: [1x13 categorical]
ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a ClassificationPartitionedLinearECOC cross-validated model. Because fitcecoc implements 10-fold cross-validation by default, CVMdl.Trained contains a 10-by-1 cell vector of ten CompactClassificationECOC models that contain the results of training ECOC models composed of binary, linear classification models for each of the folds.

Estimate labels for out-of-fold observations and estimate the generalization error by passing CVMdl to kfoldPredict and kfoldLoss, respectively.

```matlab
oofLabels = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)
```

```
ge = 0.0958
```

The estimated generalization error is about 10% misclassified observations.

To improve generalization error, try specifying another solver, such as LBFGS. To change default options when training ECOC models composed of linear classification models, create a linear classification model template using templateLinear, and then pass the template to fitcecoc.
Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```matlab
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```matlab
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-7}$ through $10^{-2}$.

```matlab
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in Lambda, train using SpaRSA, and lower the tolerance on the gradient of the objective function to $1e^{-8}$.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',...
   'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```matlab
X = X';
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Dissect CVMdl, and each model within it.

```matlab
numECOCModels = numel(CVMdl.Trained)
```

numECOCModels = 5
ECOCMdl1 = CVMdl.Trained{1}

ECOCMdl1 =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6×1 cell}
    CodingMatrix: [4×6 double]

Properties, Methods

numCLModels = numel(ECOCMdl1.BinaryLearners)

numCLModels = 6

CLMdl1 = ECOCMdl1.BinaryLearners{1}

CLMdl1 =
    ClassificationLinear

    Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04 3.1623e-04 1.0000e-03 0.0032 0.0100]
    Learner: 'logistic'

Properties, Methods

Because fitcecoc implements 5-fold cross-validation, CVMdl contains a 5-by-1 cell array of CompactClassificationECOC models that the software trains on each fold. The BinaryLearners property of each CompactClassificationECOC model contains the ClassificationLinear models. The number of ClassificationLinear models within each compact ECOC model depends on the number of distinct labels and coding design. Because Lambda is a sequence of regularization strengths, you can think of CLMdl1 as 11 models, one for each regularization strength in Lambda.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.
Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.
t = templateLinear('Learner','logistic','Solver','sparsa',...  
'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);  
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');

To estimate labels for new observations, pass MdlFinal and the new data to predict.

Introduced in R2016a
ClassificationPartitionedModel

**Package:** classreg.learning.partition

Cross-validated classification model

**Description**

ClassificationPartitionedModel is a set of classification models trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: kfoldPredict, kfoldLoss, kfoldMargin, kfoldEdge, and kfoldfun.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (i.e., roughly 4/5 of the data) and the test fold contains the other group (i.e., roughly 1/5 of the data). In this case, cross validation proceeds as follows:

- The software trains the first model (stored in CVMdl.Trained{1}) using the observations in the last four groups and reserves the observations in the first group for validation.
- The software trains the second model (stored in CVMdl.Trained{2}) using the observations in the first group and last three groups, and reserves the observations in the second group for validation.
- The software proceeds in a similar fashion for the third to fifth models.

If you validate by calling kfoldPredict, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

**Construction**

CVMdl = crossval(Mdl) creates a cross-validated classification model from a classification model (Mdl).
Alternatively:
- \( \text{CVDiscrMdl} = \text{fitcdiscr}(X,Y,\text{Name},\text{Value}) \)
- \( \text{CVKNNMdl} = \text{fitcknn}(X,Y,\text{Name},\text{Value}) \)
- \( \text{CVNBMdl} = \text{fitcnb}(X,Y,\text{Name},\text{Value}) \)
- \( \text{CVSVMMdl} = \text{fitcsvm}(X,Y,\text{Name},\text{Value}) \)
- \( \text{CVTreeMdl} = \text{fitctree}(X,Y,\text{Name},\text{Value}) \)

create a cross-validated model when name is either 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see \text{fitcdiscr}, \text{fitcknn}, \text{fitcnb}, \text{fitcsvm}, and \text{fitctree}.

**Input Arguments**

\text{Mdl}

A classification model. \text{Mdl} can be any of the following:
- A classification tree trained using \text{fitctree}
- A discriminant analysis classifier trained using \text{fitcdiscr}
- A naive Bayes classifier trained using \text{fitcnb}
- A nearest-neighbor classifier trained using \text{fitcknn}
- A support vector machine classifier trained using \text{fitcsvm}

**Properties**

\text{CategoricalPredictors}

Categorical predictor indices, specified as a vector of positive integers. \text{CategoricalPredictors} contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([ ]).

If \text{Mdl} is a trained discriminant analysis classifier, then \text{CategoricalPredictors} is always empty ([ ]).
ClassNames

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Cost

Square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \) (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response.

If CVModel is a cross-validated ClassificationDiscriminant, ClassificationKNN, or ClassificationNaiveBayes model, then you can change its cost matrix to e.g., CostMatrix, using dot notation.

CVModel.Cost = CostMatrix;

CrossValidatedModel

Name of the cross-validated model, which is a character vector.

KFold

Number of folds used in cross-validated model, which is a positive integer.

ModelParameters

Object holding parameters of CVModel.

Partition

The partition of class CVPartition used in creating the cross-validated model.

PredictorNames

Predictor variable names, specified as a cell array of character vectors. The order of the elements of PredictorNames corresponds to the order in which the predictor names appear in the training data.
**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of Prior corresponds to the order of the classes in ClassNames.

If CVModel is a cross-validated ClassificationDiscriminant or ClassificationNaiveBayes model, then you can change its vector of priors to e.g., priorVector, using dot notation.

CVModel.Prior = priorVector;

**ResponseName**

Response variable name, specified as a character vector.

**ScoreTransform**

Score transformation, specified as a character vector or function handle. ScoreTransform represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to function, for example, use dot notation.

- For a built-in function, enter a character vector:
  
  Mdl.ScoreTransform = 'function';

This table describes the available built-in functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$\frac{1}{1 + e^{-2x}}$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log\left(\frac{x}{(1-x)}\right)$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$\frac{1}{1 + e^{x}}$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'       | -1 for $x < 0$
              | 0 for $x = 0$
<pre><code>          | 1 for $x &gt; 0$ |
</code></pre>
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'symmetric'</td>
<td>$2x - 1$</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>$\frac{2}{1 + e^{-x}} - 1$</td>
</tr>
</tbody>
</table>

- For a MATLAB function or a function that you define, enter its function handle.

  ```matlab
  Mdl.ScoreTransform = @function;
  
  function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).
  ```

**Trained**

The trained learners, which is a cell array of compact classification models.

**W**

The scaled weights, which is a vector with length $n$, the number of rows in $X$.

**X**

Numeric matrix of predictor values. Each column of $X$ represents one variable, and each row represents one observation.

**Y**

Categorical or character array, logical or numeric vector, or cell array of character vectors specifying the class labels for each observation. $Y$ has the same number of rows as $X$, and each entry of $Y$ is the response to the data in the corresponding row of $X$. 
Methods

kfoldEdge Classification edge for observations not used for training
kfoldfun Cross validate function
kfoldLoss Classification loss for observations not used for training
kfoldMargin Classification margins for observations not used for training
kfoldPredict Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Evaluate the Classification Error of a Classification Tree Classifier

Evaluate the k-fold cross-validation error for a classification tree model.

Load Fisher's iris data set.

load fisheriris

Train a classification tree using default options.

Mdl = fitctree(meas,species);

Cross validate the classification tree model.

CVMdl = crossval(Mdl);

Estimate the 10-fold cross-validation loss.

L = kfoldLoss(CVMdl)

L = 0.0533
Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```matlab
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```matlab
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```matlab
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans=10×2 table
    ObservationIndex    PosteriorProbability
        ________    _________________
          6               0.17378
          7               0.89637
          8               0.0076609
```

---

32-525
Tips

To estimate posterior probabilities of trained, cross-validated SVM classifiers, use `fitSVMPosterior`.

ClassificationSVM

Support vector machine (SVM) for one-class and binary classification

Description

ClassificationSVM is a support vector machine (SVM) classifier on page 32-548 for one-class and two-class learning. Trained ClassificationSVM classifiers store training data, parameter values, prior probabilities, support vectors, and algorithmic implementation information. Use these classifiers to perform tasks such as fitting a score-to-posterior-probability transformation function (see fitPosterior) and predicting labels for new data (see predict).

Creation

Create a ClassificationSVM object by using fitcsvm.

Properties

SVM Properties

Alpha — Trained classifier coefficients

| numeric vector |

This property is read-only.

Trained classifier coefficients, specified as an s-by-1 numeric vector. \( s \) is the number of support vectors in the trained classifier, \( \text{sum(Mdl.IsSupportVector)} \).

Alpha contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, Alpha contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one
observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: single | double

**Beta — Linear predictor coefficients**

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of Beta is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Beta stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then Beta is a numeric vector containing five values.

If KernelParameters.Function is 'linear', then the classification score for the observation \( x \) is

\[
f(x) = \frac{x}{s} \beta + b.
\]

Mdl stores \( \beta \), \( b \), and \( s \) in the properties Beta, Bias, and KernelParameters.Scale, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize',true when using fitcsvm, then you must standardize the predictor data manually by using the mean Mdl.Mu and standard deviation Mdl.Sigma, and then divide the result by the kernel scale in Mdl.KernelParameters.Scale.

All SVM functions, such as resubPredict and predict, apply any required transformation before estimation.

If KernelParameters.Function is not 'linear', then Beta is empty ([]).

Data Types: single | double

**Bias — Bias term**

scalar
This property is read-only.

Bias term, specified as a scalar.

Data Types: single | double

**BoxConstraints — Box constraints**

numeric vector

This property is read-only.

Box constraints, specified as a numeric vector of \( n \)-by-1 box constraints on page 32-546. \( n \) is the number of observations in the training data (see the `NumObservations` property).

If you remove duplicates by using the `RemoveDuplicates` name-value pair argument of `fitcsvm`, then for a given set of duplicate observations, MATLAB sums the box constraints and then attributes the sum to one observation. MATLAB attributes the box constraints of 0 to all other observations in the set.

Data Types: single | double

**CacheInfo — Caching information**

structure array

This property is read-only.

Caching information, specified as a structure array. The caching information contains the fields described in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>The cache size (in MB) that the software reserves to train the SVM classifier. For details, see 'CacheSize'.</td>
</tr>
<tr>
<td>Algorithm</td>
<td>The caching algorithm that the software uses during optimization. Currently, the only available caching algorithm is Queue. You cannot set the caching algorithm.</td>
</tr>
</tbody>
</table>

Display the fields of `CacheInfo` by using dot notation. For example, `Mdl.CacheInfo.Size` displays the value of the cache size.

Data Types: struct
**IsSupportVector — Support vector indicator**

logical vector

This property is read-only.

Support vector indicator, specified as an \( n \)-by-1 logical vector that flags whether a corresponding observation in the predictor data matrix is a “Support Vector” on page 32-548. \( n \) is the number of observations in the training data (see NumObservations).

If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, IsSupportVector flags only one observation as a support vector.

Data Types: logical

**KernelParameters — Kernel parameters**

structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

<table>
<thead>
<tr>
<th><strong>Field</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>Kernel function used to compute the elements of the Gram matrix on page 32-2000. For details, see 'KernelFunction'.</td>
</tr>
<tr>
<td>Scale</td>
<td>Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'.</td>
</tr>
</tbody>
</table>

To display the values of KernelParameters, use dot notation. For example, Mdl.KernelParameters.Scale displays the kernel scale parameter value.

The software accepts KernelParameters as inputs and does not modify them.

Data Types: struct

**Nu — One-class learning parameter**

positive scalar

This property is read-only.

One-class learning on page 32-547 parameter \( \nu \), specified as a positive scalar.
Data Types: `single` | `double`

**OutlierFraction — Proportion of outliers**

numeric scalar

This property is read-only.

Proportion of outliers in the training data, specified as a numeric scalar.

Data Types: `double`

**Solver — Optimization routine**

'ISDA' | 'L1QP' | 'SMO'

This property is read-only.

Optimization routine used to train the SVM classifier, specified as 'ISDA', 'L1QP', or 'SMO'. For more details, see 'Solver'.

**SupportVectorLabels — Support vector class labels**

s-by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an s-by-1 numeric vector. s is the number of support vectors in the trained classifier, `sum(Mdl.IsSupportVector)`.

A value of `+1` in `SupportVectorLabels` indicates that the corresponding support vector is in the positive class (`ClassNames{2}`). A value of `–1` indicates that the corresponding support vector is in the negative class (`ClassNames{1}`).

If you remove duplicates by using the RemoveDuplicates name-value pair argument of `fitcsvm`, then for a given set of duplicate observations that are support vectors, `SupportVectorLabels` contains one unique support vector label.

Data Types: `single` | `double`

**SupportVectors — Support vectors**

s-by-p numeric matrix

This property is read-only.
Support vectors in the trained classifier, specified as an $s$-by-$p$ numeric matrix. $s$ is the number of support vectors in the trained classifier, $\text{sum} \left( \text{Mdl.IsSupportVector} \right)$, and $p$ is the number of predictor variables in the predictor data.

$\text{SupportVectors}$ contains rows of the predictor data $X$ that MATLAB considers to be support vectors. If you specify 'Standardize',true when training the SVM classifier using $\text{fitcsvm}$, then $\text{SupportVectors}$ contains the standardized rows of $X$.

If you remove duplicates by using the $\text{RemoveDuplicates}$ name-value pair argument of $\text{fitcsvm}$, then for a given set of duplicate observations that are support vectors, $\text{SupportVectors}$ contains one unique support vector.

Data Types: single | double

Other Classification Properties

$\text{CategoricalPredictors} — \text{Categorical predictor indices}$
vector of positive integers | []

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. $\text{CategoricalPredictors}$ contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

$\text{ClassNames} — \text{Unique class labels}$
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Data Types: single | double | logical | char | cell | categorical

$\text{Cost} — \text{Misclassification cost}$
numeric square matrix

This property is read-only.
Misclassification cost, specified as a numeric square matrix, where \( \text{Cost}(i, j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \).

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, \( \text{Cost} \) always has this form: \( \text{Cost}(i, j) = 1 \) if \( i \neq j \), and \( \text{Cost}(i, j) = 0 \) if \( i = j \). The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of \( \text{Cost} \) corresponds to the order of the classes in \text{ClassNames}.
- For one-class learning, \( \text{Cost} = 0 \).

For more details, see Algorithms on page 32-550.

Data Types: double

**ExpandedPredictorNames — Expanded predictor names**

cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors. If the model uses dummy variable encoding for categorical variables, then 
\text{ExpandedPredictorNames} \ includes the names that describe the expanded variables. Otherwise, \text{ExpandedPredictorNames} \ is the same as \text{PredictorNames}.

Data Types: cell

**Gradient — Training data gradient values**

numeric vector

This property is read-only.

Training data gradient values, specified as a numeric vector. The length of \text{Gradient} is equal to the number of observations (see \text{NumObservations}).

Data Types: single | double

**ModelParameters — Parameters used to train model**

structure array

This property is read-only.
Parameters used to train the ClassificationSVM model, specified as a structure array. ModelParameters contains parameter values such as the name-value pair argument values used to train the SVM classifier. ModelParameters does not contain estimated parameters.

Access the fields of ModelParameters by using dot notation. For example, access the initial values for estimating Alpha by using Mdl.ModelParameters.Alpha.

Data Types: struct

Mu — Predictor means
numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify 'Standardize',1 or 'Standardize',true when you train an SVM classifier using fitcsvm, then the length of Mu is equal to the number of predictors.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Mu stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize',false when you train the SVM classifier using fitcsvm, then Mu is an empty vector ([]).

Data Types: single | double

NumObservations — Number of observations
numeric scalar

This property is read-only.

Number of observations in the training data stored in X and Y, specified as a numeric scalar.

Data Types: single | double

PredictorNames — Predictor variable names
cell array of character vectors

This property is read-only.
Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

**Prior — Prior probabilities**

numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of `Prior` corresponds to the elements of `Mdl.ClassNames`.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-550.

Data Types: `single` | `double`

**ResponseName — Response variable name**

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

**RowsUsed — Rows used in fitting**

`[]` | logical vector

This property is read-only.

Rows of the original data X used in fitting the `ClassificationSVM` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

**ScoreTransform — Score transformation**

character vector | function handle
Score transformation, specified as a character vector or function handle. ScoreTransform represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to function, for example, use dot notation.

- For a built-in function, enter a character vector.

\[
\text{Mdl.ScoreTransform} = 'function';
\]

This table describes the available built-in functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log\left(\frac{x}{1-x}\right) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'           | \(-1\) for \( x < 0 \)  \\
|                  | \( 0 \) for \( x = 0 \)  \\
|                  | \( 1 \) for \( x > 0 \)                                                  |
| 'symmetric'      | \( 2x - 1 \)                                                                |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to \(-1\) |
| 'symmetriclogit' | \( \frac{2}{1 + e^{-x}} - 1 \)                                              |

- For a MATLAB function or a function that you define, enter its function handle.

\[
\text{Mdl.ScoreTransform} = @function;
\]

\( function \) should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

\textbf{Sigma — Predictor standard deviations}
[] (default) | numeric vector
This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If you specify 'Standardize',true when you train the SVM classifier using fitcsvm, then the length of Sigma is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Sigma stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize',false when you train the SVM classifier using fitcsvm, then Sigma is an empty vector ([]).

Data Types: single | double

W — Observation weights
ones(n,1) (default) | numeric vector

This property is read-only.

Observation weights used to train the SVM classifier, specified as an n-by-1 numeric vector. n is the number of observations (see NumObservations).

fitcsvm normalizes the observation weights specified in the 'Weights' name-value pair argument so that the elements of W within a particular class sum up to the prior probability of that class.

Data Types: single | double

X — Unstandardized predictors
numeric matrix | table

This property is read-only.

Unstandardized predictors used to train the SVM classifier, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

MATLAB excludes observations containing at least one missing value, and removes corresponding elements from Y.
Data Types: single | double

Y — Class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Class labels used to train the SVM classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y is the same data type as the input argument Y of `fitcsvm`. (The software treats string arrays as cell arrays of character vectors.)

Each row of Y represents the observed classification of the corresponding row of X.

MATLAB excludes elements containing missing values, and removes corresponding observations from X.

Data Types: single | double | logical | char | cell | categorical

Convergence Control Properties

ConvergenceInfo — Convergence information
structure array

This property is read-only.

Convergence information, specified as a structure array.

Data Types: struct

**NumIterations — Number of iterations**

positive integer

This property is read-only.

Number of iterations required by the optimization routine to attain convergence, specified as a positive integer.

To set the limit on the number of iterations to 1000, for example, specify '`IterationLimit',1000` when you train the SVM classifier using `fitcsvm`.

Data Types: double

**ShrinkagePeriod — Number of iterations between reductions of active set**

nonnegative integer
This property is read-only.

Number of iterations between reductions of the active set, specified as a nonnegative integer.

To set the shrinkage period to 1000, for example, specify 'ShrinkagePeriod',1000 when you train the SVM classifier using fitcsvm.

Data Types: single | double

**Hyperparameter Optimization Properties**

**HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters**

BayesianOptimization object | table

This property is read-only.

Description of the cross-validation optimization of hyperparameters, specified as a BayesianOptimization object or a table of hyperparameters and associated values. This property is nonempty when the 'OptimizeHyperparameters' name-value pair argument of fitcsvm is nonempty at creation. The value of HyperparameterOptimizationResults depends on the setting of the Optimizer field in the HyperparameterOptimizationOptions structure of fitcsvm at creation, as described in this table.

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```matlab
SVMMModel = fitcsvm(X,y)
```

SVMMModel =
    ClassificationSVM
          ResponseName: 'Y'
CategoricalPredictors: []
    ClassNames: {'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 100
        Alpha: [24x1 double]
        Bias: -14.4149
    KernelParameters: [1x1 struct]
        BoxConstraints: [100x1 double]
        ConvergenceInfo: [1x1 struct]
        IsSupportVector: [100x1 logical]
        Solver: 'SMO'

Properties, Methods

SVMModel is a trained ClassificationSVM classifier. Display the properties of SVMModel. For example, to determine the class order, use dot notation.

classOrder = SVMModel.ClassNames

classOrder = 2x1 cell array
    {'versicolor'}
    {'virginica'}

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

sv = SVMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

**Train and Cross-Validate SVM Classifier**

Load the ionosphere data set.

```
load ionosphere
```
Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```matlab
rng(1);  % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')
```

CVSVMModel =  
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'

**Properties, Methods**

**CVSVMModel** is a ClassificationPartitionedModel cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained ClassificationSVM classifier by passing it to crossval.

Inspect one of the trained folds using dot notation.

```matlab
CVSVMModel.Trained{1}
```

ans =  
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    Alpha: [78x1 double]
    Bias: -0.2209
    KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]
Properties, Methods

Each fold is a `CompactClassificationSVM` classifier trained on 90% of the data. Estimate the generalization error.

```matlab
genError = kfoldLoss(CVSVMModel)
genError = 0.1168
```

On average, the generalization error is approximately 12%.

Definitions

**Box Constraint**

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

**Gram Matrix**

The Gram matrix of a set of $n$ vectors \( \{x_1, \ldots, x_n; x_j \in \mathbb{R}^p \} \) is an $n$-by-$n$ matrix with element $(j,k)$ defined as \( G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle \), an inner product of the transformed predictors using the kernel function $\phi$.

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data $X$. The dual formalization replaces the inner product of the observations in $X$ with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.
Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

\[
\begin{align*}
\alpha_j \left[ y_j f(x_j) - 1 + \xi_j \right] &= 0 \\
\xi_j (C - \alpha_j) &= 0
\end{align*}
\]

for all \( j = 1, \ldots, n \), where \( f(x_j) = \phi(x_j)' \beta + b \), \( \phi \) is a kernel function (see Gram matrix on page 32-2000), and \( \xi_j \) is a slack variable. If the classes are perfectly separable, then \( \xi_j = 0 \) for all \( j = 1, \ldots, n \).

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-2002. The objective is to minimize the dual expression

\[
0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)
\]

with respect to \( \alpha_1, \ldots, \alpha_n \), subject to

\[
\sum \alpha_j = n \nu
\]

and \( 0 \leq \alpha_j \leq 1 \) for all \( j = 1, \ldots, n \). The value of \( G(x_j, x_k) \) is in element \((j,k)\) of the Gram matrix on page 32-2000.

A small value of \( \nu \) leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of \( \nu \) leads to more support vectors and, therefore, a curvy, flexible
decision boundary. The optimal value of $\nu$ should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see [5].

**Support Vector**

Support vectors are observations corresponding to strictly positive estimates of $a_1, ..., a_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

**Support Vector Machines for Binary Classification**

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x^\prime \beta + b,$$

where:

- $x$ is an observation (corresponding to a row of $X$).
- The vector $\beta$ contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to $\text{Mdl.Beta}$). For separable data, the optimal margin length is $\frac{2}{\|\beta\|}$.
- $b$ is the bias term (corresponding to $\text{Mdl.Bias}$).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point $z$ to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate.
For separable classes, the objective is to minimize $\|\beta\|$ with respect to the $\beta$ and $b$ subject to $y_j f(x_j) \geq 1$, for all $j = 1,...,n$. This is the primal formalization for separable classes.

For inseparable classes, the algorithm uses slack variables ($\xi_j$) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C \sum \xi_j$ with respect to the $\beta$, $b$, and $\xi_j$ subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1,...,n$, and for a positive scalar box constraint on page 32-2000 $C$. This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces $n$ coefficients $\alpha_1,..,\alpha_n$ (corresponding to Model.Alpha). The dual formalizations for linear SVM are as follows:

- **For separable classes**, minimize
  
  $$0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k x_j^t x_k - \sum_{j=1}^{n} \alpha_j$$

  with respect to $\alpha_1,..,\alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1,...,n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2001.

- **For inseparable classes**, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1,...,n$.

The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^{n} \hat{\alpha}_j y_j x^t x_j + \hat{b}.$$ 

$\hat{b}$ is the estimate of the bias and $\hat{\alpha}_j$ is the $j$th estimate of the vector $\hat{\alpha}$, $j = 1,...,n$. Written this way, the score function is free of the estimate of $\beta$ as a result of the primal formalization.
The SVM algorithm classifies a new observation $z$ using $\text{sign} \left( \hat{f}(z) \right)$.

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^{n} \alpha_j$$

with respect to $\alpha_1, ..., \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, ..., n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the Gram matrix on page 32-2000.

The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^{n} \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-183, [1], and [3].

**Algorithms**

- For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-2002 and “Understanding Support Vector Machines” on page 18-183.
- `NaN`, `<undefined>`, empty character vector (''), empty string ('"'), and `<missing>` values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitcsvm` removes observations that have zero weight or prior probability.
For two-class learning, if you specify the cost matrix $C$ (see Cost), then the software updates the class prior probabilities $p$ (see Prior) to $p_c$ by incorporating the penalties described in $C$.

Specifically, `fitcsvm` completes these steps:

1. Compute $p_c^* = p^C$.
2. Normalize $p_c^*$ so that the updated prior probabilities sum to 1.

$$p_c = \frac{1}{K} \frac{p_c^*}{\sum_{j=1}^{K} p_{c,j}^*}$$

$K$ is the number of classes.
3. Reset the cost matrix to the default

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$ 
4. Remove observations from the training data corresponding to classes with zero prior probability.

For two-class learning, `fitcsvm` normalizes all observation weights (see Weights) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation $j$ in class $k$ is

$$w_j^* = \sum_{\forall j \in \text{Class } k} w_j p_{c,k}.$$ 

$w_j$ is the normalized weight for observation $j$; $p_{c,k}$ is the updated prior probability of class $k$ (see previous bullet).

For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation $j$ is

$$C_j = nC_0 w_j^*.$$
n is the training sample size, \( C_0 \) is the initial box constraint (see the

'SBoxConstraint' name-value pair argument), and \( w_j^* \) is the total weight of
observation \( j \) (see previous bullet).

- If you set 'Standardize',true and the 'Cost', 'Prior', or 'Weights' name-
value pair argument, then fitcsvm standardizes the predictors using their
 corresponding weighted means and weighted standard deviations. That is, fitcsvm
 standardizes predictor \( j \) (\( x_j \)) using

\[
x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.
\]

\[
\mu_j^* = \frac{1}{\sum \limits_k w_k^*} \sum \limits_k w_k^* x_{jk}.
\]

\( x_{jk} \) is observation \( k \) (row) of predictor \( j \) (column).

\[
(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum \limits_k w_k^* (x_{jk} - \mu_j^*)^2.
\]

\[
v_1 = \sum \limits_j w_j^*.
\]

\[
v_2 = \sum (w_j^*)^2.
\]

- Assume that \( p \) is the proportion of outliers that you expect in the training data, and
 that you set 'OutlierFraction',\( p \).

  - For one-class learning, the software trains the bias term such that 100\( p \)% of the
 observations in the training data have negative scores.
  - The software implements robust learning for two-class learning. In other words,
 the software attempts to remove 100\( p \)% of the observations when the optimization
 algorithm converges. The removed observations correspond to gradients that are
 large in magnitude.
• If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.

• The PredictorNames property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then PredictorNames is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.

• The ExpandedPredictorNames property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then ExpandedPredictorNames is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

• Similarly, the Beta property stores one beta coefficient for each predictor, including the dummy variables.

• The SupportVectors property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are $m$ support vectors and three predictors, one of which is a categorical variable with three levels. Then SupportVectors is an $n$-by-5 matrix.

• The X property stores the training data as originally input and does not include the dummy variables. When the input is a table, X contains only the columns used as predictors.

• For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.

• For a variable with $k$ ordered levels, the software creates $k - 1$ dummy variables. The $j$th dummy variable is -1 for levels up to $j$, and +1 for levels $j + 1$ through $k$.

• The names of the dummy variables stored in the ExpandedPredictorNames property indicate the first level with the value +1. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., $k$.

• All solvers implement $L1$ soft-margin minimization.

• For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, ..., \alpha_n$, such that
\[
\sum_{j=1}^{n} \alpha_j = n\nu.
\]

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train an SVM model by using fitcsvm, the following restrictions apply.
  - The class labels input argument value \( (Y) \) cannot be a categorical array.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
• The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
• The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function. For generating code that predicts posterior probabilities given new observations, pass a trained SVM model to fitPosterior or fitSVMPosterior. The ScoreTransform property of the returned model contains an anonymous function that represents the score-to-posterior-probability function and is configured for code generation.

For more information, see “Introduction to Code Generation” on page 31-2.

**Introduced in R2014a**
ClassificationSVMCoderConfigurer

Coder configurer for support vector machine (SVM) classification model

Description

A ClassificationSVMCoderConfigurer object is a coder configurer of an SVM classification model (ClassificationSVM and CompactClassificationSVM).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

• Configure code generation options and specify the coder attributes of SVM model parameters using object properties.
• Generate C/C++ code for the predict and update functions of the SVM classification model by using generateCode. Generating C/C++ code requires MATLAB Coder.
• Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use validatedUpdateInputs to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of an SVM classification model, see the Code Generation sections of CompactClassificationSVM, predict, and update.
Creation

After training an SVM classification model by using fitcsvm, create a coder configurer for the model by using learnerCoderConfigurer.

Properties

Code Generation Options

X — Coder attributes of predictor data
LearnerCoderInput object

Coder attributes of predictor data to pass to the generated C/C++ code for the predict function of the SVM classification model, specified as a LearnerCoderInput object.

A LearnerCoderInput object includes the following attributes:

- **SizeVector**
  - Array size of the predictor data if the corresponding VariableDimensions value is false.
  - Upper bound of the array size if the corresponding VariableDimensions value is true.
- **VariableDimensions** — Indicator specifying whether each dimension of the predictor data has a variable size or fixed size. A value of `true` (logical 1) means that the corresponding dimension has a variable size; a value of `false` (logical 0) means that the corresponding dimension has a fixed size. The default value is `false` (logical 0) for all dimensions.
- **DataType** — Data type of the predictor data.
- **Tunability** — Always `true`, meaning that the generated C/C++ code accepts predictor data that satisfies the other three attributes.

When you create the coder configurer `configurer` by using the `learnerCoderConfigurer` function, the input argument `X` of the function specifies the `SizeVector` and `DataType` attributes. You can modify these two attributes and specify the `VariableDimensions` attribute by using dot notation.
For example, if you want to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, then specify the coder attributes of \( X \) as follows:

```matlab
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

\([0 \ 0]\) indicates that the first and second dimensions of \( X \) (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify the coder attributes of \( X \) as follows:

```matlab
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

\([1 \ 0]\) indicates that the first dimension of \( X \) (number of observations) has a variable size and the second dimension of \( X \) (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as Inf.

**NumOutputs — Number of outputs in predict**

1 (default) | 2

Number of output arguments to return from the generated C/C++ code for the `predict` function of the SVM classification model, specified as 1 or 2.

- 1 — `predict` returns predicted class labels in the generated C/C++ code.
- 2 — `predict` returns predicted class labels and scores (or posterior probabilities) in the generated C/C++ code.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```matlab
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `-nargout` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of an SVM classification model, respectively—and generates C/C++ code for the two entry-point

32-558
functions. The specified value for the NumOutputs property corresponds to the number of output arguments in the entry-point function predict.m.

Data Types: double

**OutputFileName — File name of generated C/C++ code**

'ClassificationSVMModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function generateCode of the coder configurer configurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating configurer, you can specify the file name by using dot notation.

```matlab
configurer.OutputFileName = 'myModel';
```

Data Types: char

**Verbose — Verbosity level**

true (logical 1) (default) | false (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>true</code> (logical 1)</td>
<td>The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.</td>
</tr>
<tr>
<td><code>false</code> (logical 0)</td>
<td>The software does not display notification messages.</td>
</tr>
</tbody>
</table>

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using the coder configurer configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The
verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating `configurer`, you can modify the verbosity level by using dot notation.

```csharp
configurer.Verbose = false;
```

Data Types: logical

### Properties for Coder Attributes of SVM Classification Model Parameters

The properties listed in this section specify the coder attributes of the SVM classification model parameters that you can update. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` object to specify the coder attributes of each parameter.

**LearnerCoderInput object** To generate C/C++ code that allows updating the parameters of a machine learning model, you must specify the coder attributes of each parameter. A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of the model parameters and their array values.

A `LearnerCoderInput` object has the attributes described in this table.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
</table>
| SizeVector    | • Array size if the corresponding `VariableDimensions` value is false.  
                • Upper bound of the array size if the corresponding `VariableDimensions` value is true.  
                To allow an unbounded array, specify the bound as `Inf`. | Array size of the corresponding model parameter |
<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VariableDimensions</td>
<td>Indicator specifying whether each dimension of the array has a variable size or fixed size. A value of true (logical 1) means that the corresponding dimension has a variable size; a value of false (logical 0) means that the corresponding dimension has a fixed size.</td>
<td>false (logical 0) for all dimensions, indicating a fixed size</td>
</tr>
<tr>
<td>DataType</td>
<td>Data type of the array</td>
<td>Data type of the corresponding model parameter</td>
</tr>
<tr>
<td>Tunability</td>
<td>Indicator specifying whether or not update in the generated C/C++ code allows the array values to be updated</td>
<td>Determined depending on the model parameter</td>
</tr>
</tbody>
</table>

You can modify the coder attributes by using dot notation. For example, after creating the coder configurer `configurer`, specify the coder attributes of the coefficients `Alpha`.

```matlab
compiler.Alpha.SizeVector = [100 1];
compiler.Alpha.VariableDimensions = [1 0];
compiler.Alpha.DataType = 'double';
compiler.Alpha.Tunability = 1;
```

If you specify the verbosity level (Verbose) as true (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

**Alpha — Coder attributes of trained classifier coefficients**

*LearnerCoderInput object*

Coder attributes of the trained classifier coefficients (Alpha of an SVM classification model), specified as a `LearnerCoderInput` object.

If you train an SVM model with a linear kernel function and discard support vectors by using `discardSupportVectors`, the Tunability value of the LearnerCoderInput object must be false for Alpha. Otherwise, the Tunability value must be true.
Beta — Coder attributes of linear predictor coefficients
LearnerCoderInput object

Coder attributes of the linear predictor coefficients (Beta of an SVM classification model), specified as a LearnerCoderInput object.

If you train an SVM model with a linear kernel function and discard support vectors by using discardSupportVectors, the Tunability value of the LearnerCoderInput object must be true for Beta. Otherwise, the Tunability value must be false.

Bias — Coder attributes of bias term
LearnerCoderInput object

Coder attributes of the bias term (Bias of an SVM classification model), specified as a LearnerCoderInput object.

The Tunability value of the LearnerCoderInput object must be true for Bias.

Cost — Coder attributes of misclassification cost
LearnerCoderInput object

Coder attributes of the misclassification cost (Cost of an SVM classification model), specified as a LearnerCoderInput object.

For two-class (binary) classification, the default Tunability value of the LearnerCoderInput object is true for Cost. The Tunability value must be false for one-class classification.

Mu — Coder attributes of predictor means
LearnerCoderInput object

Coder attributes of the predictor means (Mu of an SVM classification model), specified as a LearnerCoderInput object.

If you train an SVM model using standardized predictor data by specifying 'Standardize',true, the default Tunability value of the LearnerCoderInput object is true for Mu. Otherwise, the default value is false.

Prior — Coder attributes of prior probabilities
LearnerCoderInput object

Coder attributes of the prior probabilities (Prior of an SVM classification model), specified as a LearnerCoderInput object.
For two-class (binary) classification, the default Tunability value of the LearnerCoderInput object is true for Prior. The Tunability value must be false for one-class classification.

**Scale — Coder attributes of kernel scale parameter**
LearnerCoderInput object

Coder attributes of the kernel scale parameter (KernelParameters.Scale of an SVM classification model), specified as a LearnerCoderInput object.

The default Tunability value of the LearnerCoderInput object is true for Scale.

**Sigma — Coder attributes of predictor standard deviations**
LearnerCoderInput object

Coder attributes of the predictor standard deviations (Sigma of an SVM classification model), specified as a LearnerCoderInput object.

If you train an SVM model using standardized predictor data by specifying 'Standardize',true, the default Tunability value of the LearnerCoderInput object is true for Sigma. Otherwise, the default value is false.

**SupportVectorLabels — Coder attributes of support vector class labels**
LearnerCoderInput object

Coder attributes of the support vector class labels (SupportVectorLabels of an SVM classification model), specified as a LearnerCoderInput object.

If you train an SVM model with a linear kernel function and discard support vectors by using discardSupportVectors, the Tunability value of the LearnerCoderInput object must be false for SupportVectorLabels. Otherwise, the Tunability value must be true.

**SupportVectors — Coder attributes of support vectors**
LearnerCoderInput object

Coder attributes of the support vectors (SupportVectors of an SVM classification model), specified as a LearnerCoderInput object.

If you train an SVM model with a linear kernel function and discard support vectors by using discardSupportVectors, the Tunability value of the LearnerCoderInput object must be false for SupportVectors. Otherwise, the Tunability value must be true.
**Customization of Code Generation**

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

**CodeGenerationArguments — codegen arguments**

cell array

This property is read-only.

codegen arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```matlab
generateFiles(configurer) cgArgs = configurer.CodeGenerationArguments; codegen(cgArgs)
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

**PredictInputs — Input argument of predict**

cell array of a `coder.PrimitiveType` object

This property is read-only.
Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of predictor data stored in the `X` property.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

If you modify the coder attributes of predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

Data Types: `cell`

**UpdateInputs — List of tunable input arguments of update**

Cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

If you modify the coder attributes of a model parameter by using the coder configurer properties (“Properties for Coder Attributes of SVM Classification Model Parameters” on page 32-560), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

Data Types: `cell`

**Object Functions**

- `generateCode` Generate C/C++ code using coder configurer
- `generateFiles` Generate MATLAB files for code generation using coder configurer
- `validatedUpdateInputs` Validate and extract machine learning model parameters to update
Examples

Generate Code Using Coder Configurer

Train a machine learning model and then generate code for the predict and update functions of the model by using a coder configurer.

Load the ionosphere data set and train a binary support vector machine (SVM) classification model.

load ionosphere
Mdl = fitcsvm(X,Y);

Mdl is a ClassificationSVM object.

Create a coder configurer for the ClassificationSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

configurer = learnerCoderConfigurer(Mdl,X)

configurer =
ClassificationSVMCoderConfigurer with properties:

Update Inputs:
   Alpha: [1x1 LearnerCoderInput]
   SupportVectors: [1x1 LearnerCoderInput]
   SupportVectorLabels: [1x1 LearnerCoderInput]
   Scale: [1x1 LearnerCoderInput]
   Bias: [1x1 LearnerCoderInput]
   Prior: [1x1 LearnerCoderInput]
   Cost: [1x1 LearnerCoderInput]

Predict Inputs:
   X: [1x1 LearnerCoderInput]

Code Generation Parameters:
   NumOutputs: 1
   OutputFileName: 'ClassificationSVMModel'
Properties, Methods

`configure` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the `ClassificationSVM` model with default settings.

```matlab
generateCode(configurer)
```

These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates these files for code generation.

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of the `ClassificationSVM` model (Mdl), respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions and the code for the MEX function in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files.

```matlab
type predict.m % Display contents of predict.m

function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:15:40
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```matlab
type update.m % Display contents of update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:15:40
initialize('update',varargin{:});
end
```

```matlab
type initialize.m % Display contents of initialize.m
```

32-567
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:15:40
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('ClassificationSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       SupportVectorLabels
        %                       Scale
        %                       Bias
        %                       Prior
        %                       Cost

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end

**Update Model Parameters in Generated Code**

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model
using the whole data set and update parameters in the generated code without
regenerating the code.

**Train Model**

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses
for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model
using the first 50 observations.

```matlab
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

Mdl is a ClassificationSVM object.

**Create Coder Configurer**

Create a coder configurer for the ClassificationSVM model by using
learnerCoderConfigurer. Specify the predictor data X. The
learnerCoderConfigurer function uses the input X to configure the coder attributes of
the predict function input. Also, set the number of outputs to 2 so that the generated
code returns predicted labels and scores.

```matlab
configurer = learnerCoderConfigurer(Mdl,X(1:50,:), 'NumOutputs',2);
```

configurer is a ClassificationSVMCoderConfigurer object, which is a coder
configurer of a ClassificationSVM object.

**Specify Coder Attributes of Parameters**

Specify the coder attributes of the SVM classification model parameters so that you can
update the parameters in the generated code after retraining the model. This example
specifies the coder attributes of predictor data that you want to pass to the generated
code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of X so that the generated code accepts any number of
observations. Modify the SizeVector and VariableDimensions attributes. The
SizeVector attribute specifies the upper bound of the predictor data size, and the
VariableDimensions attribute specifies whether each dimension of the predictor data
has a variable size or fixed size.

```matlab
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```
The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is Inf and the size is variable, meaning that $X$ can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. $X$ contains 34 predictors, so the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be false.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of SupportVectors so that you can update the support vectors in the generated code.

```matlab
configurer.SupportVectors.SizeVector = [250 34];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints. SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

```matlab
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints. VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the predict and update functions of the ClassificationSVM model with default settings.

```matlab
generateCode(configurer)
```
These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
generateCode generates these files for code generation.

generateCode generates the MATLAB files required to generate code, including the two entry-point functions predict.m and update.m for the predict and update functions of the ClassificationSVM model (Mdl), respectively. Then generateCode creates a MEX function named ClassificationSVMModel for the two entry-point functions in the codegen\mex\ClassificationSVMModel folder and copies the MEX function to the current folder.

**Verify Generated Code**

Pass some predictor data to verify whether the predict function of Mdl and the predict function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

\[
\begin{align*}
\text{[label, score]} &= \text{predict(Mdl,}X)\text{;} \\
\text{[label}_\text{mex}, \text{score}_\text{mex}] &= \text{ClassificationSVMModel('predict',}X)\text{;}
\end{align*}
\]

Compare label and label_mex by using isequal.

\[
\text{isequal(label, label}_\text{mex})
\]

\[
\text{ans = logical}
\]

\[
1
\]

isequal returns logical 1 (true) if all the inputs are equal. The comparison confirms that the predict function of Mdl and the predict function in the MEX function return the same labels.

score_mex might include round-off differences compared with score. In this case, compare score_mex and score, allowing a small tolerance.

\[
\text{find(abs(score-score}_\text{mex}) > 1e-8)
\]

\[
\text{ans =}
\]

\[
\text{0x1 empty double column vector}
\]

The comparison confirms that score and score_mex are equal within the tolerance 1e–8.
Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

retrainedMdl = fitcsvm(X,Y);

Extract parameters to update by using validatedUpdateInputs. This function detects the modified model parameters in retrainedMdl and validates whether the modified parameter values satisfy the coder attributes of the parameters.

params = validatedUpdateInputs(configurer,retrainedMdl);

Update parameters in the generated code.

ClassificationSVMModel('update',params)

Verify Generated Code

Compare the outputs from the predict function of retrainedMdl and the predict function in the updated MEX function.

labels = predict(retrainedMdl,X);
label_mex = ClassificationSVMModel('predict',X);
isequal(labels,label_mex)

ans = logical
   1

find(abs(score-score_mex) > 1e-8)
ans =
   0x1 empty double column vector

The comparison confirms that labels and labels_mex are equal, and the score values are equal within the tolerance.

**Introduced in R2018b**
ClassificationTree class

Superclasses:
Binary decision tree for classification

Description

A ClassificationTree object represents a decision tree with binary splits for classification. An object of this class can predict responses for new data using the predict method. The object contains the data used for training, so it can also compute resubstitution predictions.

Construction

Create a ClassificationTree object by using fitctree.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CategoricalSplit

An n-by-2 cell array, where n is the number of categorical splits in tree. Each row in CategoricalSplits gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z, the left child is chosen if z is in CategoricalSplits(j,1) and the right child is chosen if z is in CategoricalSplits(j,2). The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting 'categorical' cuts from top to bottom in the CutType property.
Children

An n-by-2 array containing the numbers of the child nodes for each node in tree, where n is the number of nodes. Leaf nodes have child node 0.

ClassCount

An n-by-k array of class counts for the nodes in tree, where n is the number of nodes and k is the number of classes. For any node number i, the class counts ClassCount(i,:) are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node i.

ClassNames

List of the elements in Y with duplicates removed. ClassNames can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. ClassNames has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

ClassProbability

An n-by-k array of class probabilities for the nodes in tree, where n is the number of nodes and k is the number of classes. For any node number i, the class probabilities ClassProbability(i,:) are the estimated probabilities for each class for a point satisfying the conditions for node i.

Cost

Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response. This property is read-only.

CutCategories

An n-by-2 cell array of the categories used at branches in tree, where n is the number of nodes. For each branch node i based on a categorical predictor variable X, the left child is chosen if X is among the categories listed in CutCategories{i,1}, and the right child is chosen if X is among those listed in CutCategories{i,2}. Both columns of CutCategories are empty for branch nodes based on continuous predictors and for leaf nodes.
CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

**CutPoint**

An $n$-element vector of the values used as cut points in tree, where $n$ is the number of nodes. For each branch node $i$ based on a continuous predictor variable $X$, the left child is chosen if $X < \text{CutPoint}(i)$ and the right child is chosen if $X \geq \text{CutPoint}(i)$. CutPoint is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

**CutType**

An $n$-element cell array indicating the type of cut at each node in tree, where $n$ is the number of nodes. For each node $i$, CutType{$i$} is:

- 'continuous' — If the cut is defined in the form $X < v$ for a variable $X$ and cut point $v$.
- 'categorical' — If the cut is defined by whether a variable $X$ takes a value in a set of categories.
- '' — If $i$ is a leaf node.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

**CutPredictor**

An $n$-element cell array of the names of the variables used for branching in each node in tree, where $n$ is the number of nodes. These variables are sometimes known as cut variables. For leaf nodes, CutPredictor contains an empty character vector.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.
If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

**HyperparameterOptimizationResults**

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

**IsBranchNode**

An n-element logical vector that is `true` for each branch node and `false` for each leaf node of `tree`.

**ModelParameters**

Parameters used in training `tree`. To display all parameter values, enter `tree.ModelParameters`. To access a particular parameter, use dot notation.

**NumObservations**

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or `response Y`.

**NodeClass**

An n-element cell array with the names of the most probable classes in each node of `tree`, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in `ClassNames`.

**NodeError**

An n-element vector of the errors of the nodes in `tree`, where n is the number of nodes. `NodeError(i)` is the misclassification probability for node i.
**NodeProbability**

An $n$-element vector of the probabilities of the nodes in `tree`, where $n$ is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

**NodeRisk**

An $n$-element vector of the risk of the nodes in the tree, where $n$ is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node weighted by the node probability. If the tree is grown by twoing, the risk for each node is zero.

**NodeSize**

An $n$-element vector of the sizes of the nodes in `tree`, where $n$ is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

**NumNodes**

The number of nodes in `tree`.

**Parent**

An $n$-element vector containing the number of the parent node for each node in `tree`, where $n$ is the number of nodes. The parent of the root node is 0.

**PredictorNames**

Cell array of character vectors containing the predictor names, in the order which they appear in $X$.

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.
**PruneAlpha**

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to $M$, then $\text{PruneAlpha}$ has $M + 1$ elements sorted in ascending order. $\text{PruneAlpha}(1)$ is for pruning level 0 (no pruning), $\text{PruneAlpha}(2)$ is for pruning level 1, and so on.

**PruneList**

An $n$-element numeric vector with the pruning levels in each node of tree, where $n$ is the number of nodes. The pruning levels range from 0 (no pruning) to $M$, where $M$ is the distance between the deepest leaf and the root node.

**ResponseName**

A character vector that specifies the name of the response variable ($Y$).

**RowsUsed**

An $n$-element logical vector indicating which rows of the original predictor data ($X$) were used in fitting. If the software uses all rows of $X$, then $\text{RowsUsed}$ is an empty array ($[]$).

**ScoreTransform**

Function handle for transforming predicted classification scores, or character vector representing a built-in transformation function.

\texttt{none} means no transformation, or @($x$)$x$.

To change the score transformation function to, e.g., \textit{function}, use dot notation.

- For available functions (see \textit{fitctree}), enter
  
  \texttt{Mdl.ScoreTransform = 'function';}

- You can set a function handle for an available function, or a function you define yourself by entering
  
  \texttt{tree.ScoreTransform = @function;}

**SurrogateCutCategories**

An $n$-element cell array of the categories used for surrogate splits in tree, where $n$ is the number of nodes in tree. For each node $k$, $\text{SurrogateCutCategories}\{k\}$ is a cell array. The length of $\text{SurrogateCutCategories}\{k\}$ is equal to the number of surrogate
predictors found at this node. Every element of SurrogateCutCategories{k} is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutCategories contains an empty cell.

**SurrogateCutFlip**

An n-element cell array of the numeric cut assignments used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogateCutFlip{k} is a numeric vector. The length of SurrogateCutFlip{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutFlip{k} is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or +1. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if Z\(<\)C and the cut assignment for this surrogate split is +1, or if Z\(\geq\)C and the cut assignment for this surrogate split is -1. Similarly, the right child is chosen if Z\(\geq\)C and the cut assignment for this surrogate split is +1, or if Z\(<\)C and the cut assignment for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutFlip contains an empty array.

**SurrogateCutPoint**

An n-element cell array of the numeric values used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogateCutPoint{k} is a numeric vector. The length of SurrogateCutPoint{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutPoint{k} is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if Z\(<\)C and SurrogateCutFlip for this surrogate split is +1, or if Z\(\geq\)C and SurrogateCutFlip for this surrogate split is -1. Similarly, the right child is chosen if Z\(\geq\)C and SurrogateCutFlip for this surrogate split is +1, or if Z\(<\)C and SurrogateCutFlip for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables returned by
SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPoint contains an empty cell.

**SurrogateCutType**

An $n$-element cell array indicating types of surrogate splits at each node in tree, where $n$ is the number of nodes in tree. For each node $k$, SurrogateCutType{$k$} is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutType contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable $Z$ and cut point $V$ or 'categorical' if the cut is defined by whether $Z$ takes a value in a set of categories.

**SurrogateCutPredictor**

An $n$-element cell array of the names of the variables used for surrogate splits in each node in tree, where $n$ is the number of nodes in tree. Every element of SurrogateCutPredictor is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPredictor contains an empty cell.

**SurrogatePredictorAssociation**

An $n$-element cell array of the predictive measures of association for surrogate splits in tree, where $n$ is the number of nodes in tree. For each node $k$, SurrogatePredictorAssociation{$k$} is a numeric vector. The length of SurrogatePredictorAssociation{$k$} is equal to the number of surrogate predictors found at this node. Every element of SurrogatePredictorAssociation{$k$} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogatePredictorAssociation contains an empty cell.

**W**

The scaled weights, a vector with length $n$, the number of rows in $X$. 

32-581
**X**

A matrix of predictor values. Each column of X represents one variable, and each row represents one observation.

**Y**

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. Each row of Y represents the classification of the corresponding row of X.

**Methods**

- `compact` Compact tree
- `crossval` Cross-validated decision tree
- `cvloss` Classification error by cross validation
- `prune` Produce sequence of subtrees by pruning
- `resubEdge` Classification edge by resubstitution
- `resubLoss` Classification error by resubstitution
- `resubMargin` Classification margins by resubstitution
- `resubPredict` Predict resubstitution response of tree

**Inherited Methods**

- `edge` Classification edge
- `loss` Classification error
- `margin` Classification margins
- `surrogateAssociation` Mean predictive measure of association for surrogate splits in decision tree
- `predict` Predict labels using classification tree
- `predictorImportance` Estimates of predictor importance
- `view` View tree
Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Grow a Classification Tree

Grow a classification tree using the ionosphere data set.

load ionosphere
tc = fitctree(X,Y)

tc =
    ClassificationTree
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
        NumObservations: 351

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the MaxNumSplits, MinLeafSize, or MinParentSize name-value pair parameters. fitctree grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the ionosphere data set.

load ionosphere

The default values of the tree depth controllers for growing classification trees are:

• \( n - 1 \) for MaxNumSplits. \( n \) is the training sample size.
• 1 for MinLeafSize.
• 10 for MinParentSize.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross-validate the model using 10-fold cross-validation.

```matlab
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```matlab
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```
view(MdlDefault.Trained{1}, 'Mode', 'graph')
The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model using 10-fold cross-validation.

```matlab
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```
Compare the cross-validation classification errors of the models.

classErrorDefault = kfoldLoss(MdlDefault)

classErrorDefault = 0.1140

classError7 = kfoldLoss(Mdl7)

classError7 = 0.1254

Mdl7 is much less complex and performs only slightly worse than MdlDefault.
Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is
  \[ 1 - \sum_i p^2(i), \]
  where the sum is over the classes \( i \) at the node, and \( p(i) \) is the observed fraction of classes with class \( i \) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With \( p(i) \) defined the same as for the Gini index, the deviance of a node is
  \[ -\sum_i p(i) \log_2 p(i). \]
  A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let \( L(i) \) denote the fraction of members of class \( i \) in the left child node after a split, and \( R(i) \) denote the fraction of members of class \( i \) in the right child node after a split. Choose the split criterion to maximize
  \[
  P(L)P(R) \left( \sum_i |L(i) - R(i)| \right)^2,
  \]
  where \( P(L) \) and \( P(R) \) are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.
• Node error — The node error is the fraction of misclassified classes at a node. If \( j \) is the class with the largest number of training samples at a node, the node error is

\[
1 - p(j).
\]

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The predict function supports code generation.
• When you train a classification tree using fitctree, the following restrictions apply.
  • The class labels input argument value (Y) cannot be a categorical array.
  • Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
  • The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
  • The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.
  • You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a
classify

Discriminant analysis

Syntax

class = classify(sample, training, group)
class = classify(sample, training, group, 'type')
class = classify(sample, training, group, 'type', prior)
[class, err] = classify(...)
[class, err, POSTERIOR] = classify(...)
[class, err, POSTERIOR, logp] = classify(...)
[class, err, POSTERIOR, logp, coeff] = classify(...)

Description

class = classify(sample, training, group) classifies each row of the data in sample into one of the groups in training. sample and training must be matrices with the same number of columns. group is a grouping variable for training. Its unique values define groups; each element defines the group to which the corresponding row of training belongs. group can be a categorical variable, a numeric vector, a character array, a string array, or a cell array of character vectors. training and group must have the same number of rows. classify treats <undefined> values, NaNs, empty character vectors, empty strings, and <missing> string values in group as missing data values, and ignores the corresponding rows of training. The output class indicates the group to which each row of sample has been assigned, and is of the same type as group.

class = classify(sample, training, group, 'type') allows you to specify the type of discriminant function. Specify type inside single quotes. type is one of:

- linear — Fits a multivariate normal density to each group, with a pooled estimate of covariance. This is the default.
- diaglinear — Similar to linear, but with a diagonal covariance matrix estimate (naive Bayes classifiers).
- quadratic — Fits multivariate normal densities with covariance estimates stratified by group.
• **diagquadratic** — Similar to **quadratic**, but with a diagonal covariance matrix estimate (naive Bayes classifiers).

• **mahalanobis** — Uses Mahalanobis distances with stratified covariance estimates.

```
class = classify(sample,training,group,'type',prior)
```
allows you to specify prior probabilities for the groups. **prior** is one of:

- A numeric vector the same length as the number of unique values in **group** (or the number of levels defined for **group**, if **group** is categorical). If **group** is numeric or categorical, the order of **prior** must correspond to the ordered values in **group**. Otherwise, the order of **prior** must correspond to the order of the first occurrence of the values in **group**.
- A 1-by-1 structure with fields:
  - `prob` — A numeric vector.
  - `group` — Of the same type as **group**, containing unique values indicating the groups to which the elements of **prob** correspond.

As a structure, **prior** can contain groups that do not appear in **group**. This can be useful if **training** is a subset a larger training set. **classify** ignores any groups that appear in the structure but not in the **group** array.

- The character vector or string scalar 'empirical', indicating that group prior probabilities should be estimated from the group relative frequencies in **training**.

**prior** defaults to a numeric vector of equal probabilities, i.e., a uniform distribution. **prior** is not used for discrimination by Mahalanobis distance, except for error rate calculation.

```
[class,err] = classify(...)
```
also returns an estimate **err** of the misclassification error rate based on the **training** data. **classify** returns the apparent error rate, i.e., the percentage of observations in **training** that are misclassified, weighted by the prior probabilities for the groups.

```
[class,err,POSTERIOR] = classify(...)
```
also returns a matrix **POSTERIOR** of estimates of the posterior probabilities that the jth training group was the source of the ith sample observation, i.e., Pr(group j|obs i). **POSTERIOR** is not computed for Mahalanobis discrimination.

```
[class,err,POSTERIOR,logp] = classify(...)
```
also returns a vector **logp** containing estimates of the logarithms of the unconditional predictive probability density
of the sample observations, \( p(\text{obs } i) = \sum p(\text{obs } i | \text{group } j) \Pr(\text{group } j) \) over all groups. \( \log p \) is not computed for Mahalanobis discrimination.

\[ \text{[class, err, POSTERIOR, logp, coeff]} = \text{classify(...)} \]
also returns a structure array \( \text{coeff} \) containing coefficients of the boundary curves between pairs of groups. Each element \( \text{coeff}(I, J) \) contains information for comparing group \( I \) to group \( J \) in the following fields:

- **type** — Type of discriminant function, from the \( \text{type} \) input.
- **name1** — Name of the first group.
- **name2** — Name of the second group.
- **const** — Constant term of the boundary equation (\( K \))
- **linear** — Linear coefficients of the boundary equation (\( L \))
- **quadratic** — Quadratic coefficient matrix of the boundary equation (\( Q \))

For the linear and diaglinear types, the quadratic field is absent, and a row \( x \) from the sample array is classified into group \( I \) rather than group \( J \) if \( 0 < K + x^*L \). For the other types, \( x \) is classified into group \( I \) if \( 0 < K + x^*L + x^*Q*x' \).

**Examples**

**Classify Using Discriminant Analysis**

For training data, use Fisher's sepal measurements for iris versicolor and virginica:

\[ \text{load fisheriris} \]
\[ \text{SL} = \text{meas}(51:\text{end},1); \]
\[ \text{SW} = \text{meas}(51:\text{end},2); \]
\[ \text{group} = \text{species}(51:\text{end}); \]
\[ \text{h1} = \text{gscatter(SL,SW,group,'rb','v^',[],'off');} \]
\[ \text{set(h1,'LineWidth',2)} \]
\[ \text{legend('Fisher versicolor','Fisher virginica',...} \]
\[ \text{'Location','NW')} \]
Classify a grid of measurements on the same scale:

\[
[X,Y] = \text{meshgrid}(\text{linspace}(4.5,8),\text{linspace}(2,4));
X = X(:); Y = Y(:);
[C,err,P,logp,coeff] = \text{classify}([X\ Y],[SL\ SW],...
\text{group},'Quadratic');
\]

Visualize the classification:

\[
\text{hold on};
gscatter(X,Y,C,'rb','.',1,'off');
K = \text{coeff}(1,2).\text{const};
L = \text{coeff}(1,2).\text{linear};
Q = \text{coeff}(1,2).\text{quadratic};
\]
Function to compute $K + L*v + v'*Q*v$ for multiple vectors
% v=[x;y]. Accepts x and y as scalars or column vectors.
f = @(x,y) K + [x y]*L + sum(([x y]*Q) .* [x y], 2);

h2 = ezplot(f,[4.5 8 2 4]);
set(h2,'Color','m','LineWidth',2)
axis([4.5 8 2 4])
xlabel('Sepal Length')
ylabel('Sepal Width')
title('{\bf Classification with Fisher Training Data}')

Classify with Fisher Training Data

- Fisher versicolor
- Fisher virginica
- data1
- data2
- data3
Alternative Functionality

The fitcdiscr function also performs discriminant analysis. You can train a classifier by using the fitcdiscr function and predict labels of new data by using the predict function. The fitcdiscr supports cross-validation and hyperparameter optimization and does not require you to fit the classifier every time you make a new prediction or you change prior probabilities.

Introduced before R2006a
classname

Class: classregtree

(Removed) Class names for classification decision tree

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

CNAMES = classname(T)
CNAMES = classname(T,J)

Description

CNAMES = classname(T) returns a cell array of character vectors with class names for this classification decision tree.

CNAMES = classname(T,J) takes an array J of class numbers and returns the class names for the specified numbers.

See Also
classregtree
classprob

Class: classregtree

(Removed) Class probabilities

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

```matlab
P = classprob(t)
P = classprob(t,nodes)
```

**Description**

`P = classprob(t)` returns an `n`-by-`m` array `P` of class probabilities for the nodes in the classification tree `t`, where `n` is the number of nodes and `m` is the number of classes. For any node number `i`, the class probabilities `P(i,:)` are the estimated probabilities for each class for a point satisfying the conditions for node `i`.

`P = classprob(t,nodes)` takes a vector `nodes` of node numbers and returns the class probabilities for the specified nodes.

classregtree

Class: classregtree

(Removed) Construct classification and regression trees

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

t = classregtree(X,y)
t = classregtree(X,y,'Name',value)

Description

t = classregtree(X,y) creates a decision tree t for predicting the response y as a function of the predictors in the columns of X. X is an n-by-m matrix of predictor values. If y is a vector of n response values, classregtree performs regression. If y is a categorical variable, character array, or cell array of character vectors, classregtree performs classification. Either way, t is a binary tree where each branching node is split based on the values of a column of X. NaN values in X or y are taken to be missing values. Observations with all missing values for X or missing values for y are not used in the fit. Observations with some missing values for X are used to find splits on variables for which these observations have valid values.

t = classregtree(X,y,'Name',value) specifies one or more optional parameter name/value pairs. Specify Name in single quotes. The following options are available:

For all trees:

• categorical — Vector of indices of the columns of X that are to be treated as unordered categorical variables

• method — Either 'classification' (default if y is text or a categorical variable) or 'regression' (default if y is numeric).
- **names** — A cell array of names for the predictor variables, in the order in which they appear in the X from which the tree was created.

- **prune** — 'on' (default) to compute the full tree and the optimal sequence of pruned subtrees, or 'off' for the full tree without pruning.

- **minparent** — A number $k$ such that impure nodes must have $k$ or more observations to be split (default is 10).

- **minleaf** — A minimal number of observations per tree leaf (default is 1). If you supply both 'minparent' and 'minleaf', *classregtree* uses the setting which results in larger leaves: $\text{minparent} = \max(\text{minparent}, 2*\text{minleaf})$

- **mergeleaves** — 'on' (default) to merge leaves that originate from the same parent node and give the sum of risk values greater or equal to the risk associated with the parent node. If 'off', *classregtree* does not merge leaves.

- **nvartosample** — Number of predictor variables randomly selected for each split. By default all variables are considered for each decision split.

- **stream** — Random number stream. Default is the MATLAB default random number stream.

- **surrogate** — 'on' to find surrogate splits at each branch node. Default is 'off'. If you set this parameter to 'on', *classregtree* can run significantly slower and consume significantly more memory.

- **weights** — Vector of observation weights. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.

For regression trees only:

- **qetoler** — Defines tolerance on quadratic error per node for regression trees. Splitting nodes stops when quadratic error per node drops below $\text{qetoler} * \text{qed}$, where $\text{qed}$ is the quadratic error for the entire data computed before the decision tree is grown: $\text{qed} = \text{norm}(y - \text{ybar})$ with $\text{ybar}$ estimated as the average of the input array Y. Default value is 1e-6.

For classification trees only:

- **cost** — Square matrix C, where $C(i, j)$ is the cost of classifying a point into class $j$ if its true class is $i$ (default has $C(i, j)=1$ if $i\neq j$, and $C(i, j)=0$ if $i=j$). Alternatively, this value can be a structure S having two fields: S.group containing the group names as a categorical variable, character array, or cell array of character vectors; and S.cost containing the cost matrix C.
• splitcriterion — Criterion for choosing a split. One of 'gdi' (default) or Gini's diversity index, 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction.

• priorprob — Prior probabilities for each class, specified as 'empirical' or 'equal', or as a vector (one value for each distinct group name) or as a structure S with two fields:
  • S.group containing the group names as a categorical variable, character array, or cell array of character vectors.
  • S.prob containing a vector of corresponding probabilities.

If the input value is 'empirical' (default), class probabilities are determined from class frequencies in Y. If the input value is 'equal', all class probabilities are set equal. If both observation weights and class prior probabilities are supplied, the weights are renormalized to add up to the value of the prior probability in the respective class.

Introduced in R2007a
cluster

Construct agglomerative clusters from linkages

Syntax

T = cluster(Z,'cutoff',c)
T = cluster(Z,'cutoff',c,'depth',d)
T = cluster(Z,'cutoff',c,'criterion',criterion)
T = cluster(Z,'maxclust',n)

Description

T = cluster(Z,'cutoff',c) constructs clusters from the agglomerative hierarchical cluster tree, Z, as generated by the linkage function. Z is a matrix of size (m - 1)-by-3, where m is the number of observations in the original data. c is a threshold for cutting Z into clusters. Clusters are formed when a node and all of its subnodes have inconsistent value less than c. All leaves at or below the node are grouped into a cluster. t is a vector of size m containing the cluster assignments of each observation.

If c is a vector, T is a matrix of cluster assignments with one column per cutoff value.

T = cluster(Z,'cutoff',c,'depth',d) evaluates inconsistent values by looking to a depth d below each node. The default depth is 2.

T = cluster(Z,'cutoff',c,'criterion',criterion) uses the specified criterion for forming clusters, where criterion is 'inconsistent' (default) or 'distance'. The 'distance' criterion uses the distance between the two subnodes merged at a node to measure node height. All leaves at or below a node with height less than c are grouped into a cluster.

T = cluster(Z,'maxclust',n) constructs a maximum of n clusters using the 'distance' criterion. cluster finds the smallest height at which a horizontal cut through the tree leaves n or fewer clusters.

If n is a vector, T is a matrix of cluster assignments with one column per maximum value.
**Examples**

**Compare Cluster Assignments to Classes**

Compare cluster assignments of flowers to their species classification.

Load the sample data.

```matlab
load fisheriris
```

Compute three clusters of the Fisher iris data using the 'average' method and the 'chebychev' metric.

```matlab
Z = linkage(meas,'average','chebychev');
c = cluster(Z,'maxclust',3);
```

Create a dendrogram plot of Z. To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

```matlab
cutoff = median([Z(end-2,3) Z(end-1,3)]);
dendrogram(Z,'ColorThreshold',cutoff)
```
Display the last two rows of $Z$ to see how the three clusters are combined into one. The `linkage` function combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of 1.7583. `linkage` then combines the 296th (green) cluster with the 298th cluster.

```matlab
lastTwo = Z(end-1:end,:)
```

```
lastTwo = 2×3
         293.0000  297.0000    1.7583
         296.0000  298.0000    3.4445
```

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

```matlab
crosstab(c,species)
```
Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

```matlab
rng('default') % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree using Ward's linkage. In this case, 'savememory' is set to 'on' by default. In general, choose the best value for 'savememory' based on the dimensions of X and the available memory.

```matlab
Z = linkage(X,'ward');
```

Cluster data into four groups and plot the result.

```matlab
c = cluster(Z,'Maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

Introduced before R2006a
cluster

Construct clusters from Gaussian mixture distribution

Syntax

idx = cluster(gm,X)
[idx,nlogL] = cluster(gm,X)
[idx,nlogL,P] = cluster(gm,X)
[idx,nlogL,P,logpdf] = cluster(gm,X)
[idx,nlogL,P,logpdf,d2] = cluster(gm,X)

Description

idx = cluster(gm,X) partitions the data in X into k clusters determined by the k Gaussian mixture components in gm. The value in idx(i) is the cluster index of observation i and indicates the component with the largest posterior probability given the observation i.

[idx,nlogL] = cluster(gm,X) also returns the negative loglikelihood of the Gaussian mixture model gm given the data X.

[idx,nlogL,P] = cluster(gm,X) also returns the posterior probabilities of each Gaussian mixture component in gm given each observation in X.

[idx,nlogL,P,logpdf] = cluster(gm,X) also returns a logarithm of the estimated probability density function (pdf) evaluated at each observation in X.

[idx,nlogL,P,logpdf,d2] = cluster(gm,X) also returns the squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm.

Examples
Cluster Data

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function. Then, use the `cluster` function to partition the data into two clusters determined by the fitted GMM components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

\[ \mu_1 = [2 \\ 2]; \quad \mu_2 = [-2 \\ -1]; \]
\[ \Sigma_1 = [2 \\ 0; 0 \\ 1]; \quad \Sigma_2 = [1 \\ 0; 0 \\ 1]; \]

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set \( X \) contains random variates following a mixture of two bivariate Gaussian distribution.

Fit a two-component GMM to \( X \).

```
gm = fitgmdist(X,2);
```

Plot \( X \) by using `scatter`. Visualize the fitted model \( gm \) by using `pdf` and `ezcontour`.

```
figure
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
ezcontour(@(x,y)pdf(gm,[x y]),[-6 8],[-4 6])
```
Partition the data into clusters by passing the fitted GMM and the data to `cluster`.

```matlab
dx = cluster(gm,X);
```

Use `gscatter` to create a scatter plot grouped by `idx`.

```matlab
figure;
gscatter(X(:,1),X(:,2),idx);
legend('Cluster 1','Cluster 2','Location','best');
```
Input Arguments

**gm — Gaussian mixture distribution**

gmdistribution object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a gmdistribution object.

You can create a gmdistribution object using gmdistribution or fitgmdist. Use the gmdistribution function to create a gmdistribution object by specifying the
distribution parameters. Use the fitgmdist function to fit a gmdistribution model to
data given a fixed number of components.

**X — Data**

*n-by-m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and
*m* is the number of variables in each observation.

To provide meaningful clustering results, *X* must come from the same population as the
data used to create *gm*.

If a row of *X* contains NaNs, then *cluster* excludes the row from the computation. The
corresponding value in *idx*, *P*, *logpdf*, and *d2* is NaN.

Data Types: single | double

**Output Arguments**

**idx — Cluster index**

*n*-by-1 positive integer vector

Cluster index, returned as an *n*-by-1 positive integer vector, where *n* is the number of
observations in *X*.

*idx*(i) is the cluster index of observation *i* and indicates the Gaussian mixture
component with the largest posterior probability given the observation *i*.

**nlogL — Negative loglikelihood**

numeric value

Negative loglikelihood value of the Gaussian mixture model *gm* given the data *X*, returned
as a numeric value.

**P — Posterior probability**

*n*-by-*k* numeric vector

Posterior probability of each Gaussian mixture component in *gm* given each observation in
*X*, returned as an *n*-by-*k* numeric vector, where *n* is the number of observations in *X* and *k*
is the number of mixture components in *gm*. 
P(i, j) is the posterior probability of the jth Gaussian mixture component given observation i, Probability(component j | observation i).

**logpdf — Logarithm of estimated pdf**

*n*-by-1 numeric vector

Logarithm of the estimated pdf, evaluated at each observation in X, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in X.

logpdf(i) is the logarithm of the estimated pdf at observation i. The cluster function computes the estimated pdf by using the likelihood of each component given each observation and the component probabilities.

\[
\text{logpdf}(i) = \log \sum_{j=1}^{k} L(C_j | O_i) P(C_j),
\]

where \(L(C_j | O_i)\) is the likelihood of component j given observation i, and \(P(C_j)\) is the probability of component j. The cluster function computes the likelihood term by using the multivariate normal pdf of the jth Gaussian mixture component evaluated at observation i. The component probabilities are the mixing proportions of mixture components, the ComponentProportion property of gm.

**d2 — Squared Mahalanobis distance**

*n*-by-*k* numeric matrix

Squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm, returned as an *n*-by-*k* numeric matrix, where *n* is the number of observations in X and *k* is the number of mixture components in gm.

d2(i, j) is the squared distance of observation i to the jth Gaussian mixture component.

Introduced in R2007b
ClusterCriterion

Package: clustering.evaluation

Clustering evaluation object

Description

Create a clustering evaluation object using evalclusters.

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If Missing equals true, then the corresponding value in the data matrix x is not used in the clustering solution.
**NumObservations**

Number of observations in the data matrix $X$, minus the number of missing (NaN) values in $X$, stored as a positive integer value.

**OptimalK**

Optimal number of clusters, stored as a positive integer value.

**OptimalY**

Optimal clustering solution corresponding to OptimalK, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, OptimalY is empty.

**X**

Data used for clustering, stored as a matrix of numerical values.

**Methods**

- addK: Evaluate additional numbers of clusters
- plot: Plot clustering evaluation object criterion values
- compact: Compact clustering evaluation object

**See Also**

CalinskiHarabaszEvaluation | DaviesBouldinEvaluation | GapEvaluation | SilhouetteEvaluation | evalclusters

**Topics**

Class Attributes (MATLAB)
Property Attributes (MATLAB)
**clusterdata**

Agglomerative clusters from data

**Syntax**

\[
T = \text{clusterdata}(X,\text{cutoff}) \\
T = \text{clusterdata}(X,\text{Name},\text{Value})
\]

**Description**

\[
T = \text{clusterdata}(X,\text{cutoff})
\]
returns the cluster indices (T) for each observation (row) of the data (X) while adhering to a threshold for cutting the hierarchical tree (cutoff).

\[
T = \text{clusterdata}(X,\text{Name},\text{Value})
\]
clusters with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

\[x\]

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

\[\text{cutoff}\]

When \(0 < \text{cutoff} < 2\), clusterdata forms clusters when inconsistent values are greater than cutoff (see inconsistent). When cutoff is an integer \(\geq 2\), clusterdata interprets cutoff as the maximum number of clusters to keep in the hierarchical tree generated by linkage.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Criterion**

Either 'inconsistent' or 'distance'.

**Cutoff**

Cutoff for inconsistent or distance metric, a positive scalar. When $0 < \text{Cutoff} < 2$, `clusterdata` forms clusters when inconsistent values are greater than Cutoff (see inconsistent). When Cutoff is an integer $\geq 2$, `clusterdata` interprets Cutoff as the maximum number of clusters to keep in the hierarchical tree generated by `linkage`.

**Depth**

Depth for computing inconsistent values, a positive integer.

**Distance**

Any of the distance metric names allowed by `pdist`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance (default).</td>
</tr>
<tr>
<td>'squaredeuclidean'</td>
<td>Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$.</td>
</tr>
<tr>

<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>@distfun</td>
<td>Custom distance function handle. A distance function has the form</td>
</tr>
</tbody>
</table>

```matlab
function D2 = distfun(ZI,ZJ)
% calculation of distance
...
```

where

- **ZI** is a 1-by-n vector containing a single observation.
- **ZJ** is an m2-by-n matrix containing multiple observations. 
  `distfun` must accept a matrix ZJ with an arbitrary number of observations.
- **D2** is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:),.

If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.

For more information on these distance metrics, see “Distance Metrics” on page 32-4703.

**Linkage**

Any of the linkage methods allowed by the `linkage` function:

- 'average'
- 'centroid'
For details, see the definitions in the linkage function reference page.

Maxclust

Maximum number of clusters to form, a positive integer.

Savememory

Either 'on' or 'off'. When applicable, the 'on' setting causes clusterdata to construct clusters without computing the distance matrix. Savememory is applicable when:

- Linkage is 'centroid', 'median', or 'ward'
- Distance is 'euclidean' (default)

When Savememory is 'on', linkage run time is proportional to the number of dimensions (number of columns of X). When Savememory is 'off', linkage memory requirement is proportional to $N^2$, where $N$ is the number of observations. So choosing the best (least-time) setting for Savememory depends on the problem dimensions, number of observations, and available memory. The default Savememory setting is a rough approximation of an optimal setting.

Default: 'on' when X has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise 'off'

Output Arguments

T

T is a vector of size $m$ containing a cluster number for each observation.

- When $0 < \text{cutoff} < 2$, $T = \text{clusterdata}(X, \text{cutoff})$ is equivalent to:
Y = pdist(X,'euclid');
Z = linkage(Y,'single');
T = cluster(Z,'Cutoff',cutoff);

• When cutoff is an integer ≥ 2, T = clusterdata(X,cutoff) is equivalent to:

  Y = pdist(X,'euclid');
  Z = linkage(Y,'single');
  T = cluster(Z,'Maxclust',cutoff);

**Examples**

**Create Hierarchical Cluster Tree From Sample Data**

This example shows how to create a hierarchical cluster tree from sample data, and visualize the clusters using a 3-dimensional scatter plot.

Generate sample data matrices containing random numbers from the standard uniform distribution.

```matlab
rng('default');  % For reproducibility
X = [gallery('uniformdata',[10 3],12);...
    gallery('uniformdata',[10 3],13)+1.2;...
    gallery('uniformdata',[10 3],14)+2.5];
```

Compute the distances between items and create a hierarchical cluster tree from the sample data. List all of the items in cluster 2.

```matlab
T = clusterdata(X,'Maxclust',3);
find(T==2)
```

```
ans = 10×1
11
12
13
14
15
16
17
18
19
```
Plot the data with each cluster shown in a different color.

scatter3(X(:,1),X(:,2),X(:,3),100,T,'filled')

Create Hierarchical Cluster Tree Using Ward's Linkage

This example shows how to create a hierarchical cluster tree using Ward's linkage, and visualize the clusters using a 3-dimensional scatter plot.
Create a 20,000-by-3 matrix of sample data generated from the standard uniform distribution.

```matlab
rng('default');  % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree from the sample data using Ward's linkage. Set 'savememory' to 'on' to construct clusters without computing the distance matrix.

```matlab
c = clusterdata(X,'Linkage','ward','Savememory','on','Maxclust',4);
```

Plot the data with each cluster shown in a different color.

```matlab
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```
Tips

- The centroid and median methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, \( r \) and \( s \), to a third cluster is less than the distance between \( r \) and \( s \). In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

![Dendrogram Example](image)

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output \( T \) to other functions including dendrogram to display the tree, cluster to assign points to clusters, inconsistent to compute inconsistent measures, and cophenet to compute the cophenetic correlation coefficient.

Introduced before R2006a
cmdscale

Classical multidimensional scaling

Syntax

Y = cmdscale(D)
[Y,e] = cmdscale(D)
[Y,e] = cmdscale(D,p)

Description

Y = cmdscale(D) takes an n-by-n distance matrix D, and returns an n-by-p configuration matrix Y. Rows of Y are the coordinates of n points in p-dimensional space for some p < n. When D is a Euclidean distance matrix, the distances between those points are given by D. p is the dimension of the smallest space in which the n points whose inter-point distances are given by D can be embedded.

[Y,e] = cmdscale(D) also returns the eigenvalues of Y*Y'. When D is Euclidean, the first p elements of e are positive, the rest zero. If the first k elements of e are much larger than the remaining (n-k), then you can use the first k columns of Y as k-dimensional points whose inter-point distances approximate D. This can provide a useful dimension reduction for visualization, e.g., for k = 2.

D need not be a Euclidean distance matrix. If it is non-Euclidean or a more general dissimilarity matrix, then some elements of e are negative, and cmdscale chooses p as the number of positive eigenvalues. In this case, the reduction to p or fewer dimensions provides a reasonable approximation to D only if the negative elements of e are small in magnitude.

[Y,e] = cmdscale(D,p) also accepts a positive integer p between 1 and n. p specifies the dimensionality of the desired embedding Y. If a p dimensional embedding is possible, then Y will be of size n-by-p and e will be of size p-by-1. If only a q dimensional embedding with q < p is possible, then Y will be of size n-by-q and e will be of size p-by-1. Specifying p may reduce the computational burden when n is very large.

You can specify D as either a full dissimilarity matrix, or in upper triangle vector form such as is output by pdist. A full dissimilarity matrix must be real and symmetric, and
have zeros along the diagonal and positive elements everywhere else. A dissimilarity matrix in upper triangle form must have real, positive entries. You can also specify D as a full similarity matrix, with ones along the diagonal and all other elements less than one. cmdscale transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in Y equal or approximate $\sqrt{1-D}$. To use a different transformation, you must transform the similarities prior to calling cmdscale.

Examples

Construct a Map Using Multidimensional Scaling

This example shows how to construct a map of 10 US cities based on the distances between those cities, using cmdscale.

First, create the distance matrix and pass it to cmdscale. In this example, D is a full distance matrix: it is square and symmetric, has positive entries off the diagonal, and has zeros on the diagonal.

cities = ...
{'Atl','Chi','Den','Hou','LA','Mia','NYC','SF','Sea','WDC'};
D = [    0  587 1212  701 1936  604  748 2139 2182   543;
      587    0  920  940 1745 1188  713 1858 1737   597;
     1212  920    0  879  831 1726 1631  949 1021  1494;
      701  940  879    0 1374  968 1420 1645 1891  1220;
     1936 1745  831 1374    0 2339 2451  347  959  2300;
      604 1188 1726  968 2339    0 1092 2594 2734   923;
      748  713 1631 1420 2451 1092    0 2571 2408  205;
     2139 1858  949 1645  347 2594 2571    0  678  2442;
     2182 1737 1021 1891  959 2734 2408  678    0  2329;
      543  597 1494 1220 2300  923  205 2442 2329    0];
[Y,eigvals] = cmdscale(D);

Next, look at the eigenvalues returned by cmdscale. Some of these are negative, indicating that the original distances are not Euclidean. This is because of the curvature of the earth.

format short g
[eigvals eigvals/max(abs(eigvals))]

ans = 10×2
However, in this case, the two largest positive eigenvalues are much larger in magnitude than the remaining eigenvalues. So, despite the negative eigenvalues, the first two coordinates of $Y$ are sufficient for a reasonable reproduction of $D$.

```matlab
Dtriu = D(find(tril(ones(10),-1)))';
maxrelerr = max(abs(Dtriu-pdist(Y(:,1:2))))./max(Dtriu)
```

```matlab
maxrelerr =
     0.0075371
```

Here is a plot of the reconstructed city locations as a map. The orientation of the reconstruction is arbitrary.

```matlab
plot(Y(:,1),Y(:,2),'.')
text(Y(:,1)+25,Y(:,2),cities)
xlabel('Miles')
ylabel('Miles')
```
Evaluate Reconstructions Using Different Distance Metrics

Determine how the quality of reconstruction varies when you reduce points to distances using different metrics.

Generate ten points in 4-D space that are close to 3-D space. Take a linear transformation of the points so that their transformed values are close to a 3-D subspace that does not align with the coordinate axes.

```matlab
rng default  % Set the seed for reproducibility
A = [normrnd(0,1,10,3) normrnd(0,0.1,10,1)];
```
B = randn(4,4);
X = A*B;

Reduce the points in X to distances by using the Euclidean metric. Find a configuration Y with the inter-point distances.

D = pdist(X,'euclidean');
Y = cmdscale(D);

Compare the quality of the reconstructions when using 2, 3, or 4 dimensions. The small maxerr3 value indicates that the first 3 dimensions provide a good reconstruction.

maxerr2 = max(abs(pdist(X)-pdist(Y(:,1:2))))
maxerr2 = 0.1631
maxerr3 = max(abs(pdist(X)-pdist(Y(:,1:3))))
maxerr3 = 0.0187
maxerr4 = max(abs(pdist(X)-pdist(Y)))
maxerr4 = 7.9936e-15

Reduce the points in X to distances by using the 'cityblock' metric. Find a configuration Y with the inter-point distances.

D = pdist(X,'cityblock');
[Y,e] = cmdscale(D);

Evaluate the quality of the reconstruction. e contains at least one negative element of large magnitude, which might account for the poor quality of the reconstruction.

maxerr = max(abs(pdist(X)-pdist(Y)))
maxerr = 9.0488
min(e)
ans = -5.6586

Introduced before R2006a
**coefCI**

Confidence intervals of coefficient estimates of generalized linear model

**Syntax**

\[
\text{ci} = \text{coefCI}(\text{mdl})
\]

\[
\text{ci} = \text{coefCI}(\text{mdl},\alpha)
\]

**Description**

\[
\text{ci} = \text{coefCI}(\text{mdl}) \text{ returns confidence intervals for the coefficients in } \text{mdl}.
\]

\[
\text{ci} = \text{coefCI}(\text{mdl},\alpha) \text{ returns confidence intervals with confidence level } 1 - \alpha.
\]

**Input Arguments**

**mdl**

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

**alpha**

Scalar from 0 to 1, the probability that the confidence interval does not contain the true value.

**Default:** 0.05
Output Arguments

**ci**

k-by-2 matrix of confidence intervals. The jth row of ci is the confidence interval of coefficient j of mdl. The name of coefficient j of mdl is in mdl.CoefficientNames.

Examples

Confidence Interval for Coefficients of a Generalized Linear Model

Find confidence intervals for the coefficients of a fitted generalized nonlinear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors X(1) and X(2).

```matlab
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```matlab
mdl = fitglm(X,y,...
    'y ~ x1 + x2','distr','poisson')
```

mdl =

Generalized linear regression model:
log(y) ~ 1 + x1 + x2
Distribution = Poisson

Estimated Coefficients:

```

Definitions

Confidence Interval

Assume that model assumptions hold (data comes from a generalized linear model represented by the formula `mdl`.Formula and the specified link function, and with observations that are independent conditional on the predictor values). Then row j of the confidence interval matrix ci gives a confidence interval \([ci(j,1),ci(j,2)]\) computed such that, with repeated experimentation, a proportion \(1 - \alpha\) of the intervals will contain the true value of the coefficient.

**coefCI**

**Class:** GeneralizedLinearMixedModel

Confidence intervals for coefficients of generalized linear mixed-effects model

**Syntax**

feCI = coefCI(glme)
feCI = coefCI(glme,Name,Value)
[feCI,reCI] = coefCI(__)

**Description**

feCI = coefCI(glme) returns the 95% confidence intervals for the fixed-effects coefficients in the generalized linear mixed-effects model glme.

feCI = coefCI(glme,Name,Value) returns the confidence intervals using additional options specified by one or more Name,Value pair arguments. For example, you can specify a different confidence level or the method used to compute the approximate degrees of freedom.

[feCI,reCI] = coefCI(__) also returns the confidence intervals for the random-effects coefficients using any of the previous syntaxes.

**Input Arguments**

**glme — Generalized linear mixed-effects model**
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, .... NameN, ValueN.

**Alpha — Confidence level**
0.05 (default) | scalar value in the range [0, 1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0, 1]. For a value α, the confidence level is 100 × (1 – α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

**DFMethod — Method for computing approximate degrees of freedom**
'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'residual'</td>
<td>The degrees of freedom value is assumed to be constant and equal to n – p, where n is the number of observations and p is the number of fixed effects.</td>
</tr>
<tr>
<td>'none'</td>
<td>The degrees of freedom is set to infinity.</td>
</tr>
</tbody>
</table>

Example: 'DFMethod', 'none'

Output Arguments

**feCI — Fixed-effects confidence intervals**
p-by-2 matrix
Fixed-effects confidence intervals, returned as a $p$-by-2 matrix. \texttt{feCI} contains the confidence limits that correspond to the $p$-by-1 fixed-effects vector returned by the \texttt{fixedEffects} method. The first column of \texttt{feCI} contains the lower confidence limits and the second column contains the upper confidence limits.

When fitting a GLME model using \texttt{fitglme} and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'):

- If you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then the confidence intervals are conditional on the estimated covariance parameters.
- If you specify the 'CovarianceMethod' name-value pair argument as 'JointHessian', then the confidence intervals account for the uncertainty in the estimated covariance parameters.

When fitting a GLME model using \texttt{fitglme} and one of the pseudo likelihood fit methods ('MPL' or 'REML'), \texttt{coefci} uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the fixed effects.

\textbf{reCI — Random-effects confidence intervals}

$q$-by-2 matrix

Random-effects confidence intervals, returned as a $q$-by-2 matrix. \texttt{reCI} contains the confidence limits corresponding to the $q$-by-1 random-effects vector $B$ returned by the \texttt{randomEffects} method. The first column of \texttt{reCI} contains the lower confidence limits, and the second column contains the upper confidence limits.

When fitting a GLME model using \texttt{fitglme} and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), \texttt{coefCI} computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals from \texttt{coefCI} as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using \texttt{fitglme} and one of the pseudo likelihood fit methods ('MPL' or 'REML'), \texttt{coefci} uses the fitted linear mixed effects model from the final pseudo likelihood iteration to compute confidence intervals on the random effects.
Examples

95% Confidence Intervals for Fixed Effects

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]
This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,
\]

where

- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
- \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, \ldots, 20 \)) during batch \( j \) (where \( j = 1, 2, \ldots, 5 \)).
- \( \text{newprocess}_{ij}, \text{time\_dev}_{ij}, \text{and temp\_dev}_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, \( \text{newprocess}_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.
- \( \text{supplier\_C}_{ij} \) and \( \text{supplier\_B}_{ij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).
- \( b_i \sim N(0, \sigma_b^2) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

\[
\text{glme} = \text{fitglme}('mfr', '\text{defects} \sim 1 + \text{newprocess} + \text{time\_dev} + \text{temp\_dev} + \text{supplier} + (1|\text{factory}'), '\text{Distribution}', 'Poisson', '\text{Link}', '\text{log}', '\text{FitMethod}', '\text{Laplace}', '\text{DummyVarCoding}', '\text{effects}');
\]

Use \text{fixedEffects} to display the estimates and names of the fixed-effects coefficients in \text{glme}.

\[
[\text{beta, betanames}] = \text{fixedEffects}('\text{glme}');
\]

\[
\text{beta} = 6 \times 1
\]

\[
\begin{align*}
1.4689 \\
-0.3677 \\
-0.0945 \\
-0.2832 \\
-0.0719 \\
0.0711
\end{align*}
\]
betanames = 6×1 table
Name

'(Intercept)' 'newprocess' 'time_dev' 'temp_dev' 'supplier_C' 'supplier_B'

Each row of beta contains the estimated value for the coefficient named in the corresponding row of betanames. For example, the value -0.0945 in row 3 of beta is the estimated coefficient for the predictor variable time_dev.

Compute the 95% confidence intervals for the fixed-effects coefficients.

feCI = coefCI(glme)

feCI = 6×2

1.1515    1.7864
-0.7202   -0.0151
-1.7395    1.5505
-2.1926    1.6263
-0.2268    0.0831
-0.0826    0.2247

Column 1 of feCI contains the lower bound of the 95% confidence interval. Column 2 contains the upper bound. Row 1 corresponds to the intercept term. Rows 2, 3, and 4 correspond to newprocess, time_dev, and temp_dev, respectively. Rows 5 and 6 correspond to the indicator variables supplier_C and supplier_B, respectively. For example, the 95% confidence interval for the coefficient for time_dev is [-1.7395, 1.5505]. Some of the confidence intervals include 0, which indicates that those predictors are not significant at the 5% significance level. To obtain specific $P$-values for each fixed-effects term, use fixedEffects. To test significance for entire terms, use anova.
99% Confidence Intervals for Random Effects

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1\text{newprocess}_{ij} + \beta_2\text{time}_\text{dev}_{ij} + \beta_3\text{temp}_\text{dev}_{ij} + \beta_4\text{supplier}_C_{ij} + \beta_5\text{supplier}_B_{ij} + b_i,$$
where

- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
- \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, \ldots, 20 \)) during batch \( j \) (where \( j = 1, 2, \ldots, 5 \)).
- \( \text{newprocess}_{ij} \), \( \text{time}_\text{dev}_{ij} \), and \( \text{temp}_\text{dev}_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, \( \text{newprocess}_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.
- \( \text{supplier}_C_{ij} \) and \( \text{supplier}_B_{ij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).
- \( b_i \sim N(0, \sigma^2_b) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

\[
\text{glme} = \text{fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)'),'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
\]

Use \text{randomEffects} to compute and display the estimates of the empirical Bayes predictors (EBPs) for the random effects associated with factory.

\[
[B,Bnames] = \text{randomEffects(glme)}
\]

\[
B = 20\times1
\]

\[
\begin{align*}
0.2913 \\
0.1542 \\
-0.2633 \\
-0.4257 \\
0.5453 \\
-0.1069 \\
0.3040 \\
-0.1653 \\
-0.1458 \\
-0.0816 \\
\vdots
\end{align*}
\]
Each row of B contains the estimated EBPs for the random-effects coefficient named in the corresponding row of Bnames. For example, the value -0.2633 in row 3 of B is the estimated coefficient of '(Intercept)' for level '3' of factory.

Compute the 99% confidence intervals of the EBPs for the random effects.

\[
[\text{feCI}, \text{reCI}] = \text{coefCI}(\text{glme}, '\text{Alpha}', 0.01);
\]

reCI

\[
\text{reCI} = 20 \times 2
\]

-0.2125 0.7951
-0.3510 0.6595
-0.8219 0.2954
-0.9953 0.1440
0.0730 1.0176
-0.6362 0.4224
-0.1796 0.7877
-0.7044 0.3738
-0.6795 0.3880
-0.6142 0.4509
Column 1 of `reCI` contains the lower bound of the 99% confidence interval. Column 2 contains the upper bound. Each row corresponds to a level of `factory`, in the order shown in `Bnames`. For example, row 3 corresponds to the coefficient of `(Intercept)` for level '3' of `factory`, which has a 99% confidence interval of [-0.8219, 0.2954]. For additional statistics related to each random-effects term, use `randomEffects`.

coefCI

Class: CompactLinearModel

Confidence intervals of coefficient estimates of linear model

Syntax

\[ ci = \text{coefCI}(mdl) \]
\[ ci = \text{coefCI}(mdl,\alpha) \]

Description

\[ ci = \text{coefCI}(mdl) \] returns confidence intervals for the coefficients in \(mdl\).

\[ ci = \text{coefCI}(mdl,\alpha) \] returns confidence intervals using the confidence level \(1 - \alpha\).

Input Arguments

\texttt{mdl} — Linear model object
LinearModel object | CompactLinearModel object

Linear model object, specified as a full \texttt{LinearModel} object constructed using \texttt{fitlm} or \texttt{stepwiselm}, or a compacted \texttt{CompactLinearModel} object constructed using \texttt{compact}.

\texttt{alpha} — Confidence interval
0.05 (default) | numeric value in the range \([0,1]\)

Confidence interval, specified as a numeric value in the range \([0,1]\). \texttt{alpha} is the probability that the confidence interval does not contain the true value.
Output Arguments

\textbf{ci} — Confidence intervals
numeric matrix

Confidence intervals, returned as a \( k \)-by-2 numeric matrix. The \( j \)th row of \( \text{ci} \) is the confidence interval of coefficient \( j \) of \( \text{mdl} \). The name of coefficient \( j \) is stored in the \( \text{mdl} \) property \text{CoefficientNames}.

Examples

\textbf{Fit Linear Model Using Default Confidence Intervals}

Fit a linear regression model for auto mileage based on the \texttt{carbig} data. Then obtain the default 95\% confidence intervals for the resulting model coefficients.

Load the data and create a table.

```matlab
load carbig
Origin = nominal(Origin);
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model. Use horsepower, weight, and origin as predictor variables, and miles per gallon as the response variable.

```matlab
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

View the names of the coefficients.

```matlab
mdl.CoefficientNames
ans = 1x9 cell array
    Columns 1 through 4
    {'(Intercept)'}    {'Horsepower'}    {'Weight'}    {'Origin_France'}
    Columns 5 through 7
    {'Origin_Germany'}    {'Origin_Italy'}    {'Origin_Japan'}
```
Find confidence intervals for the coefficients of the model.

\[
\text{ci} = \text{coefCI}(\text{mdl})
\]

\[
\text{ci} = \begin{bmatrix}
43.3611 & 59.9390 \\
-0.0748 & -0.0315 \\
-0.0059 & -0.0037 \\
-17.3623 & -0.3477 \\
-15.7503 & 0.7434 \\
-17.2091 & 0.0613 \\
-14.5106 & 1.8738 \\
-18.5820 & -1.5036 \\
-17.3114 & -0.9642
\end{bmatrix}
\]

**Fit Linear Model with Custom Confidence Intervals**

Fit a linear regression model for auto mileage based on the carbig data. Then obtain confidence intervals for the resulting model coefficients at the 99% level.

Load the data and create a table.

```matlab
load carbig
Origin = nominal(Origin);
tbl = table(Horsepower,Weight,MPG,Origin);
```

Fit a linear regression model using horsepower, weight, and origin as the predictor variables, and miles per gallon as the response variable.

```matlab
modelspec = 'MPG ~ 1 + Horsepower + Weight + Origin';
mdl = fitlm(tbl,modelspec);
```

Find 99% confidence intervals for the coefficients.

```matlab
\text{ci} = \text{coefCI}(\text{mdl}, .01)
\```

### Definitions

#### Confidence Interval

Assume that model assumptions hold (data comes from a generalized linear model represented by the formula `mdl.Formula`, and with observations that are independent conditional on the predictor values). Then row $j$ of the confidence interval matrix $ci$ gives a confidence interval $[ci(j,1),ci(j,2)]$ computed such that, with repeated experimentation, a proportion $1 - \alpha$ of the intervals will contain the true value of the coefficient.

#### Alternatives

You can create the intervals from the model coefficients in `mdl.Coefficients.Estimate` and an appropriate multiplier of the standard errors $\sqrt{\text{diag}(mdl.CoefficientCovariance)}$. The multiplier is $\text{tinv}(1-\alpha/2,\text{dof})$, where `level` is the confidence level, and `dof` is the degrees of freedom (number of data points minus the number of coefficients).

**coefCI**

**Class:** LinearMixedModel

Confidence intervals for coefficients of linear mixed-effects model

**Syntax**

feCI = coefCI(lme)  
feCI = coefCI(lme,Name,Value)  
[feCI,reCI] = coefCI(__)

**Description**

feCI = coefCI(lme) returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model lme.

feCI = coefCI(lme,Name,Value) returns the 95% confidence intervals for the fixed-effects coefficients in the linear mixed-effects model lme with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the confidence level or method to compute the degrees of freedom.

[feCI,reCI] = coefCI(__) also returns the 95% confidence intervals for the random-effects coefficients in the linear mixed-effects model lme.

**Input Arguments**

lme — Linear mixed-effects model  
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**Alpha — Confidence level**

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

**DFMethod — Method for computing approximate degrees of freedom**

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'

Default. The degrees of freedom are assumed to be constant and equal to n - p, where n is the number of observations and p is the number of fixed effects.

'satterthwaite'

Satterthwaite approximation.

'none'

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'
Output Arguments

**feCI — Fixed-effects confidence intervals**

\[ p \times 2 \] matrix

Fixed-effects confidence intervals, returned as a \( p \times 2 \) matrix. \( \text{feCI} \) contains the confidence limits that correspond to the \( p \) fixed-effects estimates in the vector \( \text{beta} \) returned by the \text{fixedEffects} method. The first column of \( \text{feCI} \) has the lower confidence limits and the second column has the upper confidence limits.

**reCI — Random-effects confidence intervals**

\[ q \times 2 \] matrix

Random-effects confidence intervals, returned as a \( q \times 2 \) matrix. \( \text{reCI} \) contains the confidence limits corresponding to the \( q \) random-effects estimates in the vector \( \text{B} \) returned by the \text{randomEffects} method. The first column of \( \text{reCI} \) has the lower confidence limits and the second column has the upper confidence limits.

Examples

**95% Confidence Intervals for Fixed-Effects Coefficients**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'))
```

\( \text{weight} \) contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define \text{Subject} and \text{Program} as categorical variables.

```matlab
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');

Compute the fixed-effects coefficient estimates.

fe = fixedEffects(lme)

fe = 9×1

0.6610
0.0032
0.3608
-0.0333
0.1132
0.1732
0.0388
0.0305
0.0331

The first estimate, 0.6610, corresponds to the constant term. The second row, 0.0032, and
the third row, 0.3608, are estimates for the coefficient of initial weight and week,
respectively. Rows four to six correspond to the indicator variables for programs B-D, and
the last three rows correspond to the interaction of programs B-D and week.

Compute the 95% confidence intervals for the fixed-effects coefficients.

fecI = coefCI(lme)

fecI = 9×2

0.1480    1.1741
0.0005    0.0059
0.1004    0.6211
-0.2932    0.2267
-0.1471    0.3734
0.0395    0.3069
-0.1503    0.2278
-0.1585    0.2196
-0.1559    0.2221

Some confidence intervals include 0. To obtain specific \( P \)-values for each fixed-effects
term, use the fixedEffects method. To test for entire terms use the anova method.
Confidence Intervals with Specified Options

Load the sample data.

load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and a potentially correlated random effect for intercept and acceleration grouped by model year. First, store the data in a table.

tbl = table(Acceleration,Horsepower,Model_Year,MPG);

Fit the model.

lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');

Compute the fixed-effects coefficient estimates.

fe = fixedEffects(lme)

fe = 3×1
75.1325
-0.5833
-0.1695

Compute the 99% confidence intervals for fixed-effects coefficients using the residuals method to determine the degrees of freedom. This is the default method.

feCI = coefCI(lme,'Alpha',0.01)

feCI = 3×2
44.2690   55.9961
-0.9300   -0.2365
-0.1883   -0.1507

Compute the 99% confidence intervals for fixed-effects coefficients using the Satterthwaite approximation to compute the degrees of freedom.

feCI = coefCI(lme,'Alpha',0.01,'DFMethod','satterthwaite')
feCI = 3×2

<p>| | |</p>

The Satterthwaite approximation produces similar confidence intervals than the residual method.

**Compute Confidence Intervals for Random Effects**

Load the sample data.

load(fullfile(matlabroot,'examples','stats','shift.mat'))

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');

Compute the estimate of the BLUPs for random effects.

randomEffects(lme)

ans = 5×1

\]

\[
[~,\text{reCI}] = \text{coefCI}(\text{lme})
\]

\[
\text{reCI} = 5 \times 2
\]

\[
\begin{bmatrix}
-1.3916 & 2.5467 \\
-0.7934 & 3.1449 \\
-4.1407 & -0.2024 \\
0.3964 & 4.3347 \\
-3.9164 & 0.0219 \\
\end{bmatrix}
\]

Compute the 99% confidence intervals for random effects using the residuals method to determine the degrees of freedom. This is the default method.

\[
[~,\text{reCI}] = \text{coefCI}(\text{lme},'\text{Alpha}',0.01)
\]

\[
\text{reCI} = 5 \times 2
\]

\[
\begin{bmatrix}
-2.1831 & 3.3382 \\
-1.5849 & 3.9364 \\
-4.9322 & 0.5891 \\
-0.3951 & 5.1261 \\
-4.7079 & 0.8134 \\
\end{bmatrix}
\]

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to determine the degrees of freedom.

\[
[~,\text{reCI}] = \text{coefCI}(\text{lme},'\text{Alpha}',0.01,'\text{DFMethod}','\text{satterthwaite}')
\]

\[
\text{reCI} = 5 \times 2
\]

\[
\begin{bmatrix}
-2.6840 & 3.8390 \\
-2.0858 & 4.4372 \\
-5.4330 & 1.0900 \\
-0.8960 & 5.6270 \\
-5.2087 & 1.3142 \\
\end{bmatrix}
\]
The Satterthwaite approximation might produce smaller DF values than the residual method. That is why these confidence intervals are larger than the previous ones computed using the residual method.

**coefCI**

**Class:** NonLinearModel

Confidence intervals of coefficient estimates of nonlinear regression model

**Syntax**

```plaintext
ci = coefCI(mdl)
ci = coefCI(mdl,alpha)
```

**Description**

`ci = coefCI(mdl)` returns confidence intervals for the coefficients in `mdl`.

`ci = coefCI(mdl,alpha)` returns confidence intervals with confidence level $1 - \alpha$.

**Input Arguments**

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`alpha`

Scalar from 0 to 1, the probability that the confidence interval does not contain the true value.

**Default:** 0.05
Output Arguments

ci

k-by-2 matrix of confidence intervals. The jth row of ci is the confidence interval of coefficient j of mdl. The name of coefficient j of mdl is in mdl.CoeffNames.

Examples

Default Confidence Intervals

Create a nonlinear model for auto mileage based on the carbig data. Then obtain confidence intervals for the resulting model coefficients.

Load the data and create a nonlinear model.

load carbig
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1) + ...  
  b(3)*x(:,2) + b(4)*x(:,1).*x(:,2);
beta0 = [1 1 1 1];
mdl = fitnlm(ds,modelfun,beta0)

mdl =
    Nonlinear regression model:
                MPG ~ b1 + b2*Horsepower + b3*Weight + b4*Horsepower*Weight

    Estimated Coefficients:
                                Estimate     SE         tStat     pValue
                                _____      ______    _______    _______
               b1            63.558     2.3429     27.127    1.2343e-91
               b2           -0.25084    0.02728    -9.1952    2.3226e-18
               b3          -0.010772   0.0007738    -13.921    5.1372e-36
               b4        5.3554e-05   6.6491e-06      8.0542    9.9336e-15

Number of observations: 392, Error degrees of freedom: 388
Root Mean Squared Error: 3.93
R-Squared: 0.748, Adjusted R-Squared 0.746
F-statistic vs. constant model: 385, p-value = 7.26e-116
All the coefficients have extremely small $P$-values. This means a confidence interval around the coefficients will not contain the point 0, unless the confidence level is very high.

Find 95% confidence intervals for the coefficients of the model.

```matlab
ci = coefCI(mdl)
ci = 4×2
   58.9515   68.1644
  -0.3045  -0.1972
  -0.0123  -0.0093
    0.0000    0.0001
```

The confidence interval for $b4$ seems to contain 0. Examine it in more detail.

```matlab
ci(4,:) ans = 1×2
10^{-4} ×
   0.4048   0.6663
```

As expected, the confidence interval does not contain the point 0.

### Definitions

#### Confidence Interval

Assume that model assumptions hold (the data comes from a model represented by the formula $mdl$. Formula, with independent normally distributed errors). Then row $j$ of the confidence interval matrix $ci$ gives a confidence interval $[ci(j,1),ci(j,2)]$ that contains coefficient $j$ with probability $1 - \alpha$. 

32-662
Alternatives

You can create the intervals from the model coefficients in \texttt{mdl.Coefficients.Estimate} and an appropriate multiplier of the standard errors \texttt{sqrt(diag(mdl.CoefficientCovariance))}. The multiplier is \texttt{tinv(1-alpha/2,dof)}, where \texttt{level} is the confidence level, and \texttt{dof} is the degrees of freedom (number of data points minus the number of coefficients).

**coefTest**

Linear hypothesis test on generalized linear regression model coefficients

**Syntax**

\[ p = \text{coefTest}(\text{mdl}) \]
\[ p = \text{coefTest}(\text{mdl},H) \]
\[ p = \text{coefTest}(\text{mdl},H,C) \]
\[ [p,F] = \text{coefTest}(\text{mdl},...) \]
\[ [p,F,r] = \text{coefTest}(\text{mdl},...) \]

**Description**

\( p = \text{coefTest}(\text{mdl}) \) computes the \( p \)-value for an \( F \) test that all coefficient estimates in \( \text{mdl} \) are zero, except for the intercept term.

\( p = \text{coefTest}(\text{mdl},H) \) performs an \( F \) test that \( H*B = 0 \), where \( B \) represents the coefficient vector.

\( p = \text{coefTest}(\text{mdl},H,C) \) performs an \( F \) test that \( H*B = C \).

\([p,F] = \text{coefTest}(\text{mdl},...)\) returns the \( F \) test statistic.

\([p,F,r] = \text{coefTest}(\text{mdl},...)\) returns the numerator degrees of freedom for the test.

**Input Arguments**

\texttt{mdl}

Generalized linear model, specified as a full \texttt{GeneralizedLinearModel} object constructed using \texttt{fitglm} or \texttt{stepwiseglm}, or a compacted \texttt{CompactGeneralizedLinearModel} object constructed using \texttt{compact}.
**H**

Numeric matrix having one column for each coefficient in the model. When H is an input, the output p is the p-value for an F test that \( H*B = 0 \), where B represents the coefficient vector.

**C**

Numeric vector with the same number of rows as H. When C is an input, the output p is the p-value for an F test that \( H*B = C \), where B represents the coefficient vector.

**Output Arguments**

**p**

p-value of the \( F \) test (see “Definitions” on page 32-666).

**F**

Value of the test statistic for the \( F \) test (see “Definitions” on page 32-666).

**r**

Numerator degrees of freedom for the \( F \) test (see “Definitions” on page 32-666). The \( F \) statistic has r degrees of freedom in the numerator and mdl.DFE degrees of freedom in the denominator.

**Examples**

**Test Generalized Linear Model Coefficients**

Test a generalized linear model to see if its coefficients differ from zero.

Create a generalized linear regression model of Poisson data.

```matlab
X = 2 + randn(100,1);
mu = exp(1 + X/2);
y = poissrnd(mu);
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```
Test whether the fitted model has coefficients that differ significantly from zero.

\[ p = \text{coefTest}(mdl) \]
\[ p = 3.1394 \times 10^{-36} \]

There is no doubt that the coefficient of \( x1 \) is nonzero.

**Definitions**

**Test Statistics**

The \( p \)-value, \( F \) statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula \( mdl.\text{Formula} \).
- The observations are independent conditional on the predictor values.

Suppose these assumptions hold. Let \( \beta \) represent the (unknown) coefficient vector of the linear regression. Suppose \( H \) is a full-rank matrix of size \( r \)-by-\( s \), where \( s \) is the number of terms in \( \beta \). Let \( v \) be a vector the same size as \( \beta \). The following is a test statistic for the hypothesis that \( H\beta = v \):

\[
F = (H\hat{\beta} - v)'(HCH')^{-1}(H\hat{\beta} - v).
\]

Here \( \hat{\beta} \) is the estimate of the coefficient vector \( \beta \) in \( mdl.\text{Coeffs} \), and \( C \) is the estimated covariance of the coefficient estimates in \( mdl.\text{CoeffCov} \). When the hypothesis is true, the test statistic \( F \) has an “F Distribution” on page B-42 with \( r \) and \( u \) degrees of freedom.

**Alternatives**

The values of commonly used test statistics are available in the \( mdl.\text{Coefficients} \) table.

“Generalized Linear Model Workflow” on page 12-40
“Generalized Linear Models” on page 12-12
coefTest

Class: GeneralizedLinearMixedModel

Hypothesis test on fixed and random effects of generalized linear mixed-effects model

Syntax

pVal = coefTest(glme)
pVal = coefTest(glme,H)
pVal = coefTest(glme,H,C)
pVal = coefTest(glme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest(__)

Description

pVal = coefTest(glme) returns the p-value of an F-test of the null hypothesis that all fixed-effects coefficients of the generalized linear mixed-effects model glme, except for the intercept, are equal to 0.

pVal = coefTest(glme,H) returns the p-value of an F-test using a specified contrast matrix, H. The null hypothesis is $H_0: H\beta = 0$, where $\beta$ is the fixed-effects vector.

pVal = coefTest(glme,H,C) returns the p-value for an F-test using the hypothesized value, C. The null hypothesis is $H_0: H\beta = C$, where $\beta$ is the fixed-effects vector.

pVal = coefTest(glme,H,C,Name,Value) returns the p-value for an F-test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model glme, with additional options specified by one or more name-value pair arguments. For example, you can specify the method to compute the approximate denominator degrees of freedom for the F-test.

[pVal,F,DF1,DF2] = coefTest(__) also returns the F-statistic, F, and the numerator and denominator degrees of freedom for F, respectively DF1 and DF2, using any of the previous syntaxes.
Input Arguments

**glme — Generalized linear mixed-effects model**  
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**H — Fixed-effects contrasts**  
$m$-by-$p$ matrix

Fixed-effects contrasts, specified as an $m$-by-$p$ matrix, where $p$ is the number of fixed-effects coefficients in `glme`. Each row of $H$ represents one contrast. The columns of $H$ (left to right) correspond to the rows of the $p$-by-1 fixed-effects vector $\beta$ (top to bottom) whose estimate is returned by the `fixedEffects` method.

Data Types: `single` | `double`

**C — Hypothesized value**  
$m$-by-1 vector

Hypothesized value for testing the null hypothesis $H\beta = C$, specified as an $m$-by-1 vector. Here, $\beta$ is the vector of fixed-effects whose estimate is returned by `fixedEffects`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**DFMethod — Method for computing approximate degrees of freedom**  
'field' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'residual'</td>
<td>The degrees of freedom value is assumed to be constant and equal to ( n - p ), where ( n ) is the number of observations and ( p ) is the number of fixed effects.</td>
</tr>
<tr>
<td>'none'</td>
<td>The degrees of freedom is set to infinity.</td>
</tr>
</tbody>
</table>

Example: 'DFMethod', 'none'

**REContrast — Random-effects contrasts**

\( m \)-by-\( q \) matrix

Random-effects contrasts, specified as the comma-separated pair consisting of 'REContrast' and an \( m \)-by-\( q \) matrix, where \( q \) is the number of random effects parameters in \textit{glme}. The columns of the matrix (left to right) correspond to the rows of the \( q \)-by-1 random-effects vector \( B \) (top to bottom), whose estimate is returned by the \textit{randomEffects} method.

Data Types: single | double

### Output Arguments

**pVal — \( p \)-value**

scalar value

\( p \)-value for the \( F \)-test on the fixed- and/or random-effects coefficients of the generalized linear mixed-effects model \textit{glme}, returned as a scalar value.

When fitting a GLME model using \textit{fitglme} and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), \textit{coefTest} uses an approximation of the conditional mean squared error of prediction (CMSEP) of the estimated linear combination of fixed- and random-effects to compute \( p \)-values. This accounts for the uncertainty in the fixed-effects estimates, but not for the uncertainty in the covariance parameter estimates. For tests on fixed effects only, if you specify the 'CovarianceMethod' name-value pair argument in \textit{fitglme} as 'JointHessian', then \textit{coefTest} accounts for the uncertainty in the estimation of covariance parameters.

When fitting a GLME model using \textit{fitglme} and one of the pseudo likelihood fit methods ('MPL' or 'REML'), \textit{coefTest} bases the inference on the fitted linear mixed effects model from the final pseudo likelihood iteration.
F — F-statistic
scalar value

F-statistic, returned as a scalar value.

DF1 — Numerator degrees of freedom for F
scalar value

Numerator degrees of freedom for the F-statistic F, returned as a scalar value.

• If you test the null hypothesis $H_0: H\beta = 0$ or $H_0: H\beta = C$, then $DF1$ is equal to the number of linearly independent rows in $H$.
• If you test the null hypothesis $H_0: H\beta + KB = C$, then $DF1$ is equal to the number of linearly independent rows in $[H,K]$.

DF2 — Denominator degrees of freedom for F
scalar value

Denominator degrees of freedom for the F-statistic F, returned as a scalar value. The value of $DF2$ depends on the option specified by the 'DFMethod' name-value pair argument.

Examples

Test the Significance of Coefficients

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:
- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time} \_ \text{dev}_{ij} + \beta_3 \text{temp} \_ \text{dev}_{ij} + \beta_4 \text{supplier} \_ \text{C}_{ij} + \beta_5 \text{supplier} \_ \text{B}_{ij} + b_i,$$

where

- $\text{defects}_{ij}$ is the number of defects observed in the batch produced by factory $i$ during batch $j$.
- $\mu_{ij}$ is the mean number of defects corresponding to factory $i$ (where $i = 1, 2, \ldots, 20$) during batch $j$ (where $j = 1, 2, \ldots, 5$).
• \(\text{newprocess}_{ij}\), \(\text{time\_dev}_{ij}\), and \(\text{temp\_dev}_{ij}\) are the measurements for each variable that correspond to factory \(i\) during batch \(j\). For example, \(\text{newprocess}_{ij}\) indicates whether the batch produced by factory \(i\) during batch \(j\) used the new process.

• \(\text{supplier\_C}_{ij}\) and \(\text{supplier\_B}_{ij}\) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \(i\) during batch \(j\).

• \(b_i \sim N(0, \sigma^2_b)\) is a random-effects intercept for each factory \(i\) that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme(mfr,'defects} - 1 + \text{newprocess + time\_dev + temp\_dev + supplier} + (1|\text{factory})'\text{,'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects')}
\]

Test if there is any significant difference between supplier C and supplier B.

\[
H = [0,0,0,0,1,-1];
\]

\[
[pVal,F,DF1,DF2] = \text{coefTest(glme,H)}
\]

\[
pVal = 0.2793
\]
\[
F = 1.1842
\]
\[
DF1 = 1
\]
\[
DF2 = 94
\]

The large \(p\)-value indicates that there is no significant difference between supplier C and supplier B at the 5% significance level. Here, \text{coefTest} also returns the \(F\)-statistic, the numerator degrees of freedom, and the approximate denominator degrees of freedom.

Test if there is any significant difference between supplier A and supplier B.

If you specify the 'DummyVarCoding' name-value pair argument as 'effects' when fitting the model using \text{fitglme}, then

\[
\beta_A + \beta_B + \beta_C = 0,
\]
where $\beta_A$, $\beta_B$, and $\beta_C$ correspond to suppliers A, B, and C, respectively. $\beta_A$ is the effect of A minus the average effect of A, B, and C. To determine the contrast matrix corresponding to a test between supplier A and supplier B,

$$\beta_B - \beta_A = \beta_B - (-\beta_B - \beta_C) = 2\beta_B + \beta_C.$$ 

From the output of `disp(glme)`, column 5 of the contrast matrix corresponds to $\beta_C$, and column 6 corresponds to $\beta_B$. Therefore, the contrast matrix for this test is specified as $H = [0,0,0,0,1,2]$.

$$H = [0,0,0,0,1,2];$$

$$[pVal,F,DF1,DF2] = \text{coefTest}(glme,H)$$

$pVal = 0.6177$

$F = 0.2508$

$DF1 = 1$

$DF2 = 94$

The large $p$-value indicates that there is no significant difference between supplier A and supplier B at the 5% significance level.

**coefTest**

**Class:** CompactLinearModel

Linear hypothesis test on linear regression model coefficients

**Syntax**

```matlab
p = coefTest(mdl)
p = coefTest(mdl,H)
p = coefTest(mdl,H,C)
[p,F] = coefTest(mdl,___)
[p,F,r] = coefTest(mdl,___)
```

**Description**

`p = coefTest(mdl)` computes the p-value for an F test that all coefficient estimates in `mdl` are zero, except for the intercept term.

`p = coefTest(mdl,H)` performs an F test that `H × B = 0`, where `B` represents the coefficient vector.

`p = coefTest(mdl,H,C)` performs an F test that `H × B = C`.

`[p,F] = coefTest(mdl,___)` returns the F test statistic, `F`, using any of the previous syntaxes.

`[p,F,r] = coefTest(mdl,___)` returns the numerator degrees of freedom, `r`, for the test.

**Input Arguments**

`mdl` — Linear model object
LinearModel object | CompactLinearModel object
Linear model object, specified as a full `LinearModel` object constructed using `fitlm` or `stepwiselm`, or a compacted `CompactLinearModel` object constructed using `compact`.

**H — Hypothesized model coefficients**
numeric matrix

Hypothesized model coefficients, specified as a numeric matrix with one column for each coefficient in the model. If H is an input, then the output p is the p-value for an F test that \( H \times B = 0 \), where \( B \) represents the coefficient vector.

**C — Hypothesized value**
numeric vector

Hypothesized value for testing the null hypothesis, specified as a numeric vector with the same number of rows as H. When C is an input, the output p is the p-value for an F test that \( H \times B = C \), where \( B \) represents the coefficient vector.

**Output Arguments**

**p — p-value for F test**
numeric value in the range [0,1]

p-value of the F test, returned as a numeric value in the range [0,1].

**F — Test statistic for F test**
numeric value

Value of the test statistic for the F test, returned as a numeric value.

**r — Numerator degrees of freedom for F test**
positive integer

Numerator degrees of freedom for the F test, returned as a positive integer. The F statistic has \( r \) degrees of freedom in the numerator and `mdl.DFE` degrees of freedom in the denominator.

**Examples**
**Test Significance of Linear Regression Model**

Fit a linear regression model of mileage as a function of the weight, weight squared, and model year from the `carsmall` data set. Test the coefficients to see if all should be zero.

Load the data and make a table, where the model year is an ordinal variable.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight + Weight^2');
```

Test the model for significant differences from a constant model.

```matlab
p = coefTest(mdl)
```

```
p = 5.5208e-41
```

The returned $p$-value indicates that the fitted model contains more than the intercept term.

**Test Significance of Linear Model Coefficient**

Test the $Weight^2$ coefficient in a linear model of mileage as a function of the weight, weight squared, and model year.

Load the data and make a table, where the model year is an ordinal variable.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight + Weight^2');
```

Test the significance of the $Weight^2$ coefficient. To do so, find the coefficient corresponding to $Weight^2$.

```matlab
mdl.CoefficientNames
```
Weight^2 is the fifth (final) coefficient.

Test the significance of the Weight^2 coefficient.

\[
p = \text{coefTest}(mdl,[0 0 0 0 1])
\]
\[
p = 0.0022
\]

**Definitions**

**Test Statistics**

The \( p \)-value, \( F \) statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a model represented by the formula `mdl.formula`.
- The observations are independent conditional on the predictor values.

Suppose these assumptions hold. Let \( \beta \) represent the (unknown) coefficient vector of the linear regression. Suppose \( H \) is a full-rank matrix of size \( r \)-by-\( s \), where \( s \) is the number of terms in \( \beta \). Let \( v \) be a vector the same size as \( \beta \). The following is a test statistic for the hypothesis that \( H\beta = v \):

\[
F = (H\hat{\beta} - v)'(HCH')^{-1}(H\hat{\beta} - v).
\]

Here \( \hat{\beta} \) is the estimate of the coefficient vector \( \beta \) in `mdl.Coeffs`, and \( C \) is the estimated covariance of the coefficient estimates in `mdl.CoeffCov`. When the hypothesis is true, the test statistic \( F \) has an “F Distribution” on page B-42 with \( r \) and \( u \) degrees of freedom.

**Alternatives**

The values of commonly used test statistics are available in the `mdl.Coefficients` table.
anova provides a test for each model term.

“Linear Regression” on page 11-11
coefTest

Class: LinearMixedModel

Hypothesis test on fixed and random effects of linear mixed-effects model

Syntax

pVal = coefTest(lme)
pVal = coefTest(lme,H)
pVal = coefTest(lme,H,C)
pVal = coefTest(lme,H,C,Name,Value)
[pVal,F,DF1,DF2] = coefTest(____)

Description

pVal = coefTest(lme) returns the p-value for an F-test that all fixed-effects coefficients except for the intercept are 0.

pVal = coefTest(lme,H) returns the p-value for an F-test on fixed-effects coefficients of linear mixed-effects model lme, using the contrast matrix H. It tests the null hypothesis that $H\beta = 0$, where $\beta$ is the fixed-effects vector.

pVal = coefTest(lme,H,C) returns the p-value for an F-test on fixed-effects coefficients of the linear mixed-effects model lme, using the contrast matrix H. It tests the null hypothesis that $H\beta = C$, where $\beta$ is the fixed-effects vector.

pVal = coefTest(lme,H,C,Name,Value) returns the p-value for an F-test on the fixed- and/or random-effects coefficients of the linear mixed-effects model lme, with additional options specified by one or more name-value pair arguments. For example, 'REContrast',K tells coefTest to test the null hypothesis that $H_0: H\beta + KB = C$, where $\beta$ is the fixed-effects vector and $B$ is the random-effects vector.

[pVal,F,DF1,DF2] = coefTest(____) also returns the F-statistic $F$, and the numerator and denominator degrees of freedom for $F$, respectively $DF1$ and $DF2$. 
**Input Arguments**

**lme** — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

**H** — Fixed-effects contrasts

*m-by-*p matrix

Fixed-effects contrasts, specified as an *m*-by-*p* matrix, where *p* is the number of fixed-effects coefficients in `lme`. Each row of `H` represents one contrast. The columns of `H` (left to right) correspond to the rows of the *p*-by-1 fixed-effects vector `beta` (top to bottom), returned by the `fixedEffects` method.

Data Types: `single` | `double`

**C** — Hypothesized value

*m*-by-1 vector

Hypothesized value for testing the null hypothesis \( H^* \beta = C \), specified as an *m*-by-1 matrix. Here, `beta` is the vector of fixed-effects estimates returned by the `fixedEffects` method.

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**DFMethod** — Method for computing approximate denominator degrees of freedom

'`residual' (default) | 'satterthwaite' | 'none'

Method for computing the approximate denominator degrees of freedom for the *F*-test, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.
Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where $n$ is the number of observations and $p$ is the number of fixed effects.

Satterthwaite approximation.

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod','satterthwaite'

**REContrast — Random-effects contrasts**

$m$-by-$q$ matrix

Random-effects contrasts, specified as the comma-separated pair consisting of 'REContrast' and an $m$-by-$q$ matrix $K$, where $q$ is the number of random effects parameters in `lme`. The columns of $K$ (left to right) correspond to the rows of the random-effects best linear unbiased predictor vector $B$ (top to bottom), returned by the `randomEffects` method.

Data Types: single | double

**Output Arguments**

**pVal — $p$-value**

scalar value

$p$-value for the $F$-test on the fixed and/or random-effects coefficients of the linear mixed-effects model `lme`, returned as a scalar value.

**F — $F$-statistic**

scalar value

$F$-statistic, returned as a scalar value.

**DF1 — Numerator degrees of freedom for $F$**

 scalar value

Numerator degrees of freedom for $F$, returned as a scalar value.
If you test the null hypothesis $H_0: H\beta = 0$, or $H_0: H\beta = C$, then $DF_1$ is equal to the number of linearly independent rows in $H$.

If you test the null hypothesis $H_0: H\beta + KB = C$, then $DF_1$ is equal to the number of linearly independent rows in $[H, K]$.

**DF2 — Denominator degrees of freedom for $F$**  
Scalar value

Denominator degrees of freedom for $F$, returned as a scalar value. The value of $DF_2$ depends on the option you select for $DFMethod$.

**Examples**

**Test Fixed-Effects Coefficients for Categorical Data**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three different shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```matlab
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if there is significant difference in the performance according to the time of the shift.

```matlab
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)')
```

`lme =`

</table>

Test if all fixed-effects coefficients except for the intercept are 0.
pVal = coefTest(lme)
pVal = 7.5956e-04

The small *P*-value indicates that not all fixed-effects coefficients are 0.
Test the significance of the `Shift` term using a contrast matrix.

```matlab
H = [0 1 0; 0 0 1];
pVal = coefTest(lme,H)
pVal = 7.5956e-04
```

Test the significance of the `Shift` term using the `anova` method.

```matlab
anova(lme)
anova =
```

```
   ANOVA marginal tests: DFMethod = 'Residual'

   Term         FStat   DF1   DF2    pValue
   '(Intercept)' 12.375    1    12    0.0042407
   'Shift'      13.864    2    12    0.00075956
```

The $P$-value for `Shift`, 0.00075956, is the same as the $P$-value of the previous hypothesis test.

Test if there is any difference between the evening and morning shifts.

```matlab
pVal = coefTest(lme,[0 1 -1])
pVal = 3.6147e-04
```

This small $P$-value indicates that the performance of the operators are not the same in the morning and the evening shifts.

**Hypothesis Tests for Fixed-Effects Coefficients**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)')
lme =  
Linear mixed-effects model fit by ML

Model information:
  Number of observations    120
  Fixed effects coefficients    9
  Random effects coefficients  40
  Covariance parameters       4

Formula:
  y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)

Model fit statistics:
  AIC       BIC       LogLikelihood    Deviance

Fixed effects coefficients (95% CIs):

<td>0.10261</td>
<td>0.087882</td>
<td>0.11981</td>
</tr>
</tbody>
</table>

Test for the significance of the interaction between Program and Week.

\[
H = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0;
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0;
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1;
\end{bmatrix};
\]

\[
pVal = \text{coefTest}(lme,H)
\]

\[
pVal = 0.9775
\]

The high _p_-value indicates that the interaction between Program and Week is not statistically significant.

Now, test whether all coefficients involving Program are 0.

\[
H = \begin{bmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0;
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0;
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0;
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0;
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0;
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1;
\end{bmatrix};
\]

\[
C = [0;0;0;0;0;0;0;0];
\]

\[
pVal = \text{coefTest}(lme,H,C)
\]
pVal = 0.0274

The $P$-value of 0.0274 indicates that not all coefficients involving Program are zero.

**Hypothesis Tests for Fixed- and Random-Effects Coefficients**

Load the sample data.

```matlab
load flu
```

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear mixed-effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',... 'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by Date.

```matlab
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

```matlab
lme =  
Linear mixed-effects model fit by ML

Model information:  
 Number of observations 468  
 Fixed effects coefficients 9  
 Random effects coefficients 52  
 Covariance parameters 2 

Formula:  
 FluRate ~ 1 + Region + (1 | Date)
```

LinearMixedModel | anova | coefCI
**coefTest**

**Class:** NonLinearModel

Linear hypothesis test on nonlinear regression model coefficients

**Syntax**

\[ p = \text{coefTest}(mdl) \]
\[ p = \text{coefTest}(mdl,H) \]
\[ p = \text{coefTest}(mdl,H,C) \]
\[ [p,F] = \text{coefTest}(mdl,...) \]
\[ [p,F,r] = \text{coefTest}(mdl,...) \]

**Description**

\[ p = \text{coefTest}(mdl) \] computes the \( p \)-value for an \( F \) test that all coefficient estimates in \( mdl \) are zero.

\[ p = \text{coefTest}(mdl,H) \] performs an \( F \) test that \( H^*B = 0 \), where \( B \) represents the coefficient vector.

\[ p = \text{coefTest}(mdl,H,C) \] performs an \( F \) test that \( H^*B = C \).

\[ [p,F] = \text{coefTest}(mdl,...) \] returns the \( F \) test statistic.

\[ [p,F,r] = \text{coefTest}(mdl,...) \] returns the numerator degrees of freedom for the test.

**Input Arguments**

\( mdl \)

Nonlinear regression model, constructed by `fitnlm`. 
H

Numeric matrix having one column for each coefficient in the model. When H is an input, the output p is the p-value for an F test that H*B = 0, where B represents the coefficient vector.

C

Numeric vector with the same number of rows as H. When C is an input, the output p is the p-value for an F test that H*B = C, where B represents the coefficient vector.

Output Arguments

p

p-value of the F test (see “Definitions” on page 32-694).

F

Value of the test statistic for the F test (see “Definitions” on page 32-694).

r

Numerator degrees of freedom for the F test (see “Definitions” on page 32-694). The F statistic has r degrees of freedom in the numerator and mdl.DFE degrees of freedom in the denominator.

Examples

Test Nonlinear Regression Model Coefficients

Make a nonlinear model of mileage as a function of the weight from the carsmall data set. Test the coefficients to see if all should be zero.

Create an exponential model of car mileage as a function of weight from the carsmall data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);

Test the model for significant differences from a constant model.

p = coefTest(mdl)

p = 1.3708e-36

There is no doubt that the model contains nonzero terms.

Definitions

Test Statistics

The $p$-value, $F$ statistic, and numerator degrees of freedom are valid under these assumptions:

- The data comes from a normal distribution.
- The entries are independent.

Suppose these assumptions hold. Let $\beta$ represent the unknown coefficient vector of the linear regression. Suppose $H$ is a full-rank matrix of size $r$-by-$s$, where $s$ is the number of terms in $\beta$. Let $v$ be a vector the same size as $\beta$. The following is a test statistic for the hypothesis that $H\beta = v$:

$$F = (H\hat{\beta} - v)' (HCH')^{-1} (H\hat{\beta} - v).$$

Here $\hat{\beta}$ is the estimate of the coefficient vector $\beta$ in mdl.Coeffs, and $C$ is the estimated covariance of the coefficient estimates in mdl.CoeffCov. When the hypothesis is true, the test statistic $F$ has an “$F$ Distribution” on page B-42 with $r$ and $u$ degrees of freedom.
Alternatives

The values of commonly used test statistics are available in the mdl.Coefficients table.

coeftest

Class: RepeatedMeasuresModel

Linear hypothesis test on coefficients of repeated measures model

Syntax

tbl = coeftest(rm,A,C,D)

Description

tbl = coeftest(rm,A,C,D) returns a table tbl containing the multivariate analysis of variance (manova) for the repeated measures model rm.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

A — Specification representing between-subjects model
a-by-p matrix

Specification representing the between-subjects model, specified as an a-by-p numeric matrix, with rank $a \leq p$.

Data Types: single | double

C — Specification representing within-subjects hypothesis
r-by-c matrix

Specification representing the within-subjects (within time) hypotheses, specified as an r-by-c numeric matrix, with rank $c \leq r \leq n - p$. 

32-696
Data Types: single | double

D — Hypothesized value
0 (default) | scalar value | a-by-c matrix

Hypothesized value, specified as a scalar value or an a-by-c matrix.
Data Types: single | double

Output Arguments

tbl — Results of multivariate analysis of variance

Table

Results of multivariate analysis of variance for the repeated measures model rm, returned as a table containing the following columns.

Test Coefficients for First and Last Repeated Measures

Load the sample data.

load repeatedmeas
The table **between** includes the between-subject variables age, IQ, group, gender, and eight repeated measures y1 through y8 as responses. The table **within** includes the within-subject variables w1 and w2. This is simulated data.

Fit a repeated measures model, where the repeated measures y1 through y8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```matlab
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Test that the coefficients of all terms in the between-subjects model are the same for the first and last repeated measurement variable.

```matlab
coeftest(rm,eye(8),[1 0 0 0 0 0 0 -1])
```

```
ans=4×7 table
Statistic     Value       F       RSquare    df1    df2    pValue
_________    _______    ______    _______    ___    ___    _______
Pillai        0.3355    1.3884    0.3355      8     22     0.25567
Wilks         0.6645    1.3884    0.3355      8     22     0.25567
Hotelling    0.50488    1.3884    0.3355      8     22     0.25567
Roy          0.50488    1.3884    0.3355      8     22     0.25567
```

The *P*-value of 0.25567 indicates that there is not enough statistical evidence to conclude that the coefficients of all terms in the between-subjects model for the first and last repeated measures variable are different.

### Tips

- This test is defined as $A*B*C = D$, where $B$ is the matrix of coefficients in the repeated measures model. $A$ and $C$ are numeric matrices of the proper size for this multiplication. $D$ is a scalar or numeric matrix of the proper size. The default is $D = 0$.

combine

Class: CompactTreeBagger

Combine two ensembles

Syntax

$B_1 = \text{combine}(B_1,B_2)$

Description

$B_1 = \text{combine}(B_1,B_2)$ appends decision trees from ensemble $B_2$ to those stored in $B_1$ and returns ensemble $B_1$. This method requires that the class and variable names be identical in both ensembles.

See Also

TreeBagger.append
combnk

Enumeration of combinations

Syntax

C = combnk(v,k)

Description

C = combnk(v,k) returns all combinations of the n elements in v taken k at a time.

C = combnk(v,k) produces a matrix C with k columns and n!/k!(n - k)! rows, where each row contains k of the elements in the vector v.

It is not practical to use this function if v has more than about 15 elements.

Examples

Combinations of characters.

C = combnk('tendril',4);
last5 = C(31:35,:)
last5 =
tedr
tenl
teni
tenr
tend

Combinations of elements from a numeric vector.

c = combnk(1:4,2)
c =
   3  4
   2  4
   2  3

compact

Class: ClassificationDiscriminant

Compact discriminant analysis classifier

Syntax

cobj = compact(obj)

Description

`cobj = compact(obj)` creates a compact version of `obj`.

Input Arguments

`obj`

Discriminant analysis classifier created using `fitcdiscr`.

Output Arguments

`cobj`

Compact classifier. `cobj` has class `CompactClassificationDiscriminant`. You can predict classifications using `cobj` exactly as you can using `obj`. However, since `cobj` does not contain training data, you cannot perform some actions, such as cross validation.

Examples

Compare the size of the discriminant analysis classifier for Fisher's iris data to the compact version of the classifier:
load fisheriris
fullobj = fitcdiscr(meas,species);
cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory

ans =
    18578     11498

compact

**Class:** ClassificationECOC

Compact multiclass, error-correcting output codes model

**Syntax**

```matlab
CMdl = compact(Mdl)
```

**Description**

`CMdl = compact(Mdl)` returns a compact, multiclass, error-correcting output codes (ECOC) model (`CMdl`), which is the compact version of the trained ECOC model `Mdl`.

`CMdl` does not contain the training data, whereas `Mdl` contains the training data in its properties `Mdl.X` and `Mdl.Y`.

**Input Arguments**

- **Mdl** — Multiclass ECOC model
  ClassificationECOC model

  Multiclass ECOC model, specified as a `ClassificationECOC` model returned by `fitcecoc`.

**Output Arguments**

- **CMdl** — Compact ECOC model
  CompactClassificationECOC model

  Compact ECOC model, returned as a `CompactClassificationECOC` model.

  Predict class labels using `CMdl` exactly as you would using `Mdl`. However, since `CMdl` does not contain training data, you cannot implement cross validation.
Examples

Reduce the Size of Full ECOC Models

Full ECOC models (i.e., ClassificationECOC models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```matlab
t = templateSVM('Standardize',1);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. The software uses default values for empty options in `t` during training. `Mdl` is a ClassificationECOC model.

Reduce the size of the trained ECOC model.

```matlab
CMdl = compact(Mdl)
```

`CMdl` is a CompactClassificationECOC model. It does not store the training data nor some of the properties that `Mdl` stores.
Display how much memory each classifier uses.

\texttt{whos('Mdl','CMdl')} \\

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
</tr>
</thead>
<tbody>

<td>classreg.learning.classif.CompactClassificationECOC</td>
</tr>
<tr>
<td>Mdl</td>
<td>1x1</td>
<td>25784</td>
<td>ClassificationECOC</td>
</tr>
</tbody>
</table>

The full ECOC model (Mdl) is approximately double the size of the compact ECOC model (CMdl).

You can remove Mdl from the MATLAB® Workspace, and pass CMdl and new predictor values to \texttt{predict} to efficiently label new observations.

compact

Compact classification ensemble

Syntax

cens = compact(ens)

Description

cens = compact(ens) creates a compact version of ens. You can predict classifications using cens exactly as you can using ens. However, since cens does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

ens

A classification ensemble created with fitcensemble.

Output Arguments

Cens

A compact classification ensemble. Cens has class CompactClassificationEnsemble.

Examples

View Size of Compact Classification Ensemble

Compare the size of a classification ensemble for the Fisher iris data to the compact version of the ensemble.
Load the Fisher iris data set.
load fisheriris

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

\[ t = \text{templateTree('MaxNumSplits',1);} \] % Weak learner template tree object
\[ \text{ens} = \text{fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);} \]

Create a compact version of \text{ens} and compare ensemble sizes.
\[ \text{cens} = \text{compact(ens);} \]
\[ b = \text{whos('ens');} \] % \text{b.bytes} = size of \text{ens}
\[ c = \text{whos('cens');} \] % \text{c.bytes} = size of \text{cens}
\[ [b.bytes ~ c.bytes]; \] % Shows \text{cens} uses less memory
\[ \text{ans} = 1x2 \]
\[ \begin{array}{cc}
   392654 & 352622 \\
\end{array} \]

The compact version of the ensemble uses less memory than the full ensemble. Note that the ensemble sizes can vary slightly, depending on your operating system.

compact

Class: ClassificationNaiveBayes

Compact naive Bayes classifier

Syntax

CMdl = compact(Mdl)

Description

CMdl = compact(Mdl) returns a compact naive Bayes classifier (CMdl), which is the compact version of the trained naive Bayes classifier Mdl.

CMdl stores less than Mdl, e.g., CMdl does not store the training data.

Input Arguments

Mdl — Fully trained naive Bayes classifier
ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by fitcnb.

Output Arguments

CMdl — Compact naive Bayes classifier
CompactClassificationNaiveBayes model

Compact naive Bayes classifier, returned as a CompactClassificationNaiveBayes model.

Predict class labels using CMdl exactly as you would using Mdl. However, since CMdl does not contain training data, you cannot perform certain tasks, such as cross validation.
Examples

Reduce the Size of Naive Bayes Classifiers

Full naive Bayes classifiers (i.e., ClassificationNaiveBayes models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the ionosphere data set.

```matlab
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```matlab
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})
```

```
Mdl = 
    ClassificationNaiveBayes
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
        NumObservations: 351
        DistributionNames: {1x32 cell}
        DistributionParameters: {2x32 cell}
```

Properties, Methods

Mdl is a ClassificationNaiveBayes model.

Reduce the size of the naive Bayes classifier.

```matlab
CMdl = compact(Mdl)
```

```
CMdl =
    classreg.learning.classif.CompackClassificationNaiveBayes
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
```
ScoreTransform: 'none'
DistributionNames: {1x32 cell}
DistributionParameters: {2x32 cell}

Properties, Methods

CMdl is a CompactClassificationNaiveBayes model.

Display how much memory each classifier uses.

whos('Mdl','CMdl')

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>

compact

Reduce size of support vector machine (SVM) classifier

Syntax

CompactSVMModel = compact(SVMModel)

Description

CompactSVMModel = compact(SVMModel) returns a compact support vector machine (SVM) classifier (CompactSVMModel), the compact version of the trained SVM classifier SVMModel. CompactSVMModel is a CompactClassificationSVM object.

CompactSVMModel does not contain the training data, whereas SVMModel contains the training data in its X and Y properties. Therefore, although you can predict class labels using CompactSVMModel, you cannot perform tasks such as cross-validation with the compact SVM classifier.

Examples

Reduce Size of SVM Classifiers

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, ClassificationSVM classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the ionosphere data set.

load ionosphere

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

SVMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'})
SVMModel = ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
        Alpha: [90x1 double]
        Bias: -0.1343
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'

Properties, Methods

SVMModel is a ClassificationSVM classifier.

Reduce the size of the SVM classifier.

CompactSVMModel = compact(SVMModel)

CompactSVMModel =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
        CategoricalPredictors: []
            ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
            Alpha: [90x1 double]
            Bias: -0.1343
        KernelParameters: [1x1 struct]
            Mu: [1x34 double]
            Sigma: [1x34 double]
        BoxConstraints: [351x1 double]
        ConvergenceInfo: [1x1 struct]
        SupportVectors: [90x34 double]
        SupportVectorLabels: [90x1 double]

Properties, Methods
CompactSVMModel is a CompactClassificationSVM classifier.

Display the amount of memory each classifier uses.

\[
\text{whos('SVMModel','CompactSVMModel')}
\]

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>

<td>30512</td>
<td>classreg.learning.classif.CompactClassificationSVM</td>
</tr>
<tr>
<td>SVMModel</td>
<td>1x1</td>
<td>140834</td>
<td>ClassificationSVM</td>
</tr>
</tbody>
</table>

The full SVM classifier (SVMModel) is more than four times larger than the compact SVM classifier (CompactSVMModel).

To label new observations efficiently, you can remove SVMModel from the MATLAB® Workspace, and then pass CompactSVMModel and new predictor values to predict.

To further reduce the size of your compact SVM classifier, use the discardSupportVectors function to discard support vectors.

### Input Arguments

**SVMModel** — Full, trained SVM classifier
ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

### See Also

ClassificationSVM | CompactClassificationSVM | discardSupportVectors | fitcsvm

*Introduced in R2014a*
compact

Class: ClassificationTree
Compact tree

Syntax

ctree = compact(tree)

Description

ctree = compact(tree) creates a compact version of tree.

Input Arguments

tree
A classification tree created using fitctree.

Output Arguments

ctree
A compact decision tree. ctree has class CompactClassificationTree. You can predict classifications using ctree exactly as you can using tree. However, since ctree does not contain training data, you cannot perform some actions, such as cross validation.

Examples
Create a Compact Classification Tree

Compare the size of the classification tree for Fisher's iris data to the compact version of the tree.

```matlab
load fisheriris
fulltree = fitctree(meas,species);
ctree = compact(fulltree);
b = whos('fulltree'); % b.bytes = size of fulltree
c = whos('ctree'); % c.bytes = size of ctree
[b.bytes c.bytes] % shows ctree uses half the memory
```

ans = 1x2

```

compact

Class: LinearModel

Compact linear regression model

Syntax

compactMdl = compact(mdl)

Description

compactMdl = compact(mdl) returns a compact linear regression model, compactMdl, which is the compact version of the full, fitted linear regression model mdl.

Input Arguments

mdl — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a LinearModel object constructed using fitlm or stepwiselm.

Output Arguments

compactMdl — Compact linear regression model
CompactLinearModel object

Compact linear regression model, returned as a CompactLinearModel object.

Predict response values using compactMdl exactly as you would using mdl. However, since compactMdl does not contain training data, you cannot perform certain tasks, such as cross-validation.
Examples

Compact a Linear Regression Model

This example shows how to reduce the size of a full, fitted linear regression model by
discarding the sample data and some information related to the fitting process.

Load the data into the workspace.

load(fullfile(matlabroot,'examples','stats','largedata4reg.mat'))

The simulated sample data contains 15,000 observations and 45 predictor variables.

Fit a simple linear regression model to the data.

mdl = fitlm(X,Y)

mdl =
Linear regression model:

**Introduced in R2016a**
compact

Class: GeneralizedLinearModel
Compact generalized linear regression model

Syntax

```
compactMdl = compact(mdl)
```

Description

`compactMdl = compact(mdl)` returns a compact generalized linear regression model, `compactMdl`, which is the compact version of the full, fitted regression model `mdl`. The compact model uses less memory than the full model because it does not include a copy of the data or anything comparable in size to the data. However, the compact model also does not support properties (such as `Residuals`) or methods (such as `addTerms`) that require the data.

Input Arguments

`mdl` — Full, fitted generalized linear regression model
GeneralizedLinearModel object

Full, fitted generalized linear regression model, specified as a `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`.

Output Arguments

`compactMdl` — Compact generalized linear regression model
CompactGeneralizedLinearModel object

Compact generalized linear regression model, returned as a `CompactGeneralizedLinearModel` object.
Predict response values using compactMdl exactly as you would using mdl. However, since compactMdl does not contain training data, you cannot perform certain tasks, such as cross-validation.

**Examples**

**Compact a Generalized Linear Regression Model**

Reduce the size of a full, fitted generalized linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace. The simulated sample data contains 15,000 observations and 45 predictor variables.

```matlab
load(fullfile(matlabroot,'examples','stats','largedata4reg.mat'))
```

Fit a generalized linear regression model to the data using the first 15 predictor variables.

```matlab
mdl = fitglm(X(:,1:15),Y)
```

```
mdl =
Generalized linear regression model:
    y ~ [Linear formula with 16 terms in 15 predictors]
    Distribution = Normal

Introduced in R2016b
compact

Create compact regression ensemble

Syntax

cens = compact(ens)

Description

cens = compact(ens) creates a compact version of ens. You can predict regressions using cens exactly as you can using ens. However, since cens does not contain training data, you cannot perform some actions, such as cross validation.

Input Arguments

en

A regression ensemble created with fitrensemble.

Output Arguments

cens

A compact regression ensemble. cens is of class CompactRegressionEnsemble.

Examples

View Size of Compact Regression Ensemble

Compare the size of a regression ensemble for the carsmall data to the size of the compact version of the ensemble.
Load the carsmall data set and select acceleration, number of cylinders, displacement, horsepower, and vehicle weight as predictors.

```matlab
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```matlab
ens = fitrensemble(X,MPG);
```

Create a compact version of `ens` and compare ensemble sizes.

```matlab
cens = compact(ens);
b = whos('ens');
c = whos('cens');
[b.bytes c.bytes] % b.bytes = size of ens and c.bytes = size of cens
```

```matlab
ans = 1×2
    415490   389558
```

The compact ensemble uses less memory.

compact

Class: RegressionGP

Create compact Gaussian process regression model

Syntax

cgprMdl = compact(gprMdl)

Description

cgprMdl = compact(gprMdl) returns a compact version of the trained Gaussian process regression (GPR) model, gprMdl.

Input Arguments

- **gprMdl** — Gaussian process regression model
  RegressionGP object

  Gaussian process regression model, specified as a RegressionGP object.

Output Arguments

- **cgprMdl** — Compact Gaussian process regression model
  CompactRegressionGP object

  Compact Gaussian process regression model, returned as a CompactRegressionGP object.

Examples
Compute Predictions and Regression Loss for Test Data

Generate example training data.

```matlab
rng(1) % For reproducibility
n = 100000;
X = linspace(0,1,n)';
X = [X,X.^2];
y = 1 + X*[1;2] + sin(20*X*[1;-2]) + 0.2*randn(n,1);
```

Train a GPR model using the subset of regressors ('sr') approximation method and predict using the subset of data ('sd') method. Use 50 points in the active set and sparse greedy matrix approximation ('sgma') method for active set selection. Because the scales of the first and second predictors are different, it is good practice to standardize the data.

```matlab
gprMdl = fitrgp(X,y,'KernelFunction','squaredExponential','FitMethod','sr','PredictMethod','sd','Basis','none','ActiveSetSize',50,'ActiveSetMethod','sgma','Standardize',1,'KernelParameters',[1;1]);
```

`fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See “Tips” on page 32-731. And, in some cases, using the exact method might be expensive because of the size of the training data.

Create a compact GPR object.

```matlab
cgprMdl = compact(gprMdl);
```

Generate the test data.

```matlab
n = 4000;
Xnew = linspace(0,1,n)';
Xnew = [Xnew,Xnew.^2];
ynew = 1 + Xnew*[1;2] + sin(20*Xnew*[1;-2]) + 0.2*randn(n,1);
```

Use the compact object to predict the response in test data and the prediction intervals.

```matlab
[ypred,~,yci] = predict(cgprMdl,Xnew);
```

Plot the true response, predicted response, and prediction intervals.

```matlab
figure;
plot(ynew,'r');
```
hold on;
plot(ypred,'b')
plot(yci(:,1),'k--');
plot(yci(:,2),'k--');
legend('Data','Pred','Lower 95%','Upper 95%','Location','Best');
xlabel('x');
ylabel('y');
hold off

Compute the mean squared error loss on the test data using the trained GPR model.

L = loss(cgprMdl,Xnew,ynew)

L = 0.0497
**Tips**

- The compact object does not contain the training data that `fitrgp` uses in training the GPR model, `gprMdl`.
- You can use the compact object to make predictions (see `predict`) or compute the regression error (see `loss`).
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is 'bcd'.
- If `gprMdl` is a `CompactRegressionGP` object, you cannot compute standard deviations, `ysd`, or prediction intervals, `yint`, for `PredictMethod` equal to 'sr' or 'fic'. To compute `ysd` and `yint` for `PredictMethod` equal to 'sr' or 'fic', use the full regression (`RegressionGP`) object.

*Introduced in R2015b*
compact

Class: RegressionSVM

Compact support vector machine regression model

Syntax

compactMdl = compact(mdl)

Description

compactMdl = compact(mdl) returns a compact support vector machine (SVM) regression model, compactMdl, which is the compact version of the full, trained SVM regression model mdl.

compactMdl does not contain the training data, whereas mdl contains the training data in its properties mdl.X and mdl.Y.

Input Arguments

mdl — Full, trained SVM regression model
RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by fitrsvm.

Output Arguments

compactMdl — Compact SVM regression model
CompactRegressionSVM model

Compact SVM regression model, returned as a CompactRegressionSVM model.
Predict response values using `compactMdl` exactly as you would using `mdl`. However, since `compactMdl` does not contain training data, you cannot perform certain tasks, such as cross validation.

### Examples

#### Compact an SVM Regression Model

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```matlab
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true)
```

```matlab
dmdl =RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    NumObservations: 4177
```
BoxConstraints: [4177x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [4177x1 logical]
Solver: 'SMO'

Properties, Methods

Compact the model.
compactMdl = compact(mdl)

compactMdl =

    classreg.learning.regr.CompactRegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    SupportVectors: [3635x10 double]

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model mdl and the compact model compactMdl.

vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]

ans =

    323793      775968

The compacted model consumes about half the memory of the full model.
Reduce Memory Consumption of SVM Regression Model

This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the carsmall sample data.

load carsmall
rng default  % for reproducibility

Train a linear SVM regression model using Weight as the predictor variable and MPG as the response variable. Standardize the data.

mdl = fitrsvm(Weight,MPG,'Standardize',true);

Note that MPG contains several NaN values. When training a model, fitrsvm will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.

Compact the regression model to discard the training data and some information related to the training process.

compactMdl = compact(mdl);

compactMdl is a CompactRegressionSVM model that has the same parameters, support vectors, and related estimates as mdl, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

mdlOut = discardSupportVectors(compactMdl);

mdlOut is a CompactRegressionSVM model that has the same parameters as mdl and compactMdl, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, compactMdl, mdl, and mdlOut.

vars = whos('compactMdl','mdl','mdlOut');
[v harmless(1).bytes,v harmless(2).bytes,v harmless(3).bytes]

ans =
3601 13727 2305

compact
The compacted model `compactMdl` consumes 3601 bytes of memory, while the full model `mdl` consumes 13727 bytes of memory. The model `mdlOut`, which also discards the support vectors, consumes 2305 bytes of memory.

Class: RegressionTree

Compact regression tree

Syntax

ctree = compact(tree)

Description

ctree = compact(tree) creates a compact version of tree.

Input Arguments

tree

A regression tree created using fitrtree.

Output Arguments

ctree

A compact regression tree. ctree has class CompactRegressionTree. You can predict regressions using ctree exactly as you can using tree. However, since ctree does not contain training data, you cannot perform some actions, such as cross validation.

Examples
Reduce Memory Consumption of Regression Tree Model

Compare the size of a full regression tree model to the compacted model.

Load the carsmall data set. Consider Acceleration, Displacement, Horsepower, and Weight as predictor variables.

```matlab
load carsmall
X = [Acceleration Cylinders Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```matlab
Mdl = fitrtree(X,MPG)
```

```
Mdl = RegressionTree
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
```

Properties, Methods

Mdl is a RegressionTree model. It is a full model, that is, it stores information such as the predictor and response data fitrtree used in training. For a properties list of full regression tree models, see RegressionTree.

Create a compact version of the full regression tree. That is, one that contains enough information to make predictions only.

```matlab
CMdl = compact(Mdl)
```

```
CMdl =
    classreg.learning.regr.CompactRegressionTree
        ResponseName: 'Y'
        CategoricalPredictors: []
        ResponseTransform: 'none'
```

Properties, Methods
CMdl is a CompactRegressionTree model. For a properties list of compact regression tree models, see CompactRegressionTree.

Inspect the amounts of memory that the full and compact regression trees consume.

```matlab
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```
ans = 1x2
    11778       6276
```

```
cMdlInfo.bytes/mdlInfo.bytes
```

```
ans = 0.5329
```

In this case, the compact regression tree model consumes about 25% less memory than the full model consumes.

compact

Class: TreeBagger

Compact ensemble of decision trees

Description

CMdl = compact(Mdl) creates a compact version of Mdl, a TreeBagger model object. You can predict regressions using CMdl exactly as you can using Mdl. However, since CMdl does not contain training data, you cannot perform some actions, such as make out-of-bag predictions using oobPredict.

Input Arguments

Mdl

A regression ensemble created with TreeBagger.

Output Arguments

CMdl

A compact regression ensemble. CMdl is of class CompactTreeBagger.

Examples

Reduce Size of Bag of Trees

Create a compact bag of trees for efficiently making predictions on new data.

Load the ionosphere data set.

load ionosphere
Train a bag of 100 classification trees using all measurements and the AdaBoostM1 method.

Mdl = TreeBagger(100,X,Y,'Method','classification')

Mdl = 
    TreeBagger
Ensemble with 100 bagged decision trees:
    Training X:              [351x34]
    Training Y:              [351x1]
    Method:       classification
    NumPredictors:                   34
    NumPredictorsToSample:                    6
    MinLeafSize:                    1
    InBagFraction:                    1
    SampleWithReplacement:                    1
    ComputeOOBPrediction:                    0
    ComputeOOBPredictorImportance:                    0
    Proximity:                   
    ClassNames:             'b'             'g'

Properties, Methods

Mdl is a TreeBagger model object that contains the training data, among other things.

Create a compact version of Mdl.

CMdl = compact(Mdl)

CMdl = 
    CompactTreeBagger
Ensemble with 100 bagged decision trees:
    Method:       classification
    NumPredictors:                   34
    ClassNames: 'b' 'g'

Properties, Methods

CMdl is a CompactTreeBagger model object. CMdl is almost the same as Mdl. One exception is that it does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

ans = 1x2
    1031399    890204

Mdl consumes more space than CMdl.

CMdl.Trees stores the trained classification trees (CompactClassificationTree model objects) that compose Mdl.

Display a graph of the first tree in the compact model.

view(CMdl.Trees{1},'Mode','graph');
By default, TreeBagger grows deep trees.

Predict the label of the mean of $X$ using the compact ensemble.

$$\text{predMeanX} = \text{predict}(\text{CMdl}, \text{mean}(X))$$

$$\text{predMeanX} = 1x1 \text{ cell array}$$

$$\text{\{'g'\}}$$

CompactClassificationDiscriminant

**Package:** classreg.learning.classif

Compact discriminant analysis class

**Description**

A `CompactClassificationDiscriminant` object is a compact version of a discriminant analysis classifier. The compact version does not include the data for training the classifier. Therefore, you cannot perform some tasks with a compact classifier, such as cross validation. Use a compact classifier for making predictions (classifications) of new data.

**Construction**

```matlab
cobj = compact(obj)
```
constructs a compact classifier from a full classifier.

```matlab
cobj = makecdiscr(Mu,Sigma)
```
constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`. For syntax details, see `makecdiscr`.

**Input Arguments**

- **obj**
  Discriminant analysis classifier, created using `fitcdiscr`.

**Properties**

- **BetweenSigma**
  p-by-p matrix, the between-class covariance, where p is the number of predictors.
CategoricalPredictors

Categorical predictor indices, which is always empty ([]).

ClassNames

List of the elements in the training data Y with duplicates removed. ClassNames can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. ClassNames has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

Coeffs

k-by-k structure of coefficient matrices, where k is the number of classes. Coeffs(i,j) contains coefficients of the linear or quadratic boundaries between classes i and j. Fields in Coeffs(i,j):

- DiscrimType
- Class1 — ClassNames(i)
- Class2 — ClassNames(j)
- Const — A scalar
- Linear — A vector with p components, where p is the number of columns in X
- Quadratic — p-by-p matrix, exists for quadratic DiscrimType

The equation of the boundary between class i and class j is

\[ \text{Const} + \text{Linear} * x + x' * \text{Quadratic} * x = 0, \]

where x is a column vector of length p.

If fitcdiscr had the FillCoeffs name-value pair set to 'off' when constructing the classifier, Coeffs is empty ([]).

Cost

Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response.

**Delta**

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and so you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

**DeltaPredictor**

Row vector of length equal to the number of predictors in `obj`. If `DeltaPredictor(i) < Delta` then coefficient `i` of the model is 0.

If `obj` is a quadratic discriminant model, all elements of `DeltaPredictor` are 0.

**DiscrimType**

Character vector specifying the discriminant type. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Change `DiscrimType` using dot notation: `obj.DiscrimType = newDiscrimType`.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

**Gamma**

32-747
• If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.
• If you set a value between MinGamma and 1 for linear discriminant, the discriminant sets its type to 'linear'.
• You cannot set values below the value of the MinGamma property.
• For quadratic discriminant, you can set either 0 (for DiscrimType 'quadratic') or 1 (for DiscrimType 'diagQuadratic').

**LogDetSigma**

Logarithm of the determinant of the within-class covariance matrix. The type of LogDetSigma depends on the discriminant type:

• Scalar for linear discriminant analysis
• Vector of length K for quadratic discriminant analysis, where K is the number of classes

**MinGamma**

Nonnegative scalar, the minimal value of the Gamma parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, MinGamma is 0.

**Mu**

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

**PredictorNames**

Cell array of names for the predictor variables, in the order in which they appear in the training data X.

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of Prior corresponds to the order of the classes in ClassNames.

Add or change a Prior vector using dot notation: obj.Prior = priorVector.
ResponseName

Character vector describing the response variable Y.

ScoreTransform

Character vector representing a built-in transformation function, or a function handle for transforming scores. 'none' means no transformation; equivalently, 'none' means @(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see fitcdiscr.

Implement dot notation to add or change a ScoreTransform function using one of the following:

- obj.ScoreTransform = 'function'
- obj.ScoreTransform = @function

Sigma

Within-class covariance matrix or matrices. The dimensions depend on DiscrimType:

- 'linear' (default) — Matrix of size p-by-p, where p is the number of predictors
- 'quadratic' — Array of size p-by-p-by-K, where K is the number of classes
- 'diagLinear' — Row vector of length p
- 'diagQuadratic' — Array of size 1-by-p-by-K
- 'pseudoLinear' — Matrix of size p-by-p
- 'pseudoQuadratic' — Array of size p-by-p-by-K

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct a Compact Discriminant Analysis Classifier

Load the sample data.

load fisheriris

Construct a discriminant analysis classifier for the sample data.

fullobj = fitcdiscr(meas,species);

Construct a compact discriminant analysis classifier, and compare its size to that of the full classifier.

cobj = compact(fullobj);
b = whos('fullobj'); % b.bytes = size of fullobj
c = whos('cobj'); % c.bytes = size of cobj
[b.bytes c.bytes] % shows cobj uses 60% of the memory

ans = 1x2
The compact classifier is smaller than the full classifier.

**Construct Classifier Using Means and Covariances**

Construct a compact discriminant analysis classifier from the means and covariances of the Fisher iris data.

```matlab
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147;
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',
    'setosa','versicolor','virginica');
```

**Definitions**

**Discriminant Classification**

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
predict classifies so as to minimize the expected classification cost:
\[
\hat{y} = \arg\min_{y=1,\ldots,K} \sum_{k=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]
where

- \( \hat{y} \) is the predicted classification.
- \( K \) is the number of classes.
- \( \hat{P}(k \mid x) \) is the posterior probability on page 20-7 of class \( k \) for observation \( x \).
- \( C(y \mid k) \) is the cost on page 20-8 of classifying an observation as \( y \) when its true class is \( k \).

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.

**Regularization**

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, \( \gamma \) and \( \delta \), that control regularization as follows. cvshrink helps you select appropriate values of the parameters.

Let \( \Sigma \) represent the covariance matrix of the data \( X \), and let \( \hat{X} \) be the centered data (the data \( X \) minus the mean by class). Define
\[
D = \text{diag}(\hat{X}^T \ast \hat{X}).
\]

The regularized covariance matrix \( \tilde{\Sigma} \) is
\[
\tilde{\Sigma} = (1 - \gamma) \Sigma + \gamma D.
\]

Whenever \( \gamma \geq \text{MinGamma} \), \( \tilde{\Sigma} \) is nonsingular.
Let $\mu_k$ be the mean vector for those elements of $X$ in class $k$, and let $\mu_0$ be the global mean vector (the mean of the rows of $X$). Let $C$ be the correlation matrix of the data $X$, and let $\tilde{C}$ be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where $I$ is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point $x$ is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter $\delta$ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold $\delta$. Therefore, for class $k$, if component $j$ is thresholded to zero, component $j$ of $x$ does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes $k$ have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$ 

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor $i$.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
• When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the following restrictions apply.
  
  • The class labels input argument value (Y) cannot be a categorical array.
  • The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
  • The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

**Topics**
“Discriminant Analysis Classification” on page 20-2

**Introduced in R2011b**
CompactClassificationECOC

**Package:** classreg.learning.classif

Compact multiclass model for support vector machines or other classifiers

**Description**

CompactClassificationECOC is a compact, multiclass, error-correcting output codes (ECOC) model.

The compact classifier does not include the data used for training the ECOC multiclass model. Therefore, you cannot perform tasks, such as cross-validation, using the compact classifier.

Use a compact ECOC multiclass model for labeling new data (in other words, predicting the labels of new data).

**Construction**

CompactMdl = compact(Mdl) returns a compact, multiclass ECOC model (CompactModel) from a full, trained, multiclass, ECOC model (Mdl).

CompactMdl = fitcecoc(X,Y,'Learners',t) returns a compact ECOC model composed of either linear classification models (ClassificationLinear model objects) or kernel classification models (ClassificationKernel model objects). t must be 'linear' or 'kernel', a linear classification model template object returned by templateLinear, or a kernel classification model template object returned by templateKernel. For more details, see fitcecoc.

**Input Arguments**

Mdl — Full, trained, multiclass, ECOC model
ClassificationECOC classifier

Full, trained, multiclass, ECOC model, specified as a ClassificationECOC classifier trained by fitcecoc.
X — **Predictor data**
full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — **Class labels**
categorical array | character array | string array | logical vector | vector of numeric values |
| cell array of character vectors

Class labels to which the classification linear model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, each element must correspond to one row of the array. The length of Y and the number of observations in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Properties**

**BinaryLearners — Trained binary learners**
cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. BinaryLearners has as many elements as classes in Y.

The software trained BinaryLearner{j} according to the binary problem specified by CodingMatrix(:,j). For example, for multiclass learning using SVM learners, each element of BinaryLearners is a CompactClassificationSVM classifier.

Data Types: cell

**BinaryLoss — Binary learner loss function**
character vector representing the loss function name

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets BinaryLoss to 'hamming'. To potentially increase accuracy, set a different binary loss
function than this default during prediction or loss computation using the `BinaryLoss` name-value pair argument of `predict` or `loss`.

Data Types: `char`

**CategoricalPredictors — Categorical predictor indices**

vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

**ClassNames — Unique class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

**CodingMatrix — Class-assignment codes**

numeric matrix

Class-assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a $K$-by-$L$ matrix, where $K$ is the number of classes and $L$ is the number of binary learners.

Elements of `CodingMatrix` are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes the meaning of `CodingMatrix(i,j)`, that is, the class that learner $j$ assigns to observations in class $i$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>–1</td>
<td>Learner $j$ assigns observations in class $i$ to a negative class.</td>
</tr>
</tbody>
</table>
Value | Dichotomous Class Assignment
--- | ---
0 | Before training, learner \( j \) removes observations in class \( i \) from the data set.
1 | Learner \( j \) assigns observations in class \( i \) to a positive class.

Data Types: double | single | int8 | int16 | int32 | int64

**Cost — Misclassification costs**

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. \( \text{Cost} \) has \( K \) rows and columns, where \( K \) is the number of classes.

\( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \). The order of the rows and columns of \( \text{Cost} \) corresponds to the order of the classes in \( \text{ClassNames} \).

\( \text{fitcecoc} \) incorporates misclassification costs differently among different types of binary learners.

Data Types: double

**ExpandedPredictorNames — Expanded predictor names**

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then \( \text{ExpandedPredictorNames} \) includes the names that describe the expanded variables. Otherwise, \( \text{ExpandedPredictorNames} \) is the same as \( \text{PredictorNames} \).

**LearnerWeights — Binary learner weights**

numeric row vector

Binary learner weights, specified as a numeric row vector. \( \text{LearnerWeights} \) has length equal to the number of binary learners (\( \text{size(CodingMatrix,2)} \)).

\( \text{LearnerWeights}(j) \) is the sum of the observation weights that binary learner \( j \) used to train its classifier.
The software uses **LearnerWeights** to fit posterior probabilities by minimizing the Kullback-Leibler divergence.

**Data Types:** double | single

**PredictorNames — Predictor names**

cell array of character vectors

Predictor names in order of their appearance in the predictor data \( X \), specified as a cell array of character vectors. The length of **PredictorNames** is equal to the number of columns in \( X \).

**Data Types:** cell

**Prior — Prior class probabilities**

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. **Prior** has as many elements as there are classes in **ClassNames**, and the order of the elements corresponds to the elements of **ClassNames**.

**fitcecoc** incorporates misclassification costs differently among different types of binary learners.

**Data Types:** double

**ResponseName — Response variable name**

character vector

Response variable name, specified as a character vector.

**Data Types:** char

**ScoreTransform — Score transformation function to apply to predicted scores**

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to **function**, for example, use dot notation.

- For a built-in function, enter this code and replace **function** with a value in the table.
Mdl.ScoreTransform = 'function';

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$\frac{1}{1 + e^{-2x}}$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$\frac{1}{1 + e^x}$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'             | -1 for $x < 0$  
|                    | 0 for $x = 0$  
|                    | 1 for $x > 0$                                                            |
| 'symmetric'        | $2x - 1$                                                                   |
| 'symmetricismax'   | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit'   | $\frac{2}{1 + e^x} - 1$                                                   |

- For a MATLAB function or a function that you define, enter its function handle.

Mdl.ScoreTransform = @function;

`function` must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle
Methods

discardSupportVectors Discard support vectors of linear support vector machine binary learners
edge Classification edge for multiclass, error-correcting output codes model
loss Classification loss for multiclass, error-correcting output codes model

predict Predict labels using multiclass, error-correcting output codes model
selectModels Choose subset of regularized linear classification models

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce the Size of Full ECOC Models

Full ECOC models (i.e., ClassificationECOC classifiers) hold the training data. For efficiency, you might not want to predict new labels using a large classifier.

Load Fisher's iris data set.

load fisheriris
X = meas;
Y = species;

Train an ECOC model using default SVMs as binary learners.

Mdl = fitcecoc(X,Y)
Mdl = 
    ClassificationECOC
Mdl is a ClassificationECOC model.

Reduce the size of the ECOC model.

CMdl = compact(Mdl)

CMdl is a CompactClassificationECOC model.

Display how much memory each classifier consumes.

whos('Mdl','CMdl')

The full ECOC model (Mdl) is almost twice the size of the compact ECOC model (CMdl).

You can remove Mdl from the MATLAB® Workspace, and pass CMdl and new predictor values to predict to efficiently label new observations.
Train and Cross-Validate ECOC Classifiers

Train an ECOC classifier using different binary learners and the one-versus-all coding design. Then, cross validate the classifier.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
classNames = unique(species(~strcmp(species,''))); % Remove empty classes

classNames = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

K = numel(classNames) % Number of classes
K = 3
rng(1); % For reproducibility

classNames are the unique classes in the data set, and K is the number of classes. You can useclassNames to specify the order of the classes during training.

For a one-versus-all coding design, there are K = 3 binary learners. Specify templates for the binary learners such that:

- Binary learner 1 and 2 are naive Bayes classifiers. By default, each predictor is conditionally, normally distributed given its label.
- Binary learner 3 is an SVM classifier. Specify to use the Gaussian kernel.

```matlab
tNB = templateNaiveBayes();
tSVM = templateSVM('KernelFunction','gaussian');
tLearners = {tNB tNB tSVM};
```

`tNB` and `tSVM` are template objects for naive Bayes and SVM learning, respectively. They indicate what options to use during training. Most of their properties are empty, except for those specified using name-value pair arguments. The software fills in the empty properties with their default values during training.
Train and cross-validate an ECOC classifier using the binary learner templates and the one-versus-all coding design. Specify the order of the classes. By default, naive Bayes classifiers use posterior probabilities as scores, whereas SVM classifiers use distance from the decision boundary. Therefore, to aggregate the binary learners, you must specify fitting posterior probabilities.

\[
CVMdl = \text{fitcecoc}(X,Y,'\text{ClassNames}',\text{classNames},'\text{CrossVal}','on',... \\
\quad '\text{Learners}',tLearners,'\text{FitPosterior}',1);
\]

\(CVMdl\) is not a ClassificationECOC model, but a ClassificationPartitionedECOC cross-validated model. By default, the software implements 10-fold cross-validation. The scores across the binary learners are in the same form (that is, they are posterior probabilities), so the software can aggregate the results of the binary classifications properly.

Inspect one of the trained folds using dot notation.

\[
CVMdl.Trained{1}
\]

\[
\text{ans =}
\text{classreg.learning.classif.CompactClassificationECOC}
\]

\[
\quad \text{ResponseName: 'Y'}
\]

\[
\quad \text{CategoricalPredictors: []}
\]

\[
\quad \text{ClassNames: {'setosa' 'versicolor' 'virginica'}}
\]

\[
\quad \text{ScoreTransform: 'none'}
\]

\[
\quad \text{BinaryLearners: {3x1 cell}}
\]

\[
\quad \text{CodingMatrix: [3x3 double]}
\]

Properties, Methods

Each fold is a CompactClassificationECOC model trained on 90% of the data.

You can access the results of the binary learners using dot notation and cell indexing. Display the trained SVM classifier (the third binary learner) in the first fold.

\[
CVMdl.Trained{1}.BinaryLearners{3}
\]

\[
\text{ans =}
\text{classreg.learning.classif.CompactClassificationSVM}
\]

\[
\quad \text{ResponseName: 'Y'}
\]

\[
\quad \text{CategoricalPredictors: []}
\]

\[
\quad \text{ClassNames: [-1 1]}
\]
Estimate the generalization error.

\[
\text{genError} = \text{kfoldLoss(CVMdl)}
\]

\[
\text{genError} = 0.0333
\]

On average, the generalization error is approximately 3%.

**Algorithms**

**Random Coding Design Matrices**

For a given number of classes, for example, \( K \), the software generates random coding design matrices as follows.

1. The software generates one of the following:
   a. Dense random — The software assigns a 1 or -1 with equal probability to each element of the \( K \)-by-\( L_d \) coding design matrix, where \( L_d \approx [10 \log_2 K] \).
   b. Sparse random — The software assigns a 1 to each element of the \( K \)-by-\( L_s \) coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where \( L_s \approx [15 \log_2 K] \).

2. If a column does not contain at least one 1 and at least one -1, then the software removes that column.

3. For distinct columns \( u \) and \( v \), if \( u = v \) or \( u = -v \), then the software removes \( v \) from the coding design matrix.
The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

\[
\Delta(k_1,k_2) = 0.5 \sum_{l=1}^{L} |m_{k_1,l} - m_{k_2,l}|,
\]

where \( m_{k,l} \) is an element of coding design matrix \( j \).

**Support Vector Storage**

For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```matlab
T = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',T);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

**References**

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The predict function supports code generation.
• When you train an ECOC model by using fitcecoc, the following restrictions apply.
  • You cannot fit posterior probabilities by using the 'FitPosterior' name-value pair argument.
  • All binary learners must be either SVM classifiers or linear classification models. For the 'Learners' name-value pair argument, you can specify:
    • 'svm' or 'linear'
    • An SVM template object or a cell vector of such objects (see templateSVM)
    • A linear classification model template object or a cell vector of such objects (see templateLinear)
  • Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 32-554 of the ClassificationSVM class and “Code Generation” on page 32-442 of the ClassificationLinear class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2014b
CompactClassificationEnsemble

Package: classreg.learning.classif

Compact classification ensemble class

Description

Compact version of a classification ensemble (of class ClassificationEnsemble). The compact version does not include the data for training the classification ensemble. Therefore, you cannot perform some tasks with a compact classification ensemble, such as cross validation. Use a compact classification ensemble for making predictions (classifications) of new data.

Construction

ens = compact(fullEns) constructs a compact decision ensemble from a full decision ensemble.

Input Arguments

fullEns

A classification ensemble created by fitcensemble.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).
**ClassNames**

List of the elements in Y with duplicates removed. ClassNames can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. ClassNames has the same data type as the data in the argument Y. (The software treats string arrays as cell arrays of character vectors.)

**CombineWeights**

Character vector describing how ens combines weak learner weights, either 'WeightedSum' or 'WeightedAverage'.

**Cost**

Square matrix, where Cost(i, j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response. This property is read-only.

**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

**NumTrained**

Number of trained weak learners in ens, a scalar.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in X.

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of Prior corresponds to the order of the classes in ClassNames. The number of elements of Prior is the number of unique classes in the response. This property is read-only.
ResponseName

Character vector with the name of the response variable Y.

ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see fitctree.

Add or change a ScoreTransform function using dot notation:

```matlab
ens.ScoreTransform = 'function'
```

or

```matlab
ens.ScoreTransform = @function
```

Trained

A cell vector of trained classification models.

- If Method is 'LogitBoost' or 'GentleBoost', then CompactClassificationEnsemble stores trained learner \( j \) in the CompactRegressionLearner property of the object stored in Trained{\( j \)}. That is, to access trained learner \( j \), use ens.Trained{\( j \)}.CompactRegressionLearner.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

TrainedWeights

Numeric vector of trained weights for the weak learners in ens.TrainedWeights has \( T \) elements, where \( T \) is the number of weak learners in learners.

UsePredForLearner

Logical matrix of size \( P \)-by-NumTrained, where \( P \) is the number of predictors (columns) in the training data \( X \). UsePredForLearner(\( i, j \)) is true when learner \( j \) uses predictor \( i \), and is false otherwise. For each learner, the predictors have the same order as the columns in the training data \( X \).

If the ensemble is not of type Subspace, all entries in UsePredForLearner are true.
Methods

edge Classification edge
loss Classification error
margin Classification margins
predict Predict labels using ensemble of classification models
predictorImportance Estimates of predictor importance
removeLearners Remove members of compact classification ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce Size of Classification Ensemble

Create a compact classification ensemble for efficiently making predictions on new data.

Load the ionosphere data set.

load ionosphere

Train a boosted ensemble of 100 classification trees using all measurements and the AdaBoostM1 method.

Mdl = fitcensemble(X,Y,'Method','AdaBoostM1')

Mdl =
    classreg.learning.classif.ClassificationEnsemble
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
        NumObservations: 351
        NumTrained: 100
Method: 'AdaBoostM1'
LearnerNames: {'Tree'}
ReasonForTermination: 'Terminated normally after completing the requested number of training cycles.'
FitInfo: [100x1 double]
FitInfoDescription: {2x1 cell}

Properties, Methods

Mdl is a ClassificationEnsemble model object that contains the training data, among other things.

Create a compact version of Mdl.

CMdl = compact(Mdl)

CMdl =
  classreg.learning.classif.CompactClassificationEnsemble
      ResponseName: 'Y'
      CategoricalPredictors: []
      ClassNames: {'b'  'g'}
      ScoreTransform: 'none'
      NumTrained: 100

Properties, Methods

CMdl is a CompactClassificationEnsemble model object. CMdl is almost the same as Mdl. One exception is that CMdl does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.

mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

ans = 1×2
    818912      573200

Mdl consumes more space than CMdl.
CMdl.Trained stores the trained classification trees (CompactClassificationTree model objects) that compose Mdl.

Display a graph of the first tree in the compact ensemble.

view(CMdl.Trained{1},'Mode','graph');

By default, fitensemble grows shallow trees for boosted ensembles of trees.

Predict the label of the mean of X using the compact ensemble.

predMeanX = predict(CMdl,mean(X))
predMeanX = 1x1 cell array
   {'g'}

**Tip**

For an ensemble of classification trees, the Trained property of ens stores an ens.NumTrained-by-1 cell vector of compact classification models. For a textual or graphical display of tree \( t \) in the cell vector, enter:

- `view(ens.Trained{t}.CompactRegressionLearner)` for ensembles aggregated using LogitBoost or GentleBoost.
- `view(ens.Trained{t})` for all other aggregation methods.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train an ensemble by using fitensemble, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of ClassificationKNN, CompactClassificationDiscriminant, and CompactClassificationTree.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a
CompactClassificationNaiveBayes

**Package:** classreg.learning.classif

Compact naive Bayes classifier

**Description**

CompactClassificationNaiveBayes is a compact naive Bayes classifier.

The compact classifier does not include the data used for training the naive Bayes classifier. Therefore, you cannot perform tasks, such as cross validation, using the compact classifier.

Use a compact naive Bayes classifier to label new data (i.e., predicting the labels of new data) more efficiently.

**Construction**

CMdl = compact(Mdl) returns a compact naive Bayes classifier (CMdl) from a full, trained naive Bayes classifier (Mdl).

**Input Arguments**

Mdl — Fully trained naive Bayes classifier
ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by fitcnb.

**Properties**

CategoricalPredictors — Indices of categorical predictors
vector of positive integers
Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

**CategoricalLevels — Multivariate multinomial levels**
cell vector of numeric vectors

Multivariate multinomial levels, specified as a cell vector of numeric vectors. `CategoricalLevels` has length equal to the number of predictors `(size(X,2))`.

The cells of `CategoricalLevels` correspond to predictors that you specified as 'mvmn' (i.e., having a multivariate multinomial distribution) during training. Cells that do not correspond to a multivariate multinomial distribution are empty ([]).

If predictor `j` is multivariate multinomial, then `CategoricalLevels{j}` is a list of all distinct values of predictor `j` in the sample (NaNs removed from `unique(X(:,j))`).

Data Types: cell

**ClassNames — Distinct class names**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Distinct class names, specified as a categorical or character array, logical or numeric vector, or cell vector of character vectors.

`ClassNames` is the same data type as `Y`, and has `K` elements or rows for character arrays. (The software treats string arrays as cell arrays of character vectors.)

Data Types: categorical | char | logical | single | double | cell

**Cost — Misclassification cost**
square matrix

Misclassification cost, specified as a `K`-by-`K` square matrix.

The value of `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. The order of the rows and columns of `Cost` correspond to the order of the classes in `ClassNames`. 32-777
The value of Cost does not influence training. You can reset Cost after training Mdl using dot notation, e.g., Mdl.Cost = [0 0.5; 1 0].

Data Types: double | single

**DistributionNames — Predictor distributions**

'normal' (default) | 'kernel' | 'mn' | 'mvmn' | cell array of character vectors

Predictor distributions fitcnb uses to model the predictors, specified as a character vector or cell array of character vectors.

This table summarizes the available distributions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'kernel'</td>
<td>Kernel smoothing density estimate.</td>
</tr>
<tr>
<td>'mn'</td>
<td>Multinomial bag-of-tokens model on page 32-454. Indicates that all predictors have this distribution.</td>
</tr>
<tr>
<td>'mvmn'</td>
<td>Multivariate multinomial distribution.</td>
</tr>
<tr>
<td>'normal'</td>
<td>Normal (Gaussian) distribution.</td>
</tr>
</tbody>
</table>

If Distribution is a 1-by-\(P\) cell array of character vectors, then the software models feature \(j\) using the distribution in element \(j\) of the cell array.

Data Types: char | cell

**DistributionParameters — Distribution parameter estimates**

cell array

Distribution parameter estimates, specified as a cell array. DistributionParameters is a \(K\)-by-\(D\) cell array, where cell \((k,d)\) contains the distribution parameter estimates for instances of predictor \(d\) in class \(k\). The order of the rows corresponds to the order of the classes in the property ClassNames, and the order of the predictors corresponds to the order of the columns of \(X\).

If class \(k\) has no observations for predictor \(j\), then Distribution\(\{k,j\}\) is empty (\([]\))

The elements of DistributionParameters depends on the distributions of the predictors. This table describes the values in DistributionParameters\(\{k,j\}\).
<table>
<thead>
<tr>
<th>Distribution of Predictor ( j )</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kernel</td>
<td>A KernelDistribution model. Display properties using cell indexing and dot notation. For example, to display the estimated bandwidth of the kernel density for predictor 2 in the third class, use ( \text{Mdl.DistributionParameters{3,2}.BandWidth} ).</td>
</tr>
<tr>
<td>( mn )</td>
<td>A scalar representing the probability that token ( j ) appears in class ( k ). For details, see “Algorithms” on page 32-455.</td>
</tr>
<tr>
<td>( mvmn )</td>
<td>A numeric vector containing the probabilities for each possible level of predictor ( j ) in class ( k ). The software orders the probabilities by the sorted order of all unique levels of predictor ( j ) (stored in the property ( \text{CategoricalLevels} )). For more details, see “Algorithms” on page 32-455.</td>
</tr>
<tr>
<td>normal</td>
<td>A 2-by-1 numeric vector. The first element is the sample mean and the second element is the sample standard deviation.</td>
</tr>
</tbody>
</table>

**Data Types:** cell

**ExpandedPredictorNames — Expanded predictor names**
cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

**Kernel — Kernel smoother types**

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother types, specified as a character vector or cell array of character vectors. `Kernel` has length equal to the number of predictors (\( \text{size}(X,2) \)). `Kernel\{j\}`
corresponds to predictor $j$, and contains a character vector describing the type of kernel smoother. This table describes the supported kernel smoother types. Let $I\{u\}$ denote the indicator function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Kernel</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'box'</td>
<td>Box (uniform)</td>
<td>$f(x) = 0.5 I{</td>
</tr>
<tr>
<td>'epanechnikov'</td>
<td>Epanechnikov</td>
<td>$f(x) = 0.75 (1 - x^2) I{</td>
</tr>
<tr>
<td>'normal'</td>
<td>Gaussian</td>
<td>$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$</td>
</tr>
<tr>
<td>'triangle'</td>
<td>Triangular</td>
<td>$f(x) = (1 -</td>
</tr>
</tbody>
</table>

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Data Types: char | cell

**PredictorNames — Predictor names**
cell array of character vectors

Predictor names, specified as a cell array of character vectors. The order of the elements in PredictorNames corresponds to the order in $X$.

Data Types: cell

**Prior — Class prior probabilities**
numeric vector

Class prior probabilities, specified as a numeric row vector. Prior is a 1-by-$K$ vector, and the order of its elements correspond to the elements of ClassNames.

fitcnb normalizes the prior probabilities you set using the name-value pair parameter 'Prior' so that $\text{sum}(\text{Prior}) = 1$.

The value of Prior does not change the best-fitting model. Therefore, you can reset Prior after training Mdl using dot notation, e.g., Mdl.Prior = [0.2 0.8];.

Data Types: double | single
ResponseName — Response name
character vector

Response name, specified as a character vector.

Data Types: char

ScoreTransform — Classification score transformation function
'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Classification score transformation function, specified as a character vector or function handle.

To change the score transformation function to e.g., function, use dot notation.

- For a built-in function, enter this code and replace function with a value in the table.

```matlab
Mdl.ScoreTransform = 'function';
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'        | -1 for $x < 0$
|               | 0 for $x = 0$
|               | 1 for $x > 0$                                                               |
| 'symmetric'   | $2x - 1$                                                                    |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$                                           |

- For a MATLAB function, or a function that you define, enter its function handle.

```matlab
Mdl.ScoreTransform = @function;
```
function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: char | function_handle

Support — Kernel smoother density support

Kernel smoother density support, specified as a cell vector. Support has length equal to the number of predictors (size(X,2)). The cells represent the regions to apply the kernel density.

This table describes the supported options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-by-2 numeric row vector</td>
<td>For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.</td>
</tr>
<tr>
<td>'positive'</td>
<td>The density support is all positive real values.</td>
</tr>
<tr>
<td>'unbounded'</td>
<td>The density support is all real values.</td>
</tr>
</tbody>
</table>

If a cell is empty ([]), then the software did not fit a kernel distribution to the corresponding predictor.

Width — Kernel smoother window width

Kernel smoother window width, specified as a numeric matrix. Width is a K-by-P matrix, where K is the number of classes in the data, and P is the number of predictors (size(X, 2)).

Width(k,j) is the kernel smoother window width for the kernel smoothing density of predictor j within class k. NaNs in column j indicate that the software did not fit predictor j using a kernel density.
Methods

- `edge` Classification edge for naive Bayes classifiers
- `logP` Log unconditional probability density for naive Bayes classifier
- `loss` Classification error for naive Bayes classifier
- `margin` Classification margins for naive Bayes classifiers
- `predict` Predict labels using naive Bayes classification model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

**Reduce the Size of Naive Bayes Classifiers**

Full naive Bayes classifiers (i.e., `ClassificationNaiveBayes` models) hold the training data. For efficiency, you might not want to predict new labels using a large classifier. This example shows how to reduce the size of a full naive Bayes classifier.

Load the `ionosphere` data set.

```matlab
compute ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the labels.

```matlab
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'})
```

```
Mdl = ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
```
Mdl is a ClassificationNaiveBayes model.

Reduce the size of the naive Bayes classifier.

CMdl = compact(Mdl)

CMdl is a CompactClassificationNaiveBayes model.

Display how much memory each classifier uses.

whos('Mdl','CMdl')

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMdl</td>
<td>1x1</td>
<td>15244</td>
<td>classreg.learning.classif.CompactClassificationNaiveBayes</td>
</tr>
<tr>
<td>Mdl</td>
<td>1x1</td>
<td>111374</td>
<td>ClassificationNaiveBayes</td>
</tr>
</tbody>
</table>

The full naive Bayes classifier (Mdl) is much larger than the compact naive Bayes classifier (CMdl).

You can remove Mdl from the MATLAB® Workspace, and pass CMdl and new predictor values to predict to efficiently label new observations.
Train and Cross Validate Naive Bayes Classifiers

Load the ionosphere data set.

```
load ionosphere
X = X(:,3:end); % Remove two predictors for stability
```

Train and cross validate a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to specify the order of the classes.

```
rng(1); % For reproducibility
CVMdl = fitcnb(X,Y,'ClassNames',{'b','g'},'CrossVal','on')
```

```
CVMdl =  
    classreg.learning.partition.ClassificationPartitionedModel 
    CrossValidatedModel: 'NaiveBayes' 
        PredictorNames: {1x32 cell} 
        ResponseName: 'Y' 
        NumObservations: 351 
        KFold: 10 
            Partition: [1x1 cvpartition] 
            ClassNames: {'b' 'g'} 
            ScoreTransform: 'none'
```

Properties, Methods

CVMdl is not a ClassificationNaiveBayes model, but a ClassificationPartitionedModel cross-validated, naive Bayes model. By default, the software implements 10-fold cross validation.

Alternatively, you can cross validate a trained ClassificationNaiveBayes model by passing it to crossval.

Inspect one of the trained folds using dot notation.

```
CVMdl.Trained{1}
```

```
ans =  
    classreg.learning.classif.CompactClassificationNaiveBayes 
        ResponseName: 'Y' 
        CategoricalPredictors: [] 
            ClassNames: {'b' 'g'}
```
Each fold is a CompactClassificationNaiveBayes model trained on 90% of the data.

Estimate the generalization error.

generate = kfoldLoss(CVMdl)

generate = 0.1795

On average, the generalization error is approximately 17%.

One way to attempt reducing an unsatisfactory generalization error is to specify different conditional distributions for the predictors, or tune the parameters of the conditional distributions.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor $j$ is the nonnegative number of occurrences of token $j$ in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].
Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

1. Estimates the densities of the predictors within each class.
2. Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \ldots, K$,

$$
\hat{P}(Y = k | X_1, \ldots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P(X_j | Y = k)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P(X_j | Y = k)},
$$

where:

- $Y$ is the random variable corresponding to the class index of an observation.
- $X_1, \ldots, X_P$ are the random predictors of an observation.
- $\pi(Y = k)$ is the prior probability that a class index is $k$.
3. Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

$$
\hat{P}(Y = k | X_1, \ldots, X_P) \propto \pi(Y = k)P_{mn}(X_1, \ldots, X_P | Y = k), \text{ where } P_{mn}(X_1, \ldots, X_P | Y = k) \text{ is the probability mass function of a multinomial distribution.}
$$

**Algorithms**

- If you specify 'DistributionNames','mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1956. The software stores the probability that token $j$ appears in class $k$ in the property DistributionParameters{$k,j$}. Using additive smoothing [2], the estimated probability is

$$
P(\text{token } j \mid \text{class } k) = \frac{1 + c_{jk}}{P + c_k},
$$

where:
• 

\[ c_{j|k} = \frac{\sum_{i:y_i \in \text{class } k} x_{ij} w_i}{\sum_{i:y_i \in \text{class } k} w_i} \]; which is the weighted number of occurrences of token \( j \) in class \( k \).

• \( n_k \) is the number of observations in class \( k \).

• \( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.

• 

\[ c_k = \sum_{j=1}^{P} c_{j|k} \]; which is the total weighted number of occurrences of all tokens in class \( k \).

• If you specify 'DistributionNames','mvmn' when training \( Mdl \) using \( \text{fitcnb} \), then:

1. For each predictor, the software collects a list of the unique levels, stores the sorted list in \( \text{CategoricalLevels} \), and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.

2. For predictor \( j \) in class \( k \), the software counts instances of each categorical level using the list stored in \( \text{CategoricalLevels}\{j\} \).

3. The software stores the probability that predictor \( j \), in class \( k \), has level \( L \) in the property \( \text{DistributionParameters}\{k,j\} \), for all levels in \( \text{CategoricalLevels}\{j\} \). Using additive smoothing [2], the estimated probability is

\[ P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k}, \]

where:
\[
\sum_{i:y_i \in \text{class } k} I\{x_{ij} = L\}w_i
\]

\[\hat{m}_{jlk}(L) = n_k \frac{\sum_{i} w_i}{\sum_{i} w_i};\]

which is the weighted number of observations for which predictor \(j\) equals \(L\) in class \(k\).

- \(n_k\) is the number of observations in class \(k\).
- \(I\{x_{ij} = L\} = 1\) if \(x_{ij} = L\), 0 otherwise.
- \(w_i\) is the weight for observation \(i\). The software normalizes weights within a class such that they sum to the prior probability for that class.
- \(m_j\) is the number of distinct levels in predictor \(j\).
- \(m_k\) is the weighted number of observations in class \(k\).

CompactClassificationSVM

Compact support vector machine (SVM) for one-class and binary classification

Description

CompactClassificationSVM is a compact version of the support vector machine (SVM) classifier. The compact classifier does not include the data used for training the SVM classifier. Therefore, you cannot perform some tasks, such as cross-validation, using the compact classifier. Use a compact SVM classifier for tasks such as predicting the labels of new data.

Creation

Create a CompactClassificationSVM model from a full, trained ClassificationSVM classifier by using compact.

Properties

SVM Properties

Alpha — Trained classifier coefficients
numeric vector

This property is read-only.

Trained classifier coefficients, specified as an s-by-1 numeric vector. s is the number of support vectors in the trained classifier, sum(Mdl.IsSupportVector).

Alpha contains the trained classifier coefficients from the dual problem, that is, the estimated Lagrange multipliers. If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, Alpha contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one
observation from the set of duplicates and a coefficient of \( \theta \) to all other duplicate observations in the set.

Data Types: single | double

**Beta — Linear predictor coefficients**

numeric vector

This property is read-only.

Linear predictor coefficients, specified as a numeric vector. The length of Beta is equal to the number of predictors used to train the model.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Beta stores one value for each predictor variable, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then Beta is a numeric vector containing five values.

If **KernelParameters.Function** is 'linear', then the classification score for the observation \( x \) is

\[
f(x) = (x / s)' \beta + b.
\]

Mdl stores \( \beta, b, \) and \( s \) in the properties **Beta**, **Bias**, and **KernelParameters.Scale**, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize',true when using fitcsvm, then you must standardize the predictor data manually by using the mean Mdl.Mu and standard deviation Mdl.Sigma, and then divide the result by the kernel scale in Mdl.KernelParameters.Scale.

All SVM functions, such as resubPredict and predict, apply any required transformation before estimation.

If **KernelParameters.Function** is not 'linear', then Beta is empty ([]).

Data Types: single | double

**Bias — Bias term**

scalar
This property is read-only.

Bias term, specified as a scalar.

Data Types: single | double

**KernelParameters — Kernel parameters**
structure array

This property is read-only.

Kernel parameters, specified as a structure array. The kernel parameters property contains the fields listed in this table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>Kernel function used to compute the elements of the Gram matrix on page 32-2000. For details, see 'KernelFunction'.</td>
</tr>
<tr>
<td>Scale</td>
<td>Kernel scale parameter used to scale all elements of the predictor data on which the model is trained. For details, see 'KernelScale'.</td>
</tr>
</tbody>
</table>

To display the values of KernelParameters, use dot notation. For example, Mdl.KernelParameters.Scale displays the kernel scale parameter value.

The software accepts KernelParameters as inputs and does not modify them.

Data Types: struct

**SupportVectorLabels — Support vector class labels**
s-by-1 numeric vector

This property is read-only.

Support vector class labels, specified as an s-by-1 numeric vector. s is the number of support vectors in the trained classifier, sum(Mdl.IsSupportVector).

A value of +1 in SupportVectorLabels indicates that the corresponding support vector is in the positive class (ClassNames{2}). A value of −1 indicates that the corresponding support vector is in the negative class (ClassNames{1}).

If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, SupportVectorLabels contains one unique support vector label.
Data Types: single | double

**SupportVectors — Support vectors**
s-by-p numeric matrix

This property is read-only.

Support vectors in the trained classifier, specified as an s-by-p numeric matrix. s is the number of support vectors in the trained classifier, sum(Mdl.IsSupportVector), and p is the number of predictor variables in the predictor data.

SupportVectors contains rows of the predictor data X that MATLAB considers to be support vectors. If you specify 'Standardize',true when training the SVM classifier using fitcsvm, then SupportVectors contains the standardized rows of X.

If you remove duplicates by using the RemoveDuplicates name-value pair argument of fitcsvm, then for a given set of duplicate observations that are support vectors, SupportVectors contains one unique support vector.

Data Types: single | double

**Other Classification Properties**

**CategoricalPredictors — Categorical predictor indices**
vector of positive integers | []

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

Data Types: single | double

**ClassNames — Unique class labels**
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.
Data Types: single | double | logical | char | cell | categorical

Cost — Misclassification cost
numeric square matrix

This property is read-only.

Misclassification cost, specified as a numeric square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \).

During training, the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

- For two-class learning, \( \text{Cost} \) always has this form: \( \text{Cost}(i,j) = 1 \) if \( i \neq j \), and \( \text{Cost}(i,j) = 0 \) if \( i = j \). The rows correspond to the true class and the columns correspond to the predicted class. The order of the rows and columns of \( \text{Cost} \) corresponds to the order of the classes in \( \text{ClassNames} \).
- For one-class learning, \( \text{Cost} = 0 \).

For more details, see Algorithms on page 32-550.

Data Types: double

ExpandedPredictorNames — Expanded predictor names
cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

If the model uses dummy variable encoding for categorical variables, then \( \text{ExpandedPredictorNames} \) includes the names that describe the expanded variables. Otherwise, \( \text{ExpandedPredictorNames} \) is the same as \( \text{PredictorNames} \).

Data Types: cell

Mu — Predictor means
numeric vector | []

This property is read-only.

Predictor means, specified as a numeric vector. If you specify 'Standardize',1 or 'Standardize',true when you train an SVM classifier using \( \text{fitcsvm} \), then the length of \( \text{Mu} \) is equal to the number of predictors.
MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Mu stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize',false when you train the SVM classifier using fitcsvm, then Mu is an empty vector ([]).

Data Types: single | double

**PredictorNames — Predictor variable names**
cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of PredictorNames corresponds to the order in which the predictor names appear in the training data.

Data Types: cell

**Prior — Prior probabilities**
numeric vector

This property is read-only.

Prior probabilities for each class, specified as a numeric vector. The order of the elements of Prior corresponds to the elements of Mdl.ClassNames.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix.

For more details, see Algorithms on page 32-550.

Data Types: single | double

**ScoreTransform — Score transformation**
character vector | function handle

Score transformation, specified as a character vector or function handle. ScoreTransform represents a built-in transformation function or a function handle for transforming predicted classification scores.

To change the score transformation function to function, for example, use dot notation.
• For a built-in function, enter a character vector.

```matlab
Mdl.ScoreTransform = 'function';
```

This table describes the available built-in functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log\left(\frac{x}{1-x}\right) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for ( x &lt; 0 )                                                   0 for ( x = 0 ) 1 for ( x &gt; 0 )</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>( 2x - 1 )</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to (-1)</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{-x}} - 1 )</td>
</tr>
</tbody>
</table>

• For a MATLAB function or a function that you define, enter its function handle.

```matlab
Mdl.ScoreTransform = @function;
```

*function* should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: `char` | `function_handle`

**Sigma — Predictor standard deviations**

[ ] (default) | numeric vector

This property is read-only.

Predictor standard deviations, specified as a numeric vector.
If you specify 'Standardize',true when you train the SVM classifier using fitcsvm, then the length of Sigma is equal to the number of predictor variables.

MATLAB expands categorical variables in the predictor data using full dummy encoding. That is, MATLAB creates one dummy variable for each level of each categorical variable. Sigma stores one value for each predictor variable, including the dummy variables. However, MATLAB does not standardize the columns that contain categorical variables.

If you set 'Standardize',false when you train the SVM classifier using fitcsvm, then Sigma is an empty vector ([]).

Data Types: single | double

Object Functions

- compareHoldout: Compare accuracies of two classification models using new data
- discardSupportVectors: Discard support vectors for linear support vector machine (SVM) classifier
- edge: Find classification edge for support vector machine (SVM) classifier
- fitPosterior: Fit posterior probabilities for compact support vector machine (SVM) classifier
- loss: Find classification error for support vector machine (SVM) classifier
- margin: Find classification margins for support vector machine (SVM) classifier
- predict: Predict labels using support vector machine (SVM) classifier
- update: Update support vector machine (SVM) model parameters for code generation

Examples

Reduce Size of SVM Classifiers

Reduce the size of a full SVM classifier by removing the training data. Full SVM classifiers (that is, ClassificationSVM classifiers) hold the training data. To improve efficiency, use a smaller classifier.

Load the ionosphere data set.
load ionosphere

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

SVMMModel = fitcsvm(X,Y,'Standardize',true,...
               'ClassNames',{'b','g'})

SVMMModel = 
    ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    Alpha: [90x1 double]
    Bias: -0.1343
    KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'

Properties, Methods

SVMMModel is a ClassificationSVM classifier.

Reduce the size of the SVM classifier.

CompactSVMMModel = compact(SVMMModel)

CompactSVMMModel = 
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    Alpha: [90x1 double]
    Bias: -0.1343
    KernelParameters: [1x1 struct]
    Mu: [1x34 double]
**CompactSVMModel** is a CompactClassificationSVM classifier.

Display the amount of memory each classifier uses.

```matlab
whos('SVMModel','CompactSVMModel')
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompactSVMModel</td>
<td>1x1</td>
<td>30512</td>
<td>classreg.learning.classif.CompactClassificationSVM</td>
</tr>
<tr>
<td>SVMModel</td>
<td>1x1</td>
<td>140834</td>
<td>ClassificationSVM</td>
</tr>
</tbody>
</table>

The full SVM classifier (SVMModel) is more than four times larger than the compact SVM classifier (CompactSVMModel).

To label new observations efficiently, you can remove SVMModel from the MATLAB® Workspace, and then pass CompactSVMModel and new predictor values to `predict`.

To further reduce the size of your compact SVM classifier, use the `discardSupportVectors` function to discard support vectors.

---

**Train and Cross-Validate SVM Classifier**

Load the ionosphere data set.

```matlab
load ionosphere
```

Train and cross-validate an SVM classifier. Standardize the predictor data and specify the order of the classes.

```matlab
rng(1); % For reproducibility
CVSVMMModel = fitcsvm(X,Y,'Standardize',true,...
    'ClassNames',{'b','g'},'CrossVal','on')
```

`CVSVMMModel = `

classreg.learning.partition.ClassificationPartitionedModel
CrossValidatedModel: 'SVM'  
PredictorNames: {1x34 cell}  
ResponseName: 'Y'  
NumObservations: 351  
KFold: 10  
Partition: [1x1 cvpartition]  
ClassNames: {'b' 'g'}  
ScoreTransform: 'none'

Properties, Methods

CVSVMModel is a ClassificationPartitionedModel cross-validated SVM classifier. By default, the software implements 10-fold cross-validation.

Alternatively, you can cross-validate a trained ClassificationSVM classifier by passing it to crossval.

Inspect one of the trained folds using dot notation.

CVSVMModel.Trained{1}

ans =
  classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    Alpha: [78x1 double]
    Bias: -0.2209
    KernelParameters: [1x1 struct]
      Mu: [1x34 double]
      Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]

Properties, Methods

Each fold is a CompactClassificationSVM classifier trained on 90% of the data.

Estimate the generalization error.
genError = kfoldLoss(CVSVMModel)
genError = 0.1168

On average, the generalization error is approximately 12%.

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict and update functions support code generation.
- When you train an SVM model by using fitcsvm, the following restrictions apply.
  - The class labels input argument value (Y) cannot be a categorical array.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you
cannot use the 'CategoricalPredictors' name-value pair argument. To
dummy-code variables that you want treated as categorical, preprocess the
categorical data by using dummyvar before fitting the model.

- The value of the 'ClassNames' name-value pair argument cannot be a categorical
array.
- The value of the 'ScoreTransform' name-value pair argument cannot be an
anonymous function. For generating code that predicts posterior probabilities
given new observations, pass a trained SVM model to fitPosterior or
fitSVMPosterior. The ScoreTransform property of the returned model
contains an anonymous function that represents the score-to-posterior-probability
function and is configured for code generation.

For more information, see “Introduction to Code Generation” on page 31-2.

Understanding Support Vector Machines on page 18-183

Introduced in R2014a
CompactClassificationTree

**Package:** classreg.learning.classif

Compact classification tree

**Description**

Compact version of a classification tree (of class ClassificationTree). The compact version does not include the data for training the classification tree. Therefore, you cannot perform some tasks with a compact classification tree, such as cross validation. Use a compact classification tree for making predictions (classifications) of new data.

**Construction**

ctree = compact(tree) constructs a compact decision tree from a full decision tree.

**Input Arguments**

tree

A decision tree constructed using fitctree.

**Properties**

*CategoricalPredictors*

Categorical predictor indices, specified as a vector of positive integers. *CategoricalPredictors* contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

*CategoricalSplits*

An n-by-2 cell array, where n is the number of categorical splits in tree. Each row in *CategoricalSplits* gives left and right values for a categorical split. For each branch
node with categorical split \( j \) based on a categorical predictor variable \( z \), the left child is chosen if \( z \) is in \( \text{CategoricalSplits}(j,1) \) and the right child is chosen if \( z \) is in \( \text{CategoricalSplits}(j,2) \). The splits are in the same order as nodes of the tree. Find the nodes for these splits by selecting 'categorical' cuts from top to bottom in the \( \text{CutType} \) property.

**Children**

An \( n \)-by-2 array containing the numbers of the child nodes for each node in \( \text{tree} \), where \( n \) is the number of nodes. Leaf nodes have child node 0.

**ClassCount**

An \( n \)-by-\( k \) array of class counts for the nodes in \( \text{tree} \), where \( n \) is the number of nodes and \( k \) is the number of classes. For any node number \( i \), the class counts \( \text{ClassCount}(i,:) \) are counts of observations (from the data used in fitting the tree) from each class satisfying the conditions for node \( i \).

**ClassNames**

List of the elements in \( Y \) with duplicates removed. \( \text{ClassNames} \) can be a numeric vector, vector of categorical variables, logical vector, character array, or cell array of character vectors. \( \text{ClassNames} \) has the same data type as the data in the argument \( Y \). (The software treats string arrays as cell arrays of character vectors.)

If the value of a property has at least one dimension of length \( k \), then \( \text{ClassNames} \) indicates the order of the elements along that dimension (e.g., \( \text{Cost} \) and \( \text{Prior} \)).

**ClassProbability**

An \( n \)-by-\( k \) array of class probabilities for the nodes in \( \text{tree} \), where \( n \) is the number of nodes and \( k \) is the number of classes. For any node number \( i \), the class probabilities \( \text{ClassProbability}(i,:) \) are the estimated probabilities for each class for a point satisfying the conditions for node \( i \).

**Cost**

Square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \) (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of \( \text{Cost} \) corresponds to the order of the classes in \( \text{ClassNames} \). The number of rows and columns in \( \text{Cost} \) is the number of unique classes in the response. This property is read-only.
**CutCategories**

An n-by-2 cell array of the categories used at branches in `tree`, where `n` is the number of nodes. For each branch node `i` based on a categorical predictor variable `x`, the left child is chosen if `x` is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if `x` is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

**CutPoint**

An n-element vector of the values used as cut points in `tree`, where `n` is the number of nodes. For each branch node `i` based on a continuous predictor variable `x`, the left child is chosen if `x<CutPoint(i)` and the right child is chosen if `x>=CutPoint(i)`. `CutPoint` is `NaN` for branch nodes based on categorical predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

**CutType**

An n-element cell array indicating the type of cut at each node in `tree`, where `n` is the number of nodes. For each node `i`, `CutType{i}` is:

- 'continuous' — If the cut is defined in the form `x < v` for a variable `x` and cut point `v`.
- 'categorical' — If the cut is defined by whether a variable `x` takes a value in a set of categories.
- '' — If `i` is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

**CutPredictor**

An n-element cell array of the names of the variables used for branching in each node in `tree`, where `n` is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.
CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

**IsBranchNode**

An n-element logical vector that is true for each branch node and false for each leaf node of tree.

**NodeClass**

An n-element cell array with the names of the most probable classes in each node of tree, where n is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names in ClassNames.

**NodeError**

An n-element vector of the errors of the nodes in tree, where n is the number of nodes. NodeError(i) is the misclassification probability for node i.

**NodeProbability**

An n-element vector of the probabilities of the nodes in tree, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

**NodeRisk**

An n-element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the measure of impurity (Gini index or deviance) for this node weighted by the node probability. If the tree is grown by twoing, the risk for each node is zero.
**NodeSize**

An $n$-element vector of the sizes of the nodes in `tree`, where $n$ is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

**NumNodes**

The number of nodes in `tree`.

**Parent**

An $n$-element vector containing the number of the parent node for each node in `tree`, where $n$ is the number of nodes. The parent of the root node is 0.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

**Prior**

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

**PruneAlpha**

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to $M$, then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

**PruneList**

An $n$-element numeric vector with the pruning levels in each node of `tree`, where $n$ is the number of nodes. The pruning levels range from 0 (no pruning) to $M$, where $M$ is the distance between the deepest leaf and the root node.

**ResponseName**

Character vector describing the response variable $Y$. 
ScoreTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @(x)x. For a list of built-in transformation functions and the syntax of custom transformation functions, see fitctree.

Add or change a ScoreTransform function using dot notation:

ctree.ScoreTransform = 'function'

or

ctree.ScoreTransform = @function

SurrogateCutCategories

An n-element cell array of the categories used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogateCutCategories{k} is a cell array. The length of SurrogateCutCategories{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutCategories{k} is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutCategories contains an empty cell.

SurrogateCutFlip

An n-element cell array of the numeric cut assignments used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrSurrogateCutFlip{k} is a numeric vector. The length of SurrogateCutFlip{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutFlip{k} is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or +1. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if Z<C and the cut assignment for this surrogate split is +1, or if Z≥C and the cut assignment for this surrogate split is -1. Similarly, the right child is chosen if Z≥C and the cut assignment for this surrogate split is +1, or if Z<C and the cut assignment for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split
variable at this node does not appear. For nonbranch (leaf) nodes, \textit{SurrogateCutFlip} contains an empty array.

\textbf{SurrogateCutPoint}

An $n$-element cell array of the numeric values used for surrogate splits in \textit{tree}, where $n$ is the number of nodes in \textit{tree}. For each node $k$, \textit{SurrogateCutPoint}{\{k\}} is a numeric vector. The length of \textit{SurrogateCutPoint}{\{k\}} is equal to the number of surrogate predictors found at this node. Every element of \textit{SurrogateCutPoint}{\{k\}} is either \texttt{NaN} for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut $C$ based on a continuous predictor variable $Z$, the left child is chosen if $Z < C$ and \textit{SurrogateCutFlip} for this surrogate split is $+1$, or if $Z \geq C$ and \textit{SurrogateCutFlip} for this surrogate split is $-1$. Similarly, the right child is chosen if $Z \geq C$ and \textit{SurrogateCutFlip} for this surrogate split is $+1$, or if $Z < C$ and \textit{SurrogateCutFlip} for this surrogate split is $-1$. The order of the surrogate split variables at each node is matched to the order of variables returned by \textit{SurrogateCutPredictor}. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, \textit{SurrogateCutPoint} contains an empty cell.

\textbf{SurrogateCutType}

An $n$-element cell array indicating types of surrogate splits at each node in \textit{tree}, where $n$ is the number of nodes in \textit{tree}. For each node $k$, \textit{SurrogateCutType}{\{k\}} is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in \textit{SurrogateCutPredictor}. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, \textit{SurrogateCutType} contains an empty cell. A surrogate split type can be either \texttt{'continuous'} if the cut is defined in the form $Z < V$ for a variable $Z$ and cut point $V$ or \texttt{'categorical'} if the cut is defined by whether $Z$ takes a value in a set of categories.

\textbf{SurrogateCutPredictor}

An $n$-element cell array of the names of the variables used for surrogate splits in each node in \textit{tree}, where $n$ is the number of nodes in \textit{tree}. Every element of \textit{SurrogateCutPredictor} is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order; and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, \textit{SurrogateCutPredictor} contains an empty cell.
SurrogatePredictorAssociation

An n-element cell array of the predictive measures of association for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogatePredictorAssociation{k} is a numeric vector. The length of SurrogatePredictorAssociation{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogatePredictorAssociation{k} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogatePredictorAssociation contains an empty cell.

Methods

- edge: Classification edge
- loss: Classification error
- margin: Classification margins
- surrogateAssociation: Mean predictive measure of association for surrogate splits in decision tree
- predict: Predict labels using classification tree
- predictorImportance: Estimates of predictor importance
- view: View tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct a Compact Classification Tree

Construct a compact classification tree for the Fisher iris data.
load fisheriris
tree = fitctree(meas,species);
c = compact(tree);

Compare the size of the resulting tree to that of the original tree.

t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]

ans = 1×2
    4572    11260

The compact tree is smaller than the original tree.

Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

\[ 1 - \sum_i p^2(i), \]

where the sum is over the classes \( i \) at the node, and \( p(i) \) is the observed fraction of classes with class \( i \) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With \( p(i) \) defined the same as for the Gini index, the deviance of a node is

\[ -\sum_i p(i) \log_2 p(i). \]
A pure node has deviance $0$; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class $i$ in the left child node after a split, and $R(i)$ denote the fraction of members of class $i$ in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If $j$ is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict function supports code generation.
- When you train a classification tree using fitctree, the following restrictions apply.
  - The class labels input argument value (Y) cannot be a categorical array.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
• The value of the 'ClassNames' name-value pair argument cannot be a categorical array.
• The value of the 'ScoreTransform' name-value pair argument cannot be an anonymous function.
• You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a
CompactLinearModel class

Compact linear regression model class

Description

CompactLinearModel is a compact linear regression model object. It consumes less memory than a full, fitted linear regression model (LinearModel model) because it does not store the data used to fit the model. Because the compact model does not store the input data, you cannot use it to perform certain tasks. However, you can use a compact linear regression model to predict responses using new input data.

Construction

compactMdl = compact(mdl) returns a compact linear regression model compactMdl from the full, fitted linear regression model mdl. For more information, see compact.

Input Arguments

mdl — Full, fitted linear regression model
    LinearModel object

Full, fitted linear regression model, specified as a LinearModel object.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates
    numeric matrix

Covariance matrix of coefficient estimates, specified as a p-by-p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names
    cell array of character vectors
Coefficient names, specified as a cell array of character vectors containing a label for each coefficient.

**Coefficients — Coefficient values**

`table`

Coefficient values, specified as a table. `Coefficients` has one row for each coefficient and the following columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — $t$ statistic for a test that the coefficient is zero
- **pValue** — $p$-value for the $t$ statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```matlab
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

**DFE — Degrees of freedom for error**

`positive integer value`

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer value.

**Formula — Model information**

`LinearFormula object | NonLinearFormula object`

Model information, specified as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

**LogLikelihood — Log likelihood**

`numeric value`

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.
**ModelCriterion — Criterion for model comparison**

structure

Criterion for model comparison, specified as a structure with the following fields:

- **AIC** — Akaike information criterion. \( AIC = -2 \log L + 2m \), where \( \log L \) is the loglikelihood and \( m \) is the number of estimated parameters.

- **AICc** — Akaike information criterion corrected for the sample size. \( AICc = AIC + \frac{2m(m+1)}{n-m-1} \), where \( n \) is the number of observations.

- **BIC** — Bayesian information criterion. \( BIC = -2 \log L + m \log(n) \).

- **CAIC** — Consistent Akaike information criterion. \( CAIC = -2 \log L + m(\log(n) + 1) \).

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model `mdl`, the AIC value `aic` is:

\[
aic = mdl.ModelCriterion.AIC
\]

**MSE — Mean squared error**

numeric value

Mean squared error (residuals), specified as a numeric value. Mean square error is calculated as \( MSE = \frac{SSE}{DFE} \), where \( MSE \) is the mean square error, \( SSE \) is the sum of squared errors, and \( DFE \) is the degrees of freedom.

**NumCoefficients — Number of model coefficients**

positive integer

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

**NumEstimatedCoefficients — Number of estimated coefficients**

positive integer
Number of estimated coefficients in the model, specified as a positive integer. NumEstimatedCoefficients does not include coefficients that are set to zero when the model terms are rank deficient. NumEstimatedCoefficients is the degrees of freedom for regression.

**NumObservations — Number of observations**
positive integer

Number of observations the fitting function used in fitting, specified as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the Exclude name-value pair) or rows with missing values.

**NumPredictors — Number of predictor variables**
positive integer

Number of predictor variables used to fit the model, specified as a positive integer.

**NumVariables — Number of variables**
positive integer

Number of variables in the input data, specified as a positive integer. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

**PredictorNames — Names of predictors used to fit the model**
cell array of character vectors

Names of predictors used to fit the model, specified as a cell array of character vectors.

**ResponseName — Response variable name**
character vector

Response variable name, specified as a character vector.

**RMSE — Root mean squared error**
numeric value

Root mean squared error (residuals), specified as a numeric value. The root mean squared error (RMSE) is equal to $RMSE = \sqrt{MSE}$, where $MSE$ is the mean squared error.
Robust — Robust fit information
structure

Robust fit information, specified as a structure with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WgtFun</td>
<td>Robust weighting function, such as 'bisquare' (see robustfit)</td>
</tr>
<tr>
<td>Tune</td>
<td>Value specified for tuning parameter (can be [])</td>
</tr>
<tr>
<td>Weights</td>
<td>Vector of weights used in final iteration of robust fit. This field is</td>
</tr>
<tr>
<td></td>
<td>empty for compacted CompactLinearModel models.</td>
</tr>
</tbody>
</table>

This structure is empty unless fitlm constructed the model using robust regression.

R­squared — R­squared value for the model
structure

R-squared value for the model, specified as a structure.

For a linear or nonlinear model, Rsquared is a structure with two fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients

For a generalized linear model, Rsquared is a structure with five fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients
- LLR — Log-likelihood ratio
- Deviance — Deviance
- AdjGeneralized — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

\[ \text{Rsquared} = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SST}}. \]

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in mdl is
r2 = mdl.Rsquared.Adjusted

**SSE — Sum of squared errors**

numeric value

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]

**SSR — Regression sum of squares**

numeric value

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]

**SST — Total sum of squares**

numeric value

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector \( y \) from \( \text{mean}(y) \).

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]

**VariableInfo — Information about input variables**

table

Information about input variables contained in Variables, specified as a table with one row for each model term and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Character vector giving variable class, such as 'double'</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Range</td>
<td>Cell array giving variable range:</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector $[\text{min}, \text{max}]$, the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Cell array of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Logical vector, where $\text{true}$ indicates the variable is in the model</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Logical vector, where $\text{true}$ indicates a categorical variable</td>
</tr>
</tbody>
</table>

**VariableNames — Names of variables used in fit**

cell array of character vectors

Names of variables used in fit, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, **VariableNames** is the values in the **VarNames** name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

**Methods**

- **anova** Analysis of variance for linear model
- **coefCI** Confidence intervals of coefficient estimates of linear model
- **coefTest** Linear hypothesis test on linear regression model coefficients
- **disp** Display linear regression model
- **feval** Evaluate linear regression model prediction
- **plotEffects** Plot main effects of each predictor in linear regression model
- **plotInteraction** Plot interaction effects of two predictors in linear regression model
- **plotSlice** Plot of slices through fitted linear regression surface
- **predict** Predict response of linear regression model
- **random** Simulate responses for linear regression model
Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Compact a Linear Regression Model

This example shows how to reduce the size of a full, fitted linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace.

load(fullfile(matlabroot,'examples','stats','largedata4reg.mat'))

The simulated sample data contains 15,000 observations and 45 predictor variables.

Fit a simple linear regression model to the data.

mdl = fitlm(X,Y)

mdl =
Linear regression model:
    y ~ [Linear formula with 46 terms in 45 predictors]

Estimated Coefficients:
                      Estimate      SE         tStat      pValue

F-statistic vs. constant model: 2.82e+08, p-value = 0

The compact model discards the original sample data and some information related to the fitting process.

Compare the size of the full model mdl and the compact model compactMdl.

vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]

ans = 1×2
    83506   11410618

The compacted model consumes less memory than the full model.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The predict and random functions support code generation.
• When you fit a model by using fitlm or stepwiselm, you cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalVars' name-value pair argument. Code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a
CompactGeneralizedLinearModel

Package: classreg.regr

Compact generalized linear regression model class

Description

CompactGeneralizedLinearModel is a compact generalized linear regression model object. It consumes less memory than a full generalized linear regression model (GeneralizedLinearModel) because it does not store the data used to fit the model. The compact model does not store the input data, so you cannot use it to perform certain tasks. However, you can use a compact generalized linear regression model to predict responses using new input data.

Fitting operations (fitlm, fitglm, ...) automatically use compact objects when you work with tall arrays. Fitting operations with in-memory tables and arrays produce full objects. You can use the compact method to make them smaller.

Construction

compactMdl = compact(mdl) returns a compact generalized linear regression model compactMdl from the full generalized linear regression model mdl. For more information, see compact.

Input Arguments

mdl — Full generalized linear regression model
GeneralizedLinearModel object

Full generalized linear regression model, specified as a GeneralizedLinearModel object.
Properties

**CoefficientCovariance — Covariance matrix of coefficient estimates**
numeric matrix

Covariance matrix of coefficient estimates, specified as a \( p \)-by-\( p \) matrix of numeric values. \( p \) is the number of coefficients in the fitted model.

**CoefficientNames — Coefficient names**
cell array of character vectors

Coefficient names, specified as a cell array of character vectors containing a label for each coefficient.

**Coefficients — Coefficient values**
table

Coefficient values, specified as a table. `Coefficients` has one row for each coefficient and the following columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — \( t \) statistic for a test that the coefficient is zero
- **pValue** — \( p \)-value for the \( t \) statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

\[
\text{beta} = \text{mdl.Coefficients.Estimate}
\]

Use `coefTest` to perform other tests on the coefficients.

**Deviance — Deviance of fit**
numeric value

Deviance of fit, specified as a numeric value. Deviance is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 32-2746.
DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer value.

Dispersion — Scale factor of the variance of the response

structure

Scale factor of the variance of the response, specified as a structure. Dispersion multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is \( p(1-p)/n \), where \( p \) is the probability parameter and \( n \) is the sample size parameter. If Dispersion is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If Dispersion is larger than 1, the data are “overdispersed” relative to the binomial distribution.

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

Flag to indicate use of dispersion scale factor, specified as a logical value. Use DispersionEstimated to indicate whether fitglm used the Dispersion scale factor to compute standard errors for the coefficients in Coefficients.SE. If DispersionEstimated is false, then fitglm used the theoretical value of the variance.

- DispersionEstimated can be false only for 'binomial' or 'poisson' distributions.
- To set DispersionEstimated, set the DispersionFlag name-value pair in fitglm.

Distribution — Generalized distribution information

structure

Generalized distribution information, specified as a structure with the following fields relating to the generalized distribution.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the distribution. Options are: 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gaussian'.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
DevianceFunction | Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction | Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When DispersionEstimated is true, Dispersion multiplies the variance function in the computation of the coefficient standard errors.

**Formula — Model information**

*LinearFormula object | NonLinearFormula object*

Model information, specified as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

**Link — Link function**

*structure*

Link function, specified as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the link function, or '' if you specified the link as a function handle rather than a character vector</td>
</tr>
<tr>
<td>LinkFunction</td>
<td>The function that defines $f$, a function handle</td>
</tr>
<tr>
<td>DevianceFunction</td>
<td>Derivative of $f$, a function handle</td>
</tr>
<tr>
<td>VarianceFunction</td>
<td>Inverse of $f$, a function handle</td>
</tr>
</tbody>
</table>

The link is a function $f$ that links the distribution parameter $\mu$ to the fitted linear combination $Xb$ of the predictors:

$$f(\mu) = Xb.$$  

**LogLikelihood — Log likelihood**

*numeric value*

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.
ModelCriterion — Criterion for model comparison
structure

Criterion for model comparison, specified as a structure with the following fields:

- AIC — Akaike information criterion. \( \text{AIC} = -2\log L + 2m \), where \( \log L \) is the loglikelihood and \( m \) is the number of estimated parameters.
- AICc — Akaike information criterion corrected for the sample size. \( \text{AICc} = \text{AIC} + \frac{2m(m+1)}{(n-m-1)} \), where \( n \) is the number of observations.
- BIC — Bayesian information criterion. \( \text{BIC} = -2\log L + m \log(n) \).
- CAIC — Consistent Akaike information criterion. \( \text{CAIC} = -2\log L + m(\log(n) + 1) \).

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model \( \text{mdl} \), the AIC value \( \text{aic} \) is:

\[ \text{aic} = \text{mdl.ModelCriterion.AIC} \]

NumCoefficients — Number of model coefficients
positive integer

Number of model coefficients, specified as a positive integer. \( \text{NumCoefficients} \) includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients — Number of estimated coefficients
positive integer

Number of estimated coefficients in the model, specified as a positive integer. \( \text{NumEstimatedCoefficients} \) does not include coefficients that are set to zero when the model terms are rank deficient. \( \text{NumEstimatedCoefficients} \) is the degrees of freedom for regression.
NumObservations — Number of observations
positive integer

Number of observations the fitting function used in fitting, specified as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the Exclude name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables
positive integer

Number of predictor variables used to fit the model, specified as a positive integer.

NumVariables — Number of variables
positive integer

Number of variables in the input data, specified as a positive integer. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

PredictorNames — Names of predictors used to fit the model
cell array of character vectors

Names of predictors used to fit the model, specified as a cell array of character vectors.

ResponseName — Response variable name
character vector

Response variable name, specified as a character vector.

R_squared — R-squared value for the model
structure

R-squared value for the model, specified as a structure.

For a linear or nonlinear model, R_squared is a structure with two fields:

• Ordinary — Ordinary (unadjusted) R-squared
• Adjusted — R-squared adjusted for the number of coefficients

For a generalized linear model, R_squared is a structure with five fields:
• **Ordinary** — Ordinary (unadjusted) R-squared
• **Adjusted** — R-squared adjusted for the number of coefficients
• **LLR** — Log-likelihood ratio
• **Deviance** — Deviance
• **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

\[ \text{R}^2 = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SST}}. \]

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

\[ r_2 = \text{mdl.Rsquared.Adjusted} \]

**SSE — Sum of squared errors**  
numeric value

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**SSR — Regression sum of squares**  
numeric value

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**SST — Total sum of squares**  
numeric value

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector \( y \) from \( \text{mean}(y) \).

The Pythagorean theorem implies
SST = SSE + SSR.

**VariableInfo — Information about input variables**

Table

Information about input variables contained in Variables, specified as a table with one row for each model term and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Character vector giving variable class, such as 'double'</td>
</tr>
<tr>
<td>Range</td>
<td>Cell array giving variable range:</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector $[\text{min}, \text{max}]$, the</td>
</tr>
<tr>
<td></td>
<td>minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Cell array of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Logical vector, where true indicates the variable is in the model</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Logical vector, where true indicates a categorical variable</td>
</tr>
</tbody>
</table>

**VariableNames — Names of variables used in fit**

Cell array of character vectors

Names of variables used in fit, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames is the values in the VarNames name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.
Methods

coefCI  Confidence intervals of coefficient estimates of generalized linear model
coefTest  Linear hypothesis test on generalized linear regression model coefficients
devianceTest  Analysis of deviance
disp  Display generalized linear regression model
feval  Evaluate generalized linear regression model prediction
plotSlice  Plot of slices through fitted generalized linear regression surface
predict  Predict response of generalized linear regression model
random  Simulate responses for generalized linear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Compact a Generalized Linear Regression Model

Reduce the size of a full, fitted generalized linear regression model by discarding the sample data and some information related to the fitting process.

Load the data into the workspace. The simulated sample data contains 15,000 observations and 45 predictor variables.

load(fullfile(matlabroot,'examples','stats','largedata4reg.mat'))

Fit a generalized linear regression model to the data using the first 15 predictor variables.

mdl = fitglm(X(:,1:15),Y)

mdl =
Generalized linear regression model:
    y ~ [Linear formula with 16 terms in 15 predictors]
Distribution = Normal

32-835
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict and random functions support code generation.
- When you fit a model by using fitglm or stepwiseglm, the following restrictions apply.
  - Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalVars' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
  - The Link, Derivative, and Inverse fields of the 'Link' name-value pair argument cannot be anonymous functions. That is, you cannot generate code using
a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016b
CompactRegressionEnsemble

**Package:** classreg.learning.regr

Compact regression ensemble class

**Description**

Compact version of a regression ensemble (of class RegressionEnsemble). The compact version does not include the data for training the regression ensemble. Therefore, you cannot perform some tasks with a compact regression ensemble, such as cross validation. Use a compact regression ensemble for making predictions (regressions) of new data.

**Construction**

```matlab
ens = compact(fullEns)
```

constructs a compact decision ensemble from a full decision ensemble.

**Input Arguments**

- **fullEns**
  
  A regression ensemble created by `fitrensemble`.

**Properties**

- **CategoricalPredictors**
  
  Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

- **CombineWeights**
  
  A character vector describing how the ensemble combines learner predictions.
**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

**NumTrained**

Number of trained learners in the ensemble, a positive scalar.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in X.

**ResponseName**

A character vector with the name of the response variable Y.

**ResponseTransform**

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means @((x)x).

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

**Trained**

The trained learners, a cell array of compact regression models.

**TrainedWeights**

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.
Methods

loss Regression error
predict Predict responses using ensemble of regression models
predictorImportance Estimates of predictor importance
removeLearners Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Reduce Size of Regression Ensemble

Create a compact regression ensemble for efficiently making predictions on new data.

Load the carsmall data set. Consider a model that explains a car's fuel economy (MPG) using its weight (Weight) and number of cylinders (Cylinders).

load carsmall
X = [Weight Cylinders];
Y = MPG;

Train a boosted ensemble of 100 regression trees using the LSBoost. Specify that Cylinders is a categorical variable.

Mdl = fitrensemble(X,Y,'PredictorNames',{'W','C'},...
    'CategoricalPredictors',2)

Mdl =
classreg.learning.regr.RegressionEnsemble
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
    CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumObservations: 94
Mdl is a RegressionEnsemble model object that contains the training data, among other things.

Create a compact version of Mdl.

```matlab
CMdl = compact(Mdl)
```

```matlab
CMdl =
    classreg.learning.regr.CompactRegressionEnsemble
    PredictorNames: {'W'  'C'}
    ResponseName: 'Y'
    CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumTrained: 100
```

CMdl is a CompactRegressionEnsemble model object. CMdl is almost the same as Mdl. One exception is that CMdl does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.

```matlab
mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]
```

```matlab
ans = 1x2
    452006   430682
```

Mdl consumes more space than CMdl.
CMdl.Trained stores the trained regression trees (CompactRegressionTree model objects) that compose Mdl.

Display a graph of the first tree in the compact ensemble.

view(CMdl.Trained{1}, 'Mode', 'graph');

By default, fitrensemble grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of a typical car using the compact ensemble.
typicalX = [mean(X(:,1)) mode(X(:,2))];
predMeanX = predict(CMdl,typicalX)

predMeanX = 26.2520

Tip
For a compact ensemble of regression trees, the Trained property of ens stores a cell vector of ens.NumTrained CompactRegressionTree model objects. For a textual or graphical display of tree t in the cell vector, enter

view(ens.Trained{t})

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- The predict function supports code generation.
- When you train an ensemble by using fitrensemble, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-867 of the CompactRegressionTree class.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionEnsemble | compact | fitrensemble | plotPartialDependence | predict | templateTree | view

Introduced in R2011a
CompactRegressionGP

Package: classreg.learning.regr

Compact Gaussian process regression model class

Description

CompactRegressionGP is a compact Gaussian process regression (GPR) model. The compact model consumes less memory than a full model, because it does not include the data used for training the GPR model.

Because the compact model does not include the training data, you cannot perform some tasks, such as cross-validation, using the compact model. However, you can use the compact model for making predictions or calculate regression loss for new data (use `predict` and `loss`).

Construction

`compactMdl = compact(gprMdl)` returns a compact GPR model, `compactMdl`, from a full, trained GPR model, `gprMdl`. For more information, see `compact`.

Input Arguments

`gprMdl` — Full, trained Gaussian process regression model
RegressionGP model

Full, trained Gaussian process regression model, specified as a `RegressionGP` model, returned by `fitrgp`.

Properties

Fitting

`FitMethod` — Method used to estimate the parameters

- 'none'
- 'exact'
- 'sd'
- 'sr'
- 'fic'

32-844
Method used to estimate the basis function coefficients, \( \beta \); noise standard deviation, \( \sigma \); and kernel parameters, \( \theta \), of the GPR model, stored as a character vector. It can be one of the following.

<table>
<thead>
<tr>
<th>Fit Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>No estimation. <code>fitrgp</code> uses the initial parameter values as the parameter values.</td>
</tr>
<tr>
<td>'exact'</td>
<td>Exact Gaussian process regression.</td>
</tr>
<tr>
<td>'sd'</td>
<td>Subset of data points approximation.</td>
</tr>
<tr>
<td>'sr'</td>
<td>Subset of regressors approximation.</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully independent conditional approximation.</td>
</tr>
</tbody>
</table>

**BasisFunction — Explicit basis function**

'none' | 'constant' | 'linear' | 'pureQuadratic' | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If \( n \) is the number of observations, the basis function adds the term \( H^*\beta \) to the model, where \( H \) is the basis matrix and \( \beta \) is a \( p \)-by-1 vector of basis coefficients.

<table>
<thead>
<tr>
<th>Explicit Basis</th>
<th>Basis Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>Empty matrix.</td>
</tr>
<tr>
<td>'constant'</td>
<td>( H = 1 )</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
Explicit Basis | Basis Matrix
---|---
'pureQuadratic' | \( \mathbf{H} = [1, \mathbf{X}, \mathbf{X}_2], \)

where

\[
\mathbf{X}_2 = \begin{bmatrix}
x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\
x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\
\vdots & \vdots & \ddots & \vdots \\
x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2
\end{bmatrix}.
\]

Function handle | Function handle, \( \text{hfcn} \), that \( \text{fitrgp} \) calls as:

\[ \mathbf{H} = \text{hfcn}(\mathbf{X}), \]

where \( \mathbf{X} \) is an \( n \)-by-\( d \) matrix of predictors and \( \mathbf{H} \) is an \( n \)-by-\( p \) matrix of basis functions.

Data Types: char | function_handle

CategoricalPredictors — Indices of categorical predictors
vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. \( \text{CategoricalPredictors} \) contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (\([\ ]\)).

Data Types: single | double

Beta — Estimated coefficients
vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the \( \text{BasisFunction} \) name-value pair argument in \( \text{fitrgp} \).

Data Types: double
**Sigma — Estimated noise standard deviation**

scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: double

**ModelParameters — Parameters used for training**

GPParams object

Parameters used for training the GPR model, stored as a GPParams object.

**Kernel Function**

**KernelFunction — Form of the covariance function**

'squaredExponential' | 'matern32' | 'matern52' | 'ardsquaredexponential' | 'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'squaredExponential'</td>
<td>Squared exponential kernel.</td>
</tr>
<tr>
<td>'matern32'</td>
<td>Matern kernel with parameter 3/2.</td>
</tr>
<tr>

<td>Matern kernel with parameter 3/2 and a separate length scale per predictor.</td>
</tr>
<tr>
<td>'ardmatern52'</td>
<td>Matern kernel with parameter 5/2 and a separate length scale per predictor.</td>
</tr>
</tbody>
</table>
Function handle

A function handle that `fitrgp` can call like this:

\[ K_{mn} = kfcn(X_m, X_n, \theta) \]

where \( X_m \) is an \( m \)-by-\( d \) matrix, \( X_n \) is an \( n \)-by-\( d \) matrix and \( K_{mn} \) is an \( m \)-by-\( n \) matrix of kernel products such that \( K_{mn}(i,j) \) is the kernel product between \( X_m(i,:) \) and \( X_n(j,:) \).

\( \theta \) is the \( r \)-by-1 unconstrained parameter vector for \( kfcn \).

Data Types: `char` | `function_handle`

**KernelInformation — Information about the parameters of the kernel function**

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the kernel function</td>
</tr>
<tr>
<td>KernelParameters</td>
<td>Vector of the estimated kernel parameters</td>
</tr>
<tr>
<td>KernelParameterNames</td>
<td>Names associated with the elements of KernelParameters.</td>
</tr>
</tbody>
</table>

Data Types: `struct`

**Prediction**

**PredictMethod — Method used to make predictions**

- `'exact'` | `'bcd'` | `'sd'` | `'sr'` | `'fic'`

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

<table>
<thead>
<tr>
<th>PredictMethod</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'exact'</code></td>
<td>Exact Gaussian process regression</td>
</tr>
<tr>
<td><code>'bcd'</code></td>

</tr>
<tr>
<td>'sr'</td>
<td>Subset of Regressors approximation</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully Independent Conditional approximation</td>
</tr>
</tbody>
</table>

**Alpha — Weights**

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix $X_{new}$ by using the product

$$K(X_{new}, A) \alpha.$$  

$K(X_{new}, A)$ is the matrix of kernel products between $X_{new}$ and active set vector $A$ and $\alpha$ is a vector of weights.

Data Types: double

**ResponseTransform — Transformation applied to predicted response**

'none' (default)

Transformation applied to the predicted response, stored as a character vector describing how the response values predicted by the model are transformed. In RegressionGP, `ResponseTransform` is 'none' by default, and RegressionGP does not use `ResponseTransform` when making predictions.

**Active Set Selection**

**ActiveSetVectors — Subset of training data**

matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix. `predict` computes the predictions for a new predictor matrix $X_{new}$ by using the product

$$K(X_{new}, A) \alpha.$$
\( K(\mathbf{X}_{\text{new}}, \mathbf{A}) \) is the matrix of kernel products between \( \mathbf{X}_{\text{new}} \) and active set vector \( \mathbf{A} \) and \( \alpha \) is a vector of weights.

ActiveSetVectors is equal to the training data \( \mathbf{X} \) for exact GPR fitting and a subset of the training data \( \mathbf{X} \) for sparse GPR methods. When there are categorical predictors in the model, ActiveSetVectors contains dummy variables for the corresponding predictors.

Data Types: double

**ActiveSetMethod** — Method used to select the active set

'\text{sgma}' | 'entropy' | 'likelihood' | 'random'

Method used to select the active set for sparse methods ('sd','sr', or 'fic'), stored as a character vector. It can be one of the following.

<table>
<thead>
<tr>
<th>ActiveSetMethod</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sgma'</td>
<td>Sparse greedy matrix approximation</td>
</tr>
<tr>
<td>'entropy'</td>
<td>Differential entropy-based selection</td>
</tr>
<tr>
<td>'likelihood'</td>
<td>Subset of regressors log likelihood-based selection</td>
</tr>
<tr>
<td>'random'</td>
<td>Random selection</td>
</tr>
</tbody>
</table>

The selected active set is used in parameter estimation or prediction, depending on the choice of FitMethod and PredictMethod in fitrgp.

**ActiveSetSize** — Size of the active set

integer value

Size of the active set for sparse methods ('sd','sr', or 'fic'), stored as an integer value.

Data Types: double

**Methods**

- **loss** Regression error for Gaussian process regression model
- **predict** Predict response of Gaussian process regression model
Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The predict function supports code generation.
• When you train a Gaussian process regression model by using fitrgp, you cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. Code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics

Class Attributes (MATLAB)
Property Attributes (MATLAB)

Introduced in R2015b
CompactRegressionSVM

Package: classreg.learning.regr

Compact support vector machine regression model

Description

CompactRegressionSVM is a compact support vector machine (SVM) regression model. It consumes less memory than a full, trained support vector machine model (RegressionSVM model) because it does not store the data used to train the model.

Because the compact model does not store the training data, you cannot use it to perform certain tasks, such as cross validation. However, you can use a compact SVM regression model to predict responses using new input data.

Construction

compactMdl = compact(mdl) returns a compact SVM regression model compactMdl from a full, trained SVM regression model, mdl. For more information, see compact.

Input Arguments

mdl — Full, trained SVM regression model
RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by fitrsvm.

Properties

Alpha — Dual problem coefficients
vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. Alpha contains m elements, where m is the number of support vectors in the trained SVM regression model.
The dual problem introduces two Lagrange multipliers for each support vector. The values of Alpha are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using RemoveDuplicates, then, for a particular set of duplicate observations that are support vectors, Alpha contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: single | double

**Beta — Primal linear problem coefficients**

vector of numeric values | '[]'

Primal linear problem coefficients, stored as a numeric vector of length \( p \), where \( p \) is the number of predictors in the SVM regression model.

The values in Beta are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than 'linear', this property is empty ('[]').

The predict method computes predicted response values for the model as \( YFIT = (X/S) \times Beta + Bias \), where \( S \) is the value of the kernel scale stored in the KernelParameters.Scale property.

Data Types: double

**Bias — Bias term**

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: double

**CategoricalPredictors — Indices of categorical predictors**

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).
Data Types: single | double

**ExpandedPredictorNames — Expanded predictor names**
cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: cell

**KernelParameters — Kernel function parameters**
structure

Kernel function parameters, stored as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>Kernel function name (a character vector).</td>
</tr>
<tr>
<td>Scale</td>
<td>Numeric scale factor used to divide predictor values.</td>
</tr>
</tbody>
</table>

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: struct

**Mu — Predictor means**
vector of numeric values | '[]'

Predictor means, stored as a vector of numeric values.

If the training data is standardized, then `Mu` is a numeric vector of length `p`, where `p` is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix `X` by subtracting the corresponding element of `Mu` from each column.

If the training data is not standardized, then `Mu` is empty ('[]').

Data Types: single | double
**PredictorNames — Predictor names**  
cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

**ResponseName — Response variable name**  
character vector

Response variable name, stored as a character vector.

Data Types: `char`

**ResponseTransform — Response transformation function**  
'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where `function` accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

**Sigma — Predictor standard deviations**  
vector of numeric values | '[]'

Predictor standard deviations, stored as a vector of numeric values.

If the training data is standardized, then `Sigma` is a numeric vector of length `p`, where `p` is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix `X` by dividing each column by the corresponding element of `Sigma`, after centering each element using `Mu`.

If the training data is not standardized, then `Sigma` is empty ('[]').

Data Types: `single` | `double`

**SupportVectors — Support vectors**  
matrix of numeric values
Support vectors, stored as an \( m \)-by-\( p \) matrix of numeric values. \( m \) is the number of support vectors \( \text{sum(Mdl.IsSupportVector)} \), and \( p \) is the number of predictors in \( X \).

If you specified to remove duplicates using \text{RemoveDuplicates}, then for a given set of duplicate observations that are support vectors, \text{SupportVectors} contains one unique support vector.

Data Types: \text{single} | \text{double}

**Methods**

- \text{discardSupportVectors} Discard support vectors
- \text{loss} Regression error for support vector machine regression model
- \text{predict} Predict responses using support vector machine regression model

**Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

**Examples**

**Compact an SVM Regression Model**

This example shows how to reduce the size of a full, trained SVM regression model by discarding the training data and some information related to the training process.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);rng default  \% for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for \text{sex}, which is a categorical variable with possible values 'M' (for males), 'F'
(for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model using a Gaussian kernel function and an automatic kernel scale. Standardize the data.

```matlab
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true)
mdl =
    RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    NumObservations: 4177
    BoxConstraints: [4177x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [4177x1 logical]
    Solver: 'SMO'
```

Properties, Methods

Compact the model.

```matlab
compactMdl = compact(mdl)
compactMdl =
    classreg.learning.regr.CompactRegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
SupportVectors: [3635x10 double]

Properties, Methods

The compacted model discards the training data and some information related to the training process.

Compare the size of the full model `mdl` and the compact model `compactMdl`.

```matlab
vars = whos('compactMdl','mdl');
[vars(1).bytes,vars(2).bytes]
```

```matlab
ans =
    323793      775968
```

The compacted model consumes about half the memory of the full model.

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The predict and update functions support code generation.
• When you train an SVM regression model by using fitrsvm, the following restrictions apply.
  • Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
  • The value of the 'ResponseTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2015b
CompactRegressionTree

Package: classreg.learning.regr

Compact regression tree

Description

Compact version of a regression tree (of class RegressionTree). The compact version does not include the data for training the regression tree. Therefore, you cannot perform some tasks with a compact regression tree, such as cross validation. Use a compact regression tree for making predictions (regressions) of new data.

Construction

ctree = compact(tree) constructs a compact decision tree from a full decision tree.

Input Arguments

tree — Full, trained regression tree
RegressionTree object

Full, trained regression tree, specified as a RegressionTree object constructed by fitrtree.

Properties

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).
CategoricalSplits

An n-by-2 cell array, where n is the number of categorical splits in tree. Each row in CategoricalSplits gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z, the left child is chosen if z is in CategoricalSplits(j,1) and the right child is chosen if z is in CategoricalSplits(j,2). The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running cuttype and selecting 'categorical' cuts from top to bottom.

Children

An n-by-2 array containing the numbers of the child nodes for each node in tree, where n is the number of nodes. Leaf nodes have child node 0.

CutCategories

An n-by-2 cell array of the categories used at branches in tree, where n is the number of nodes. For each branch node i based on a categorical predictor variable x, the left child is chosen if x is among the categories listed in CutCategories{i,1}, and the right child is chosen if x is among those listed in CutCategories{i,2}. Both columns of CutCategories are empty for branch nodes based on continuous predictors and for leaf nodes.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

CutPoint

An n-element vector of the values used as cut points in tree, where n is the number of nodes. For each branch node i based on a continuous predictor variable x, the left child is chosen if CutPoint<v(i) and the right child is chosen if x>=CutPoint(i).

CutPoint is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n-element cell array indicating the type of cut at each node in tree, where n is the number of nodes. For each node i, CutType{i} is:

• 'continuous' — If the cut is defined in the form x < v for a variable x and cut point v.
• 'categorical' — If the cut is defined by whether a variable \( x \) takes a value in a set of categories.
• ' ' — If \( i \) is a leaf node.

**CutPoint** contains the cut points for 'continuous' cuts, and **CutCategories** contains the set of categories.

**CutPredictor**

An \( n \)-element cell array of the names of the variables used for branching in each node in \( \text{tree} \), where \( n \) is the number of nodes. These variables are sometimes known as cut variables. For leaf nodes, **CutPredictor** contains an empty character vector.

**CutPoint** contains the cut points for 'continuous' cuts, and **CutCategories** contains the set of categories.

**ExpandedPredictorNames**

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then **ExpandedPredictorNames** includes the names that describe the expanded variables. Otherwise, **ExpandedPredictorNames** is the same as **PredictorNames**.

**IsBranchNode**

An \( n \)-element logical vector \( \text{ib} \) that is \( \text{true} \) for each branch node and \( \text{false} \) for each leaf node of \( \text{tree} \).

**NodeError**

An \( n \)-element vector \( \text{e} \) of the errors of the nodes in \( \text{tree} \), where \( n \) is the number of nodes. \( \text{e}(i) \) is the misclassification probability for node \( i \).

**NodeMean**

An \( n \)-element numeric array with mean values in each node of \( \text{tree} \), where \( n \) is the number of nodes in the tree. Every element in **NodeMean** is the average of the true \( Y \) values over all observations in the node.

**NodeProbability**

An \( n \)-element vector \( \text{p} \) of the probabilities of the nodes in \( \text{tree} \), where \( n \) is the number of nodes. The probability of a node is computed as the proportion of observations from the
original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

**NodeRisk**

An \( n \)-element vector of the risk of the nodes in the tree, where \( n \) is the number of nodes. The risk for each node is the node error weighted by the node probability.

**NodeSize**

An \( n \)-element vector \( \text{sizes} \) of the sizes of the nodes in \( \text{tree} \), where \( n \) is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

**NumNodes**

The number of nodes \( n \) in \( \text{tree} \).

**Parent**

An \( n \)-element vector \( \text{p} \) containing the number of the parent node for each node in \( \text{tree} \), where \( n \) is the number of nodes. The parent of the root node is 0.

**PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in \( X \).

**PruneAlpha**

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to \( M \), then \( \text{PruneAlpha} \) has \( M + 1 \) elements sorted in ascending order. \( \text{PruneAlpha}(1) \) is for pruning level 0 (no pruning), \( \text{PruneAlpha}(2) \) is for pruning level 1, and so on.

**PruneList**

An \( n \)-element numeric vector with the pruning levels in each node of \( \text{tree} \), where \( n \) is the number of nodes. The pruning levels range from 0 (no pruning) to \( M \), where \( M \) is the distance between the deepest leaf and the root node.

**ResponseName**

Name of the response variable \( Y \), a character vector.
**ResponseTransform**

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default 'none' means @(x)x, or no transformation.

Add or change a ResponseTransform function using dot notation:

```matlab
ctree.ResponseTransform = @function
```

**SurrogateCutCategories**

An n-element cell array of the categories used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogateCutCategories{k} is a cell array. The length of SurrogateCutCategories{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutCategories{k} is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutCategories contains an empty cell.

**SurrogateCutFlip**

An n-element cell array of the numeric cut assignments used for surrogate splits in tree, where n is the number of nodes in tree. For each node k, SurrogateCutFlip{k} is a numeric vector. The length of SurrogateCutFlip{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutFlip{k} is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or +1. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if Z<C and the cut assignment for this surrogate split is +1, or if Z≥C and the cut assignment for this surrogate split is -1. Similarly, the right child is chosen if Z≥C and the cut assignment for this surrogate split is +1, or if Z<C and the cut assignment for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutFlip contains an empty array.
**SurrogateCutPoint**

An $n$-element cell array of the numeric values used for surrogate splits in tree, where $n$ is the number of nodes in tree. For each node $k$, SurrogateCutPoint{$k$} is a numeric vector. The length of SurrogateCutPoint{$k$} is equal to the number of surrogate predictors found at this node. Every element of SurrogateCutPoint{$k$} is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut $C$ based on a continuous predictor variable $Z$, the left child is chosen if $Z<C$ and SurrogateCutFlip for this surrogate split is +1, or if $Z\geq C$ and SurrogateCutFlip for this surrogate split is -1. Similarly, the right child is chosen if $Z\geq C$ and SurrogateCutFlip for this surrogate split is +1, or if $Z<C$ and SurrogateCutFlip for this surrogate split is -1. The order of the surrogate split variables at each node is matched to the order of variables returned by SurrogateCutVar. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPoint contains an empty cell.

**SurrogateCutType**

An $n$-element cell array indicating types of surrogate splits at each node in tree, where $n$ is the number of nodes in tree. For each node $k$, SurrogateCutType{$k$} is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutType contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z<V$ for a variable $Z$ and cut point $V$ or 'categorical' if the cut is defined by whether $Z$ takes a value in a set of categories.

**SurrogateCutPredictor**

An $n$-element cell array of the names of the variables used for surrogate splits in each node in tree, where $n$ is the number of nodes in tree. Every element of SurrogateCutPredictor is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPredictor contains an empty cell.
SurrogatePredictorAssociation

An \( n \)-element cell array of the predictive measures of association for surrogate splits in tree, where \( n \) is the number of nodes in tree. For each node \( k \), \( \text{SurrogatePredictorAssociation}{k} \) is a numeric vector. The length of \( \text{SurrogatePredictorAssociation}{k} \) is equal to the number of surrogate predictors found at this node. Every element of \( \text{SurrogatePredictorAssociation}{k} \) gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in \( \text{SurrogateCutPredictor} \). The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, \( \text{SurrogatePredictorAssociation} \) contains an empty cell.

Methods

- **loss** Regression error
- **surrogateAssociation** Mean predictive measure of association for surrogate splits in decision tree
- **predict** Predict responses using regression tree
- **predictorImportance** Estimates of predictor importance
- **view** View tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct and Compact a Regression Tree

Load the sample data.

```matlab
load carsmall
```

Construct a regression tree for the sample data.
tree = fitrtree([Weight, Cylinders],MPG,...
   'MinParentSize',20,...
   'PredictorNames',{'W','C'});

Make a compact version of the tree.
ctree = compact(tree);

Compare the size of the compact tree to that of the full tree.
t = whos('tree'); % t.bytes = size of tree in bytes
c = whos('ctree'); % c.bytes = size of ctree in bytes
[c.bytes t.bytes]

ans = 1x2
      3708     6954

The compact tree is smaller than the full tree.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The predict function supports code generation.
• When you train a regression tree model by using fitrtree, the following restrictions apply.
  • Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalPredictors' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
  • The value of the 'ResponseTransform' name-value pair argument cannot be an anonymous function.
You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For more information, see “Introduction to Code Generation” on page 31-2.

*Introduced in R2011a*
CompactTreeBagger class

Compact ensemble of decision trees grown by bootstrap aggregation

Description

CompactTreeBagger class is a lightweight class that contains the trees grown using TreeBagger. CompactTreeBagger does not preserve any information about how TreeBagger grew the decision trees. It does not contain the input data used for growing trees, nor does it contain training parameters such as minimal leaf size or number of variables sampled for each decision split at random. You can only use CompactTreeBagger for predicting the response of the trained ensemble given new data X, and other related functions.

CompactTreeBagger lets you save the trained ensemble to disk, or use it in any other way, while discarding training data and various parameters of the training configuration irrelevant for predicting response of the fully grown ensemble. This reduces storage and memory requirements, especially for ensembles trained on large data sets.

Construction

CompactTreeBagger Create CompactTreeBagger object

CMdl = compact(Mdl) creates a compact version of Mdl, a TreeBagger model object. You can predict regressions using CMdl exactly as you can using Mdl. However, since CMdl does not contain training data, you cannot perform some actions, such as make out-of-bag predictions using oobPredict.
Methods

- **combine**: Combine two ensembles
- **error**: Error (misclassification probability or MSE)
- **margin**: Classification margin
- **mdsprox**: Multidimensional scaling of proximity matrix
- **meanMargin**: Mean classification margin
- **outlierMeasure**: Outlier measure for data
- **predict**: Predict responses using ensemble of bagged decision trees
- **proximity**: Proximity matrix for data
- **setDefaultYfit**: Set default value for predict

Properties

**ClassNames**

The `ClassNames` property is a cell array containing the class names for the response variable `Y` supplied to `TreeBagger`. This property is empty for regression trees.

**DefaultYfit**

The `DefaultYfit` property controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'useifort'` argument.

For classification, you can set this property to either '' or 'MostPopular'. If you choose 'MostPopular' (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.
**DeltaCriterionDecisionSplit**

The DeltaCriterionDecisionSplit property is a numeric array of size 1-by-Nvars of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

**Method**

The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

**NumPredictorSplit**

The NumPredictorSplit property is a numeric array of size 1-by-Nvars, where every element gives a number of splits on this predictor summed over all trees.

**NumTrees**

The NumTrees property is a scalar equal to the number of decision trees in the ensemble.

**PredictorNames**

The PredictorNames property is a cell array containing the names of the predictor variables (features). These names are taken from the optional 'names' parameter that supplied to TreeBagger. The default names are 'x1', 'x2', etc.

**SurrogateAssociation**

The SurrogateAssociation property is a matrix of size Nvars-by-Nvars with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), SurrogateAssociation is diagonal.

**Trees**

The Trees property is a cell array of size NumTrees-by-1 containing the trees in the ensemble.
Examples

Reduce Size of Bag of Trees

Create a compact bag of trees for efficiently making predictions on new data.

Load the ionosphere data set.

load ionosphere

Train a bag of 100 classification trees using all measurements and the AdaBoostM1 method.

Mdl = TreeBagger(100,X,Y,'Method','classification')

Mdl = TreeBagger
Ensemble with 100 bagged decision trees:
    Training X:     [351x34]
    Training Y:     [351x1]
    Method:       classification
    NumPredictors:                   34
    NumPredictorsToSample:                    6
    MinLeafSize:                    1
    InBagFraction:                    1
    SampleWithReplacement:                    1
    ComputeOOBPrediction:                    0
    ComputeOOBPredictorImportance:                    0
    Proximity:                   []
    ClassNames:             'b'             'g'

Properties, Methods

Mdl is a TreeBagger model object that contains the training data, among other things.

Create a compact version of Mdl.

CMdl = compact(Mdl)

CMdl = CompactTreeBagger
Ensemble with 100 bagged decision trees:
Method: classification
NumPredictors: 34
ClassNames: 'b' 'g'

Properties, Methods

CMdl is a CompactTreeBagger model object. CMdl is almost the same as Mdl. One exception is that it does not store the training data.

Compare the amounts of space consumed by Mdl and CMdl.

mdlInfo = whos('Mdl');
cMdlInfo = whos('CMdl');
[mdlInfo.bytes cMdlInfo.bytes]

ans = 1x2
1031399  890204

Mdl consumes more space than CMdl.

CMdl.Trees stores the trained classification trees (CompactClassificationTree model objects) that compose Mdl.

Display a graph of the first tree in the compact model.

view(CMdl.Trees{1},'Mode','graph');
By default, TreeBagger grows deep trees.

Predict the label of the mean of \( X \) using the compact ensemble.

\[
predMeanX = \text{predict}(\text{CMdl},\text{mean}(X))
\]

\[
predMeanX = 1x1 \ cell \ array
\begin{array}{c}
\{'g'\}
\end{array}
\]
Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes (MATLAB) in the MATLAB Object-Oriented Programming documentation.

Tip

The Trees property of CMdl stores a cell vector of CMdl.NumTrees CompactClassificationTree or CompactRegressionTree model objects. For a textual or graphical display of tree $t$ in the cell vector, enter

view(CMdl.Trees{t})

CompactTreeBagger

Class: CompactTreeBagger

Create CompactTreeBagger object

Description

When you use the TreeBagger constructor to grow trees, it creates a CompactTreeBagger object. You can obtain the compact object from the full TreeBagger object using the TreeBagger/compact method. You do not create an instance of CompactTreeBagger directly.

Introduced in R2009a
compare

Class: GeneralizedLinearMixedModel

Compare generalized linear mixed-effects models

Syntax

results = compare(glme,altglme)
results = compare(glme,altglme,Name,Value)

Description

results = compare(glme,altglme) returns the results of a likelihood ratio test on page 32-882 that compares the generalized linear mixed-effects models glme and altglme. To conduct a valid likelihood ratio test, both models must use the same response vector in the fit, and glme must be nested in altglme. Always input the smaller model first, and the larger model second.

compare tests the following null and alternate hypotheses:

- \( H_0 \): Observed response vector is generated by glme.
- \( H_1 \): Observed response vector is generated by model altglme.

results = compare(glme,altglme,Name,Value) returns the results of a likelihood ratio test using additional options specified by one or more Name,Value pair arguments. For example, you can check if the first input model, glme, is nested in the second input model, altglme.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.
You can create a GeneralizedLinearMixedModel object by fitting a generalized linear mixed-effects model to your sample data using fitglme. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REMPL' cannot be compared using a likelihood ratio test.

**altglme — Alternative generalized linear mixed-effects model**

GeneralizedLinearMixedModel object

Alternative generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. altglme be must fit to the same response vector as glme, but with different model specifications. glme must be nested in altglme, such that you can obtain glme from altglme by setting some of the model parameters of altglme to fixed values such as 0.

You can create a GeneralizedLinearMixedModel object by fitting a generalized linear mixed-effects model to your sample data using fitglme. To conduct a valid likelihood ratio test on two models that have response distributions other than normal, you must fit both models using the 'ApproximateLaplace' or 'Laplace' fit method. Models with response distributions other than normal that are fitted using 'MPL' or 'REMPL' cannot be compared using a likelihood ratio test.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CheckNesting — Indicator to check nesting between two models**

true (default) | false

Indicator to check nesting on page 32-882 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and either true or false. If 'CheckNesting' is true, then compare checks if the smaller model glme is nested in the larger model altglme. If the nesting requirements are not satisfied, then compare returns an error. If 'CheckNesting' is false, then compare does not perform this check.

Example: 'CheckNesting',true
Output Arguments

**results — Results of likelihood ratio test**  
*table*

Results of the likelihood ratio test, returned as a table with two rows. The first row is for `glme`, and the second row is for `altglme`. The columns of `results` contain the following.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>Name of the model</td>
</tr>
<tr>
<td>DF</td>
<td>Degrees of freedom</td>
</tr>
<tr>
<td>AIC</td>
<td>Akaike information criterion for the model</td>
</tr>
<tr>
<td>BIC</td>
<td>Bayesian information criterion for the model</td>
</tr>
<tr>
<td>LogLik</td>
<td>Maximized log likelihood for the model</td>
</tr>
<tr>
<td>LRStat</td>
<td>Likelihood ratio test statistic for comparing <code>altglme</code> and <code>glme</code></td>
</tr>
<tr>
<td>deltaDF</td>
<td>DF for <code>altglme</code> minus DF for <code>glme</code></td>
</tr>
<tr>
<td>pValue</td>
<td>p-value for the likelihood ratio test</td>
</tr>
</tbody>
</table>

**Examples**

**Compare Mixed-Effects Models**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:
• Flag to indicate whether the batch used the new process (newprocess)
• Processing time for each batch, in hours (time)
• Temperature of the batch, in degrees Celsius (temp)
• Categorical variable indicating the supplier of the chemical used in the batch (supplier)
• Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a fixed-effects-only model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Specify the response distribution as Poisson, the link function as log, and the fit method as Laplace. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

FEglm = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier','Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');

Fit a second model that uses the same fixed-effects predictors, response distribution, link function, and fit method. This time, include a random-effects intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log(\mu_{ij}) = \beta_0 + \beta_1\text{newprocess}_{ij} + \beta_2\text{time_dev}_{ij} + \beta_3\text{temp_dev}_{ij} + \beta_4\text{supplier}_C_{ij} + \beta_5\text{supplier}_B_{ij} + b_i, \]

where

• \text{defects}_{ij} is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
• \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, ..., 20 \)) during batch \( j \) (where \( j = 1, 2, ..., 5 \)).
• `newprocess_{ij}`, `time_dev_{ij}`, and `temp_dev_{ij}` are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, `newprocess_{ij}` indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• `supplier_C_{ij}` and `supplier_B_{ij}` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Compare the two models using a theoretical likelihood ratio test. Specify 'CheckNesting' as true, so `compare` returns a warning if the nesting requirements are not satisfied.

```matlab
results = compare(FEglme,glme,'CheckNesting',true)
```

```
results =
    Theoretical Likelihood Ratio Test
        Model    DF    AIC      BIC      LogLik    LRStat   deltaDF
     FEglme    6    431.02    446.65    -209.51    209.51    0
        glme    7    416.35    434.58    -201.17    16.672    1

    pValue

      4.4435e-05
```

Since `compare` did not return an error, the nesting requirements are satisfied. The small $p$-value indicates that `compare` rejects the null hypothesis that the observed response vector is generated by the model `FEglme`, and instead accepts the alternate model `glme`. The smaller AIC and BIC values for `glme` also support the conclusion that `glme` provides a better fitting model for the response.
Definitions

Likelihood Ratio Test

A likelihood ratio test compares the specifications of two nested models by assessing the significance of restrictions to an extended model with unrestricted parameters. Under the null hypothesis $H_0$, the likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom $\delta DF$.

When comparing two models, `compare` computes the $p$-value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution. A small $p$-value leads to a rejection of $H_0$ in favor of $H_1$, and acceptance of the alternate model `altglme`. On the other hand, a large $p$-value indicates that we cannot reject $H_0$, and reflects insufficient evidence to accept the model `altglme`.

The $p$-values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms, and anti-conservative when testing for the presence or absence of fixed-effects terms. Instead, use the `fixedEffects` or `coefTest` methods to test for fixed effects.

To conduct a valid likelihood ratio test on GLME models, both models must be fitted using a Laplace or approximate Laplace fit method. Models fitted using a maximum pseudo likelihood (MPL) or restricted maximum pseudo likelihood (REMPL) method cannot be compared using a likelihood ratio test. When comparing models fitted using MPL, the maximized log likelihood of the pseudodata from the final pseudo likelihood iteration is used in the likelihood ratio test. If you compare models with non-normal distributions fitted using MPL, then `compare` gives a warning that the likelihood ratio test is using maximized log likelihood of pseudodata from the final pseudo likelihood iteration. To use the true maximized log likelihood in the likelihood ratio test, fit both `glme` and `altglme` using approximate Laplace or Laplace prior to model comparison.

Nesting Requirements

To conduct a valid likelihood ratio test, `glme` must be nested in `altglme`. The `'CheckNesting',true` name-value pair argument checks the following requirements, and returns an error if any are not satisfied:

- You must fit both models (`glme` and `altglme`) using the `'ApproximateLaplace'` or `'Laplace'` fit method. You cannot compare GLME models fitted using `'MPL'` or `'REMPL'` using a likelihood ratio test.
You must fit both models using the same response vector, response distribution, and link function.

The smaller model (glme) must be nested within the larger model (altglme), such that you can obtain glme from altglme by setting some of the model parameters of altglme to fixed values such as 0.

The maximized log likelihood of the larger model (altglme) must be greater than or equal to the maximized log likelihood of the smaller model (glme).

The weight vectors used to fit glme and altglme must be identical.

The random-effects design matrix of the larger model (altglme) must contain the random-effects design matrix of the smaller model (glme).

The fixed-effects design matrix of the larger model (altglme) must contain the fixed-effects design matrix of the smaller model (glme).

**Akaike and Bayesian Information Criteria**

The Akaike information criterion (AIC) is \( AIC = -2 \log L_M + 2(\text{param}) \).

\( \log L_M \) depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then \( \log L_M \) is the maximized log likelihood.
- If you use 'MPL', then \( \log L_M \) is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then \( \log L_M \) is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

\( \text{param} \) is the total number of parameters estimated in the model. For most GLME models, \( \text{param} \) is equal to \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance, excluding the residual variance, and \( p \) is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then \( \text{param} \) is equal to \( (nc + p) \).

The Bayesian information criterion (BIC) is \( BIC = -2^{*}\log L_M + \ln(n_{eff})(\text{param}) \).

\( \log L_M \) depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then \( \log L_M \) is the maximized log likelihood.
• If you use 'MPL', then log$L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.

• If you use 'REPL', then log$L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

$n_{eff}$ is the effective number of observations.

• If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then $n_{eff} = n$, where $n$ is the number of observations.

• If you use 'REPL', then $n_{eff} = n - p$.

`param` is the total number of parameters estimated in the model. For most GLME models, `param` is equal to $nc + p + 1$, where $nc$ is the total number of parameters in the random-effects covariance, excluding the residual variance, and $p$ is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then `param` is equal to $(nc + p)$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, $p$. So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REPL', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REPL' is not appropriate.

**compare**

**Class:** LinearMixedModel

Compare linear mixed-effects models

**Syntax**

```matlab
results = compare(lme,altlme)
results = compare(___,Name,Value)
```

```matlab
[results,siminfo] = compare(lme,altlme,'NSim',nsim)
[results,siminfo] = compare(___,Name,Value)
```

**Description**

`results = compare(lme,altlme)` returns the results of a likelihood ratio test on page 32-897 that compares the linear mixed-effects models `lme` and `altlme`. Both models must use the same response vector in the fit and `lme` must be nested in `altlme` for a valid theoretical likelihood ratio test. Always input the smaller model first, and the larger model second.

`compare` tests the following null and alternate hypotheses:

$H_0$: Observed response vector is generated by `lme`.

$H_1$: Observed response vector is generated by model `altlme`.

It is recommended that you fit `lme` and `altlme` using the maximum likelihood (ML) method prior to model comparison. If you use the restricted maximum likelihood (REML) method, then both models must have the same fixed-effects design matrix.

To test for fixed effects, use `compare` with the simulated likelihood ratio test on page 32-897 when `lme` and `altlme` are fit using ML or use the `fixedEffects`, `anova`, or `coefTest` methods.
results = compare(___,'Name',Value) also returns the results of a likelihood ratio test that compares linear mixed-effects models lme and altlme with additional options specified by one or more Name,Value pair arguments.

For example, you can check if the first input model is nested in the second input model.

[results,siminfo] = compare(lme,altlme,'NSim',nsim) returns the results of a simulated likelihood ratio test that compares linear mixed-effects models lme and altlme.

You can fit lme and altlme using ML or REML. Also, lme does not have to be nested in altlme. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

[results,siminfo] = compare(___,'Name',Value) also returns the results of a simulated likelihood ratio test that compares linear mixed-effects models lme and altlme with additional options specified by one or more Name,Value pair arguments.

For example, you can change the options for performing the simulated likelihood ratio test, or change the confidence level of the confidence interval for the $p$-value.

### Input Arguments

- **lme — Linear mixed-effects model**
  LinearMixedModel object

  Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

- **altlme — Alternative linear mixed-effects model**
  LinearMixedModel object

  Alternative linear mixed-effects model fit to the same response vector but with different model specifications, specified as a LinearMixedModel object. lme must be nested in altlme, that is, lme should be obtained from altlme by setting some parameters to fixed values, such as 0. You can create a linear mixed-effects object using fitlme or fitlmematrix.

- **nsim — Number of replications for simulations**
  positive integer number
Number of replications for simulations in the simulated likelihood ratio test, specified as a positive integer number. You must specify nsim to do a simulated likelihood ratio test.

Example: 'NSim',1000

Data Types: double | single

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Alpha — Confidence level**

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

**Options — Options for performing simulated likelihood ratio test**

structure

Options for performing the simulated likelihood ratio test in parallel, specified as the comma-separated pair consisting of 'Options', and a structure created by statset('LinearMixedModel').

These options require Parallel Computing Toolbox.

compare uses the following fields.
'UseParallel'
• False for serial computation. Default.
• True for parallel computation.

You need Parallel Computing Toolbox for parallel computation.

'UseSubstreams'
• False for not using a separate substream of the random number generator for each iteration. Default.
• True for using a separate substream of the random number generator for each iteration. You can only use this option with random stream types that support substreams.

'Streams'
• If 'UseSubstreams' is True, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
• If 'UseSubstreams' is False and
  • 'UseParallel' is False, then 'Streams' must be a single random number stream, or a scalar cell array containing a single stream.
  • 'UseParallel' is True, then 'Streams' must be equal to the number of processors used. If a parallel pool is open, then the 'Streams' is the same length as the size of the parallel pool. If 'UseParallel' is True, a parallel pool might open up for you. But since 'Streams' must be equal to the number of processors used, it is best to open a pool explicitly using the parpool command, before calling compare with the 'UseParallel','True' option.
For information on parallel statistical computing at the command line, enter
help parallelstats

Data Types: struct

CheckNesting — Indicator to check nesting between two models
false (default) | true

Indicator to check nesting on page 32-898 between two models, specified as the comma-separated pair consisting of 'CheckNesting' and one of the following.

false
  Default. No checks.
true
  compare checks if the smaller model lme is nested in the bigger model altlme.

lme must be nested in the alternate model altlme for a valid theoretical likelihood ratio test on page 32-897. compare returns an error message if the nesting requirements are not satisfied.

Although valid for both tests, the nesting requirements are weaker for the simulated likelihood ratio test on page 32-897.

Example: 'CheckNesting',true

Data Types: single | double

Output Arguments

results — Results of likelihood ratio test or simulated likelihood ratio test
dataset array

Results of the likelihood ratio test or simulated likelihood ratio test, returned as a dataset array with two rows. The first row is for lme, and the second row is for altlme. The columns of results depend on whether the test is a likelihood ratio or a simulated likelihood ratio test.

- If you use the likelihood ratio test on page 32-897, then results contains the following columns.

  Model       Name of the model
DF
Degrees of freedom, that is, the number of free parameters in the model

AIC
Akaike information criterion for the model

BIC
Bayesian information criterion for the model

LogLik
Maximized log likelihood for the model

LRStat
Likelihood ratio test statistic for comparing \textit{altlme} versus \textit{lme}

deltaDF
DF for \textit{altlme} minus DF for \textit{lme}

pValue
p-value for the likelihood ratio test

• If you use the simulated likelihood ratio test on page 32-897, then \textit{results} contains the following columns.

<table>
<thead>
<tr>
<th>Model</th>
<th>Name of the model</th>

</tbody>
</table>
pValueSimCI  Confidence interval for pValueSim. The first element of the vector is the lower limit and the second element of the vector contains the upper limit.

deltaDF  The number of free parameters in altlme minus the number of free parameters in lme. DF for altlme minus DF for lme.

TH0  A vector of simulated likelihood ratio test statistics under the null hypothesis that the model lme generated the observed response vector y.

Examples

Test for Random Effects

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate','...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Fit a linear mixed-effects model, with a varying intercept and varying slope for each region, grouped by Date.

altlme = fitlme(flu2,'FluRate ~ 1 + Region + (1 + Region|Date)');
Fit a linear mixed-effects model with fixed effects for the region and a random intercept that varies by Date.

\[
lme = \text{fitlme}(\text{flu2}, 'FluRate \sim 1 + \text{Region} + (1|\text{Date})');
\]

Compare the two models. Also check if lme2 is nested in lme.

\[
\text{compare(lme, altlme, 'CheckNesting', true)}
\]

\[
\begin{array}{ccccccccc}
\text{Model} & \text{DF} & \text{AIC} & \text{BIC} & \text{LogLik} & \text{LRStat} & \text{deltaDF} & \text{pValue} \\
lme & 11 & 318.71 & 364.35 & -148.36 & & & \\
altlme & 55 & -305.51 & -77.346 & 207.76 & 712.22 & 44 & 0 \\
\end{array}
\]

The small \( p \)-value of 0 indicates that model altlme is significantly better than the simpler model lme.

**Test for Fixed and Random Effects**

Load the sample data.

\[
\text{load(fullfile(matlabroot,'examples','stats','fertilizer.mat'))}
\]

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called ds, for practical purposes, and define Tomato, Soil, and Fertilizer as categorical variables.

\[
ds = \text{fertilizer}; \\
ds.\text{Tomato} = \text{nominal}(ds.\text{Tomato}); \\
ds.\text{Soil} = \text{nominal}(ds.\text{Soil}); \\
ds.\text{Fertilizer} = \text{nominal}(ds.\text{Fertilizer});
\]
Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

lmeBig = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');

Refit the model after removing the interaction term Tomato:Fertilizer and the random-effects term (1 | Soil).

lmeSmall = fitlme(ds,'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');

Compare the two models using the simulated likelihood ratio test with 1000 replications. You must use this test to test for both fixed- and random-effect terms. Note that both models are fit using the default fitting method, ML. That’s why, there is no restriction on the fixed-effects design matrices. If you use restricted maximum likelihood (REML) method, both models must have identical fixed-effects design matrices.

[table,siminfo] = compare(lmeSmall,lmeBig,'nsim',1000)

<table>
<thead>
<tr>

<td>0.57343</td>
</tr>
</tbody>
</table>

Lower       Upper
0.54211     0.60431

The high P-value suggests that the larger model, lme is not significantly better than the smaller model, lme2. The smaller values of “Akaike and Bayesian Information Criteria” on page 32-899 for lme2 also support this.
Models with Correlated and Uncorrelated Random Effects

Load the sample data.

load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices.

X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;

Now, fit the model using fitlmatrix with the defined design matrices and grouping variables.

lme = fitlmatrix(X,MPG,Z,G,'FixedEffectPredictors', ....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors', ....
{{'Intercept','Acceleration'}},'RandomEffectGroups',{Model_Year});

Refit the model with uncorrelated random effects for intercept and acceleration. First prepare the random effects design and the random effects grouping variables.

Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme2 = fitlmatrix(X,MPG,Z,G,'FixedEffectPredictors', ....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors', ....
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{... 
{'Model_Year','Model_Year'}});

Compare lme and lme2 using the simulated likelihood ratio test.

compare(lme2,lme,'CheckNesting',true,'NSim',1000)

ans =
SIMULATED LIKELIHOOD RATIO TEST: NSIM = 1000, ALPHA = 0.05

<table>
<thead>
<tr>

<td>2221.3</td>
<td>-1089.7</td>
<td>3.0323</td>
<td>0.094905</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The high $p$-value indicates that lme2 is not a significantly better fit than lme.

Simulated Likelihood Ratio Test Using Parallel Computing

Load the sample data.

load(fullfile(matlabroot,'examples','stats','fertilizer.mat'));

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called ds, for practical purposes, and define Tomato, Soil, and Fertilizer as categorical variables.

ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');

Refit the model after removing the interaction term Tomato:Fertilizer and the random-effects term (1|Soil).
lme2 = fitlme(ds,'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)');

Create the options structure for LinearMixedModel.

opt = statset('LinearMixedModel')

opt = struct with fields:

Change the options for parallel testing.

opt.UseParallel = true;

Start a parallel environment.

mypool = parpool();

Starting parallel pool (parpool) using the 'local' profile ... connected to 12 workers.

Compare lme2 and lme using the simulated likelihood ratio test with 1000 replications and parallel computing.

compare(lme2,lme,'nsim',1000,'Options',opt)

ans =
    Simulated Likelihood Ratio Test: Nsim = 1000, Alpha = 0.05
The high $p$-value suggests that the larger model, lme, is not significantly better than the smaller model, lme2. The smaller values of AIC and BIC for lme2 also support this.

**Definitions**

**Likelihood Ratio Test**

Under the null hypothesis $H_0$, the observed likelihood ratio test statistic has an approximate chi-squared reference distribution with degrees of freedom $\delta DF$. When comparing two models, compare computes the $p$-value for the likelihood ratio test by comparing the observed likelihood ratio test statistic with this chi-squared reference distribution.

The $p$-values obtained using the likelihood ratio test can be conservative when testing for the presence or absence of random-effects terms and anticonservative when testing for the presence or absence of fixed-effects terms. Hence, use the `fixedEffects`, `anova`, or `coefTest` method or the simulated likelihood ratio test while testing for fixed effects.

**Simulated Likelihood Ratio Test**

To perform the simulated likelihood ratio test, compare first generates the reference distribution of the likelihood ratio test statistic under the null hypothesis. Then, it assesses the statistical significance of the alternate model by comparing the observed likelihood ratio test statistic to this reference distribution.

`compare` produces the simulated reference distribution of the likelihood ratio test statistic under the null hypothesis as follows:
- Generate random data $ysim$ from the fitted model $lme$.
- Fit the model specified in $lme$ and alternate model $altlme$ to the simulated data $ysim$.
- Calculate the likelihood ratio test statistic using results from step 2 and store the value.
- Repeat step 1 to 3 $nsim$ times.

Then, `compare` computes the $p$-value for the simulated likelihood ratio test by comparing the observed likelihood ratio test statistic with the simulated reference distribution. The $p$-value estimate is the ratio of the number of times the simulated likelihood ratio test statistic is equal to or exceeds the observed value plus one, to the number of replications plus one.

Suppose the observed likelihood ratio statistic is $T$, and the simulated reference distribution is stored in vector $T_{H_0}$. Then,

$$p - value = \frac{n_{sim} \sum_{j=1}^{n_{sim}} I(T_{H_0}(j) \geq T) + 1}{n_{sim} + 1}.$$

To account for the uncertainty in the simulated reference distribution, `compare` computes a $100* (1 - \alpha)\%$ confidence interval for the true $p$-value.

You can use the simulated likelihood ratio test to compare arbitrary linear mixed-effects models. That is, when you are using the simulated likelihood ratio test, $lme$ does not have to be nested within $altlme$, and you can fit $lme$ and $altlme$ using either maximum likelihood (ML) or restricted maximum likelihood (REML) methods. If you use the restricted maximum likelihood (REML) method to fit the models, then both models must have the same fixed-effects design matrix.

**Nesting Requirements**

The 'CheckNesting','True' name-value pair argument checks the following requirements.

For a simulated likelihood ratio test:
- You must use the same method to fit both models ($lme$ and $altlme$). `compare` cannot compare a model fit using ML to a model fit using REML.
• You must fit both models to the same response vector.
• If you use REML to fit lme and altlme, then both models must have the same fixed-effects design matrix.
• The maximized log likelihood or restricted log likelihood of the bigger model (altlme) must be greater than or equal to that of the smaller model (lme).

For a theoretical test, 'CheckNesting','True' checks all the requirements listed for a simulated likelihood ratio test and the following:
• Weight vectors you use to fit lme and altlme must be identical.
• If you use ML to fit lme and altlme, the fixed-effects design matrix of the bigger model (altlme) must contain that of the smaller model (lme).
• The random-effects design matrix of the bigger model (altlme) must contain that of the smaller model (lme).

**Akaike and Bayesian Information Criteria**

Akaike information criterion (AIC) is \( AIC = -2 \log L_M + 2(nc + p + 1) \), where \( \log L_M \) is the maximized log likelihood (or maximized restricted log likelihood) of the model, and \( nc + p + 1 \) is the number of parameters estimated in the model. \( p \) is the number of fixed-effects coefficients, and \( nc \) is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is \( BIC = -2 \log L_M + \ln(n_{eff})(nc + p + 1) \), where \( \log L_M \) is the maximized log likelihood (or maximized restricted log likelihood) of the model, \( n_{eff} \) is the effective number of observations, and \( (nc + p + 1) \) is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then \( n_{eff} = n \), where \( n \) is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then \( n_{eff} = n - p \).

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, \( p \). So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.
### Deviance

`LinearMixedModel` computes the deviance of model $M$ as minus two times the loglikelihood of that model. Let $L_M$ denote the maximum value of the likelihood function for model $M$. Then, the deviance of model $M$ is

$$-2 \times \log L_M.$$ 

A lower value of deviance indicates a better fit. Suppose $M_1$ and $M_2$ are two different models, where $M_1$ is nested in $M_2$. Then, the fit of the models can be assessed by comparing the deviances $Dev_1$ and $Dev_2$ of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log L_{M_2} - \log L_{M_1}).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom $v$ equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can get the $p$-value for this test using $1 - \text{chi2cdf}(Dev, V)$, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$H_0$: $D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}$, $D$ is a $q$-by-$q$ symmetric positive semidefinite matrix.

$H_1$: $D$ is a $(q+1)$-by-$(q+1)$ symmetric positive semidefinite matrix.

That is, $H_1$ states that the last row and column of $D$ are different from zero. Here, the bigger model $M_2$ has $q + 1$ parameters and the smaller model $M_1$ has $q$ parameters. And $Dev$ has a 50:50 mixture of $\chi^2_q$ and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

## Extended Capabilities

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options', statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

compareHoldout

Package:

Compare accuracies of two classification models using new data

Compare accuracies of two classification models using new data

h = compareHoldout(C1,C2,T1,T2,ResponseVarName)

h = compareHoldout(C1,C2,T1,T2,Y)
h = compareHoldout(C1,C2,X1,X2,Y)

h = compareHoldout(___,Name,Value)
[h,p,e1,e2] = compareHoldout(___)
the same response variable but can contain different sets of predictors. By default, the software conducts the mid-p-value McNemar test to compare the accuracies.

\( h = 1 \) indicates rejecting the null hypothesis at the 5% significance level. \( h = 0 \) indicates not rejecting the null hypothesis at the 5% level.

The following are examples of tests you can conduct:

- Compare the accuracies of a simple classification model and a model that is more complex by passing the same set of predictor data (that is, \( T_1 = T_2 \)).
- Compare the accuracies of two potentially different models using two potentially different sets of predictors.
- Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of those predictors. You can choose the set of predictors arbitrarily, or use a feature selection technique such as PCA or sequential feature selection (see \texttt{pca} and \texttt{sequentialfs}).

\( h = \text{compareHoldout}(C_1,C_2,T_1,T_2,Y) \) returns the test decision from testing the null hypothesis that the trained classification models \( C_1 \) and \( C_2 \) have equal accuracy for predicting the true class labels \( Y \). The alternative hypothesis is that the labels have unequal accuracy.

The first classification model \( C_1 \) uses the predictor data \( T_1 \), and the second classification model \( C_2 \) uses the predictor data \( T_2 \). By default, the software conducts the mid-p-value McNemar test to compare the accuracies.

\( h = \text{compareHoldout}(C_1,C_2,X_1,X_2,Y) \) returns the test decision from testing the null hypothesis that the trained classification models \( C_1 \) and \( C_2 \) have equal accuracy for predicting the true class labels \( Y \). The alternative hypothesis is that the labels have unequal accuracy.

The first classification model \( C_1 \) uses the predictor data \( X_1 \), and the second classification model \( C_2 \) uses the predictor data \( X_2 \). By default, the software conducts the mid-p-value McNemar test to compare the accuracies.

\( h = \text{compareHoldout}(\_\_,\_\_,\text{Name,Value}) \) specifies options using one or more name-value pair arguments in addition to the input argument combinations in previous syntaxes. For example, you can specify the type of alternative hypothesis, specify the type of test, and supply a cost matrix.
[h, p, e1, e2] = compareHoldout(___) returns the p-value for the hypothesis test (p) and the respective classification losses on page 32-926 of each set of predicted class labels (e1 and e2) using any of the input arguments in the previous syntaxes.

**Examples**

**Compare Accuracies of Full and Reduced Classification Models**

Train two k-nearest neighbor classifiers, one using a subset of the predictors used for the other. Conduct a statistical test comparing the accuracies of the two models on a test set.

Load the carsmall data set.

```matlab
load carsmall
```

Create two tables of input data, where the second table excludes the predictor Acceleration. Specify Model_Year as the response variable.

```matlab
T1 = table(Acceleration,Displacement,Horsepower,MPG,Model_Year);
T2 = T1(:,2:end);
```

Create a partition that splits the data into training and test sets. Keep 30% of the data for testing.

```matlab
rng(1) % For reproducibility
CVP = cvpartition(Model_Year,'holdout',0.3);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train the ClassificationKNN models using the T1 and T2 data.

```matlab
C1 = fitcknn(T1(idxTrain,:),'Model_Year');
C2 = fitcknn(T2(idxTrain,:),'Model_Year');
```

C1 and C2 are trained ClassificationKNN models.

Test whether the two models have equal predictive accuracies on the test set.

```matlab
h = compareHoldout(C1,C2,T1(idxTest,:),T2(idxTest,:),'Model_Year')
```
\( h = 0 \) indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

**Compare Accuracies of Two Different Classification Models**

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a test set.

Load the `ionosphere` data set.

```matlab
load ionosphere;
```

Create a partition that evenly splits the data into training and test sets.

```matlab
rng(1);                             % For reproducibility
CVP = cvpartition(Y,'holdout',0.5); % Training-set indices
idxTrain = training(CVP);           % Test-set indices
idxTest = test(CVP);                % Training-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```matlab
C1 = fitcsvm(X(idxTrain,:),Y(idxTrain), ... 'Standardize',true,... 'KernelFunction','RBF','KernelScale','auto');
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag');
```

C1 is a trained `ClassificationSVM` model. C2 is a trained `ClassificationBaggedEnsemble` model.

Test whether the two models have equal predictive accuracies. Use the same test-set predictor data for each model.

```matlab
h = compareHoldout(C1,C2,X(idxTest,:),X(idxTest,:),Y(idxTest))
```
h = logical
    0

h = 0 indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

**Compare Classification Model to More Complex Model**

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy on test data than the more complex model.

Load the ionosphere data set.

load ionosphere;

Create a partition that evenly splits the data into training and test sets.

rng(1);                             % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);  % Training-set indices
idxTrain = training(CVP);           % Test-set indices
idxTest = test(CVP);                % Test-set indices

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

C1 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
C2 = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');

C1 and C2 are trained ClassificationSVM models.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid-p-value test (the cost-insensitive testing default). Request to return p-values and misclassification rates.

Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);
[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = compareHoldout(C1,C2,...
   X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater',... 
   'Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = compareHoldout(C1,C2,...
   X(idxTest,:),X(idxTest,:),Y(idxTest),'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})

ans=4×2 table
    Asymp    MidP
     ________    ________
        h            1     1
        p        7.2801e-09 2.7649e-10
        e1        0.13714  0.13714
        e2        0.33143  0.33143

The p-value is close to zero for both tests, providing strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, compareHoldout returns the same type of misclassification measure for both models.

**Conduct Cost-Sensitive Comparison of Two Classification Models**

For data sets with imbalanced class representations, or for data sets with imbalanced false-positive and false-negative costs, you can statistically compare the predictive performance of two classification models by including a cost matrix in the analysis.

Load the arrhythmia data set. Determine the class representations in the data.

load arrhythmia;
Y = categorical(Y);
tabulate(Y);

<td>25</td>
<td>5.53%</td>
</tr>
</tbody>
</table>
There are 16 classes, however some are not represented in the data set (for example, class 13). Most observations are classified as not having arrhythmia (class 1). The data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status (class 16) from the data set.

```matlab
idx = (Y ~= '16');
Y = Y(idx);
X = X(idx,:);
Y(Y ~= '1') = 'WithArrhythmia';
Y(Y == '1') = 'NoArrhythmia';
Y = removecats(Y);
```

Create a partition that evenly splits the data into training and test sets.

```matlab
rng(1);                             % For reproducibility
CVP = cvpartition(Y,'holdout',0.5); % Training-set indices
idxTrain = training(CVP);           % Test-set indices
idxTest = test(CVP);                % Training-set indices
CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the "no arrhythmia" class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate the predicted class. When you conduct a cost-sensitive analysis, a good practice is to specify the order of the classes.

```matlab
cost = [0 1;5 0];
ClassNames = {'NoArrhythmia','WithArrhythmia'};
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and another that uses LogitBoost. Because the data set contains missing values, specify to use surrogate splits. Train the models using the cost matrix.
t = templateTree('Surrogate','on');
numTrees = 50;
C1 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1', ...
    'NumLearningCycles',numTrees,'Learners',t, ... 
    'Cost',cost,'ClassNames',ClassNames);
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost', ... 
    'NumLearningCycles',numTrees,'Learners',t, ... 
    'Cost',cost,'ClassNames',ClassNames);

C1 and C2 are trained ClassificationEnsemble models.

Test whether the AdaBoostM1 ensemble (C1) and the LogitBoost ensemble (C2) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p-values and misclassification costs.

[h,p,e1,e2] = compareHoldout(C1,C2,X(idxTest,:),Y(idxTest),... 
    'Cost',cost)

h = logical
  0

p = 0.1944

e1 = 0.5953

e2 = 0.4698

h = 0 indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

**Select Features Using Statistical Accuracy Comparison**

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the out-of-sample accuracy between the two models.

Load the ionosphere data set.

load ionosphere;

Create a partition that evenly splits the data into training and test sets.
rng(1);  % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP);      % Test-set indices

CVP is a cross-validation partition object that specifies the training and test sets.

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor:

t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C2 = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'Learners',t);
predImp = predictorImportance(C2);

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2)

h =
    Axes with properties:

        XLim:  [-0.2000 35.2000]
        YLim:  [0 0.0090]
        XScale: 'linear'
        YScale: 'linear'
    GridLineStyle: '-'
        Position: [0.1300 0.1100 0.7750 0.8150]
        Units: 'normalized'

    Show all properties

    title('Predictor Importance');
xlabel('Predictor');
ylabel('Importance measure');
Identify the top five predictors in terms of their importance.

\[
[~,idxSort] = \text{sort}(	ext{predImp},'\text{descend}');
\]
\[
idx5 = \text{id}xSort(1:5);
\]

Train another ensemble of 100 boosted classification trees using AdaBoostM1 and the five predictors with the greatest importance.

\[
\text{C1} = \text{fitcensemble}(X(idxTrain,idx5),Y(idxTrain),'\text{Method}',\text{''AdaBoostM1''},...\nonumber\
\text{\quad'}\text{\text{'Learners'}','t});
\]

Test whether the two models have equal predictive accuracies. Specify the reduced test-set predictor data for C1 and the full test-set predictor data for C2.

\[
[h,p,e1,e2] = \text{compareHoldout}(\text{C1,C2,X(idxTest,idx5)},X(idxTest,:),Y(idxTest))
\]
\[ h = \text{logical} \quad 0 \]

\[ p = 0.7744 \]
\[ e_1 = 0.0914 \]
\[ e_2 = 0.0857 \]

\( h = 0 \) indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble, \( C_1 \).

**Input Arguments**

**C1 — First trained classification model**

trained classification model object | trained, compact classification model object

First trained classification model, specified as any trained classification model object or compact classification model object described in this table.

</table>

**C2 — Second trained classification model**

*trained classification model object | trained, compact classification model object*

Second trained classification model, specified as any trained classification model object or compact classification model object that is a valid choice for C1.

**T1 — Test-set predictor data for first classification model**

*table*

Test-set predictor data for the first classification model, C1, specified as a table. Each row of T1 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T1 can contain an additional column for the response variable. T1 must contain all the predictors used to train C1. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName or Y.

Data Types: table

**T2 — Test-set predictor data for second classification model**

*table*

Test-set predictor data for the second classification model, C2, specified as a table. Each row of T2 corresponds to one observation, and each column corresponds to one predictor variable. Optionally, T2 can contain an additional column for the response variable. T2 must contain all the predictors used to train C2. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
T1 and T2 must have the same number of rows and the same response values. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName or Y.

Data Types: table

X1 — Test-set predictor data for first classification model
classic.matrix

Test-set predictor data for the first classification model, C1, specified as a numeric matrix.

Each row of X1 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C1 must compose X1.

The number of rows in X1 and X2 must equal the number of rows in Y.

Data Types: double | single

X2 — Test-set predictor data for second classification model
classic.matrix

Test-set predictor data for the second classification model, C2, specified as a numeric matrix.

Each row of X2 corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a predictor or feature). The variables used to train C2 must compose X2.

The number of rows in X2 and X1 must equal the number of rows in Y.

Data Types: double | single

ResponseVarName — Response variable name
name of a variable in T1 and T2

Response variable name, specified as the name of a variable in T1 and T2. If T1 and T2 contain the response variable used to train C1 and C2, then you do not need to specify ResponseVarName.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable is stored as T1.Response, then specify it as 'Response'. Otherwise, the software treats all columns of T1 and T2, including Response, as predictors.
The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

**Y — True class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

True class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

When you specify `Y`, `compareHoldout` treats all variables in the matrices `X1` and `X2` or the tables `T1` and `T2` as predictor variables.

If `Y` is a character array, then each element must correspond to one row of the array.

The number of rows in the predictor data must equal the number of rows in `Y`.

Data Types: categorical | char | string | logical | single | double | cell

**Note** NaNs, `<undefined>` values, empty character vectors (``), empty strings (""), and `<missing>` values indicate missing values. `compareHoldout` removes missing values in `Y` and the corresponding rows of `X1` and `X2`. Additionally, `compareHoldout` predicts classes whether `X1` and `X2` have missing observations.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```matlab
compareHoldout(C1,C2,X1,X2,Y,'Alternative','greater','Test','asymptotic','Cost',[0 2;1 0])
```
tests whether the first set of predicted class labels is more accurate than the second set, conducts the asymptotic McNemar test, and penalizes misclassifying observations with the true label `ClassNames{1}` twice as much as misclassifying observations with the true label `ClassNames{2}`.
Alpha — Hypothesis test significance level
0.05 (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the interval (0,1).

Example: 'Alpha',0.1

Data Types: single | double

Alternative — Alternative hypothesis to assess
'unequal' (default) | 'greater' | 'less'

Alternative hypothesis to assess, specified as the comma-separated pair consisting of 'Alternative' and one of the values listed in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Alternative Hypothesis</th>
</tr>
</thead>
<tbody>
<tr>
<td>'unequal'</td>
<td>For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies.</td>
</tr>
<tr>
<td>'greater'</td>
<td>For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2.</td>
</tr>
<tr>
<td>'less'</td>
<td>For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2.</td>
</tr>
</tbody>
</table>

Example: 'Alternative','greater'

ClassNames — Class names
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
• Select a subset of classes for testing. For example, suppose that the set of all distinct class names in \( Y \) is \{'a','b','c'\}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames',\{'a','c'\}.

The default is the set of all distinct class names in \( Y \).

Example: 'ClassNames',\{'b','g'\}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Misclassification cost**

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

• If you specify the square matrix \( \text{Cost} \), then \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \). That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of \( \text{Cost} \), additionally specify the 'ClassNames' name-value pair argument.

• If you specify the structure \( S \), then \( S \) must have two fields:
  - \( S\text{.ClassNames} \), which contains the class names as a variable of the same data type as \( Y \). You can use this field to specify the order of the classes.
  - \( S\text{.ClassificationCosts} \), which contains the cost matrix, with rows and columns ordered as in \( S\text{.ClassNames} \).

If you specify \( \text{Cost} \), then `compareHoldout` cannot conduct one-sided, exact, or mid-p tests. You must also specify 'Alternative','unequal','Test','asymptotic'. For cost-sensitive testing options, see the 'CostTest' name-value pair argument.

A best practice is to supply the same cost matrix used to train the classification models.

The default is \( \text{Cost}(i,j) = 1 \) if \( i \neq j \), and \( \text{Cost}(i,j) = 0 \) if \( i = j \).

Example: 'Cost',[0 1 2; 1 0 2; 2 2 0]

Data Types: single | double | struct

**CostTest — Cost-sensitive test type**

'likelihood' (default) | 'chisquare'
Cost-sensitive test type, specified as the comma-separated pair consisting of 'CostTest' and 'chisquare' or 'likelihood'. If you do not specify a cost matrix using the Cost name-value pair argument, compareHoldout ignores CostTest.

This table summarizes the available options for cost-sensitive testing.

<table>
<thead>
<tr>
<th>Value</th>
<th>Asymptotic Test Type</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chisquare'</td>
<td>Chi-square test</td>
<td>Optimization Toolbox to implement quadprog</td>
</tr>
<tr>
<td>'likelihood'</td>
<td>Likelihood ratio test</td>
<td>None</td>
</tr>
</tbody>
</table>

For more details, see “Cost-Sensitive Testing” on page 32-921.

Example: 'CostTest','chisquare'

**Test — Test to conduct**

'asymptotic' | 'exact' | 'midp'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and 'asymptotic', 'exact', or 'midp'.

This table summarizes the available options for cost-insensitive testing.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'asymptotic'</td>
<td>Asymptotic McNemar test</td>
</tr>
<tr>
<td>'exact'</td>
<td>Exact-conditional McNemar test</td>
</tr>
<tr>
<td>'midp' (default)</td>
<td>Mid-p-value McNemar test</td>
</tr>
</tbody>
</table>

For more details, see “McNemar Tests” on page 32-923.

For cost-sensitive testing, Test must be 'asymptotic'. When you specify the Cost name-value pair argument and choose a cost-sensitive test using the CostTest name-value pair argument, 'asymptotic' is the default.

Example: 'Test','asymptotic'
Output Arguments

**h — Hypothesis test result**

| h = 1 indicates the rejection of the null hypothesis at the \( \text{Alpha} \) significance level. 
| h = 0 indicates failure to reject the null hypothesis at the \( \text{Alpha} \) significance level. 

Data Types: logical

**p — \( p \)-value**

| scalar in the interval \([0,1]\) 
| \( p \)-value of the test, returned as a scalar in the interval \([0,1]\). \( p \) is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true. 

**compareHoldout** estimates \( p \) using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-923. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-921. 

Data Types: double

**e1 — Classification loss**

| numeric scalar 
| Classification loss, returned as a numeric scalar. \( e1 \) summarizes the accuracy of the first set of class labels predicting the true class labels (Y). **compareHoldout** applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels. Then, the function compares the estimated labels to Y to obtain the classification loss. 

For cost-insensitive testing, \( e1 \) is the misclassification rate. That is, \( e1 \) is the proportion of misclassified observations, which is a scalar in the interval \([0,1]\). 

For cost-sensitive testing, \( e1 \) is the misclassification cost. That is, \( e1 \) is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.
For more information, see “Classification Loss” on page 32-926.

Data Types: double

**e2 — Classification loss**

numeric scalar

Classification loss, returned as a numeric scalar. `e2` summarizes the accuracy of the second set of class labels predicting the true class labels (`Y`). `compareHoldout` applies the second test-set predictor data (`X2`) to the second classification model (`C2`) to estimate the second set of class labels. Then, the function compares the estimated labels to `Y` to obtain the classification loss.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval `[0,1]`.

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

For more information, see “Classification Loss” on page 32-926.

Data Types: double

**Limitations**

- `compareHoldout` does not compare ECOC models composed of linear or kernel classification models (that is, `ClassificationLinear` or `ClassificationKernel` model objects). To compare `ClassificationECOC` models composed of linear or kernel classification models, use `testcholdout` instead.

- Similarly, `compareHoldout` does not compare `ClassificationLinear` or `ClassificationKernel` model objects. To compare these models, use `testcholdout` instead.
Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. By conducting a cost-sensitive analysis, you can account for the cost imbalance when you train the classification models and when you statistically compare them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss. Use misclassification cost instead to compare classification models.

Misclassification costs are often imbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick typically causes some inconvenience, but does not pose significant danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- $n_{ijk}$ and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with the following characteristics. $k$ is the true class, $i$ is the label assigned by the first classification model, and $j$ is the label assigned by the second classification model. The unknown true value of $\hat{\pi}_{ijk}$ is $\pi_{ijk}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{\text{test}}$.

- Additionally, $\sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \hat{\pi}_{ijk} = 1$.

- $c_{ij}$ is the relative cost of assigning label $j$ to an observation with true class $i$. $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one $(i,j)$ pair, $c_{ij} > 0$.

- All subscripts take on integer values from 1 through $K$, which is the number of classes.

- The expected difference in the misclassification costs of the two classification models is
The hypothesis test is

\[ H_0 : \delta = 0 \]
\[ H_1 : \delta \neq 0. \]

The available cost-sensitive tests are appropriate for two-tailed testing.

Available asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

• Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any \( n_{ijk} = 0 \). The test statistic is

\[
t^*_{\chi^2} = \sum_{i \neq j} \sum_k \left( \frac{\left( n_{ijk} + 1 - \left( n_{\text{test}} + K^3 \right) \hat{\pi}^{(1)}_{ijk} \right)^2}{n_{ijk} + 1} \right).
\]

If \( 1 - F_{\chi^2}(t^*_{\chi^2};1) < \alpha \), then reject \( H_0 \).

• \( \hat{\pi}^{(1)}_{ijk} \) are estimated by minimizing \( t^*_{\chi^2} \) under the constraint that \( \delta = 0 \).

• \( F_{\chi^2}(x;1) \) is the \( \chi^2 \) cdf with one degree of freedom evaluated at \( x \).

• Likelihood ratio test — The likelihood ratio test is based on \( N_{ijk} \), which are binomial random variables with sample size \( n_{\text{test}} \) and success probability \( \pi_{ijk} \). The random variables represent the random number of observations with: true class \( k \), label \( i \) assigned by the first classification model, and label \( j \) assigned by the second classification model. Jointly, the distribution of the random variables is multinomial.

The test statistic is

\[
\delta = \sum_{i=1}^{K} \sum_{j=1}^{K} \sum_{k=1}^{K} (c_{ki} - c_{kj}) \pi_{ijk}.
\]
\[
I_{LRT}^* = 2\log \left[ \frac{P\left( \bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(2)} \right)}{P\left( \bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \pi_{ijk} = \pi_{ijk}^{(3)} \right)} \right].
\]

If \(1 - F_{\chi^2} \left( t_{LRT}^*; 1 \right) < \alpha\), then reject \(H_0\).

- \(\hat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}\) is the unrestricted MLE of \(\pi_{ijk}\).
- \(\hat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{\text{solution to } \lambda(c_{ki} - c_{kj})} + \lambda(c_{ki} - c_{kj})\) is the MLE under the null hypothesis that \(\delta = 0\). \(\lambda\) is the solution to \(\lambda(c_{ki} - c_{kj})\).

\[
\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.
\]

- \(F_{\chi^2}(x; 1)\) is the \(\chi^2\) cdf with one degree of freedom evaluated at \(x\).

\section*{McNemar Tests}

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

\begin{enumerate}
  \item Partition the data into training and test sets.
  \item Train both classification models using the training set.
  \item Predict class labels using the test set.
  \item Summarize the results in a two-by-two table similar to this figure.
\end{enumerate}
The misclassification rates for Models 1 and 2 are \( \hat{\pi}_{12} = \frac{n_{12}}{n} \) and \( \hat{\pi}_{21} = \frac{n_{21}}{n} \), respectively. A two-sided test for comparing the accuracy of the two models is

\[
H_0 : \pi_{12} = \pi_{21} \\
H_1 : \pi_{12} \neq \pi_{21}.
\]

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to \( H_0 : \pi_{12} = \pi_{21} \). Also, under the null hypothesis, \( N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5) \) [1].

These facts are the basis for the available McNemar test variants: the asymptotic, exact-conditional, and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance level \( \alpha \)) are:
• For one-sided tests, the test statistic is

\[ t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}} \]

If \( 1 - \Phi \left( |t_1^*| \right) < \alpha \), where \( \Phi \) is the standard Gaussian cdf, then reject \( H_0 \).

• For two-sided tests, the test statistic is

\[ t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}} \]

If \( 1 - F_{\chi^2}(t_2^*; m) < \alpha \), where \( F_{\chi^2}(x; m) \) is the \( \chi^2 \) cdf evaluated at \( x \), then reject \( H_0 \).

The asymptotic test requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution.

• The total number of discordant pairs, \( n_d = n_{12} + n_{21} \), must be greater than 10 ([1], Ch. 10.1.4).

• In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed \( \alpha \), as suggested in simulation studies in [18]. However, the asymptotic McNemar test performs well in terms of statistical power.

• Exact-Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance level \( \alpha \)) are ([36], [38]):

• For one-sided tests, the test statistic is

\[ t_1^* = n_{12} \]

If \( F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha \), where \( F_{\text{Bin}}(x; n, p) \) is the binomial cdf with sample size \( n \) and success probability \( p \) evaluated at \( x \), then reject \( H_0 \).

• For two-sided tests, the test statistic is
If \( F_{\text{Bin}}(t^*_2; n_2, 0.5) < \alpha / 2 \), then reject \( H_0 \).

The exact-conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid-p-value test ([1], Ch. 3.6.3).

• Mid-p-value test — The mid-p-value McNemar test statistics and rejection regions (for significance level \( \alpha \)) are ([32]):

  • For one-sided tests, the test statistic is

    \[ t_1^* = n_{12}. \]

    If \( F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha \), where \( F_{\text{Bin}}(x; n, p) \) and \( f_{\text{Bin}}(x; n, p) \) are the binomial cdf and pdf, respectively, with sample size \( n \) and success probability \( p \) evaluated at \( x \), then reject \( H_0 \).

  • For two-sided tests, the test statistic is

    \[ t_2^* = \min(n_{12}, n_{21}). \]

    If \( F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha / 2 \), then reject \( H_0 \).

The mid-p-value test addresses the over-conservative behavior of the exact-conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

**Classification Loss**

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are the misclassification rate and cost.

\texttt{compareHoldout} returns the classification losses (see \texttt{e1} and \texttt{e2}) under the alternative hypothesis (that is, the unrestricted classification losses). \( n_{ijk} \) is the number of test-sample
observations with: true class \( k \), label \( i \) assigned by the first classification model, and label \( j \) assigned by the second classification model. The corresponding estimated proportion is

\[
\hat{\pi}_{ijk} = \frac{n_{ijk}}{\sum_{i,j,k} n_{ijk}}. \quad \text{The test-set sample size is } \sum_{i,j,k} n_{ijk} = n_{\text{test}}. \quad \text{The indices are taken from 1 through } K, \text{ the number of classes.}
\]

- The misclassification rate, or classification error, is a scalar in the interval \([0,1]\) representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

\[
e_1 = \sum_{j=1}^{K} \sum_{k=1}^{K} \sum_{i \neq k} \hat{\pi}_{ijk}.
\]

For the misclassification rate of the second classification model \((e_2)\), switch the indices \(i\) and \(j\) in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- The misclassification cost is a nonnegative scalar that is a measure of classification quality relative to the values of the specified cost matrix. Its interpretation depends on the specified costs of misclassification. The misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, \(C\)) in which the weights are the respective estimated proportions of misclassified observations. The misclassification cost for the first classification model is

\[
e_1 = \sum_{j=1}^{K} \sum_{k=1}^{K} \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki},
\]

where \(c_{kj}\) is the cost of classifying an observation into class \( j \) if its true class is \( k \). For the misclassification cost of the second classification model \((e_2)\), switch the indices \(i\) and \(j\) in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as the misclassification cost increases.
Tips

- One way to perform cost-insensitive feature selection is:

  1. Train the first classification model (C1) using the full predictor set.
  2. Train the second classification model (C2) using the reduced predictor set.
  3. Specify X1 as the full test-set predictor data and X2 as the reduced test-set predictor data.
  4. Enter `compareHoldout(C1,C2,X1,X2,Y,'Alternative','less')`. If `compareHoldout` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the `'Alternative','less'` specification in step 4. `compareHoldout` conducts a two-sided test, and \( h = 0 \) indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see CostTest and “Cost-Sensitive Testing” on page 32-921.

Alternative Functionality

To directly compare the accuracy of two sets of class labels in predicting a set of true class labels, use `testcholdout`.

Topics
“Hypothesis Tests”

Introduced in R2015a
**confusionchart**

Create confusion matrix chart for classification problem

**Syntax**

```matlab
cm = confusionchart(trueLabels,predictedLabels)
cm = confusionchart(m)
cm = confusionchart(m,classLabels)
cm = confusionchart(parent,___)
cm = confusionchart(____,Name,Value)
```

**Description**

`cm = confusionchart(trueLabels,predictedLabels)` creates a confusion matrix chart from true labels `trueLabels` and predicted labels `predictedLabels` and returns a `ConfusionMatrixChart` object. The rows of the confusion matrix correspond to the true class and the columns correspond to the predicted class. Diagonal and off-diagonal cells correspond to correctly and incorrectly classified observations, respectively. Use `cm` to modify the confusion matrix chart after it is created. For a list of properties, see `ConfusionMatrixChart Properties`.

`cm = confusionchart(m)` creates a confusion matrix chart from the numeric confusion matrix `m`. Use this syntax if you already have a numeric confusion matrix in the workspace.

`cm = confusionchart(m,classLabels)` specifies class labels that appear along the x-axis and y-axis. Use this syntax if you already have a numeric confusion matrix and class labels in the workspace.

`cm = confusionchart(parent,___)` creates the confusion chart in the figure, panel, or tab specified by `parent`.

`cm = confusionchart(____,Name,Value)` specifies additional `ConfusionMatrixChart` properties using one or more name-value pair arguments. Specify the properties after all other input arguments. For a list of properties, see `ConfusionMatrixChart Properties`. 
Examples

Create Confusion Matrix Chart

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a k-nearest neighbor (KNN) classifier, where the number of nearest neighbors in the predictors (k) is 5. A good practice is to standardize numeric predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the labels of the training data.

```matlab
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY.

```matlab
cm = confusionchart(Y,predictedY);
```
The confusion matrix displays the total number of observations in each cell. The rows of the confusion matrix correspond to the true class, and the columns correspond to the predicted class. Diagonal and off-diagonal cells correspond to correctly and incorrectly classified observations, respectively.

By default, confusionchart sorts the classes into their natural order as defined by sort. In this example, the class labels are character vectors, so confusionchart sorts the classes alphabetically. Use sortClasses to sort the classes by a specified order or by the confusion matrix values.

The NormalizedValues property contains the values of the confusion matrix. Display these values using dot notation.

cm.NormalizedValues
ans = 3×3

50  0  0
0  47  3
0  4  46

Modify the appearance and behavior of the confusion matrix chart by changing property values. Add a title.

cm.Title = 'Iris Flower Classification Using KNN';

Add column and row summaries.

cm.RowSummary = 'row-normalized';
cm.ColumnSummary = 'column-normalized';
A row-normalized row summary displays the percentages of correctly and incorrectly classified observations for each true class. A column-normalized column summary displays the percentages of correctly and incorrectly classified observations for each predicted class.

**Sort Classes by Precision or Recall**

Create a confusion matrix chart and sort the classes of the chart according to the class-wise true positive rate (recall) or the class-wise positive predictive value (precision).

Load and inspect the arrhythmia data set.
load arrhythmia
isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))

<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>245</td>
<td>54.20%</td>
</tr>
<tr>
<td>2</td>
<td>44</td>
<td>9.73%</td>
</tr>
<tr>
<td>3</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>4</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>5</td>
<td>13</td>
<td>2.88%</td>
</tr>
<tr>
<td>6</td>
<td>25</td>
<td>5.53%</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>0.66%</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>0.44%</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>1.99%</td>
</tr>
<tr>
<td>10</td>
<td>50</td>
<td>11.06%</td>
</tr>
<tr>
<td>14</td>
<td>4</td>
<td>0.88%</td>
</tr>
<tr>
<td>15</td>
<td>5</td>
<td>1.11%</td>
</tr>
<tr>
<td>16</td>
<td>22</td>
<td>4.87%</td>
</tr>
</tbody>
</table>

The data contains 16 distinct labels that describe various degrees of arrhythmia, but the response (Y) includes only 13 distinct labels.

Train a classification tree and predict the resubstitution response of the tree.

Mdl = fitctree(X,Y);
predictedY = resubPredict(Mdl);

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY. Specify 'RowSummary' as 'row-normalized' to display the true positive rates and false positive rates in the row summary. Also, specify 'ColumnSummary' as 'column-normalized' to display the positive predictive values and false discovery rates in the column summary.

fig = figure;
cm = confusionchart(Y,predictedY,'RowSummary','row-normalized','ColumnSummary','column-normalized');
% Resize the container of the confusion chart so percentages appear in the row summary
fig_Position = fig.Position;
fig_Position(3) = fig_Position(3)*1.5;
fig.Position = fig_Position;
To sort the confusion matrix according to the true positive rate, normalize the cell values across each row by setting the `Normalization` property to 'row-normalized' and then use `sortClasses`. After sorting, reset the `Normalization` property back to 'absolute' to display the total number of observations in each cell.

```matlab
cm.Normalization = 'row-normalized';
sortClasses(cm,'descending-diagonal')
cm.Normalization = 'absolute';
```
To sort the confusion matrix according to the positive predictive value, normalize the cell values across each column by setting the `Normalization` property to 'column-normalized' and then use `sortClasses`. After sorting, reset the `Normalization` property back to 'absolute' to display the total number of observations in each cell.

```matlab
cm.Normalization = 'column-normalized';
sortClasses(cm,'descending-diagonal')
cm.Normalization = 'absolute';
```
Confusion Matrix for Classification Using Tall Arrays

Perform classification on a tall array of the fisheriris data set, compute a confusion matrix for the known and predicted tall labels by using the confusionmat function, and plot the confusion matrix by using the confusionchart function.

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the mapreducer function to change the execution environment.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Convert the in-memory arrays `meas` and `species` to tall arrays.

```matlab
tx = tall(meas);
ty = tall(species);
```
Find the number of observations in the tall array.

```matlab
numObs = gather(length(ty));   % gather collects tall array into memory
```

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.23 sec

Set the random number stream for reproducibility, and randomly select training samples.

```matlab
s = RandStream('mlfg6331_64'); % For reproducibility
numTrain = floor(numObs/2);  
[txTrain,trIdx] = datasample(s,tx,numTrain,'Replace',false);
tyTrain = ty(trIdx);
```

Fit a decision tree classifier model on the training samples.

```matlab
mdl = fitctree(txTrain,tyTrain);
```

Predict labels for the test samples by using the trained model.

```matlab
txTest = tx(~trIdx,:);
label = predict(mdl,txTest);
```

Compute the confusion matrix for the resulting classification.

```matlab
tyTest = ty(~trIdx);
[C,order] = confusionmat(tyTest,label)
```

```
C =

3x3 tall double matrix

20     0     0
0    27     2
0     1    25
```

32-939
order =

3×1 tall cell array

{'setosa'    }
{'versicolor'}
{'virginica' }

The confusion matrix shows that two measurements in the versicolor class are misclassified as virginica, and one measurement in the virginica class is misclassified as versicolor. All the measurements belonging to setosa are classified correctly.

To compute and plot the confusion matrix, use gather and confusionchart.

```matlab
cm = confusionchart(gather(tyTest),gather(label))
```

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.021 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.021 sec
ConfusionMatrixChart with properties:

- NormalizedValues: [3x3 double]
- ClassLabels: [3x1 categorical]

Show all properties
Input Arguments

trueLabels — True labels of classification problem
categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

True labels of classification problem, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If trueLabels is a vector, then each element corresponds to one observation. If trueLabels is a character array, then it must be two-dimensional with each row corresponding to the label of one observation.

predictedLabels — Predicted labels of classification problem
categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

Predicted labels of classification problem, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If predictedLabels is a vector, then each element corresponds to one observation. If predictedLabels is a character array, then it must be two-dimensional with each row corresponding to the label of one observation.

m — Confusion matrix
matrix

Confusion matrix, specified as a matrix. m must be square and its elements must be positive integers. The element m(i, j) is the number of times an observation of the ith true class was predicted to be of the jth class. Each colored cell of the confusion matrix chart corresponds to one element of the confusion matrix m.

classLabels — Class labels
categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

Class labels of the confusion matrix chart, specified as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. If classLabels is a vector, then it must have the same number of elements as the confusion matrix has rows and columns. If classLabels is a character array, then it must be two-dimensional with each row corresponding to the label of one class.

parent — Parent container
Figure object | Panel object | Tab object
Parent container in which to plot, specified as a Figure, Panel, or Tab object.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `cm = confusionchart(trueLabels,predictedLabels,'Title','My Title Text','ColumnSummary','column-normalized')`

**Note** The properties listed here are only a subset. For a complete list, see ConfusionMatrixChart Properties.

**Title — Title**

```
' ' (default) | character vector | string scalar
```

Title of the confusion matrix chart, specified as a character vector or string scalar.

Example: `cm = confusionchart(__,'Title','My Title Text')`

Example: `cm.Title = 'My Title Text'`

**ColumnSummary — Column summary**

```
'off' (default) | 'absolute' | 'column-normalized' | 'total-normalized'
```

Column summary of the confusion matrix chart, specified as one of the following:

<table>
<thead>
<tr>
<th>'off'</th>
<th>Do not display a column summary.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'absolute'</td>
<td>Display the total number of correctly and incorrectly classified observations for each predicted class.</td>
</tr>
</tbody>
</table>
Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the number of observations of the corresponding predicted class. The percentages of correctly classified observations can be thought of as class-wise precisions (or positive predictive values).

**'total-normalized'**

Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the total number of observations.

Example: `cm = confusionchart(__,'ColumnSummary','column-normalized')`
Example: `cm.ColumnSummary = 'column-normalized'`

**RowSummary — Row summary**

'off' (default) | 'absolute' | 'row-normalized' | 'total-normalized'

Row summary of the confusion matrix chart, specified as one of the following:

<table>
<thead>
<tr>
<th>'off'</th>
<th>Do not display a row summary.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'absolute'</td>
<td>Display the total number of correctly and incorrectly classified observations for each true class.</td>
</tr>
<tr>
<td>'row-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each true class as percentages of the number of observations of the corresponding true class. The percentages of correctly classified observations can be thought of as class-wise recalls (or true positive rates).</td>
</tr>
<tr>
<td>'total-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each true class as percentages of the total number of observations.</td>
</tr>
</tbody>
</table>

Example: `cm = confusionchart(__,'RowSummary','row-normalized')`
Example: cm.RowSummary = 'row-normalized'

**Normalization — Normalization of cell values**

'absolute' (default) | 'column-normalized' | 'row-normalized' | 'total-normalized'

Normalization of cell values, specified as one of the following:

<table>
<thead>
<tr>
<th>Normalization</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'absolute'</td>
<td>Display the total number of observations in each cell.</td>
</tr>
<tr>
<td>'column-normalized'</td>
<td>Normalize each cell value by the number of observations that has the same predicted class.</td>
</tr>
<tr>
<td>'row-normalized'</td>
<td>Normalize each cell value by the number of observations that has the same true class.</td>
</tr>
<tr>
<td>'total-normalized'</td>
<td>Normalize each cell value by the total number of observations.</td>
</tr>
</tbody>
</table>

Modifying the normalization of cell values also affects the colours of the cells.

Example: cm = confusionchart(__,'Normalization','total-normalized')
Example: cm.Normalization = 'total-normalized'

**Properties**

ConfusionMatrixChart Properties

**Introduced in R2018b**
ConfusionMatrixChart Properties

Confusion matrix chart appearance and behavior

Description

ConfusionMatrixChart properties control the appearance and behavior of a ConfusionMatrixChart object. By changing property values, you can modify certain aspects of the confusion matrix chart. For example, you can add a title:

```matlab
cm = confusionchart([1 3 5; 2 4 6; 11 7 3]);
cm.Title = 'My Confusion Matrix Title';
```

Properties

Labels

Title — Title

' ' (default) | character vector | string scalar

Title of the confusion matrix chart, specified as a character vector or string scalar.

Example: `cm = confusionchart(__,'Title','My Title Text')`
Example: `cm.Title = 'My Title Text'`

XLabel — Label for x-axis

'Predicted class' (default) | string scalar | character vector

Label for the x-axis, specified as a string scalar or character vector.

Example: `cm = confusionchart(__,'XLabel','My Label')`
Example: `cm.XLabel = 'My Label'`

YLabel — Label for y-axis

'True class' (default) | string scalar | character vector

Label for the x-axis, specified as a string scalar or character vector.
ConfusionMatrixChart Properties

Example: `cm = confusionchart(__,'YLabel','My Label')`
Example: `cm.YLabel = 'My Label'`

**ClassLabels — Class labels**
categorical vector | numeric vector | string vector | character array | cell array of character vectors | logical vector

This property is read-only.

Class labels of the confusion matrix chart, stored as a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector.

**Row and Column Summaries**

**ColumnSummary — Column summary**
'off' (default) | 'absolute' | 'column-normalized' | 'total-normalized'

Column summary of the confusion matrix chart, specified as one of the following:

<table>
<thead>
<tr>
<th>ColumnSummary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'off'</td>
<td>Do not display a column summary.</td>
</tr>
<tr>
<td>'absolute'</td>
<td>Display the total number of correctly and incorrectly classified observations for each predicted class.</td>
</tr>
<tr>
<td>'column-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the number of observations of the corresponding predicted class. The percentages of correctly classified observations can be thought of as class-wise precisions (or positive predictive values).</td>
</tr>
<tr>
<td>'total-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each predicted class as percentages of the total number of observations.</td>
</tr>
</tbody>
</table>

Example: `cm = confusionchart(__,'ColumnSummary','column-normalized')`
Example: `cm.ColumnSummary = 'column-normalized'`
**RowSummary — Row summary**

'off' (default) | 'absolute' | 'row-normalized' | 'total-normalized'

Row summary of the confusion matrix chart, specified as one of the following:

<table>
<thead>
<tr>
<th>'off'</th>
<th>Do not display a row summary.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'absolute'</td>
<td>Display the total number of correctly and incorrectly classified observations for each true class.</td>
</tr>
<tr>
<td>'row-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each true class as percentages of the number of observations of the corresponding true class. The percentages of correctly classified observations can be thought of as class-wise recalls (or true positive rates).</td>
</tr>
<tr>
<td>'total-normalized'</td>
<td>Display the number of correctly and incorrectly classified observations for each true class as percentages of the total number of observations.</td>
</tr>
</tbody>
</table>

Example: `cm = confusionchart(__,'RowSummary','row-normalized')`

Example: `cm.RowSummary = 'row-normalized'`

**Data**

**NormalizedValues — Values of the confusion matrix**

numeric matrix

This property is read-only.

Values of the confusion matrix, stored as a numeric matrix. This property equals the values of the confusion matrix normalized using the method of the Normalization property. The software recalculates the normalized values of the confusion matrix each time you modify the Normalization property.

**Normalization — Normalization of cell values**

'absolute' (default) | 'column-normalized' | 'row-normalized' | 'total-normalized'

Normalization of cell values, specified as one of the following:
Display the total number of observations in each cell.

Normalize each cell value by the number of observations that has the same predicted class.

Normalize each cell value by the number of observations that has the same true class.

Normalize each cell value by the total number of observations.

Modifying the normalization of cell values also affects the colours of the cells.

Example: `cm = confusionchart(__,'Normalization','total-normalized')`
Example: `cm.Normalization = 'total-normalized'`

**Color and Styling**

**GridVisible — State of grid visibility**

`'on'` (default) | `'off'`

State of grid visibility, specified as one of the following:

- `'on'` — Display grid lines between the chart cells.
- `'off'` — Do not display grid lines between the chart cells.

Example: `cm = confusionchart(__,'GridVisible','off')`
Example: `cm.GridVisible = 'off'`

**DiagonalColor — Color for diagonal cells**

`[0 0.4471 0.7412]` (default) | color name | RGB triplet

Color for diagonal cells, specified as a color name or an RGB triplet. The color of each diagonal cell is proportional to the cell value and the `DiagonalColor` property, normalized to the largest cell value of the confusion matrix chart. Cells with positive values are colored with a minimum amount of color, proportional to the `DiagonalColor` property.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`. Alternatively, you can specify some common colors by
The software chooses an appropriate text color for cell labels automatically, depending on the color of the chart cells.

Example: cm = confusionchart(__,'DiagonalColor','blue')

Example: cm.DiagonalColor = 'blue'

### OffDiagonalColor — Color for off-diagonal cells
```
[0.8510 0.3255 0.0980] (default) | color name | RGB triplet
```

Color for off-diagonal cells, specified as a color name or an RGB triplet. The color of each diagonal cell is proportional to the cell value and the OffDiagonalColor property, normalized to the largest cell value of the confusion matrix chart. Cells with positive values are colored with a minimum amount of color, proportional to the OffDiagonalColor property.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7]. Alternatively, you can specify some common colors by name. This table lists the long and short color name options and the equivalent RGB triplet values.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Equivalent RGB Triplet</th>
</tr>
</thead>
<tbody>
<tr>
<td>'green' or 'g'</td>
<td>Green</td>
<td>[0 1 0]</td>
</tr>
<tr>
<td>'blue' or 'b'</td>
<td>Blue</td>
<td>[0 0 1]</td>
</tr>
<tr>
<td>'yellow' or 'y'</td>
<td>Yellow</td>
<td>[1 1 0]</td>
</tr>
<tr>
<td>'magenta' or 'm'</td>
<td>Magenta</td>
<td>[1 0 1]</td>
</tr>
<tr>
<td>'cyan' or 'c'</td>
<td>Cyan</td>
<td>[0 1 1]</td>
</tr>
<tr>
<td>'white' or 'w'</td>
<td>White</td>
<td>[1 1 1]</td>
</tr>
<tr>
<td>'black' or 'k'</td>
<td>Black</td>
<td>[0 0 0]</td>
</tr>
</tbody>
</table>

The software chooses an appropriate text color for cell labels automatically, depending on the color of the chart cells.

Example: `cm = confusionchart(__,'OffDiagonalColor','blue')`

Example: `cm.OffDiagonalColor = 'blue'`

**FontColor — Text color for title, axis labels, and class labels**

[0.1500 0.1500 0.1500] (default) | color name | RGB triplet

Text color for title, axis labels, and class labels, specified as a color name or an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0,1]$; for example, $[0.4 0.6 0.7]$. Alternatively, you can specify some common colors by name. This table lists the long and short color name options and the equivalent RGB triplet values.

<table>

Example: `cm.FontColor = 'blue'

**Font**

**FontName** — Font name

*system supported font name*

Font name, specified as a system supported font name. The default font depends on the specific operating system and locale.

Example: `cm = confusionchart(__,'FontName','Cambria')`
Example: `cm.FontName = 'Cambria'`

**FontSize** — Font size

*positive scalar*

Font size used for the title, axis labels, class labels, and cell labels, specified as a positive scalar. The default font depends on the specific operating system and locale.

The title and axis labels use a slightly larger font size (scaled up by 10%). If there is not enough room to display the cell labels within the cells, then the cell labels use a smaller font size. If the cell labels become too small, then they are hidden.

Example: `cm = confusionchart(__,'FontSize',12)`
Example: `cm.FontSize = 12`

**Position**

**ActivePositionProperty** — Position property to hold constant

'outerposition' (default) | 'innerposition'

Position property to hold constant during resize operations, specified as 'outerposition' or 'innerposition'. The default value of 'outerposition' means that the OuterPosition property remains constant. The InnerPosition
property value can change when the parent container changes size, the data changes, or
the labels change.

Example:
```matlab
cm = confusionchart(__,'ActivePositionProperty','innerposition')
```
Example:
```matlab
cm.ActivePositionProperty = 'innerposition'
```

**OuterPosition — Outer size and position**

[0 0 1 1] (default) | four-element vector

Outer size and position within the parent container (a figure, panel, or tab), specified as a
four-element vector of the form [left bottom width height]. The outer position
includes the title, axis labels, and class labels.

- The left and bottom elements define the distance from the lower left corner of the
  container to the lower left corner of the chart.
- The width and height elements are the chart dimensions, which include the chart
cells, plus a margin for the surrounding text.

The default value of [0 0 1 1] is the whole interior of the container.

By default, the values are normalized to the container. To change the units, set the Units
property.

Example:
```matlab
cm = confusionchart(__,'OuterPosition',[0.1 0.1 0.8 0.8])
```
Example:
```matlab
cm.OuterPosition = [0.1 0.1 0.8 0.8]
```

**InnerPosition — Inner size and position**

[0.1300 0.1100 0.7750 0.8150] (default) | four-element vector

Inner size and position of the chart within the parent container (a figure, panel, or tab)
returned as a four-element vector of the form [left bottom width height]. The
inner position does not include the title, axis labels, or class labels.

- The left and bottom elements define the distance from the lower left corner of the
  container to the lower left corner of the chart.
- The width and height elements are the chart dimensions, which include only the
  chart cells.

Example:
```matlab
cm = confusionchart(__,'InnerPosition',[0.1 0.1 0.8 0.8])
```
Example:
```matlab
cm.InnerPosition = [0.1 0.1 0.8 0.8]
```
**Position — Inner size and position**

four-element vector

Inner size and position of the chart within the parent container (a figure, panel, or tab) returned as a four-element vector of the form [left bottom width height]. This property is equivalent to the InnerPosition property.

**Units — Position units**

'normalized' (default) | 'inches' | 'centimeters' | 'points' | 'pixels' | 'characters'

Position units, specified as one of these values:

<table>
<thead>
<tr>
<th>Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'normalized'</td>
<td>Normalized with respect to the container, which is typically the figure or a panel. The lower left corner of the container maps to (0,0), and the upper right corner maps to (1,1).</td>
</tr>
<tr>
<td>'inches'</td>
<td>Inches.</td>
</tr>
<tr>
<td>'centimeters'</td>
<td>Centimeters.</td>
</tr>
<tr>
<td>'characters'</td>
<td>Based on the default uicontrol font of the graphics root object: * Character width = width of letter x. * Character height = distance between the baselines of two lines of text.</td>
</tr>
<tr>
<td>'points'</td>
<td>Typography points. One point equals 1/72 inch.</td>
</tr>
</tbody>
</table>
### Units

<table>
<thead>
<tr>
<th>Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pixels'</td>
<td>Pixels. Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</td>
</tr>
<tr>
<td></td>
<td>• On Windows systems, a pixel is 1/96th of an inch.</td>
</tr>
<tr>
<td></td>
<td>• On Macintosh systems, a pixel is 1/72nd of an inch.</td>
</tr>
<tr>
<td></td>
<td>On Linux® systems, the size of a pixel is determined by your system resolution.</td>
</tr>
</tbody>
</table>

When specifying the units as a name-value pair during object creation, you must set the **Units** property before specifying the properties that you want to use these units for, such as **OuterPosition**.

### Visible — State of visibility

'off' (default) | 'on'

State of visibility, specified as one of these values:

- 'on' — Display the chart.
- 'off' — Hide the chart without deleting it. You still can access the properties of an invisible chart.

### Parent/Child

#### Parent — Parent container

figure object | panel object | tab object

Parent container, specified as a figure, panel, or tab object.

#### HandleVisibility — Visibility of object handle

'off' (default) | 'on' | 'callback'

Visibility of the chart object handle in the **Children** property of the parent, specified as one of these values:
• 'on' — Object handle is always visible.
• 'off' — Object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. To temporarily hide the handle during the execution of that function, set the HandleVisibility to 'off'.
• 'callback' — Object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the object at the command line, but allows callback functions to access it.

If the object is not listed in the Children property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes get, findobj, gca, gcf, gco, newplot, cla, clf, and close.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to 'on' to list all object handles, regardless of their HandleVisibility property setting.

Introduced in R2018b
confusionmat

Compute confusion matrix for classification problem

Syntax

C = confusionmat(group,grouphat)
C = confusionmat(group,grouphat,'Order',grouporder)
[C,order] = confusionmat(__)

Description

C = confusionmat(group,grouphat) returns the confusion matrix C determined by the known and predicted groups in group and grouphat, respectively.

C = confusionmat(group,grouphat,'Order',grouporder) uses grouporder to order the rows and columns of C.

[C,order] = confusionmat(__) also returns the order of the rows and columns of C in the variable order using any of the input arguments in previous syntaxes.

Examples

Display Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification.

Create vectors for the known groups and the predicted groups.

g1 = [3 2 2 3 1 1]';   % Known groups
g2 = [4 2 3 NaN 1 1]'; % Predicted groups

Return the confusion matrix.

C = confusionmat(g1,g2)
C = 4×4

2 0 0 0
0 1 1 0
0 0 0 1
0 0 0 0

The indices of the rows and columns of the confusion matrix C are identical and arranged by default in the sorted order of \([g1; g2]\), that is, \((1, 2, 3, 4)\).

The confusion matrix shows that the two data points known to be in group 1 are classified correctly. For group 2, one of the data points is misclassified into group 3. Also, one of the data points known to be in group 3 is misclassified into group 4. `confusionmat` treats the `NaN` value in the grouping variable `g2` as a missing value and does not include it in the rows and columns of C.

Plot the confusion matrix as a confusion matrix chart by using `confusionchart`.

```matlab
classificationchart(C);
```
You do not need to calculate the confusion matrix first and then plot it. Instead, plot a confusion matrix chart directly from the true and predicted labels by using `confusionchart`.

```matlab
cm = confusionchart(g1,g2)
```
The `ConfusionMatrixChart` object stores the numeric confusion matrix in the `NormalizedValues` property and the classes in the `ClassLabels` property. Display these properties using dot notation.

```matlab
cm = ConfusionMatrixChart with properties:

    NormalizedValues: [4x4 double]
    ClassLabels: [4x1 double]
```

Show all properties
Specify Group Order of Confusion Matrix

Display the confusion matrix for data with two misclassifications and one missing classification, and specify the group order.

Create vectors for the known groups and the predicted groups.

```matlab
g1 = [3 2 2 3 1 1]'; % Known groups
g2 = [4 2 3 NaN 1 1]'; % Predicted groups
```

Specify the group order and return the confusion matrix.

```matlab
C = confusionmat(g1,g2,'Order',[4 3 2 1])
```

The indices of the rows and columns of the confusion matrix `C` are identical and arranged in the order specified by the group order, that is, `[4, 3, 2, 1]`. 

32-961
The second row of the confusion matrix $C$ shows that one of the data points known to be in group 3 is misclassified into group 4. The third row of $C$ shows that one of the data points belonging to group 2 is misclassified into group 3, and the fourth row shows that the two data points known to be in group 1 are classified correctly. $\text{confusionmat}$ treats the NaN value in the grouping variable $g2$ as a missing value and does not include it in the rows and columns of $C$.

**Confusion Matrix for Classification**

Perform classification on a sample of the fisheriris data set and display the confusion matrix for the resulting classification.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Randomize the measurements and groups in the data.

```matlab
rng(0,'twister'); % For reproducibility
numObs = length(species);
p = randperm(numObs);
meas = meas(p,:);
species = species(p);
```

Train a discriminant analysis classifier by using measurements in the first half of the data.

```matlab
half = floor(numObs/2);
training = meas(1:half,:);
trainingSpecies = species(1:half);
Mdl = fitcdiscr(training,trainingSpecies);
```

Predict labels for the measurements in the second half of the data by using the trained classifier.

```matlab
sample = meas(half+1:end,:);
grouphat = predict(Mdl,sample);
```

Specify the group order and display the confusion matrix for the resulting classification.

```matlab
group = species(half+1:end);
[C,order] = confusionmat(group,grouphat,'Order',
 {'setosa','versicolor','virginica'})
```
The confusion matrix shows that the measurements belonging to setosa and virginica are classified correctly, while two of the measurements belonging to versicolor are misclassified as virginica. The output order contains the order of the rows and columns of the confusion matrix in the sequence specified by the group order {'setosa','versicolor','virginica'}. 

**Confusion Matrix for Classification Using Tall Arrays**

Perform classification on a tall array of the fisheriris data set, compute a confusion matrix for the known and predicted tall labels by using the confusionmat function, and plot the confusion matrix by using the confusionchart function.

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the mapreducer function to change the execution environment.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Convert the in-memory arrays meas and species to tall arrays.

```matlab
tx = tall(meas);
ty = tall(species);
```

Find the number of observations in the tall array.

```matlab
numObs = gather(length(ty));  
% gather collects tall array into memory
```
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.23 sec

Set the random number stream for reproducibility, and randomly select training samples.

```matlab
s = RandStream('mlfg6331_64'); % For reproducibility
numTrain = floor(numObs/2);
[txTrain,trIdx] = datasample(s,tx,numTrain,'Replace',false);
tyTrain = ty(trIdx);
```

Fit a decision tree classifier model on the training samples.

```matlab
mdl = fitctree(txTrain,tyTrain);
```

Predict labels for the test samples by using the trained model.

```matlab
txTest = tx(~trIdx,:);
label = predict(mdl,txTest);
```

Compute the confusion matrix for the resulting classification.

```matlab
tyTest = ty(~trIdx);
[C,order] = confusionmat(tyTest,label)
```

```
C =

3×3 tall double matrix

   20   0   0
    0  27   2
    0   1  25

order =
```
3×1 tall cell array

{ 'setosa' }
{ 'versicolor' }
{ 'virginica' }

The confusion matrix shows that two measurements in the versicolor class are misclassified as virginica, and one measurement in the virginica class is misclassified as versicolor. All the measurements belonging to setosa are classified correctly.

To compute and plot the confusion matrix, use gather and confusionchart.

```
cm = confusionchart(gather(tyTest), gather(label))
```

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.021 sec
Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.021 sec
cm = ConfusionMatrixChart with properties:

    NormalizedValues: [3×3 double]
    ClassLabels: [3×1 categorical]

Show all properties
Input Arguments

**group — Known groups**
numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Known groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

group is a grouping variable of the same type as grouphat. The group argument must have the same number of observations as grouphat, as described in “Grouping Variables” on page 2-57. The confusionmat function treats character arrays and string arrays as cell arrays of character vectors. Additionally, confusionmat treats NaN, empty, and 'undefined' values in group as missing values and does not count them as distinct groups or categories.

Example: {'Male','Female','Female','Male','Female'}
Data Types: single | double | logical | char | string | cell | categorical

**grouphat — Predicted groups**
numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector

Predicted groups for categorizing observations, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

grouphat is a grouping variable of the same type as group. The grouphat argument must have the same number of observations as group, as described in “Grouping Variables” on page 2-57. The confusionmat function treats character arrays and string arrays as cell arrays of character vectors. Additionally, confusionmat treats NaN, empty, and 'undefined' values in grouphat as missing values and does not count them as distinct groups or categories.

Example: [1 0 0 1 0]
Data Types: single | double | logical | char | string | cell | categorical

**grouporder — Group order**
numeric vector | logical vector | character array | string array | cell array of character vectors | categorical vector
Group order, specified as a numeric vector, logical vector, character array, string array, cell array of character vectors, or categorical vector.

grouporder is a grouping variable containing all the distinct elements in group and grouphat. Specify grouporder to define the order of the rows and columns of C. If grouporder contains elements that are not in group or grouphat, the corresponding entries in C are 0.

By default, the group order depends on the data type of s = [group;grouphat]:

- For numeric and logical vectors, the order is the sorted order of s.
- For categorical vectors, the order is the order returned by categories(s).
- For other data types, the order is the order of first appearance in s.

Example: 'order',{'setosa','versicolor','virginica'}

Data Types: single | double | logical | char | string | cell | categorical

Output Arguments

C — Confusion matrix

matrix

Confusion matrix, returned as a square matrix with size equal to the total number of distinct elements in the group and grouphat arguments. C(i,j) is the count of observations known to be in group i but predicted to be in group j.

The rows and columns of C have identical ordering of the same group indices. By default, the group order depends on the data type of s = [group;grouphat]:

- For numeric and logical vectors, the order is the sorted order of s.
- For categorical vectors, the order is the order returned by categories(s).
- For other data types, the order is the order of first appearance in s.

To change the order, specify grouporder,

The confusionmat function treats NaN, empty, and 'undefined' values in the grouping variables as missing values and does not include them in the rows and columns of C.
**order — Order of rows and columns**

numeric vector | logical vector | categorical vector | cell array of character vectors

Order of rows and columns in C, returned as a numeric vector, logical vector, categorical vector, or cell array of character vectors. If `group` and `grouphat` are character arrays, string arrays, or cell arrays of character vectors, then the variable `order` is a cell array of character vectors. Otherwise, `order` is of the same type as `group` and `grouphat`.

**Alternative Functionality**

- Use `confusionchart` to calculate and plot a confusion matrix. Additionally, `confusionchart` displays summary statistics about your data and sorts the classes of the confusion matrix according to the class-wise precision (positive predictive value), class-wise recall (true positive rate), or total number of correctly classified observations.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

“Grouping Variables” on page 2-57

**Introduced in R2008b**
controlchart

Shewhart control charts

Syntax

controlchart(X)
colorchart(x,group)
colorchart(X,group)
[stats,plotdata] = controlchart(x,[group])
colorchart(x,group,'name',value)

Description

colorchart(X) produces an xbar chart of the measurements in matrix X. Each row of X is considered to be a subgroup of measurements containing replicate observations taken at the same time. The rows should be in time order. If X is a time series object, the time samples should contain replicate observations.

The chart plots the means of the subgroups in time order, a center line (CL) at the average of the means, and upper and lower control limits (UCL, LCL) at three standard errors from the center line. The standard error is the estimated process standard deviation divided by the square root of the subgroup size. Process standard deviation is estimated from the average of the subgroup standard deviations. Out of control measurements are marked as violations and drawn with a red circle. Data cursor mode is enabled, so clicking any data point displays information about that point.

colorchart(x,group) accepts a grouping variable group for a vector of measurements x. group is a categorical variable, numeric vector, character vector, string array, or cell array of character vectors the same length as x. Consecutive measurements x(n) sharing the same value of group(n) for 1 ≤ n ≤ length(x) are defined to be a subgroup. Subgroups can have different numbers of observations.

colorchart(X,group) accepts a grouping variable group for a matrix of measurements in X. In this case, group is only used to label the time axis; it does not change the default grouping by rows.
[stats, plotdata] = controlchart(x, [group]) returns a structure stats of subgroup statistics and parameter estimates, and a structure plotdata of plotted values. plotdata contains one record for each chart.

The fields in stats and plotdata depend on the chart type.

The fields in stats are selected from the following:

- mean — Subgroup means
- std — Subgroup standard deviations
- range — Subgroup ranges
- n — Subgroup size, or total inspection size or area
- i — Individual data values
- ma — Moving averages
- mr — Moving ranges
- count — Count of defects or defective items
- mu — Estimated process mean
- sigma — Estimated process standard deviation
- p — Estimated proportion defective
- m — Estimated mean defects per unit

The fields in plotdata are the following:

- pts — Plotted point values
- cl — Center line
- lcl — Lower control limit
- ucl — Upper control limit
- se — Standard error of plotted point
- n — Subgroup size
- ooc — Logical that is true for points that are out of control

controlchart(x, group, 'name', value) specifies one or more of the following optional parameter name/value pairs, with name in single quotes:

- charttype — The name of a chart type chosen from among the following:
• 'xbar' — Xbar or mean
• 's' — Standard deviation
• 'r' — Range
• 'ewma' — Exponentially weighted moving average
• 'i' — Individual observation
• 'mr' — Moving range of individual observations
• 'ma' — Moving average of individual observations
• 'p' — Proportion defective
• 'np' — Number of defectives
• 'u' — Defects per unit
• 'c' — Count of defects

Alternatively, a parameter can be a string array or cell array listing multiple compatible chart types. There are four sets of compatible types:

• 'xbar', 's', 'r', and 'ewma'
• 'i', 'mr', and 'ma'
• 'p' and 'np'
• 'u' and 'c'

• display — Either 'on' (default) to display the control chart, or 'off' to omit the display

• label — A character vector, string array, or cell array of character vectors, one per subgroup. This label is displayed as part of the data cursor for a point on the plot.

• lambda — A parameter between 0 and 1 controlling how much the current prediction is influenced by past observations in an EWMA plot. Higher values of 'lambda' give less weight to past observations and more weight to the current observation. The default is 0.4.

• limits — A three-element vector specifying the values of the lower control limit, center line, and upper control limits. Default is to estimate the center line and to compute control limits based on the estimated value of sigma. Not permitted if there are multiple chart types.

• mean — Value for the process mean, or an empty value (default) to estimate the mean from X. This is the p parameter for p and np charts, the mean defects per unit for u and c charts, and the normal mu parameter for other charts.
• **nsigma** — The number of sigma multiples from the center line to a control limit. Default is 3.

• **parent** — The handle of the axes to receive the control chart plot. Default is to create axes in a new figure. Not permitted if there are multiple chart types.

• **rules** — The name of a control rule, or a string array or cell array containing multiple control rule names. These rules, together with the control limits, determine if a point is marked as out of control. The default is to apply no control rules, and to use only the control limits to decide if a point is out of control. See controlrules for more information. Control rules are applied to charts that measure the process level (xbar, i, c, u, p, and np) rather than the variability (r, s), and they are not applied to charts based on moving statistics (ma, mr, ewma).

• **sigma** — Either a value for sigma, or a method of estimating sigma chosen from among 'std' (the default) to use the average within-subgroup standard deviation, 'range' to use the average subgroup range, and 'variance' to use the square root of the pooled variance. When creating i, mr, or ma charts for data not in subgroups, the estimate is always based on a moving range.

• **specs** — A vector specifying specification limits. Typically this is a two-element vector of lower and upper specification limits. Since specification limits typically apply to individual measurements, this parameter is primarily suitable for i charts. These limits are not plotted on r, s, or mr charts.

• **unit** — The total number of inspected items for p and np charts, and the size of the inspected unit for u and c charts. In both cases X must be the count of the number of defects or defectives found. Default is 1 for u and c charts. This argument is required (no default) for p and np charts.

• **width** — The width of the window used for computing the moving ranges and averages in mr and ma charts, and for computing the sigma estimate in i, mr, and ma charts. Default is 5.

## Examples

### XBar and R Charts

Load the sample data.

```matlab
close all
load parts
```

Create xbar and r control charts for the data.
```matlab
st = controlchart(runout,'charttype',{'xbar' 'r'});

Display the process mean and standard deviation.

fprintf('Parameter estimates:  mu = %g, sigma = %g\n',st.mu,st.sigma);

Parameter estimates:  mu = -0.0863889, sigma = 0.130215

“Grouping Variables” on page 2-57

Introduced in R2006b
controlrules

Western Electric and Nelson control rules

Syntax

R = controlrules('rules',x,cl,se)
[R,RULES] = controlrules('rules',x,cl,se)

Description

R = controlrules('rules',x,cl,se) determines which points in the vector x violate the control rules in rules. cl is a vector of center-line values. se is a vector of standard errors. (Typically, control limits on a control chart are at the values cl - 3*se and cl + 3*se.) rules is the name of a control rule, or a string array or cell array containing multiple control rule names. If x has n values and rules contains m rules, then R is an n-by-m logical array, with R(i,j) assigned the value 1 if point i violates rule j, 0 if it does not.

The following are accepted values for rules (specified inside single quotes):

- we1 — 1 point above cl + 3*se
- we2 — 2 of 3 above cl + 2*se
- we3 — 4 of 5 above cl + se
- we4 — 8 of 8 above cl
- we5 — 1 below cl - 3*se
- we6 — 2 of 3 below cl - 2*se
- we7 — 4 of 5 below cl - se
- we8 — 8 of 8 below cl
- we9 — 15 of 15 between cl - se and cl + se
- we10 — 8 of 8 below cl - se or above cl + se
- n1 — 1 point below cl - 3*se or above cl + 3*se
• n2 — 9 of 9 on the same side of cl
• n3 — 6 of 6 increasing or decreasing
• n4 — 14 alternating up/down
• n5 — 2 of 3 below cl – 2*se or above cl + 2*se, same side
• n6 — 4 of 5 below cl – se or above cl + se, same side
• n7 — 15 of 15 between cl – se and cl + se
• n8 — 8 of 8 below cl – se or above cl + se, either side
• we — All Western Electric rules
• n — All Nelson rules

For multi-point rules, a rule violation at point i indicates that the set of points ending at point i triggered the rule. Point i is considered to have violated the rule only if it is one of the points violating the rule's condition.

Any points with NaN as their x, cl, or se values are not considered to have violated rules, and are not counted in the rules for other points.

Control rules can be specified in the controlchart function as values for the 'rules' parameter.

[R,RULES] = controlrules('rules',x,cl,se) returns a cell array of text RULES listing the rules applied.

## Examples

### Use Western Electric Control Rule

Load the sample data.

load parts;

Create an Xbar chart using the we2 rule to mark out of control measurements.

```matlab
st = controlchart(runout,'rules','we2');
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
```
You can see the out of control points marked with a red circle.

Use `controlrules` to identify the measurements that violate the control rule.

```matlab
R = controlrules('we2',x,cl,se);
I = find(R)
```

```
I = 6×1
    21
    23
    24
```
See Also
controlchart

Introduced in R2006b
cophenet

Cophenetic correlation coefficient

Syntax

c = cophenet(Z,Y)
[c,d] = cophenet(Z,Y)

Description

c = cophenet(Z,Y) computes the cophenetic correlation coefficient for the hierarchical cluster tree represented by Z. Z is the output of the linkage function. Y contains the distances or dissimilarities used to construct Z, as output by the pdist function. Z is a matrix of size (m–1)-by-3, with distance information in the third column. Y is a vector of size m*(m-1)/2.

[c, d] = cophenet(Z,Y) returns the cophenetic distances d in the same lower triangular distance vector format as Y.

The cophenetic correlation for a cluster tree is defined as the linear correlation coefficient between the cophenetic distances obtained from the tree, and the original distances (or dissimilarities) used to construct the tree. Thus, it is a measure of how faithfully the tree represents the dissimilarities among observations.

The cophenetic distance between two observations is represented in a dendrogram by the height of the link at which those two observations are first joined. That height is the distance between the two subclusters that are merged by that link.

The output value, c, is the cophenetic correlation coefficient. The magnitude of this value should be very close to 1 for a high-quality solution. This measure can be used to compare alternative cluster solutions obtained using different algorithms.

The cophenetic correlation between Z(:,3) and Y is defined as

\[ c = \frac{\sum_{i<j} (Y_{ij} - y)(Z_{ij} - z)}{\sqrt{\sum_{i<j} (Y_{ij} - y)^2} \sqrt{\sum_{i<j} (Z_{ij} - z)^2}} \]
where:

• $Y_{ij}$ is the distance between objects $i$ and $j$ in $Y$.
• $Z_{ij}$ is the cophenetic distance between objects $i$ and $j$, from $Z(:,3)$.
• $y$ and $z$ are the average of $Y$ and $Z(:,3)$, respectively.

### Examples

```matlab
X = [rand(10,3); rand(10,3)+1; rand(10,3)+2];
Y = pdist(X);
Z = linkage(Y,'average');

% Compute Spearman's rank correlation between the
dissimilarities and the cophenetic distances
[c,D] = cophenet(Z,Y);
r = corr(Y',D','type','spearman')
r =
   0.8279
```

*Introduced before R2006a*
copulacdf

Copula cumulative distribution function

Syntax

\[ y = \text{copulacdf}('Gaussian',u,rho) \]
\[ y = \text{copulacdf}('t',u,rho,nu) \]
\[ y = \text{copulacdf}(\text{family},u,\alpha) \]

Description

\[ y = \text{copulacdf}('Gaussian',u,rho) \] returns the cumulative probability of the Gaussian copula, with linear correlation parameters \( \rho \) evaluated at the points in \( u \).

\[ y = \text{copulacdf}('t',u,rho,nu) \] returns the cumulative probability of the \( t \) copula, with linear correlation parameters, \( \rho \), and degrees of freedom parameter \( \nu \) evaluated at the points in \( u \).

\[ y = \text{copulacdf}(\text{family},u,\alpha) \] returns the cumulative probability of the bivariate Archimedean copula of the type specified by \( \text{family} \), with scalar parameter \( \alpha \) evaluated at the points in \( u \).

Examples

Compute the Clayton Copula cdf

Define two 10-by-10 matrices containing the values at which to compute the cdf.

\[ u = \text{linspace}(0,1,10); \]
\[ [u1,u2] = \text{meshgrid}(u,u); \]

Compute the cdf of a Clayton copula that has an alpha parameter equal to 1, at the values in \( u \).
y = copulacdf('Clayton', [u1(:), u2(:)], 1);

Plot the cdf as a surface, and label the axes.

surf(u1, u2, reshape(y, 10, 10))
xlabel('u1')
ylabel('u2')

**Input Arguments**

**u** — Values at which to evaluate cdf
matrix of scalar values in the range [0,1]
Values at which to evaluate the cdf, specified as a matrix of scalar values in the range [0,1]. If u is an n-by-p matrix, then its values represent n points in the p-dimensional unit hypercube. If u is an n-by-2 matrix, then its values represent n points in the unit square.

If you specify a bivariate Archimedean copula type (‘Clayton’, ‘Frank’, or ‘Gumbel’), then u must be an n-by-2 matrix.

Data Types: single | double

**rho — Linear correlation parameters**

scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If u is an n-by-p matrix, then rho is a p-by-p correlation matrix.
- If u is an n-by-2 matrix, then rho can be a scalar correlation coefficient.

Data Types: single | double

**nu — Degrees of freedom**

positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.

Data Types: single | double

**family — Bivariate Archimedean copula family**

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

- ‘Clayton’ Clayton copula
- ‘Frank’ Frank copula
- ‘Gumbel’ Gumbel copula

**alpha — Bivariate Archimedean copula parameter**

scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.
Copula Family | Permitted Alpha Values
--- | ---
'Clayton' | $[0, \infty)$
'Frank' | $(-\infty, \infty)$
'Gumbel' | $[1, \infty)$

Data Types: single | double

**Output Arguments**

* $y$ — **Cumulative distribution function**
vector of scalar values

Cumulative distribution function of the copula, evaluated at the points in $u$, returned as a vector of scalar values.

**Introduced in R2006a**
copulafit

Fit copula to data

Syntax

rhohat = copulafit('Gaussian',u)

[rhohat,nuhat] = copulafit('t',u)
[rhohat,nuhat,nuci] = copulafit('t',u)

paramhat = copulafit(family,u)
[paramhat,paramci] = copulafit(family,u)

___ = copulafit(___,Name,Value)

Description

rhohat = copulafit('Gaussian',u) returns an estimate, rhohat, of the matrix of linear correlation parameters for a Gaussian copula, given the data in u.

[rhohat,nuhat] = copulafit('t',u) returns an estimate, rhohat, of the matrix of linear correlation parameters for a t copula, and an estimate of the degrees of freedom parameter, nuhat, given the data in u.

[rhohat,nuhat,nuci] = copulafit('t',u) also returns an approximate 95% confidence interval, nuci, for the degrees of freedom estimated in nuhat.

paramhat = copulafit(family,u) returns an estimate, paramhat, of the copula parameter for a bivariate Archimedean copula of the type specified by family, given the data in u.

[paramhat,paramci] = copulafit(family,u) also returns an approximate 95% confidence interval, paramci, for the copula parameter estimated in paramhat.

___ = copulafit(___,Name,Value) returns any of the previous syntaxes, with additional options specified by one or more Name,Value pair arguments. For example,
you can specify the confidence interval to compute, or specify control parameters for the iterative parameter estimation algorithm using a options structure.

**Examples**

**Fit a t Copula to Data**

Load and plot simulated stock return data.

```matlab
load stockreturns
x = stocks(:,1);
y = stocks(:,2);
figure;
scatterhist(x,y)
```
Transform the data to the copula scale (unit square) using a kernel estimator of the cumulative distribution function.

\[ u = \text{ksdensity}(x,x,\text{function}'cdf'); \]
\[ v = \text{ksdensity}(y,y,\text{function}'cdf'); \]

\begin{verbatim}
figure;
scatterhist(u,v)
xlabel('u')
ylabel('v')
\end{verbatim}
Fit a $t$ copula to the data.

```matlab
rng default  % For reproducibility
[Rho,nu] = copulafit('t',[u v],'Method','ApproximateML')
```

$$Rho =$$

\[
\begin{array}{cc}
1.0000 & 0.7220 \\
0.7220 & 1.0000 \\
\end{array}
\]

$$nu =$$
Generate a random sample from the $t$ copula.

```matlab
r = copularnd('t',Rho,nu,1000);
u1 = r(:,1);
v1 = r(:,2);

figure;
scatterhist(u1,v1)
xlabel('u')
ylabel('v')
set(get(gca,'children'),'marker','.')
```
Transform the random sample back to the original scale of the data.

\[ x_1 = \text{ksdensity}(x, u_1, 'function', 'icdf'); \]
\[ y_1 = \text{ksdensity}(y, v_1, 'function', 'icdf'); \]

```matlab
figure;
scatterhist(x1, y1)
set(get(gca,'children'),'marker','.')```

**Input Arguments**

- **u** — Copula values
  - matrix of scalar values in the range (0,1)
Copula values, specified as a matrix of scalar values in the range (0,1). If \( u \) is an \( n \)-by-\( p \) matrix, then its values represent \( n \) points in the \( p \)-dimensional unit hypercube. If \( u \) is an \( n \)-by-2 matrix, then its values represent \( n \) points in the unit square.

If you specify a bivariate Archimedean copula type ('Clayton', 'Frank', or 'Gumbel'), then \( u \) must be an \( n \)-by-2 matrix.

Data Types: single | double

**family — Bivariate Archimedean copula family**

'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

- 'Clayton': Clayton copula
- 'Frank': Frank copula
- 'Gumbel': Gumbel copula

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Alpha',0.01,'Method','ApproximateML' computes 99% confidence intervals for the estimated copula parameter and uses an approximation method to fit the copula.

**Alpha — Significance level for confidence intervals**

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). copulafit returns approximate \( 100 \times (1-\text{Alpha})\% \) confidence intervals.

Example: 'Alpha',0.01

Data Types: single | double

**Method — Method for fitting \( t \) copula**

'ML' (default) | 'ApproximateML'
Method for fitting t copula, specified as the comma-separated pair consisting of 'Method' and either 'ML' or 'ApproximateML'.

If you specify 'ApproximateML', then copulafit fits a t copula for large samples by maximizing an objective function that approximates the profile log likelihood for the degrees of freedom parameter [1]. This method can be significantly faster than maximum likelihood ('ML'), but the estimates and confidence limits may not be accurate for small to moderate sample sizes.

Example: 'Method','ApproximateML'

Options — Control parameter specifications

structure

Control parameter specifications, specified as the comma-separated pair consisting of 'Options' and an options structure created by statset. To see the fields and default values used by copulafit, type statset('copulafit') at the command prompt.

This name-value pair is not applicable when you specify the copula type as 'Gaussian'.

Data Types: struct

Output Arguments

rhohat — Estimated correlation parameters for the fitted Gaussian copula

matrix of scalar values

Estimated correlation parameters for the fitted Gaussian copula, given the data in u, returned as a matrix of scalar values.

nuhat — Estimated degrees of freedom parameter for the fitted t copula

scalar value

Estimated degrees of freedom parameter for the fitted t copula, returned as a scalar value.

nuci — Approximate confidence interval for the degrees of freedom parameter

1-by-2 matrix of scalar values

Approximate confidence interval for the degrees of freedom parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second
column contains the upper boundary. By default, \texttt{copulafit} returns the approximate 95\% confidence interval. You can specify a different confidence interval using the \texttt{'Alpha'} name-value pair.

\textbf{paramhat — Estimated copula parameter for the fitted Archimedean copula}

\texttt{scalar value}

Estimated copula parameter for the fitted Archimedean copula, returned as a scalar value.

\textbf{paramci — Approximate confidence interval for the copula parameter}

\texttt{1-by-2 matrix of scalar values}

Approximate confidence interval for the copula parameter, returned as a 1-by-2 matrix of scalar values. The first column contains the lower boundary, and the second column contains the upper boundary. By default, \texttt{copulafit} returns the approximate 95\% confidence interval. You can specify a different confidence interval using the \texttt{'Alpha'} name-value pair.

\textbf{Algorithms}

By default, \texttt{copulafit} uses maximum likelihood to fit a copula to \texttt{u}. When \texttt{u} contains data transformed to the unit hypercube by parametric estimates of their marginal cumulative distribution functions, this is known as the \textit{Inference Functions for Margins (IFM)} method. When \texttt{u} contains data transformed by the empirical cdf (see \texttt{ecdf}), this is known as \textit{Canonical Maximum Likelihood (CML)}.

Introduced in R2007b
copulaparam

Copula parameters as function of rank correlation

Syntax

rho = copulaparam('Gaussian',r)
rho = copulaparam('t',r,nu)
alpha = copulaparam(family,r)
___ = copulaparam(___,Name,Value)

Description

rho = copulaparam('Gaussian',r) returns the linear correlation parameters, rho, that correspond to a Gaussian copula with Kendall’s rank correlation, r.

rho = copulaparam('t',r,nu) returns the linear correlation parameters, rho, that correspond to a t copula with Kendall’s rank correlation, r, and degrees of freedom, nu.

alpha = copulaparam(family,r) returns the copula parameter, alpha, that corresponds to a bivariate Archimedean copula of the type specified by family, with Kendall’s rank correlation, r.

___ = copulaparam(___,Name,Value) returns the correlation parameter using any of the previous syntaxes, with additional options specified by one or more Name,Value pair arguments. For example, you can specify whether the input rank correlation value is Spearman’s rho or Kendall’s tau.

Examples
Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's tau rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```matlab
rng default  % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)
rho = -0.7071
```

Use a Gaussian copula to generate a two-column matrix of dependent random values.

```matlab
u = copularnd('gaussian',rho,100);
```

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a scatterhist plot to visualize the random numbers generated using the copula.

```matlab
figure
scatterhist(u(:,1),u(:,2))
```
The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter $A$ is equal to 1, and a second shape parameter $B$ is equal to 2. In the second column, the first shape parameter $A$ is equal to 1.5, and a second shape parameter $B$ is equal to 2.

```
b = [betainv(u(:,1),1,2), betainv(u(:,2),1.5,2)];
```

Create a `scatterhist` plot to visualize the correlated beta distribution data.
The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's \textit{tau}.

\begin{verbatim}
tau_sample = corr(b,'type','kendall')
\end{verbatim}

\begin{verbatim}
tau_sample = 2x2

1.0000   -0.5135
\end{verbatim}
The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for \( \tau \).

**Input Arguments**

**r — Copula rank correlation**  
scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If \( r \) is a scalar correlation coefficient, then \( \rho \) is a scalar correlation coefficient corresponding to a bivariate copula.
- If \( r \) is a \( p \)-by-\( p \) correlation matrix, then \( \rho \) is a \( p \)-by-\( p \) correlation matrix.

If the copula is specified as one of the bivariate Archimedean copula types ('Clayton', 'Frank', or 'Gumbel'), then \( r \) is a scalar value.

**nu — Degrees of freedom**  
positive integer value

Degrees of freedom for the \( t \) copula, specified as a positive integer value.

Data Types: single | double

**family — Bivariate Archimedean copula family**  
'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

- 'Clayton'
- 'Frank'
- 'Gumbel'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'type','Spearman' computes Spearman’s rank correlation.

**type — Type of rank correlation**

'value' | 'Spearman'

Type of rank correlation, specified as the comma-separated pair consisting of 'type' and one of the following.

- 'Kendall' — Indicates that the input value for \( r \) is a Kendall’s \( \tau \) correlation value
- 'Spearman' — Indicates that the input value for \( r \) is a Spearman’s \( \rho \) rank correlation value

`copulaparam` uses an approximation to Spearman’s rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a \( t \) copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: 'type','Spearman'

**Output Arguments**

**rho — Linear correlation parameter**

scalar value | matrix of scalar values

Linear correlation parameter, returned as a scalar value or matrix of scalar values.

- If \( r \) is a scalar correlation coefficient, then \( \rho \) is a scalar correlation coefficient corresponding to a bivariate copula.
- If \( r \) is a \( p \)-by-\( p \) correlation matrix, then \( \rho \) is a \( p \)-by-\( p \) correlation matrix.

**alpha — Bivariate Archimedean copula parameter**

scalar value

Bivariate Archimedean copula parameter, returned as a scalar value. Permitted values for \( \alpha \) depend on the specified copula family.

Introduced in R2006a
copulapdf

Copula probability density function

Syntax

\[ y = \text{copulapdf('Gaussian',} u, \text{rho}) \]
\[ y = \text{copulapdf('t',} u, \text{rho,nu}) \]
\[ y = \text{copulapdf(family,} u, \text{alpha}) \]

Description

\[ y = \text{copulapdf('Gaussian',} u, \text{rho}) \] returns the probability density of the Gaussian copula with linear correlation parameters, \( \rho \), evaluated at the points in \( u \).

\[ y = \text{copulapdf('t',} u, \text{rho,nu}) \] returns the probability density of the \( t \) copula with linear correlation parameters, \( \rho \), and degrees of freedom parameter, \( \nu \), evaluated at the points in \( u \).

\[ y = \text{copulapdf(family,} u, \text{alpha}) \] returns the probability density of the bivariate Archimedean copula of the type specified by \( \text{family} \), with scalar parameter, \( \alpha \), evaluated at the points in \( u \).

Examples

Compute the Clayton Copula pdf

Define two 10-by-10 matrices containing the values at which to compute the pdf.

\[ u = \text{linspace(0,1,10);} \]
\[ [u1,u2] = \text{meshgrid(u,u);} \]

Compute the pdf of a Clayton copula that has an alpha parameter equal to 1, at the values in \( u \).
\begin{verbatim}
y = copulapdf('Clayton', [u1(:,), u2(:)], 1);

Plot the pdf as a surface, and label the axes.
surf(u1, u2, reshape(y, 10, 10))
xlabel('u1')
ylabel('u2')
\end{verbatim}

\section*{Input Arguments}

\textbf{u} — Values at which to evaluate pdf

matrix of scalar values in the range [0,1]
Values at which to evaluate the pdf, specified as a matrix of scalar values in the range [0,1]. If \( u \) is an \( n \)-by-\( p \) matrix, then its values represent \( n \) points in the \( p \)-dimensional unit hypercube. If \( u \) is an \( n \)-by-2 matrix, then its values represent \( n \) points in the unit square.

If you specify a bivariate Archimedean copula type (‘Clayton’, ‘Frank’, or ‘Gumbel’), then \( u \) must be an \( n \)-by-2 matrix.

Data Types: single | double

**rho — Linear correlation parameters**

| scalar values | matrix of scalar values |

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If \( u \) is an \( n \)-by-\( p \) matrix, then \( \rho \) is a \( p \)-by-\( p \) correlation matrix.
- If \( u \) is an \( n \)-by-2 matrix, then \( \rho \) can be a scalar correlation coefficient.

Data Types: single | double

**nu — Degrees of freedom**

| positive integer value |

Degrees of freedom for the \( t \) copula, specified as a positive integer value.

Data Types: single | double

**family — Bivariate Archimedean copula family**

| ‘Clayton’ | ‘Frank’ | ‘Gumbel’ |

Bivariate Archimedean copula family, specified as one of the following.

- ‘Clayton’ Clayton copula
- ‘Frank’ Frank copula
- ‘Gumbel’ Gumbel copula

**alpha — Bivariate Archimedean copula parameter**

| scalar value |

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for \( \alpha \) depend on the specified copula family.
Copula Family | Permitted Alpha Values
--- | ---
'Clayton' | $[0, \infty)$
'Frank' | $(-\infty, \infty)$
'Gumbel' | $[1, \infty)$

Data Types: single | double

**Output Arguments**

$y$ — Probability density function  
vector of scalar values

Probability density function, evaluated at the values in $u$, returned as a vector of scalar values.

**See Also**
copulacdf | copulaparam | copularnd | copulastat

**Topics**

“Generate Correlated Data Using Rank Correlation” on page 5-139  
“Copulas: Generate Correlated Samples” on page 5-159

**Introduced in R2006a**
copulastat

Copula rank correlation

Syntax

\[ r = \text{copulastat}('\text{Gaussian}', \rho) \]
\[ r = \text{copulastat}('t', \rho, \nu) \]
\[ r = \text{copulastat}(\text{family}, \alpha) \]
\[ r = \text{copulastat}(\text{__}, \text{Name, Value}) \]

Description

\[ r = \text{copulastat}('\text{Gaussian}', \rho) \] returns the Kendall’s rank correlation, \( r \), that corresponds to a Gaussian copula with linear correlation parameters \( \rho \).

\[ r = \text{copulastat}('t', \rho, \nu) \] returns the Kendall’s rank correlation, \( r \), that corresponds to a \( t \) copula with linear correlation parameters, \( \rho \), and degrees of freedom parameter, \( \nu \).

\[ r = \text{copulastat}(\text{family}, \alpha) \] returns the Kendall’s rank correlation, \( r \), that corresponds to a bivariate Archimedean copula that has the type specified by \( \text{family} \) and scalar parameter \( \alpha \).

\[ r = \text{copulastat}(\text{__}, \text{Name, Value}) \] returns the copula rank correlation with additional options specified by one or more \( \text{Name, Value} \) pair arguments, using any of the previous syntaxes. For example, you can return Spearman’s \( \rho \) rank correlation.

Examples
Compute the Gaussian Copula Rank Correlation

Compute the rank correlation for a Gaussian copula with the specified linear correlation parameter $\rho$.

$$\rho = -0.7071;$$
$$\tau = \text{copulastat}('\text{gaussian}',\rho)$$

$$\tau = -0.5000$$

Use the copula to generate dependent random values from a beta distribution that has parameters $a$ and $b$ equal to 2.

rng default  % For reproducibility
$$u = \text{copularnd}('\text{gaussian}',\rho,100);$$
$$b = \text{betainv}(u,2,2);$$

Verify that the sample has a rank correlation approximately equal to $\tau$.

$$\tau_{\text{sample}} = \text{corr}(b,'\text{type}','k')$$

$$\tau_{\text{sample}} = 2\times2$$

1.0000  -0.5135
-0.5135  1.0000

Input Arguments

rho — Linear correlation parameters
scalar values | matrix of scalar values

Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If $\rho$ is a scalar correlation coefficient, then $r$ is a scalar correlation coefficient corresponding to a bivariate copula.
- If $\rho$ is a $p$-by-$p$ correlation matrix, then $r$ is a $p$-by-$p$ correlation matrix.

Data Types: single | double
nu — Degrees of freedom
positive integer value

Degrees of freedom for the t copula, specified as a positive integer value.
Data Types: single | double

family — Bivariate Archimedean copula family
'Clayton' | 'Frank' | 'Gumbel'

Bivariate Archimedean copula family, specified as one of the following.

'Clayton' Clayton copula
'Frank' Frank copula
'Gumbel' Gumbel copula

alpha — Bivariate Archimedean copula parameter
scalar value

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

<table>

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'type', 'Spearman' computes Spearman’s rank correlation.

type — Type of rank correlation
'Kendall' (default) | 'Spearman'
Type of rank correlation, specified as the comma-separated pair consisting of 'type' and one of the following.

• 'Kendall' — Compute Kendall's \( \tau \).
• 'Spearman' — Compute Spearman's \( \rho \) (rank correlation).

copulastat uses an approximation to Spearman’s rank correlation for copula families that do not have an existing analytic formula. The approximation is based on a smooth fit to values computed at discrete values of the copula parameters. For a \( t \) copula, the approximation is accurate for degrees of freedom larger than 0.05.

Example: 'type','Spearman'

**Output Arguments**

\( \text{r} \) — Copula rank correlation

scalar value | matrix of scalar values

Copula rank correlation, returned as a scalar value or matrix of scalar values.

- If \( \rho \) is a scalar correlation coefficient, then \( \text{r} \) is a scalar correlation coefficient corresponding to a bivariate copula.
- If \( \rho \) is a \( p \)-by-\( p \) correlation matrix, then \( \text{r} \) is a \( p \)-by-\( p \) correlation matrix.

**Introduced in R2006a**
copularnd

Copula random numbers

Syntax

\[ u = \text{copularnd('Gaussian',rho,n)} \]
\[ u = \text{copularnd('t',rho,nu,n)} \]
\[ u = \text{copularnd(family,alpha,n)} \]

Description

\[ u = \text{copularnd('Gaussian',rho,n)} \] returns \( n \) random vectors generated from a Gaussian copula with linear correlation parameters \( \rho \).

\[ u = \text{copularnd('t',rho,nu,n)} \] returns \( n \) random vectors generated from a \( t \) copula with linear correlation parameters \( \rho \) and degrees of freedom \( \nu \).

\[ u = \text{copularnd(family,alpha,n)} \] returns \( n \) random vectors generated from a bivariate Archimedean copula that has the type specified by \( \text{family} \) and the scalar parameter \( \alpha \).

Examples

Generate Correlated Data Using the Inverse cdf

Generate correlated random data from a beta distribution using a bivariate Gaussian copula with Kendall's \( \tau \) rank correlation equal to -0.5.

Compute the linear correlation parameter from the rank correlation value.

```matlab
rng default  % For reproducibility
tau = -0.5;
rho = copulaparam('Gaussian',tau)
```
rho = -0.7071

Use a Gaussian copula to generate a two-column matrix of dependent random values.

\texttt{u = copularnd('gaussian', rho, 100);} 

Each column contains 100 random values between 0 and 1, inclusive, sampled from a continuous uniform distribution.

Create a \texttt{scatterhist} plot to visualize the random numbers generated using the copula.

\texttt{figure}
\texttt{scatterhist(u(:,1), u(:,2))}
The histograms show that the data in each column of the copula has a marginal uniform distribution. The scatterplot shows that the data in the two columns is negatively correlated.

Use the inverse cdf function `betainv` to transform each column of the uniform marginal distributions into random numbers from a beta distribution. In the first column, the first shape parameter $A$ is equal to 1, and a second shape parameter $B$ is equal to 2. In the second column, the first shape parameter $A$ is equal to 1.5, and a second shape parameter $B$ is equal to 2.

$$b = \text{[betainv}(u(:,1),1,2), \text{betainv}(u(:,2),1.5,2)]$$

Create a `scatterhist` plot to visualize the correlated beta distribution data.

```matlab
figure
scatterhist(b(:,1),b(:,2))
```
The histograms show the marginal beta distributions for each variable. The scatterplot shows the negative correlation.

Verify that the sample has a rank correlation approximately equal to the initial value for Kendall's $\tau$.

```matlab
tau_sample = corr(b,'type','kendall')
```

```
tau_sample = 2x2
    1.0000   -0.5135
   -0.5135    1.0000
```
The sample rank correlation of -0.5135 is approximately equal to the -0.5 initial value for \( \tau \).

## Input Arguments

**rho — Linear correlation parameters**  
Scalar values | Matrix of scalar values  
---  
Linear correlation parameters for the copula, specified as a scalar value or matrix of scalar values.

- If \( \rho \) is a \( p \)-by-\( p \) correlation matrix, then the output argument \( u \) is an \( n \)-by-\( p \) matrix.
- If \( \rho \) is a scalar correlation coefficient, then the output argument \( u \) is an \( n \)-by-2 matrix.

Data Types: single | double

**n — Number of random vectors to return**  
Positive scalar value  
Number of random vectors to return, specified as a positive scalar value.

- If you specify the copula type as 'Gaussian' or 't', and \( \rho \) is a \( p \)-by-\( p \) correlation matrix, then \( u \) is an \( n \)-by-\( p \) matrix.
- If you specify the copula type as 'Gaussian' or 't', and \( \rho \) is a scalar correlation coefficient, then \( u \) is an \( n \)-by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then \( u \) is an \( n \)-by-2 matrix.

Data Types: single | double

**nu — Degrees of freedom**  
Positive integer value  
Degrees of freedom for the \( t \) copula, specified as a positive integer value.

Data Types: single | double

**family — Bivariate Archimedean copula family**  
'Clayton' | 'Frank' | 'Gumbel'
Bivariate Archimedean copula family, specified as one of the following.

- 'Clayton'
- 'Frank'
- 'Gumbel'

alpha — Bivariate Archimedean copula parameter

Bivariate Archimedean copula parameter, specified as a scalar value. Permitted values for alpha depend on the specified copula family.

<table>
<thead>
<tr>
<th>Copula Family</th>
<th>Permitted Alpha Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Clayton'</td>
<td>[0,∞)</td>
</tr>
<tr>
<td>'Frank'</td>
<td>(-∞,∞)</td>
</tr>
<tr>
<td>'Gumbel'</td>
<td>[1,∞)</td>
</tr>
</tbody>
</table>

Data Types: single | double

Output Arguments

u — Copula random numbers

matrix of scalar values

Copula random numbers, returned as a matrix of scalar values. Each column of u is a sample from a Uniform(0,1) marginal distribution.

- If you specify the copula type as 'Gaussian' or 't', and rho is a p-by-p correlation matrix, then u is an n-by-p matrix.
- If you specify the copula type as 'Gaussian' or 't', and rho is a scalar correlation coefficient, then u is an n-by-2 matrix.
- If you specify the copula type as 'Clayton', 'Frank', or 'Gumbel', then u is an n-by-2 matrix.

Topics
“Generate Correlated Data Using Rank Correlation” on page 5-139
“Copulas: Generate Correlated Samples” on page 5-159

Introduced in R2006a
cordexch

Coordinate exchange

Syntax

dCE = cordexch(nfactors,nruns)
[dCE,X] = cordexch(nfactors,nruns)
[dCE,X] = cordexch(nfactors,nruns,'model')
[dCE,X] = cordexch(...,'name',value)

Description

dCE = cordexch(nfactors,nruns) uses a coordinate-exchange algorithm to generate a $D$-optimal design $dCE$ with $nruns$ runs (the rows of $dCE$) for a linear additive model with $nfactors$ factors (the columns of $dCE$). The model includes a constant term.

[dCE,X] = cordexch(nfactors,nruns) also returns the associated design matrix $X$, whose columns are the model terms evaluated at each treatment (row) of $dCE$.

[dCE,X] = cordexch(nfactors,nruns,'model') uses the linear regression model specified in $model$. $model$ is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of $X$ for a full quadratic model with $n$ terms is:

1. The constant term
2. The linear terms in order $1, 2, ..., n$
3. The interaction terms in order $(1, 2), (1, 3), ..., (1, n), (2, 3), ..., (n-1, n)$
4. The squared terms in order $1, 2, ..., n$

Other models use a subset of these terms, in the same order.
Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors $X_1$, $X_2$, and $X_3$, then a row $[0 \ 1 \ 2]$ in `model` specifies the term $(X_1.^{0}) \cdot (X_2.^{1}) \cdot (X_3.^{2})$. A row of all zeros in `model` specifies a constant term, which can be omitted.

$[dCE,X] = cordexch(...,'name',value)$ specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify `name` inside single quotes.

<table>
<thead>
<tr>
<th>name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>bounds</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>categorical</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>display</td>
<td>Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.</td>
</tr>
<tr>
<td>excludefun</td>
<td>Handle to a function that excludes undesirable runs. If the function is f, it must support the syntax $b = f(S)$, where $S$ is a matrix of treatments with nfactors columns and $b$ is a vector of Boolean values with the same number of rows as $S$. $b(i)$ is true if the method should exclude $i$th row $S$.</td>
</tr>
<tr>
<td>init</td>
<td>Initial design as a nruns-by-nfactors matrix. The default is a randomly selected set of points.</td>
</tr>
<tr>
<td>levels</td>
<td>Vector of number of levels for each factor. Not used when bounds is specified as a cell array.</td>
</tr>
<tr>
<td>maxiter</td>
<td>Maximum number of iterations. The default is 10.</td>
</tr>
<tr>
<td>tries</td>
<td>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</td>
</tr>
<tr>
<td>name</td>
<td>Value</td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>options</td>
<td>A structure that specifies whether to run in parallel, and specifies the random stream or streams. This option requires Parallel Computing Toolbox.</td>
</tr>
</tbody>
</table>

Create the options structure with statset. Structure fields:

- **UseParallel** — Set to true to compute in parallel. Default is false.
- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
- **Streams** — A RandStream object or cell array of such objects. If you do not specify Streams, cordexch uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
  - You have an open Parallel pool
  - UseParallel is true
  - UseSubstreams is false

In that case, use a cell array the same size as the Parallel pool.

**Examples**

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

\[
y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \epsilon
\]

Use cordexch to generate a D-optimal design with seven runs:

```matlab
defactors = 3;
nruns = 7;
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
-1 1 1
```

32-1020
Columns of the design matrix \( X \) are the model terms evaluated at each row of the design \( dCE \). The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use \( X \) to fit the model, as described in “Linear Regression” on page 11-11, to response data measured at the design points in \( dCE \).

**Algorithms**

Both \texttt{cordexch} and \texttt{rowexch} use iterative search algorithms. They operate by incrementally changing an initial design matrix \( X \) to increase \( D = |X^TX| \) at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, \( D \)-optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a ‘\texttt{tries}’ parameter that automates this repetition and comparison.

Unlike the row-exchange algorithm used by \texttt{rowexch}, \texttt{cordexch} does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of \( X \) with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum.
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `options = statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

Introduced before R2006a
corr

Linear or rank correlation

Syntax

rho = corr(X)
rho = corr(X,Y)
[rho,pval] = corr(X,Y)
[rho,pval] = corr(___ ,Name,Value)

Description

rho = corr(X) returns a matrix of the pairwise linear correlation coefficient between each pair of columns in the input matrix X.

rho = corr(X,Y) returns a matrix of the pairwise correlation coefficient between each pair of columns in the input matrices X and Y.

[rho,pval] = corr(X,Y) also returns pval, a matrix of p-values for testing the hypothesis of no correlation against the alternative hypothesis of a nonzero correlation.

[rho,pval] = corr(___ ,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, 'Type','Kendall' specifies computing Kendall's tau correlation coefficient.

Examples

Find Correlation Between Two Matrices

Find the correlation between two matrices and compare it to the correlation between two column vectors.

Generate sample data.
rng('default')
X = randn(30,4);
Y = randn(30,4);

Introduce correlation between column two of the matrix X and column four of the matrix Y.

Y(:,4) = Y(:,4)+X(:,2);

Calculate the correlation between columns of X and Y.

[rho,pval] = corr(X,Y)

rho = 4×4

<table>

</tbody>
</table>

As expected, the correlation coefficient between column two of X and column four of Y, \( \rho_{2,4} \), is the highest, and it represents a high positive correlation between the two columns. The corresponding \( p \)-value, \( pval(2,4) \), is zero to the four digits shown. Because the \( p \)-value is less than the significance level of 0.05, it indicates rejection of the hypothesis that no correlation exists between the two columns.

Calculate the correlation between X and Y using corrcov.

[r,p] = corrcov(X,Y)

r = 2×2

<table>
<thead>
<tr>
<th></th>
<th>1.0000</th>
<th>-0.0329</th>
</tr>
</thead>
<tbody>
<tr>
<td>-0.0329</td>
<td>1.0000</td>
<td></td>
</tr>
</tbody>
</table>
p = 2×2
     1.0000    0.7213
     0.7213    1.0000

The MATLAB® function *corrcoef*, unlike the *corr* function, converts the input matrices X and Y into column vectors, \(X(:)\) and \(Y(:)\), before computing the correlation between them. Therefore, the introduction of correlation between column two of matrix X and column four of matrix Y no longer exists, because those two columns are in different sections of the converted column vectors.

The value of the off-diagonal elements of \(r\), which represents the correlation coefficient between X and Y, is low. This value indicates little to no correlation between X and Y. Likewise, the value of the off-diagonal elements of \(p\), which represents the \(p\)-value, is much higher than the significance level of 0.05. This value indicates that not enough evidence exists to reject the hypothesis of no correlation between X and Y.

**Test Alternative Hypotheses for Correlation**

Test alternative hypotheses for positive, negative, and nonzero correlation between the columns of two matrices. Compare values of the correlation coefficient and \(p\)-value in each case.

Generate sample data.

```matlab
rng('default')
X = randn(50,4);
Y = randn(50,4);
```

Introduce positive correlation between column one of the matrix X and column four of the matrix Y.

```matlab
Y(:,4) = Y(:,4)+0.7*X(:,1);
```

Introduce negative correlation between column two of X and column two of Y.

```matlab
Y(:,2) = Y(:,2)-2*X(:,2);
```

Test the alternative hypothesis that the correlation is greater than zero.
[rho,pval] = corr(X,Y,'Tail','right')

rho = 4x4

0.0627  -0.1438   -0.0035    0.7060
-0.1197  -0.8600   -0.0440    0.1984
-0.1119    0.2210   -0.3433    0.1070
-0.3526   -0.2224    0.1023    0.0374

pval = 4x4

0.3327    0.8405    0.5097    0.0000
0.7962    1.0000    0.6192    0.0836
0.7803    0.0615    0.9927    0.2298
0.9940    0.9397    0.2398    0.3982

As expected, the correlation coefficient between column one of X and column four of Y, \( \rho(1,4) \), has the highest positive value, representing a high positive correlation between the two columns. The corresponding \( p \)-value, \( pval(1,4) \), is zero to the four digits shown, which is lower than the significance level of 0.05. These results indicate rejection of the null hypothesis that no correlation exists between the two columns and lead to the conclusion that the correlation is greater than zero.

Test the alternative hypothesis that the correlation is less than zero.

[rho,pval] = corr(X,Y,'Tail','left')

rho = 4x4

0.0627  -0.1438   -0.0035    0.7060
-0.1197  -0.8600   -0.0440    0.1984
-0.1119    0.2210   -0.3433    0.1070
-0.3526   -0.2224    0.1023    0.0374

pval = 4x4

0.6673    0.1595    0.4903    1.0000
0.2038    0.0000    0.3808    0.9164
0.2197    0.9385    0.0073    0.7702
0.0060    0.0603    0.7602    0.6018
As expected, the correlation coefficient between column two of X and column two of Y, \( \rho(2,2) \), has the negative number with the largest absolute value (\(-0.86\)), representing a high negative correlation between the two columns. The corresponding \( p \)-value, \( p\text{val}(2,2) \), is zero to the four digits shown, which is lower than the significance level of 0.05. Again, these results indicate rejection of the null hypothesis and lead to the conclusion that the correlation is less than zero.

Test the alternative hypothesis that the correlation is not zero.

\[
[rho, pval] = \text{corr}(X,Y)
\]

\[
\begin{bmatrix}
0.0627 & -0.1438 & -0.0035 & 0.7060 \\
-0.1197 & -0.8600 & -0.0440 & 0.1984 \\
-0.1119 & 0.2210 & -0.3433 & 0.1070 \\
-0.3526 & -0.2224 & 0.1023 & 0.0374 \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
0.6654 & 0.3190 & 0.9807 & 0.0000 \\
0.4075 & 0.0000 & 0.7615 & 0.1673 \\
0.4393 & 0.1231 & 0.0147 & 0.4595 \\
0.0120 & 0.1206 & 0.4797 & 0.7964 \\
\end{bmatrix}
\]

The \( p \)-values, \( p\text{val}(1,4) \) and \( p\text{val}(2,2) \), are both zero to the four digits shown. Because the \( p \)-values are lower than the significance level of 0.05, the correlation coefficients \( \rho(1,4) \) and \( \rho(2,2) \) are significantly different from zero. Therefore, the null hypothesis is rejected; the correlation is not zero.

## Input Arguments

**X — Input matrix**

matrix

Input matrix, specified as an \( n \times k \) matrix. The rows of X correspond to observations, and the columns correspond to variables.

Example: \( X = \text{randn}(10,5) \)
Data Types: single | double

Y — Input matrix
matrix

Input matrix, specified as an \( n \)-by-\( k_2 \) matrix when \( X \) is specified as an \( n \)-by-\( k_1 \) matrix. The rows of \( Y \) correspond to observations, and the columns correspond to variables.

Example: \( Y = \text{randn}(20,7) \)

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: \( \text{corr}(X,Y,'Type','Kendall','Rows','complete') \) returns Kendall's tau correlation coefficient using only the rows that contain no missing values.

Type — Type of correlation

'Pearson' (default) | 'Kendall' | 'Spearman'

Type of correlation, specified as the comma-separated pair consisting of 'Type' and one of these values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Pearson'</td>
<td>“Pearson's Linear Correlation Coefficient” on page 32-1030</td>
</tr>
<tr>
<td>'Kendall'</td>
<td>“Kendall's Tau Coefficient” on page 32-1031</td>
</tr>
<tr>
<td>'Spearman'</td>
<td>“Spearman's Rho” on page 32-1032</td>
</tr>
</tbody>
</table>

corr computes the \( p \)-values for Pearson's correlation using a Student's \( t \) distribution for a transformation of the correlation. This correlation is exact when \( X \) and \( Y \) come from a normal distribution. corr computes the \( p \)-values for Kendall's tau and Spearman's rho using either the exact permutation distributions (for small sample sizes) or large-sample approximations.

Example: 'Type','Spearman'
**Rows — Rows to use in computation**

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of these values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'all'</td>
<td>Use all rows of the input regardless of missing values (NaNs).</td>
</tr>
<tr>
<td>'complete'</td>
<td>Use only rows of the input with no missing values.</td>
</tr>
<tr>
<td>'pairwise'</td>
<td>Compute ( \rho(i,j) ) using rows with no missing values in column ( i ) or ( j ).</td>
</tr>
</tbody>
</table>

The 'complete' value, unlike the 'pairwise' value, always produces a positive definite or positive semidefinite \( \rho \). Also, the 'complete' value generally uses fewer observations to estimate \( \rho \) when rows of the input (\( X \) or \( Y \)) contain missing values.

Example: 'Rows','pairwise'

**Tail — Alternative hypothesis**

'both' (default) | 'right' | 'left'

Alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the values in the table. 'Tail' specifies the alternative hypothesis against which to compute \( p \)-values for testing the hypothesis of no correlation.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'both'</td>
<td>Test the alternative hypothesis that the correlation is not 0.</td>
</tr>
<tr>
<td>'right'</td>
<td>Test the alternative hypothesis that the correlation is greater than 0.</td>
</tr>
<tr>
<td>'left'</td>
<td>Test the alternative hypothesis that the correlation is less than 0.</td>
</tr>
</tbody>
</table>

corr computes the \( p \)-values for the two-tailed test by doubling the more significant of the two one-tailed \( p \)-values.

Example: 'Tail','left'
Output Arguments

**rho — Pairwise linear correlation coefficient**

matrix

Pairwise linear correlation coefficient, returned as a matrix.

- If you input only a matrix $X$, \( \rho \) is a symmetric $k$-by-$k$ matrix, where $k$ is the number of columns in $X$. The entry $\rho(a, b)$ is the pairwise linear correlation coefficient between column $a$ and column $b$ in $X$.
- If you input matrices $X$ and $Y$, \( \rho \) is a $k_1$-by-$k_2$ matrix, where $k_1$ and $k_2$ are the number of columns in $X$ and $Y$, respectively. The entry $\rho(a, b)$ is the pairwise linear correlation coefficient between column $a$ in $X$ and column $b$ in $Y$.

**pval — p-values**

matrix

$p$-values, returned as a matrix. Each element of \( pval \) is the $p$-value for the corresponding element of \( \rho \).

If $pval(a, b)$ is small (less than 0.05), then the correlation $\rho(a, b)$ is significantly different from zero.

Definitions

**Pearson's Linear Correlation Coefficient**

Pearson's linear correlation coefficient is the most commonly used linear correlation coefficient. For column $X_a$ in matrix $X$ and column $Y_b$ in matrix $Y$, having means

\[
\bar{X}_a = \frac{\sum (X_{a,i})}{n}, \quad \text{and} \quad \bar{Y}_b = \frac{\sum (X_{b,j})}{n},
\]

Pearson's linear correlation coefficient \( \rho(a, b) \) is defined as:

\[
\rho(a, b) = \frac{\sum (X_{a,i} - \bar{X}_a)(X_{b,j} - \bar{Y}_b)}{\sqrt{\sum (X_{a,i} - \bar{X}_a)^2 \sum (X_{b,j} - \bar{Y}_b)^2}}.
\]
\[ \rho(a, b) = \frac{\sum_{i=1}^{n} (X_{a,i} - \bar{X}_{a})(Y_{b,i} - \bar{Y}_{b})}{\left( \sum_{i=1}^{n} (X_{a,i} - \bar{X}_{a})^2 \sum_{j=1}^{n} (Y_{b,j} - \bar{Y}_{b})^2 \right)^{1/2}}, \]

where \( n \) is the length of each column.

Values of the correlation coefficient can range from \(-1\) to \(+1\). A value of \(-1\) indicates perfect negative correlation, while a value of \(+1\) indicates perfect positive correlation. A value of 0 indicates no correlation between the columns.

**Kendall's Tau Coefficient**

Kendall's tau is based on counting the number of \((i,j)\) pairs, for \(i<j\), that are concordant—that is, for which \(X_{a,i} - X_{a,j}\) and \(Y_{b,i} - Y_{b,j}\) have the same sign. The equation for Kendall's tau includes an adjustment for ties in the normalizing constant and is often referred to as tau-b.

For column \(X_a\) in matrix \(X\) and column \(Y_b\) in matrix \(Y\), Kendall's tau coefficient is defined as:

\[ \tau = \frac{2K}{n(n-1)}, \]

where \( K = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \xi^*(X_{a,i}, X_{a,j}, Y_{b,j}, Y_{b,j}), \) and

\[ \xi^*(X_{a,i}, X_{a,j}, Y_{b,j}, Y_{b,j}) = \begin{cases} 
1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) > 0 \\
0 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) = 0 \\
-1 & \text{if } (X_{a,i} - X_{a,j})(Y_{b,i} - Y_{b,j}) < 0 
\end{cases} \]

Values of the correlation coefficient can range from \(-1\) to \(+1\). A value of \(-1\) indicates that one column ranking is the reverse of the other, while a value of \(+1\) indicates that the two rankings are the same. A value of 0 indicates no relationship between the columns.
Spearman's Rho

Spearman's rho is equivalent to “Pearson's Linear Correlation Coefficient” on page 32-1030 applied to the rankings of the columns $X_a$ and $Y_b$.

If all the ranks in each column are distinct, the equation simplifies to:

$$\rho(a,b) = 1 - \frac{6\sum d^2}{n(n^2 - 1)},$$

where $d$ is the difference between the ranks of the two columns, and $n$ is the length of each column.

Tips

The difference between `corr(X,Y)` and the MATLAB function `corrcoef(X,Y)` is that `corrcoef(X,Y)` returns a matrix of correlation coefficients for two column vectors $X$ and $Y$. If $X$ and $Y$ are not column vectors, `corrcoef(X,Y)` converts them to column vectors.

References

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.
This function supports tall arrays for out-of-memory data with the limitation:

Only the 'Pearson' type is supported.

For more information, see “Tall Arrays” (MATLAB).

corrcov | partialcorr | tiedrank

Introduced before R2006a
corrcov

Convert covariance matrix to correlation matrix

Syntax

R = corrcov(C)
[R,sigma] = corrcov(C)

Description

R = corrcov(C) computes the correlation matrix R corresponding to the covariance matrix C. C must be square, symmetric, and positive semi-definite.

[R,sigma] = corrcov(C) also computes the vector of standard deviations sigma.

Examples

Use cov and corrcoef to compute covariances and correlations, respectively, for sample data on weight and blood pressure (systolic, diastolic) in hospital.mat:

load hospital
X = [hospital.Weight hospital.BloodPressure];
C = cov(X)
C =
    706.0404   27.7879   41.0202
    27.7879   45.0622   23.8194
    41.0202   23.8194   48.0590
R = corrcoef(X)
R =
    1.0000   0.1558   0.2227
    0.1558   1.0000   0.5118
    0.2227   0.5118   1.0000

Compare R with the correlation matrix computed from C by corrcov:

corrcov(C)
ans =
Extended Capabilities

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

*Introduced in R2007b*
covarianceParameters

Class: GeneralizedLinearMixedModel

Extract covariance parameters of generalized linear mixed-effects model

Syntax

psi = covarianceParameters(glme)
[psi,dispersion] = covarianceParameters(glme)
[psi,dispersion,stats] = covarianceParameters(glme)
[___] = covarianceParameters(glme,Name,Value)

Description

psi = covarianceParameters(glme) returns the estimated prior covariance parameters of random-effects predictors in the generalized linear mixed-effects model glme.

[psi,dispersion] = covarianceParameters(glme) also returns an estimate of the dispersion parameter.

[psi,dispersion,stats] = covarianceParameters(glme) also returns a cell array stats containing the covariance parameter estimates and related statistics.

[___] = covarianceParameters(glme,Name,Value) returns any of the above output arguments using additional options specified by one or more Name,Value pair arguments. For example, you can specify the confidence level for the confidence limits of covariance parameters.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object
Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Alpha — Confidence level**

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value `α`, the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: `single` | `double`

**Output Arguments**

**psi — Estimated prior covariance parameters**

cell array

Estimated prior covariance parameters for the random-effects predictors, returned as a cell array of length `R`, where `R` is the number of grouping variables used in the model. `psi{r}` contains the covariance matrix of random effects associated with grouping variable `g_r`, where `r = 1, 2, ..., R`, The order of grouping variables in `psi` is the same as the order entered when fitting the model. For more information on grouping variables, see “Grouping Variables” on page 2-57.

**dispersion — Dispersion parameter**

scalar value

Dispersion parameter, returned as a scalar value.
stats — Covariance parameter estimates and related statistics

cell array

Covariance parameter estimates and related statistics, returned as a cell array of length \((R + 1)\), where \(R\) is the number of grouping variables used in the model. The first \(R\) cells of stats each contain a dataset array with the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Grouping variable name</td>
</tr>
<tr>
<td>Name1</td>
<td>Name of the first predictor variable</td>
</tr>
<tr>
<td>Name2</td>
<td>Name of the second predictor variable</td>
</tr>
<tr>
<td>Type</td>
<td>If Name1 and Name2 are the same, then Type is std (standard deviation). If Name1 and Name2 are different, then Type is corr (correlation).</td>
</tr>
<tr>
<td>Estimate</td>
<td>If Name1 and Name2 are the same, then Estimate is the standard deviation of the random effect associated with predictor Name1 or Name2. If Name1 and Name2 are different, then Estimate is the correlation between the random effects associated with predictors Name1 and Name2.</td>
</tr>
<tr>
<td>Lower</td>
<td>Lower limit of the confidence interval for the covariance parameter</td>
</tr>
<tr>
<td>Upper</td>
<td>Upper limit of the confidence interval for the covariance parameter</td>
</tr>
</tbody>
</table>

Cell \(R + 1\) contains related statistics for the dispersion parameter.

It is recommended that the presence or absence of covariance parameters in glme be tested using the compare method, which uses a likelihood ratio test.

When fitting a GLME model using fitglme and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), covarianceParameters derives the confidence intervals in stats based on a Laplace approximation to the log likelihood of the generalized linear mixed-effects model.
When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `covarianceParameters` derives the confidence intervals in `stats` based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

**Examples**

**Obtain Estimated Covariance Parameters**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the
coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time} \_\text{dev}_{ij} + \beta_3 \text{temp} \_\text{dev}_{ij} + \beta_4 \text{supplier} \_C_{ij} + \beta_5 \text{supplier} \_B_{ij} + b_i,
\]

where

- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
- \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, \ldots, 20 \)) during batch \( j \) (where \( j = 1, 2, \ldots, 5 \)).
- \( \text{newprocess}_{ij} \), \( \text{time} \_\text{dev}_{ij} \), and \( \text{temp} \_\text{dev}_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, \( \text{newprocess}_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.
- \( \text{supplier} \_C_{ij} \) and \( \text{supplier} \_B_{ij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).
- \( b_i \sim N(0, \sigma_b^2) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

\[
\text{glme} = \text{fitglme(mfr,}'\text{defects} \sim 1 + \text{newprocess} + \text{time} \_\text{dev} + \text{temp} \_\text{dev} + \text{supplier} + (1|\text{factory})',\text{Distribution}'\text{Poisson}',\text{Link}'\log',\text{FitMethod}'\text{Laplace}',\text{DummyVarCoding}'\text{effects}');
\]

Compute and display the estimate of the prior covariance parameter for the random-effects predictor:

\[
[\psi,\text{dispersion,stats}] = \text{covarianceParameters(glme)};
\psi[1]
\]

\[
\text{ans} = 0.0985
\]
psi{1} is an estimate of the prior covariance matrix of the first grouping variable. In this example, there is only one grouping variable (factory), so psi{1} is an estimate of \( \sigma_b^2 \).

Display the dispersion parameter.

dispersion
dispersion = 1

Display the estimated standard deviation of the random effect associated with the predictor. The first cell of stats contains statistics for factory, while the second cell contains statistics for the dispersion parameter.

stats{1}

ans =
  Covariance Type: Isotropic

<table>
<thead>
<tr>
<th>Group</th>
<th>Name1</th>
<th>Name2</th>
<th>Type</th>
<th>Estimate</th>
</tr>
</thead>
<tbody>
<tr>
<td>factory</td>
<td>'(Intercept)'</td>
<td>'(Intercept)'</td>
<td>'std'</td>
<td>0.31381</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.19253</td>
<td>0.51148</td>
</tr>
</tbody>
</table>

The estimated standard deviation of the random effect associated with the predictor is 0.31381. The 95% confidence interval is [0.19253 , 0.51148]. Because the confidence interval does not contain 0, the random intercept is significant at the 5% significance level.

covarianceParameters

**Class:** LinearMixedModel

Extract covariance parameters of linear mixed-effects model

**Syntax**

```matlab
psi = covarianceParameters(lme)
[psi,mse] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme)
[psi,mse,stats] = covarianceParameters(lme,Name,Value)
```

**Description**

`psi = covarianceParameters(lme)` returns the estimated covariance parameters that parameterize the prior covariance of random effects.

`[psi,mse] = covarianceParameters(lme)` also returns an estimate of the residual variance.

`[psi,mse,stats] = covarianceParameters(lme)` also returns a cell array, `stats`, containing the covariance parameters and related statistics.

`[psi,mse,stats] = covarianceParameters(lme,Name,Value)` returns the covariance parameters and related statistics in `stats` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the confidence level for the confidence limits of covariance parameters.

**Input Arguments**

`lme` — Linear mixed-effects model
LinearMixedModel object
Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Alpha — Confidence level**

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value \( \alpha \), the confidence level is \( 100*(1-\alpha)\% \).

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

**Output Arguments**

**psi — Estimate of covariance parameters**

cell array

Estimate of covariance parameters that parameterize the prior covariance of the random effects, returned as a cell array of length \( R \), such that \( \text{psi}\{r\} \) contains the covariance matrix of random effects associated with grouping variable \( g_r \), \( r = 1, 2, ..., R \). The order of grouping variables is the same order you enter when you fit the model.

**mse — Residual variance estimate**

scalar value

Residual variance estimate, returned as a scalar value.

**stats — Covariance parameter estimates and related statistics**

cell array
Covariance parameter estimates and related statistics, returned as a cell array of length \( R + 1 \) containing dataset arrays with the following columns.

<table>
<thead>
<tr>
<th>Group</th>
<th>Grouping variable name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name1</td>
<td>Name of the first predictor variable</td>
</tr>
<tr>
<td>Name2</td>
<td>Name of the second predictor variable</td>
</tr>
</tbody>
</table>
| Type    | \( \text{std} \) (standard deviation), if \( \text{Name1} \) and \( \text{Name2} \) are the same  
|         | \( \text{corr} \) (correlation), if \( \text{Name1} \) and \( \text{Name2} \) are different |
| Estimate| Standard deviation of the random effect associated with predictor \( \text{Name1} \) or \( \text{Name2} \), if \( \text{Name1} \) and \( \text{Name2} \) are the same  
|         | Correlation between the random effects associated with predictors \( \text{Name1} \) and \( \text{Name2} \), if \( \text{Name1} \) and \( \text{Name2} \) are different |
| Lower   | Lower limit of a 95\% confidence interval for the covariance parameter |
| Upper   | Upper limit of a 95\% confidence interval for the covariance parameter |

\( \text{stats}\{r\} \) is a dataset array containing statistics on covariance parameters for the \( r \)th grouping variable, \( r = 1, 2, ..., R \). \( \text{stats}\{R+1\} \) contains statistics on the residual standard deviation. The dataset array for the residual error has the fields \text{Group}, \text{Name}, \text{Estimate}, \text{Lower}, and \text{Upper}.

### Examples

#### Two Random-Effects Terms for Intercept

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five
plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` is the fixed-effects variable, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently. This model corresponds to

\[ y_{ijk} = \beta_0 + \sum_{j=2}^{5} \beta_{2j} I[T]_{ij} + b_{0jk}(S \times T)_{jk} + e_{ijk}, \]

where \( i = 1, 2, ..., 60 \) corresponds to the observations, \( j = 2, ..., 5 \) corresponds to the tomato types, and \( k = 1, 2, 3 \) corresponds to the blocks (soil). \( S_k \) represents the \( k \) th soil type, and \( (S \times T)_{jk} \) represents the \( j \) th tomato type nested in the \( k \) th soil type. \( I[T]_{ij} \) is the dummy variable representing the level \( j \) of the tomato type.

The random effects and observation error have the following prior distributions:

\[ b_{0k} \sim N(0, \sigma_S^2), \quad b_{0jk} \sim N(0, \sigma_{S \times T}^2), \quad \text{and} \quad e_{ijk} \sim N(0, \sigma^2). \]

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer + (1|Soil) + (1|Soil:Tomato)');
```

Compute the covariance parameter estimates (estimates of \( \sigma_S^2 \) and \( \sigma_{S \times T}^2 \)) of the random-effects terms.

```matlab
psi = covarianceParameters(lme)
```

\[ \text{psi} = 2 \times 1 \text{ cell array} \]

\[ \{[4.2642e-17]\} \]

\[ \{[352.8481]\} \]
Compute the residual variance ($\sigma^2$).

\[
[-, \text{mse}] = \text{covarianceParameters(lme)}
\]

\[
\text{mse} = 151.9007
\]

**Potentially Correlated Random-Effects Terms**

Load the sample data.

\[
\text{load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))};
\]

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

\[
\text{ds} = \text{dataset(InitialWeight, Program, Subject, Week, y)};
\]

\[
\text{ds.Subject} = \text{nominal(ds.Subject)};
\]

\[
\text{ds.Program} = \text{nominal(ds.Program)};
\]

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

For `'reference'` dummy variable coding, `fitlme` uses Program A as reference and creates the necessary dummy variables $I[.]$. This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i + b_{0m} + b_{1m} \text{Week}_{im} + e_{im}
\]

where $i$ corresponds to the observation number, $i = 1, 2, ..., 120$, and $m$ corresponds to the subject number, $m = 1, 2, ..., 20$. $\beta_j$ are the fixed-effects coefficients, $j = 0, 1, ..., 8$, and $b_{0m}$ and $b_{1m}$ are random effects. $IW$ stands for initial weight and $I[.]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing Program B.
The random effects and observation error have the following prior distributions:

\[
\begin{pmatrix}
    b_{0im} \\
    b_{1im}
\end{pmatrix}
\sim N\left(0,\begin{pmatrix}
    \sigma_0^2 & \sigma_{0,1} \\
    \sigma_{0,1} & \sigma_1^2
\end{pmatrix}\right)
\]

and

\[e_{im} \sim N(0, \sigma^2).\]

```matlab
lme = fitlme(ds,'y ~ InitialWeight + Program + (Week|Subject)');
Compute the estimates of covariance parameters for the random effects.
[psi,mse,stats] = covarianceParameters(lme)
psi = 1x1 cell array
   {2x2 double}
mse = 0.0105
stats = 2x1 cell array
   {3x7 classreg.regr.lmeutils.titledataset}
   {1x5 classreg.regr.lmeutils.titledataset}
```

`mse` is the estimated residual variance. It is the estimate for \(\sigma^2\).

To see the covariance parameters estimates for the random-effects terms (\(\sigma_0^2\), \(\sigma_1^2\), and \(\sigma_{0,1}\)), index into `psi`.

```matlab
psi{1}
ans = 2x2
   0.0572   0.0490
   0.0490   0.0624
```

The estimate of the variance of the random effects term for the intercept, \(\sigma_0^2\), is 0.0572.

The estimate of the variance of the random effects term for week, \(\sigma_1^2\), is 0.0624. The
estimate for the covariance of the random effects terms for the intercept and week, \( \sigma_{0.1} \), is 0.0490.

stats is a 2-by-1 cell array. The first cell of stats contains the confidence intervals for the standard deviation of the random effects and the correlation between the random effects for intercept and week. To display them, index into stats.

stats{1}

ans =

Covariance Type: FullCholesky

<table>
<thead>
<tr>
<th>Group</th>
<th>Name1</th>
<th>Name2</th>
<th>Type</th>
<th>Estimate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject</td>

<td>'(Intercept)'</td>
<td>'std'</td>
<td>0.23927</td>
</tr>
<tr>
<td>Subject</td>
<td>'Week'</td>
<td>'(Intercept)'</td>
<td>'corr'</td>
<td>0.81971</td>
</tr>
<tr>
<td>Subject</td>
<td>'Week'</td>
<td>'Week'</td>
<td>'std'</td>
<td>0.2497</td>
</tr>
</tbody>
</table>

The display shows the name of the grouping parameter (Group), the random-effects variables (Name1, Name2), the type of the covariance parameters (Type), the estimate (Estimate) for each parameter, and the 95\% confidence intervals for the parameters (Lower, Upper). The estimates in this table are related to the estimates in psi as follows.

The standard deviation of the random-effects term for intercept is 0.23927 = sqrt(0.0527). Likewise, the standard deviation of the random effects term for week is 0.2497 = sqrt(0.0624). Finally, the correlation between the random-effects terms of intercept and week is 0.81971 = 0.0490/(0.23927*0.2497).

Note that this display also shows which covariance pattern you use when fitting the model. In this case, the covariance pattern is FullCholesky. To change the covariance pattern for the random-effects terms, you must use the 'CovariancePattern' name-value pair argument when fitting the model.

The second cell of stats includes similar statistics for the residual standard deviation. Display the contents of the second cell.

stats{2}
ans =
<table>
<thead>
<tr>
<th>Group</th>
<th>Name</th>

<tbody>
<tr>
<td>Error</td>
<td>'Res Std'</td>
<td>0.10261</td>
<td>0.087882</td>
<td>0.11981</td>
</tr>
</tbody>
</table>

The estimate for residual standard deviation is the square root of \( \text{mse} \), \( 0.10261 = \sqrt{0.0105} \).

## Two Grouping Variables

Load the sample data.

```matlab
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and weight, a potentially correlated random effect for intercept and acceleration grouped by model year, and an independent random effect for weight, grouped by the origin of the car. This model corresponds to

\[
\text{MPG}_{ink} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{Weight}_i + b_{10m} + b_{11m} \text{Acc}_i + b_{21k} \text{Weight}_i + \epsilon_{ink}
\]

where \( m = 1, 2, ..., 13 \) represents the levels for the variable `Model_Year`, and \( k = 1, 2, ..., 8 \) represents the levels for the variable `Origin`. \( \text{MPG}_{ink} \) is the miles per gallon for the \( i \)th observation, \( |m| \) th model year, and \( |k| \) th origin that correspond to the \( i \)th observation. The random-effects terms and the observation error have the following prior distributions:

\[
b_{1m} = \begin{pmatrix} b_{10m} \\ b_{11m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma^2_{10} & \sigma_{10,11} \\ \sigma_{10,11} & \sigma^2_{11} \end{pmatrix}\right),
\]

\[
b_{2k} \sim N(0, \sigma^2_2),
\]

\[
\epsilon_{ink} \sim N(0, \sigma^2).
\]

Here, the random-effects term \( b_{1m} \) represents the first random effect at level \( m \) of the first grouping variable. The random-effects term \( b_{10m} \) corresponds to the first random
effects term (1), for the intercept (0), at the $m$th level ($m$) of the first grouping variable. Likewise $b_{11m}$ is the level $m$ for the first predictor (1) in the first random-effects term (1).

Similarly, $b_{2k}$ stands for the second random effects-term at level $k$ of the second grouping variable.

$\sigma_{10}^2$ is the variance of the random-effects term for the intercept, $\sigma_{11}^2$ is the variance of the random effects term for the predictor acceleration, and $\sigma_{10,11}$ is the covariance of the random-effects terms for the intercept and the predictor acceleration. $\sigma_{2}^2$ is the variance of the second random-effects term, and $\sigma^2$ is the residual variance.

First, prepare the design matrices for fitting the linear mixed-effects model.

\[
X = \begin{bmatrix} \text{ones}(406,1) & \text{Acceleration} & \text{Weight} \end{bmatrix};
\]

\[
Z = \{\begin{bmatrix} \text{ones}(406,1) & \text{Acceleration} \end{bmatrix}, [\text{Weight}]\};
\]

\[
\text{Model\_Year} = \text{nominal} (\text{Model\_Year});
\]

\[
\text{Origin} = \text{nominal} (\text{Origin});
\]

\[
G = \{\text{Model\_Year}, \text{Origin}\};
\]

Fit the model using the design matrices.

\[
lme = \text{fitlmematrix}(X, \text{MPG}, Z, G, 'FixedEffectPredictors', ..., '\text{FixedEffectPredictors}', ..., '\text{FixedEffectPredictors}', ..., '\text{FixedEffectPredictors}', ..., '\text{FixedEffectPredictors}', ..., '\text{FixedEffectPredictors}', ..., '\text{FixedEffectPredictors}', ...)
\]

\[
\text{RandomEffectGroups}', '\text{Model\_Year}', '\text{Origin}')
\]

Compute the estimates of covariance parameters for the random effects.

\[
[\psi, \text{mse}, \text{stats}] = \text{covarianceParameters}(lme)
\]

\[
\psi = \begin{bmatrix} 2 x 1 \text{ cell array} \\
{\begin{bmatrix} 2 x 2 \text{ double} \end{bmatrix}} \\
\{[6.7587e-08] \}
\end{bmatrix}
\]

\[
\text{mse} = 9.0802
\]

\[
\text{stats} = \begin{bmatrix} 3 x 1 \text{ cell array} \\
{\begin{bmatrix} 3 x 7 \text{ classreg.regr.lmeutils.titledataset} \end{bmatrix}} \\
{\begin{bmatrix} 1 x 7 \text{ classreg.regr.lmeutils.titledataset} \end{bmatrix}}
\end{bmatrix}
\]
The residual variance $\text{mse}$ is 9.0755. $\mathbf{psi}$ is a 2-by-1 cell array, and $\mathbf{stats}$ is a 3-by-1 cell array. To see the contents, you must index into these cell arrays.

First, index into the first cell of $\mathbf{psi}$.

$\mathbf{psi}\{1\}$

ans = 2×2

8.3081   -0.8359
-0.8359    0.1093

The first cell of $\mathbf{psi}$ contains the covariance parameters for the correlated random effects for intercept $\sigma_{10}^2$ as 8.5160, and for acceleration $\sigma_{11}^2$ as 0.1087. The estimate for the covariance of the random-effects terms for the intercept and acceleration $\sigma_{10,11}$ is -0.8387.

Now, index into the second cell of $\mathbf{psi}$.

$\mathbf{psi}\{2\}$

ans = 6.7587e-08

The second cell of $\mathbf{psi}$ contains the estimate for the variance of the random-effects term for weight $\sigma_2^2$.

Index into the first cell of $\mathbf{stats}$.

$\mathbf{stats}\{1\}$

ans =
Covariance Type: FullCholesky

<table>
<thead>
<tr>

<td>'Intercept'</td>
<td>'std'</td>
</tr>
<tr>
<td>Model_Year</td>
<td>'Acceleration'</td>
<td>'Intercept'</td>
<td>'corr'</td>
</tr>
<tr>
<td>Model_Year</td>
<td>'Acceleration'</td>
<td>'Acceleration'</td>
<td>'std'</td>
</tr>
</tbody>
</table>
This table shows the standard deviation estimates for the random-effects terms for intercept and acceleration. Note that the standard deviations estimates are the square roots of the diagonal elements in the first cell of psi. Specifically, \(2.9182 = \sqrt{8.5160}\) and \(0.32968 = \sqrt{0.1087}\). The correlation is a function of the covariance of intercept and acceleration, and the standard deviations of intercept and acceleration. The covariance of intercept and acceleration is the off-diagonal value in the first cell of psi, \(-0.8387\). So, the correlation is \(-0.8387/(0.32968*2.92182) = -0.87\).

The grouping variable for intercept and acceleration is Model_Year.

Index into the second cell of stats.

stats{2}

ans =
   Covariance Type: FullCholesky

<table>
<thead>
<tr>
<th>Group</th>
<th>Name1</th>
<th>Name2</th>
<th>Type</th>
<th>Estimate</th>

coxphfit

Cox proportional hazards regression

Syntax

b = coxphfit(X,T)
b = coxphfit(X,T,Name,Value)
[b,logl,H,stats] = coxphfit(__)

Description

b = coxphfit(X,T) returns a p-by-1 vector, b, of coefficient estimates for a Cox proportional hazards regression on page 32-1064 of the observed responses T on the predictors X, where T is either an n-by-1 vector or an n-by-2 matrix, and X is an n-by-p matrix.

The model does not include a constant term, and X cannot contain a column of 1s.

b = coxphfit(X,T,Name,Value) returns a vector of coefficient estimates, with additional options specified by one or more Name,Value pair arguments.

[b,logl,H,stats] = coxphfit(__) also returns the loglikelihood, logl, a structure, stats, that contains additional statistics, and a two-column matrix, H, that contains the T values in the first column and the estimated baseline cumulative hazard, in the second column. You can use any of the input arguments in the previous syntaxes.

Examples

Use Cox Proportional Hazards Regression to Model Lifetime of Light Bulbs

Load the sample data.

load(fullfile(matlabroot,'examples','stats','lightbulb.mat'));
The first column of the light bulb data has the lifetime (in hours) of two different types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 0 indicates that the bulb is incandescent, and 1 indicates that it is fluorescent. The third column contains the censorship information, where 0 indicates the bulb was observed until failure, and 1 indicates the bulb was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, also accounting for censoring. The predictor variable is the type of bulb.

\[
b = \text{coxphfit(lightbulb(:,2),lightbulb(:,1), ...}
\text{ 'Censoring',lightbulb(:,3))}
\]

\[
b = 4.7262
\]

The estimate of the hazard ratio is \( e^b = 112.8646 \). This means that the hazard for the incandescent bulbs is 112.86 times the hazard for the fluorescent bulbs.

### Change Algorithm Parameters for Cox Proportional Hazards Model

Load the sample data.

\[
\text{load(fullfile(matlabroot,'examples','stats','lightbulb.mat'))}
\]

The first column of the data has the lifetime (in hours) of two types of bulbs. The second column has the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent and 0 indicates that it is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Fit a Cox proportional hazards model, also accounting for censoring. The predictor variable is the type of bulb.

\[
b = \text{coxphfit(lightbulb(:,2),lightbulb(:,1), ...}
\text{ 'Censoring',lightbulb(:,3))}
\]

\[
b = 4.7262
\]

Display the default control parameters for the algorithm `coxphfit` uses to estimate the coefficients.

\[
\text{statset('coxphfit')}
\]
ans = struct with fields:
    Display: 'off'
    MaxFunEvals: 200
    MaxIter: 100
    TolBnd: 1.0000e-06
    TolFun: 1.0000e-08
    TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: {}
    OutputFcn: []

Save the options under a different name and change how the results will be displayed and the maximum number of iterations, Display and MaxIter.

coxphopt = statset('coxphfit');
coxphopt.Display = 'final';
coxphopt.MaxIter = 50;

Run coxphfit with the new algorithm parameters.

b = coxphfit(lightbulb(:,2),lightbulb(:,1),...
    'Censoring',lightbulb(:,3),'Options',coxphopt)

Successful convergence: Norm of gradient less than OPTIONS.TolFun

b = 4.7262

coxphfit displays a report on the final iteration. Changing the maximum number of iterations did not affect the coefficient estimate.
**Fit and Compare Cox and Weibull Survivor Functions**

Generate Weibull data depending on predictor \( X \).

```matlab
rng('default') % for reproducibility
X = 4*rand(100,1);
A = 50*exp(-0.5*X);
B = 2;
y = wblrnd(A,B);
```

The response values are generated from a Weibull distribution with a shape parameter depending on the predictor variable \( X \) and a scale parameter of 2.

Fit a Cox proportional hazards model.

```matlab
[b,logL,H,stats] = coxphfit(X,y);
[b logL]
ans = 1×2
0.9409 -331.1479
```

The coefficient estimate is 0.9409 and the log likelihood value is –331.1479.

Request the model statistics.

```matlab
stats
```

```matlab
stats = struct with fields:
  covb: 0.0158
  beta: 0.9409
  se: 0.1256
  z: 7.4889
  p: 6.9462e-14
  csres: [100x1 double]
  devres: [100x1 double]
  martres: [100x1 double]
  schres: [100x1 double]
  sshres: [100x1 double]
  scores: [100x1 double]
  sscores: [100x1 double]
```

The covariance matrix of the coefficient estimates, \( \text{covb} \), contains only one value, which is equal to the variance of the coefficient estimate in this example. The coefficient
estimate, $\beta$, is the same as $b$ and is equal to 0.9409. The standard error of the coefficient estimate, $se$, is 0.1256, which is the square root of the variance 0.0158. The $z$-statistic, $z$, is $\beta/se = 0.9409/0.1256 = 7.4880$. The p-value, $p$, indicates that the effect of $X$ is significant.

Plot the Cox estimate of the baseline survivor function together with the known Weibull function.

```matlab
stairs(H(:,1),exp(-H(:,2)),'LineWidth',2)
xx = linspace(0,100);
line(xx,1-wblcdf(xx,50*exp(-0.5*mean(X)),B),'color','r','LineWidth',2)
xlim([0,50])
legend('Estimated Survivor Function','Weibull Survivor Function')
```
The fitted model gives a close estimate to the survivor function of the actual distribution.

**Input Arguments**

**X — Observations on predictor variables**

matrix

Observations on predictor variables, specified as an \(n\)-by-\(p\) matrix of \(p\) predictors for each of \(n\) observations.

The model does not include a constant term, thus \(X\) cannot contain a column of 1s.

If \(X\), \(T\), or the value of 'Frequency' or 'Strata' contain NaN values, then \texttt{coxphfit} removes rows with NaN values from all data when fitting a Cox model.

Data Types: double

**T — Time-to-event data**

vector | two-column matrix

Time-to-event data, specified as an \(n\)-by-1 vector or a two-column matrix.

- When \(T\) is an \(n\)-by-1 vector, it represents the event time of right-censored time-to-event data.
- When \(T\) is an \(n\)-by-2 matrix, each row represents the risk interval (start,stop] in the counting process format for time-dependent covariates. The first column is the start time and the second column is the stop time. For an example, see “Cox Proportional Hazards Model with Time-Dependent Covariates” on page 14-42.

If \(X\), \(T\), or the value of 'Frequency' or 'Strata' contain NaN values, then \texttt{coxphfit} removes rows with NaN values from all data when fitting a Cox model.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
Example: 'Baseline',0,'Censoring',censoreddata,'Frequency',freq specifies that `coxphfit` calculates the baseline hazard rate relative to 0, considering the censoring information in the vector censoreddata, and the frequency of observations on T and X given in the vector freq.

**B0 — Coefficient initial values**
0.01/\text{std}(X) (default) | numeric vector

Coefficient initial values, specified as the comma-separated value consisting of 'B0' and a numeric vector.

Data Types: double

**Baseline — X values at which to compute the baseline hazard**
mean(X) (default) | scalar value

X values at which to compute the baseline hazard, specified as the comma-separated pair consisting of 'Baseline' and a scalar value.

The default is mean(X), so the hazard rate at X is \( h(t) \exp((X-\text{mean}(X))*b) \). Enter 0 to compute the baseline relative to 0, so the hazard rate at X is \( h(t) \exp(X*b) \). Changing the baseline does not affect the coefficient estimates, but the hazard ratio changes.

Example: 'Baseline',0

Data Types: double

**Censoring — Indicator for censoring**
an array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as T. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed. For an example, see “Cox Proportional Hazards Model for Censored Data” on page 14-37.

Example: 'Censoring',cens

Data Types: logical

**Frequency — Frequency or weights of observations**
an array of 1s (default) | vector of nonnegative scalar values

Data Types: double
Frequency or weights of observations, specified as the comma-separated pair consisting of 'Frequency' and an array that is the same size as T containing nonnegative scalar values. The array can contain integer values corresponding to frequencies of observations or nonnegative values corresponding to observation weights.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then coxphfit removes rows with NaN values from all data when fitting a Cox model.

The default is 1 per row of X and T.

Example: 'Frequency',w

Data Types: double

**Strata — Stratification variables**

[] (default) | matrix of real values

Stratification variables, specified as the comma-separated pair consisting of a matrix of real values. The matrix must have the same number of rows as T, with each row corresponding to an observation.

If X, T, or the value of 'Frequency' or 'Strata' contain NaN values, then coxphfit removes rows with NaN values from all data when fitting a Cox model.

The default, [], is no stratification variable.

Example: 'Strata',Gender

Data Types: single | double

**Ties — Method to handle tied failure times**

'breslow' (default) | 'efron'

Method to handle tied failure times, specified as the comma-separated pair consisting of 'Ties' and either 'breslow' (Breslow's method) or 'efron' (Efron's method).

Example: 'Ties','efron'

**Options — Algorithm control parameters**

structure

Algorithm control parameters for the iterative algorithm used to estimate b, specified as the comma-separated pair consisting of 'Options' and a structure. A call to statset creates this argument. For parameter names and default values, type

`statset('coxphfit'). You can set the options under a new name and use that in the name-value pair argument.

Example: 'Options',statset('coxphfit')

**Output Arguments**

**b — Coefficient estimates**

vector

Coefficient estimates for a Cox proportional hazards regression on page 32-1064, returned as a \( p \)-by-1 vector.

**logl — Loglikelihood**

scalar

Loglikelihood of the fitted model, returned as a scalar.

You can use log likelihood values to compare different models and assess the significance of effects of terms in the model.

**H — Estimated baseline cumulative hazard**

two-column matrix | (2+k) column matrix

Estimated baseline cumulative hazard rate evaluated at \( T \) values, returned as one of the following.

- If the model is unstratified, then \( H \) is a two-column matrix. The first column of the matrix contains \( T \) values, and the second column contains cumulative hazard rate estimates.
- If the model is stratified, then \( H \) is a \((2+k)\) column matrix, where the last \( k \) columns correspond to the stratification variables using the `Strata` name-value pair argument.

**stats — Coefficient statistics**

structure

Coefficient statistics, returned as a structure that contains the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beta</td>
<td>Coefficient estimates (same as b)</td>
</tr>
<tr>
<td>se</td>
<td>Standard errors of coefficient estimates, b</td>
</tr>
</tbody>
</table>
z-statistics for b (that is, b divided by standard error)

<table>
<thead>
<tr>
<th>z</th>
<th>p-values for b</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>Estimated covariance matrix for b</td>
</tr>
<tr>
<td>covb</td>
<td>Cox-Snell residuals</td>
</tr>
<tr>
<td>csres</td>
<td>Deviance residuals</td>

<tr>
<td>schres</td>
<td>Scaled Schoenfeld residuals</td>
</tr>
<tr>
<td>sshres</td>
<td>Score residuals</td>
</tr>
<tr>
<td>scores</td>
<td>Scaled score residuals</td>
</tr>
</tbody>
</table>

coxphfit returns the Cox-Snell, martingale, and deviance residuals as a column vector with one row per observation. It returns the Schoenfeld, scaled Schoenfeld, score, and scaled score residuals as matrices of the same size as X. Schoenfeld and scaled Schoenfeld residuals of censored data are NaNs.

Definitions

Cox Proportional Hazards Regression

Cox proportional hazards regression is a semiparametric method for adjusting survival rate estimates to remove the effect of confounding variables and to quantify the effect of predictor variables. The method represents the effects of explanatory and confounding variables as a multiplier of a common baseline hazard function, $h_0(t)$.

For a baseline relative to 0, this model corresponds to

$$h(X_i, t) = h_0(t) \exp \left( \sum_{j=1}^{p} x_{ij} b_j \right),$$

where $X_i = (x_{i1}, x_{i2}, \ldots, x_{ip})$ is the predictor variable for the $i$th subject, $h(X_i, t)$ is the hazard rate at time $t$ for $X_i$, and $h_0(t)$ is the baseline hazard rate function. The baseline hazard function is the nonparametric part of the Cox proportional hazards regression.
function, whereas the impact of the predictor variables is a loglinear regression. The assumption is that the baseline hazard function depends on time, \( t \), but the predictor variables do not depend on time. See “Cox Proportional Hazards Model” on page 14-30 for details, including the extensions for stratification and time-dependent variables, tied events, and observation weights.

References

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- \( X \) can be a single- or double-precision matrix and can be variable-size.
- The value of the 'Ties' name-value pair argument must be a compile-time constant. For example, to use Efron's method to handle tied failure times, include \{coder.Constant('Ties'),coder.Constant('efron')\} in the -args value of codegen.
- Names in name-value pair arguments must be compile-time constants.

Introduced before R2006a
createns

Create nearest neighbor searcher object

Syntax

NS = createns(X)
NS = createns(X,Name,Value)

Description

NS = createns(X) creates either an ExhaustiveSearcher or KDTreeSearcher model object using the \( n \)-by-\( K \) numeric matrix of the training data \( X \).

NS = createns(X,Name,Value) specifies additional options using one or more name-value pair arguments. For example, you can specify NSMethod to determine which type of object to create.

Examples

Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher’s iris data set.

load fisheriris
X = meas;
[n,k] = size(X)

n = 150
k = 4

\( X \) has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.
Mdl1 = ExhaustiveSearcher(X)

Mdl1 =
  ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]

Mdl1 is an ExhaustiveSearcher model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can prepare an exhaustive nearest neighbor searcher by using createns and specifying 'exhaustive' as the search method.

Mdl2 = createns(X,'NSMethod','exhaustive')

Mdl2 =
  ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]

Mdl2 is also an ExhaustiveSearcher model object, and it is equivalent to Mdl1.

To search X for the nearest neighbors to a batch of query data, pass the ExhaustiveSearcher model object and the query data to knnsearch or rangesearch.

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

load fisheriris
X = meas;
[n,k] = size(X)
\[ n = 150 \]
\[ k = 4 \]

\( X \) has 150 observations and 4 predictors.

Grow a four-dimensional \( Kd \)-tree using the entire data set as training data.

\[
\text{Mdl1} = \text{KDTreeSearcher}(X)
\]

\[
\text{Mdl1} = \text{KDTreeSearcher with properties:}
\]
\[
\begin{align*}
\text{BucketSize}: & \ 50 \\
\text{Distance}: & \ '\text{euclidean}' \\
\text{DistParameter}: & \ [] \\
\text{X}: & \ [150\times4 \text{ double}]
\end{align*}
\]

\( \text{Mdl1} \) is a \text{KDTreeSearcher} model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional \( Kd \)-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a \( Kd \)-tree by using \text{createns}.

\[
\text{Mdl2} = \text{createns}(X)
\]

\[
\text{Mdl2} = \text{KDTreeSearcher with properties:}
\]
\[
\begin{align*}
\text{BucketSize}: & \ 50 \\
\text{Distance}: & \ '\text{euclidean}' \\
\text{DistParameter}: & \ [] \\
\text{X}: & \ [150\times4 \text{ double}]
\end{align*}
\]

\( \text{Mdl2} \) is also a \text{KDTreeSearcher} model object, and it is equivalent to \( \text{Mdl1} \). Because \( X \) has four columns and the default distance metric is Euclidean, \text{createns} creates a \text{KDTreeSearcher} model by default.

To find the nearest neighbors in \( X \) to a batch of query data, pass the \text{KDTreeSearcher} model object and the query data to \text{knnsearch} or \text{rangesearch}.
Grow *K*-Tree Using Minkowski Distance Metric

Grow a *K*-tree that uses the Minkowski distance with an exponent of five.

Load Fisher's iris data set. Create a variable for the petal dimensions.

```matlab
load fisheriris
X = meas(:,3:4);
```

Grow a *K*-tree. Specify the Minkowski distance with an exponent of five.

```matlab
Mdl = createns(X,'Distance','minkowski','P',5)
```

```
Mdl =
    KDTreeSearcher with properties:
       BucketSize: 50
        Distance: 'minkowski'
    DistParameter: 5
            X: [150x2 double]
```

Because *X* has two columns and the distance metric is Minkowski, *createns* creates a *KDTreeSearcher* model object by default.

Search for Nearest Neighbors of Query Data Using Mahalanobis Distance

Create an exhaustive searcher object by using the *createns* function. Pass the object and query data to the *knnsearch* function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```matlab
rng('default');             % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis distance for finding nearest neighbors.
Mdl = createns(X,'Distance','mahalanobis')

Mdl = 
    ExhaustiveSearcher with properties:
        Distance: 'mahalanobis'
        DistParameter: [4x4 double]
        X: [145x4 double]

Because the distance metric is Mahalanobis, createns creates an
ExhaustiveSearcher model object by default.

The software uses the covariance matrix of the predictors (columns) in the training data
for computing the Mahalanobis distance. To display this value, use Mdl.DistParameter.

Mdl.DistParameter
ans = 4x4

    0.6547   -0.0368    1.2320    0.5026
-0.0368    0.1914   -0.3227   -0.1193
  1.2320   -0.3227    3.0671    1.2842
  0.5026   -0.1193    1.2842    0.5800

Find the indices of the training data (Mdl.X) that are the two nearest neighbors of each
point in the query data (Y).

IdxNN = knnsearch(Mdl,Y,'K',2)

IdxNN = 5x2

    5  6
   98  95
  104 128
  135  65
  102 115

Each row ofIdxNN corresponds to a query data observation. The column order
corresponds to the order of the nearest neighbors with respect to ascending distance. For
example, based on the Mahalanobis metric, the second nearest neighbor of Y(3,:) is
X(128,:).
**Input Arguments**

**X — Training data**

numeric matrix

Training data, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as

```Name1,Value1,...,NameN,ValueN```

Example: `NS = createns(X,'Distance','mahalanobis')` creates an ExhaustiveSearcher model object that uses the Mahalanobis distance metric when searching for nearest neighbors.

**For Exhaustive and Kd-Tree Nearest Neighbor Searchers**

**NSMethod — Nearest neighbor search method**

`'kdtree' | 'exhaustive'

Nearest neighbor search method used to define the type of object created, specified as the comma-separated pair consisting of `NSMethod` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — `createns` creates a KDTreeSearcher model object using the Kd-tree algorithm.
- `'exhaustive'` — `createns` creates an ExhaustiveSearcher model object using the exhaustive search algorithm.

The default value is `'kdtree'` when these three conditions are true:

- The number of columns of X (K) is less than or equal to 10 (that is, K ≤ 10).
- X is not sparse.
- Distance is `'euclidean'`, `'cityblock'`, `'chebychev'`, or `'minkowski'`.
Otherwise, the default value is 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

**Distance — Distance metric**

'euclidean' (default) | character vector or string scalar of distance metric name | custom distance function

Distance metric used when you call knnsearch or rangesearch to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and a character vector or string scalar of distance metric name or function handle.

For both types of nearest neighbor searchers, createns supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
</tbody>
</table>

If createns uses the exhaustive search algorithm ('NSMethod' is 'exhaustive'), then createns also supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values)</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as row vectors)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values)</td>
</tr>
</tbody>
</table>

If `createns` uses the exhaustive search algorithm ('NSMethod' is 'exhaustive'), then you can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form function `D2 = distfun(ZI,ZJ).`
- Take as arguments:
  - A 1-by-`K` vector `ZI` containing a single row from `X` or from the query points `Y`, where `K` is the number of columns in `X`.
  - An `m`-by-`K` matrix `ZJ` containing multiple rows of `X` or `Y`, where `m` is a positive integer.
  - Return an `m`-by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-16.

Example: 'Distance','minkowski'

**P — Exponent for Minkowski distance metric**

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: `single` | `double`

**For Exhaustive Nearest Neighbor Searchers**

**Cov — Covariance matrix for Mahalanobis distance metric**

`nancov(X)` (default) | positive definite matrix
Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a $K$-by-$K$ positive definite matrix, where $K$ is the number of columns in $X$. This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov',eye(3)

Data Types: single | double

**Scale** — Scale parameter value for standardized Euclidean distance metric

`nanstd(X)` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length $K$, where $K$ is the number of columns in $X$. The software scales each difference between the training and query data using the corresponding element of Scale. This argument is valid only if 'Distance' is 'seuclidean'.

Example: 'Scale',quantile(X,0.75) - quantile(X,0.25)

Data Types: single | double

**For Nearest Neighbor Searchers Using Kd-Tree**

**BucketSize** — Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer.

This argument is valid only when you create a `KDTreeSearcher` model object.

Example: 'BucketSize',10

Data Types: single | double

**Output Arguments**

**NS** — Nearest neighbor searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbor searcher, returned as an `ExhaustiveSearcher` model object or a `KDTreeSearcher` model object.
Once you create a nearest neighbor searcher model object, you can find the neighboring points in the training data to the query data by performing a nearest neighbor search using knnsearch or a radius search using rangesearch.

ExhaustiveSearcher | KDTreeSearcher | knnsearch | rangesearch

**Topics**
“k-Nearest Neighbor Search and Radius Search” on page 18-19

**Introduced in R2010a**
crosstab

Cross-tabulation

Syntax

tbl = crosstab(x1,x2)
tbl = crosstab(x1,...,xn)
[tbl,chi2,p] = crosstab(__)
[tbl,chi2,p,labels] = crosstab(__)

Description

tbl = crosstab(x1,x2) returns a cross-tabulation, tbl, of two vectors of the same length, x1 and x2.

tbl = crosstab(x1,...,xn) returns a multi-dimensional cross-tabulation, tbl, of data for multiple input vectors, x1, x2, ..., xn.

[tbl,chi2,p] = crosstab(__) also returns the chi-square statistic, chi2, and its p-value, p, for a test that tbl is independent in each dimension. You can use any of the previous syntaxes.

[tbl,chi2,p,labels] = crosstab(__) also returns a cell array, labels, which contains one column of labels for each input argument, x1 ... xn.

Examples

Cross-Tabulate Two Data Vectors

Create two sample data vectors, containing three and four distinct values, respectively.

x = [1 1 2 3 1];
y = [1 2 5 3 1];
Cross-tabulate x and y.

\[ \text{table} = \text{crosstab}(x,y) \]

\[
\begin{array}{cccc}
2 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
\end{array}
\]

The rows in \texttt{table} correspond to the three distinct values in \( x \), and the columns correspond to the four distinct values in \( y \).

**Cross-Tabulate Independent Data Vectors**

Generate two independent vectors, \( x_1 \) and \( x_2 \), each containing 50 discrete uniform random numbers in the range \( 1:3 \).

\[
\text{rng default; \hspace{1em} \% for reproducibility} \\
x_1 = \text{unidrnd}(3,50,1); \\
x_2 = \text{unidrnd}(3,50,1);
\]

Cross-tabulate \( x_1 \) and \( x_2 \).

\[ \text{[table,chi2,p]} = \text{crosstab}(x_1,x_2) \]

\[
\begin{array}{ccc}
1 & 6 & 7 \\
5 & 5 & 2 \\
11 & 7 & 6 \\
\end{array}
\]

\[ \text{chi2} = 7.5449 \]

\[ p = 0.1097 \]

The returned p value of \( 0.1097 \) indicates that, at the 5% significance level, \texttt{crosstab} fails to reject the null hypothesis that \texttt{table} is independent in each dimension.
Cross-Tabulate Grouped Data

Load the sample data, which contains measurements of large model cars during the years 1970-1982.

```matlab
load carbig
```

Cross-tabulate the data of four-cylinder cars (cyl4) based on model year (when) and country of origin (org).

```matlab
[table,chi2,p,labels] = crosstab(cyl4,when,org);
```

Use `labels` to determine the index location in `table` for the number of four-cylinder cars made in the USA during the late period of the data.

```matlab
labels
```

```matlab
labels = 3x3 cell array
    {'Other' }    {'Early'}    {'USA' }
    {'Four'    }    {'Mid'  }    {'Europe'}
    {0x0 double}    {'Late' }    {'Japan' }
```

The first column of `labels` corresponds to the data in `cyl4`, and indicates that row 2 of `table` contains data on cars with four cylinders. The second column of `labels` corresponds to the data in `when`, and indicates that column 3 of `table` contains data on cars made during the late period. The third column of `labels` corresponds to the data in `org`, and indicates that location 1 of the third dimension of `table` contains data on cars made in the USA.

Therefore, `table(2,3,1)` contains the number of four-cylinder cars made in the USA during the late period.

```matlab
table(2,3,1)
```

```matlab
ans = 38
```

The data contains 38 four-cylinder cars made in the USA during the late period.

Generate Contingency Table Using `crosstab`

Load the hospital data.
load hospital

The hospital dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine whether smoking status is independent of gender, use crosstab to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

[tbl,chi2,p,labels] = crosstab(hospital.Sex, hospital.Smoker)

tbl = 2x2

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>40</td>
<td>13</td>
</tr>
<tr>
<td>1</td>
<td>26</td>
<td>21</td>
</tr>
</tbody>
</table>

chi2 = 4.5083

p = 0.0337

labels = 2x2 cell array

{'Female'} {'0'}
{'Male'   } {'1'}

The rows of the resulting contingency table tbl correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result chi2 = 4.5083 is the value of the chi-squared test statistic for a Pearson's chi-squared test of independence. The returned value p = 0.0337 is an approximate p-value based on the chi-squared distribution.

**Input Arguments**

x1 — Input vector

vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x1, x2, ..., xn, must be the same length.
Data Types: single | double | char | string | logical

**x2 — Input vector**
vector of grouping variables

Input vector, specified as a vector of grouping variables. All input vectors, including x1, x2, ..., xn, must be the same length.

Data Types: single | double | char | string | logical

**x1, ... , xn — Input vectors**

vectors of grouping variables

Input vectors, specified as vectors of grouping variables. If you use this syntax to specify more than two input vectors, then crosstab generates a multi-dimensional cross-tabulation table. All input vectors, including x1, x2, ..., xn, must be the same length.

Data Types: single | double | char | string | logical

**Output Arguments**

**tbl — Cross-tabulation table**

matrix of integer values

Cross-tabulation table, returned as a matrix of integer values.

If you specify two input vectors, x1 and x2, then tbl is an m-by-n matrix, where m is the number of distinct values in x1 and n is the number of distinct values in x2.

If you specify three or more input vectors, then tbl(i,j,...,n) is a count of indices where grp2idx(x1) is i, grp2idx(x2) is j, grp2idx(x3) is k, and so on.

**chi2 — Chi-square statistic**

positive scalar value

Chi-square statistic, returned as a positive scalar value. The null hypothesis is that the proportion in any entry of tbl is the product of the proportions in each dimension.

**p — p-Value**

scalar value in the range [0,1]
p-value for the chi-square test statistic, returned as a scalar value in the range \([0,1]\). `crosstab` tests that `tbl` is independent in each dimension.

**labels — Data labels**

cell array

Data labels, returned as a cell array. The entries in the first column are labels for the rows of `tbl`, the entries in the second column are labels for the columns, and so on, for a multi-dimensional `tbl`.

**Algorithms**

crosstab uses `grp2idx` to assign a positive integer to each distinct value. `tbl(i,j)` is a count of indices where `grp2idx(x1)` is `i` and `grp2idx(x2)` is `j`. The numerical order of `grp2idx(x1)` and `grp2idx(x2)` order rows and columns of `tbl`, respectively.

In this case, the returned value of `tbl(i,j,...,n)` is a count of indices where `grp2idx(x1)` is `i`, `grp2idx(x2)` is `j`, `grp2idx(x3)` is `k`, and so on.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

The fourth output, `labels`, is returned as a cell array containing \( M \) unevaluated tall cell arrays, where \( M \) is the number of input grouping variables. Each unevaluated tall cell array, `labels{j}`, contains the labels for one grouping variable.

For more information, see “Tall Arrays” (MATLAB).

`grp2idx` | `tabulate`
Topics
“Grouping Variables” on page 2-57

Introduced before R2006a
crossval

Loss estimate using cross-validation

Syntax

vals = crossval(fun,X)
vals = crossval(fun,X,Y,...)
mse = crossval('mse',X,y,'Predfun',predfun)
mcr = crossval('mcr',X,y,'Predfun',predfun)
val = crossval(criterion,X1,X2,...,y,'Predfun',predfun)
vals = crossval(...,'name',value)

Description

vals = crossval(fun,X) performs 10-fold cross-validation for the function fun, applied to the data in X.

fun is a function handle to a function with two inputs, the training subset of X, XTRAIN, and the test subset of X, XTEST, as follows:

testval = fun(XTRAIN,XTEST)

Each time it is called, fun should use XTRAIN to fit a model, then return some criterion testval computed on XTEST using that fitted model.

X can be a column vector or a matrix. Rows of X correspond to observations; columns correspond to variables or features. Each row of vals contains the result of applying fun to one test set. If testval is a non-scalar value, crossval converts it to a row vector using linear indexing and stored in one row of vals.

vals = crossval(fun,X,Y,...) is used when data are stored in separate variables X, Y, ... All variables (column vectors, matrices, or arrays) must have the same number of rows. fun is called with the training subsets of X, Y, ..., followed by the test subsets of X, Y, ..., as follows:

testvals = fun(XTRAIN,YTRAIN,...,XTEST,YTEST,...)
mse = crossval('mse', X, y, 'Predfun', predfun) returns mse, a scalar containing a 10-fold cross-validation estimate of mean-squared error for the function predfun. X can be a column vector, matrix, or array of predictors. y is a column vector of response values. X and y must have the same number of rows.

predfun is a function handle called with the training subset of X, the training subset of y, and the test subset of X as follows:

yfit = predfun(XTRAIN, ytrain, XTEST)

Each time it is called, predfun should use XTRAIN and ytrain to fit a regression model and then return fitted values in a column vector yfit. Each row of yfit contains the predicted values for the corresponding row of XTEST. crossval computes the squared errors between yfit and the corresponding response test set, and returns the overall mean across all test sets.

mcr = crossval('mcr', X, y, 'Predfun', predfun) returns mcr, a scalar containing a 10-fold cross-validation estimate of misclassification rate (the proportion of misclassified samples) for the function predfun. The matrix X contains predictor values and the vector y contains class labels. predfun should use XTRAIN and YTRAIN to fit a classification model and return yfit as the predicted class labels for XTEST. crossval computes the number of misclassifications between yfit and the corresponding response test set, and returns the overall misclassification rate across all test sets.

val = crossval(criterion, X1, X2, ..., y, 'Predfun', predfun), where criterion is 'mse' or 'mcr', returns a cross-validation estimate of mean-squared error (for a regression model) or misclassification rate (for a classification model) with predictor values in X1, X2, ... and, respectively, response values or class labels in y. X1, X2, ... and y must have the same number of rows. predfun is a function handle called with the training subsets of X1, X2, ..., the training subset of y, and the test subsets of X1, X2, ..., as follows:

yfit=predfun(X1TRAIN, X2TRAIN, ..., ytrain, X1TEST, X2TEST, ...)

yfit should be a column vector containing the fitted values.

vals = crossval(..., 'name', value) specifies one or more optional parameter name/value pairs from the following table. Specify name inside single quotes.
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>holdout</td>
<td>A scalar specifying the ratio or the number of observations ( p ) for holdout cross-validation. When ( 0 &lt; p &lt; 1 ), approximately ( p*n ) observations for the test set are randomly selected. When ( p ) is an integer, ( p ) observations for the test set are randomly selected.</td>
</tr>
<tr>
<td>kfold</td>
<td>A positive integer that is greater than 1 specifying the number of folds ( k ) for ( k )-fold cross-validation.</td>
</tr>
<tr>
<td>leaveout</td>
<td>Specifies leave-one-out cross-validation. The value must be 1.</td>
</tr>
<tr>
<td>mcreps</td>
<td>A positive integer specifying the number of Monte-Carlo repetitions for validation. If the first input of crossval is ( 'mse' ) or ( 'mcr' ), crossval returns the mean of mean-squared error or misclassification rate across all of the Monte-Carlo repetitions. Otherwise, crossval concatenates the values vals from all of the Monte-Carlo repetitions along the first dimension.</td>
</tr>
<tr>
<td>partition</td>
<td>An object ( c ) of the cvpartition on page 32-1169 class, specifying the cross-validation type and partition.</td>
</tr>
<tr>
<td>stratify</td>
<td>A column vector group specifying groups for stratification. Both training and test sets have roughly the same class proportions as in group. NaNs, empty character vectors, empty strings, (&lt;\text{missing}&gt;) values, and (&lt;\text{undefined}&gt;) values in group are treated as missing data values, and the corresponding rows of the data are ignored.</td>
</tr>
</tbody>
</table>
Name | Value
--- | ---
options | A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with `statset`. Option fields:
- **UseParallel** — Set to `true` to compute in parallel. Default is `false`.
  
  You need Parallel Computing Toolbox for parallel computation.
- **UseSubstreams** — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `crossval` uses the default stream.

Only one of `kfold`, `holdout`, `leaveout`, or `partition` can be specified, and `partition` cannot be specified with `stratify`. If both `partition` and `mcreps` are specified, the first Monte-Carlo repetition uses the partition information in the `cvpartition` object, and the `repartition` method is called to generate new partitions for each of the remaining repetitions. If no cross-validation type is specified, the default is 10-fold cross-validation.

**Note** When using cross-validation with classification algorithms, stratification is preferred. Otherwise, some test sets may not include observations from all classes.

### Examples

#### Example 1

Compute mean-squared error for regression using 10-fold cross-validation:

```matlab
load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
```
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'predfun',regf)
cvMse =
  0.1015

Example 2

Compute misclassification rate using stratified 10-fold cross-validation:

load('fisheriris');
y = species;
X = meas;
cp = cvpartition(y,'k',10); % Stratified cross-validation

classf = @(XTRAIN, ytrain,XTEST)(classify(XTEST,XTRAIN,...
ytrain));

cvMCR = crossval('mcr',X,y,'predfun',classf,'partition',cp)
cvMCR =
  0.0200

Example 3

Compute the confusion matrix using stratified 10-fold cross-validation:

load('fisheriris');
y = species;
X = meas;
order = unique(y); % Order of the group labels
cp = cvpartition(y,'k',10); % Stratified cross-validation

f = @(xtr,ytr,xte,yte)confusionmat(yte,...
classify(xte,xtr,ytr),'order',order);

cfMat = crossval(f,X,y,'partition',cp);
cfMat = reshape(sum(cfMat),3,3)
cfMat =
   50     0     0
    0    48     2
    0     1    49

cfMat is the summation of 10 confusion matrices from 10 test sets.
References

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Topics
“Grouping Variables” on page 2-57

Introduced in R2008a
crossval

Class: ClassificationDiscriminant

Cross-validated discriminant analysis classifier

Syntax

cvmodel = crossval(obj)
cvmodel = crossval(obj,Name,Value)

Description

cvmodel = crossval(obj) creates a partitioned model from obj, a fitted discriminant analysis classifier. By default, crossval uses 10-fold cross validation on the training data to create cvmodel.

cvmodel = crossval(obj,Name,Value) creates a partitioned model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using fitcdiscr.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
CVPartition

Object of class cvpartition, created by the cvpartition function. crossval splits the data into subsets with cvpartition.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: []

Holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: []

KFold

Number of folds to use in a cross-validated classifier, a positive integer value greater than 1.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Default: 10

Leaveout

Set to 'on' for leave-one-out cross validation.

Use only one of these options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Examples

Create a classification model for the Fisher iris data, and then create a cross-validation model. Evaluate the quality the model using kfoldLoss.

load fisheriris
obj = fitcdiscr(meas,species);
cvmodel = crossval(obj);
L = kfoldLoss(cvmodel)
L = 0.0200

**Tips**

- Assess the predictive performance of `obj` on cross-validated data using the “kfold” methods and properties of `cvmode`, such as `kfoldLoss`.

**Alternatives**

You can create a cross-validation classifier directly from the data, instead of creating a discriminant analysis classifier followed by a cross-validation classifier. To do so, include one of these options in `fitcdiscr`: 'CrossVal', 'CVP', 'Holdout', 'K', or 'Leaveout'.

**See Also**

crossval|fitcdiscr|kfoldEdge|kfoldLoss|kfoldMargin|kfoldPredict|kfoldfun

**Topics**

“Discriminant Analysis Classification” on page 20-2
crossval

**Class:** ClassificationECOC

Cross-validate multiclass, error-correcting output codes model

**Syntax**

CVMdl = crossval(Mdl)
CVMdl = crossval(Mdl,Name,Value)

**Description**

CVMdl = crossval(Mdl) returns a cross-validated (partitioned), multiclass, error-correcting output codes (ECOC) model (CVMdl) from a trained ECOC model (Mdl).

By default, crossval uses 10-fold cross validation on the training data to create CVMdl.

CVMdl = crossval(Mdl,Name,Value) returns a partitioned ECOC model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the number of folds or a holdout sample proportion.

**Input Arguments**

Mdl — Multiclass ECOC model
ClassificationECOC model

Multiclass ECOC model, specified as a ClassificationECOC model returned by fitcecoc.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps.
1 Randomly partition the data into \( k \) sets.
2 For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.
3 Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the \texttt{Trained} property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: \texttt{CVPartition}, \texttt{Holdout}, \texttt{KFold}, or \texttt{Leaveout}.

Example: \texttt{'}KFold',5\texttt{'}

Data Types: \texttt{single} | \texttt{double}

**Leaveout — Leave-one-out cross-validation flag**

\texttt{'}off' (default) | \texttt{'}on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of \texttt{'}Leaveout' and \texttt{'}on'} or \texttt{'}off'\texttt{'.} If you specify \texttt{'}Leaveout','on'}, then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the \texttt{NumObservations} property of the model), the software completes these steps:

1 Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.
2 Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the \texttt{Trained} property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: \texttt{CVPartition}, \texttt{Holdout}, \texttt{KFold}, or \texttt{Leaveout}.

Example: \texttt{'}Leaveout','on'}

**Options — Estimation options**

\texttt{[]} (default) | structure array returned by \texttt{statset}

Estimation options, specified as the comma-separated pair consisting of \texttt{'}Options'} and a structure array returned by \texttt{statset}.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify \texttt{'}Options'}, \texttt{statset('UseParallel',1)}. 

32-1095
Output Arguments

CVMdl — Cross-validated ECOC model
ClassificationPartitionedECOC model

Cross-validated ECOC model, returned as a ClassificationPartitionedECOC model.

Examples

Cross-Validate ECOC Classifier

Load Fisher's iris data set. Specify the predictor data X and the response data Y.

load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility

Create an SVM template, and standardize the predictors.

t = templateSVM('Standardize',1)

t =
Fit template for classification SVM.

    Alpha: [0x1 double]
    BoxConstraint: []
    CacheSize: []
    CachingMethod: ''
    ClipAlphas: []
    DeltaGradientTolerance: []
    Epsilon: []
    GapTolerance: []
    KKTolerance: []
    IterationLimit: []
    KernelFunction: ''
    KernelScale: []
    KernelOffset: []
    KernelPolynomialOrder: []
    NumPrint: []
    Nu: []
t is an SVM template. Most of the template object's properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```matlab
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate Mdl using 10-fold cross-validation.

```matlab
CVMdl = crossval(Mdl);
```

CVMdl is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the classification error.

```matlab
loss = kfoldLoss(CVMdl)
```

loss = 0.0400

The classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

**Cross Validate an ECOC Classifier Using Parallel Computing**

Consider the arrhythmia data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia,
and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia.

Train an ECOC classifier with a custom coding design specified by the description of the classes.

Load the arrhythmia data set.

```matlab
load arrhythmia
Y = categorical(Y);
K = unique(Y); % Number of distinct classes

Construct a coding matrix that describes the nature of the classes.

```matlab
OrdMat = designecoc(11,'ordinal');
nOM = size(OrdMat);
class1VSOrd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VSOrd class1VSClass16 OrdVSClass16; ...
        zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))];
```

Train an ECOC classifier using the custom coding design (Coding) and parallel computing. Specify to use an ensemble of 50 classification trees boosted using GentleBoost.

```matlab
t = templateEnsemble('GentleBoost',50,'Tree');
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learners',t,'Options',options);
```

Mdl is a ClassificationECOC model. You can access its properties using dot notation.

Cross validate Mdl using 8-fold cross validation and parallel computing.

```matlab
rng(1); % For reproducibility
CVMdl = crossval(Mdl,'Options',options,'KFold',8);
```

Warning: One or more folds do not contain points from all the groups.

Since some of the classes have low relative frequency, some of the folds do not train using observations from those classes. CVMdl is a ClassificationPartitionedECOC cross-validated ECOC model.

Estimate the generalization error using parallel computing.
The out-of-sample classification error is 32%, which indicates that this model does not generalize well. To improve the model, try training using a different boosting method, such as RobustBoost, or a different algorithm altogether, such as SVM.

**Tips**

Assess the predictive performance of Mdl on cross-validated data using the kfold functions and properties of CVMdl, such as kfoldLoss.

**Alternatives**

Instead of training an ECOC model and then cross validating it, you can create a cross-validated ECOC model directly using fitcecoc and by specifying any of these name-value pair arguments: CrossVal, CVPartition, Holdout, Leaveout, or KFold.

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel', true)

For more information, see the 'Options' name-value pair argument.

crossval

Cross validate ensemble

Syntax

cvens = crossval(ens)
cvens = crossval(ens,Name,Value)

Description

cvens = crossval(ens) creates a cross-validated ensemble from ens, a classification ensemble. Default is 10-fold cross validation.

cvens = crossval(ens,Name,Value) creates a cross-validated ensemble with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

ens

A classification ensemble created with fitcensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

cvpartition

A partition of class cvpartition. Sets the partition for cross validation.
Use no more than one of the name-value pairs cvpartition, holdout, kfold, or leaveout.

**holdout**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**kfold**

Number of folds for cross validation, a numeric positive scalar greater than 1.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**leaveout**

If 'on', use leave-one-out cross validation.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**nprint**

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

**Default:** 'off', meaning no printout

**Output Arguments**

**cvens**

A cross-validated classification ensemble of class ClassificationPartitionedEnsemble.
Examples

Cross-Validate Classification Ensemble

Create a cross-validated classification model for the Fisher iris data, and assess its quality using the kfoldLoss method.

Load the Fisher iris data set.

load fisheriris

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);

Create a cross-validated ensemble from ens and find the classification error averaged over all folds.

rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)

L = 0.0467

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in fitcensemble: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

See Also
ClassificationPartitionedEnsemble | cvpartition
**crossval**

Cross-validated k-nearest neighbor classifier

**Syntax**

\[
\text{cvmodel} = \text{crossval}(\text{mdl})
\]
\[
\text{cvmodel} = \text{crossval}(\text{mdl},\text{Name},\text{Value})
\]

**Description**

\[
\text{cvmodel} = \text{crossval}(\text{mdl})\] creates a cross-validated (partitioned) model from \(\text{mdl}\), a fitted KNN classification model. By default, \text{crossval} uses 10-fold cross-validation on the training data to create \text{cvmodel}, a ClassificationPartitionedModel object.

\[
\text{cvmodel} = \text{crossval}(\text{mdl},\text{Name},\text{Value})\] creates a partitioned model with additional options specified by one or more name-value pair arguments. For example, specify \'Leaveout\',\'on\' for leave-one-out cross-validation.

**Examples**

**Cross-Validated k-Nearest Neighbor Model**

Create a cross-validated k-nearest neighbor model, and assess classification performance using the model.

Load the Fisher iris data set.

load fisheriris
\[
\text{X} = \text{meas};
\]
\[
\text{Y} = \text{species};
\]

Create a classifier for nearest neighbors.

\[
\text{mdl} = \text{fitcknn}(\text{X},\text{Y});
\]
Create a cross-validated classifier.

`cvmdl = crossval(mdl)`

```matlab
cvmdl = 
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'KNN'
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

Find the cross-validated loss of the classifier.

`cvmdlloss = kfoldLoss(cvmdl)`

`cvmdlloss = 0.0467`

The cross-validated loss is less than 5%. You can expect `mdl` to have a similar error rate.

**Input Arguments**

`mdl` — *k*-nearest neighbor classifier model
ClassificationKNN object

`k`-nearest neighbor classifier model, specified as a `ClassificationKNN` object.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. 
Example: `crossval.mdl,'KFold',5)` creates a partitioned model with 5-fold cross-validation.

**CVP** — Cross-validation partition

`[]` (default) | `cvpartition` object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVP' and a `cvpartition` object created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: 'CVP', 'Holdout', 'KFold', or 'Leaveout'.

**Holdout** — Fraction of data for holdout validation

Scalar value in the range $$(0,1)$$

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range $$(0,1)$$. Use only one of these four options at a time: 'CVP', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Holdout', 0.3

Data Types: `single` | `double`

**KFold** — Number of folds

10 (default) | Positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. Use only one of these four options at a time: 'CVP', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'KFold', 3

Data Types: `single` | `double`

**Leaveout** — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.
Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout', 'on'

**Tips**

- Assess the predictive performance of mdl on cross-validated data by using the “kfold” methods and properties of cvmodel, such as kfoldLoss.

**Alternative Functionality**

You can create a cross-validated model directly from the data instead of creating a model followed by a cross-validated model. To do so, specify one of these options in fitcknn: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval

Class: ClassificationNaiveBayes

Cross-validated naive Bayes classifier

Syntax

CVMdl = crossval(Mdl)
CVMdl = crossval(Mdl,Name,Value)

Description

CVMdl = crossval(Mdl) returns a partitioned naive Bayes classifier (CVMdl) from a trained naive Bayes classifier (Mdl).

By default, crossval uses 10-fold cross validation on the training data to create CVMdl.

CVMdl = crossval(Mdl,Name,Value) returns a partitioned naive Bayes classifier with additional options specified by one or more Name,Value pair arguments.

For example, you can specify a holdout sample proportion.

Input Arguments

Mdl — Fully trained naive Bayes classifier
ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by fitcnb.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CVP** — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVP' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVP', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVP', cvp.

**Holdout** — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve \( p \times 100\% \) of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVP, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold** — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps.
Randomly partition the data into \( k \) sets. For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets. Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.
2. Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Output Arguments**

**CVMdl — Cross-validated naive Bayes classifier**

ClassificationPartitionedModel model

Cross-validated naive Bayes classifier, returned as a ClassificationPartitionedModel model.
Examples

Cross Validate a Naive Bayes Classifier Using crossval

Load the ionosphere data set.

```matlab
load ionosphere
X = X(:,3:end);  % Remove first two predictors for stability
rng(1);         % For reproducibility
```

Train a naive Bayes classifier. It is good practice to define the class order. Assume that each predictor is conditionally, normally distributed given its label.

```matlab
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```matlab
CVMdl = crossval(Mdl)
```

CVMdl = classreg.learning.partition.ClassificationPartitionedModel

```matlab
CrossValidatedModel: 'NaiveBayes'
PredictorNames: {1x32 cell}
ResponseName: 'Y'
NumObservations: 351
KFold: 10
Partition: [1x1 cvpartition]
ClassNames: {'b' 'g'}
ScoreTransform: 'none'
```

Properties, Methods

```matlab
FirstModel = CVMdl.Trained{1}
```

FirstModel = classreg.learning.classif.CompactClassificationNaiveBayes

```matlab
ResponseName: 'Y'
CategoricalPredictors: []
```
CVMdl is a `ClassificationPartitionedModel` cross-validated classifier. The software:

1. Randomly partitions the data into 10, equally sized sets.
2. Trains a naive Bayes classifier on nine of the sets.
3. Repeats steps 1 and 2 $k = 10$ times. It excludes one partition each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationNaiveBayes` model.

You can estimate the generalization error by passing `CVMdl` to `kfoldLoss`.

Specify a Holdout-Sample Proportion for Naive Bayes Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate a naive Bayes classifier. You have several other options, such as specifying a different number of folds or holdout-sample proportion. This example shows how to specify a holdout-sample proportion.

Load the `ionosphere` data set.

```matlab
load ionosphere
X = X(:,3:end); % Remove first two predictors for stability
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Assume that each predictor is conditionally, normally distributed given its label. It is good practice to define the class order.

```matlab
Mdl = fitcnb(X,Y,'ClassNames',{'b','g'});
```
Mdl is a trained ClassificationNaiveBayes classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 30% holdout sample.

```matlab
CVMdl = crossval(Mdl,'Holdout',0.30)
```

CVMdl is a ClassificationPartitionedModel. TrainedModel is a CompactClassificationNaiveBayes classifier trained using 70% of the data.

Estimate the generalization error.

```matlab
kfoldLoss(CVMdl)
```

ans = 0.2571
The out-of-sample misclassification error is approximately 2.6%.

**Tips**

Assess the predictive performance of `Mdl` on cross-validated data using the “kfold” function and properties of `CVMdl`, such as `kfoldLoss`.

**Alternatives**

Instead of creating a naive Bayes classifier followed by a cross-validation classifier, create a cross-validated classifier directly using `fitcnb` and by specifying any of these name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Leaveout'`, or `'KFold'`.

**See Also**

`ClassificationNaiveBayes` | `ClassificationPartitionedModel` | `CompactClassificationNaiveBayes` | `fitcnb` | `kfoldLoss`
crossval

Cross-validate support vector machine (SVM) classifier

Syntax

CVSVMModel = crossval(SVMModel)
CVSVMModel = crossval(SVMModel,Name,Value)

Description

CVSVMModel = crossval(SVMModel) returns a cross-validated (partitioned) support vector machine (SVM) classifier (CVSVMModel) from a trained SVM classifier (SVMModel). By default, crossval uses 10-fold cross-validation on the training data to create CVSVMModel, a ClassificationPartitionedModel classifier.

CVSVMModel = crossval(SVMModel,Name,Value) returns a partitioned SVM classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or holdout sample proportion.

Examples

Cross-Validate SVM Classifier

Load the ionosphere data set.

load ionosphere
rng(1); % For reproducibility

Train an SVM classifier. Standardize the predictor data and specify the order of the classes.

SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});

SVMModel is a trained ClassificationSVM classifier. 'b' is the negative class and 'g' is the positive class.
Cross-validate the classifier using 10-fold cross-validation.

CVSVMModel = crossval(SVMModel)

CVSVMModel = 
    classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'

Properties, Methods

FirstModel = CVSVMModel.Trained{1}

FirstModel = 
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    Alpha: [78x1 double]
    Bias: -0.2209
    KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
    SupportVectors: [78x34 double]
    SupportVectorLabels: [78x1 double]

Properties, Methods

CVSVMModel is a ClassificationPartitionedModel cross-validated classifier. During cross-validation, the software completes these steps:

1  Randomly partition the data into 10 sets of equal size.
2  Train an SVM classifier on nine of the sets.
3 Repeat steps 1 and 2 \( k = 10 \) times. The software leaves out one partition each time and trains on the other nine partitions.

4 Combine generalization statistics for each fold.

FirstModel is the first of the 10 trained classifiers. It is a CompactClassificationSVM classifier.

You can estimate the generalization error by passing CVSVMModel to kfoldLoss.

**Specify Holdout Sample Proportion for SVM Cross-Validation**

Specify a holdout sample proportion for cross-validation. By default, crossval uses 10-fold cross-validation to cross-validate an SVM classifier. However, you have several other options for cross-validation. For example, you can specify a different number of folds or holdout sample proportion.

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```matlab
SVMMModel = fitcsvm(X,Y, 'Standardize',true,'ClassNames',{'b','g'});
```

SVMMModel is a trained ClassificationSVM classifier.

Cross-validate the classifier by specifying a 15% holdout sample.

```matlab
CVSVMModel = crossval(SVMMModel,'Holdout',0.15)
```

CVSVMModel =
```
classreg.learning.partition.ClassificationPartitionedModel
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 1
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```
Properties, Methods

**CVSVMModel** is a *ClassificationPartitionedModel*.

Display properties of the classifier trained using 85% of the data.

```matlab
TrainedModel = CVSVMModel.Trained{1}
```

```matlab
TrainedModel =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
        Alpha: [74x1 double]
        Bias: -0.2952
        KernelParameters: [1x1 struct]
            Mu: [1x34 double]
            Sigma: [1x34 double]
        SupportVectors: [74x34 double]
        SupportVectorLabels: [74x1 double]
```

Properties, Methods

**TrainedModel** is a *CompactClassificationSVM* classifier trained using 85% of the data.

Estimate the generalization error.

```matlab
kfoldLoss(CVSVMModel)
```

```matlab
ans = 0.0769
```

The out-of-sample misclassification error is approximately 8%.
**Input Arguments**

**SVMModel** — Full, trained SVM classifier

*ClassificationSVM* classifier

Full, trained SVM classifier, specified as a *ClassificationSVM* model trained with *fitcsvm*.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name, Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as

```
Name1,Value1,...,NameN,ValueN
```

Example: `crossval(SVMModel,'KFold',5)` specifies using five folds in a cross-validated model.

**CVPartition** — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of

'CVPartition' and a *cvpartition* partition object as created by *cvpartition*. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout** — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', *p*, then the software completes these steps:

1. Randomly select and reserve *p*\*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps.

1 Randomly partition the data into `k` sets.
2 For each set, reserve the set as validation data, and train the model using the other `k - 1` sets.
3 Store the `k` compact, trained models in the cells of a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the `n` observations (where `n` is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1 Reserve the observation as validation data, and train the model using the other `n - 1` observations.
2 Store the `n` compact, trained models in the cells of an `n`-by-1 cell vector in the `Trained` property of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

Tips

Assess the predictive performance of SVMModel on cross-validated data by using the “kfold” methods and properties of CVSVMModel, such as kfoldLoss.

Alternative Functionality

Instead of training an SVM classifier and then cross-validating it, you can create a cross-validated classifier directly by using fitcsvm and specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

Introduced in R2014a
crossval

Class: ClassificationTree
Cross-validated decision tree

Syntax

cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)

Description

cvmodel = crossval(model) creates a partitioned model from model, a fitted classification tree. By default, crossval uses 10-fold cross validation on the training data to create cvmodel.

cvmodel = crossval(model,Name,Value) creates a partitioned model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

model
A classification model, produced using fitctree.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

CVPartition — Cross-validation partition
[] (default) | cvpartition object
Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object created by the cvpartition function. crossval splits the data into subsets with cvpartition.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Holdout — Fraction of data for holdout validation**
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1).

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Holdout', 0.3
Data Types: single | double

**KFold — Number of folds**
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'KFold', 3
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**
'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.

Use only one of these four options at a time: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout', 'on'
**Output Arguments**

`cvm` — Partitioned model
ClassificationPartitionedModel object

Partitioned model, returned as a `ClassificationPartitionedModel` object.

**Examples**

**Create a Cross-Validation Model**

Create a classification model for the ionosphere data, then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```matlab
load ionosphere
tree = fitctree(X,Y);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```matlab
L = 0.1111
```

**Tips**

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvm`, such as `kfoldLoss`.

**Alternatives**

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitctree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.
See Also
crossval | fitctree
crossval

Cross validate ensemble

Syntax

cvens = crossval(ens)
cvens = crossval(ens,Name,Value)

Description

cvens = crossval(ens) creates a cross-validated ensemble from ens, a regression ensemble. Default is 10-fold cross validation.

cvens = crossval(ens,Name,Value) creates a cross-validated ensemble with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

ens

A regression ensemble created with fitrensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

cvpartition

A partition of class cvpartition. Sets the partition for cross validation.
Use no more than one of the name-value pairs `cvguchi`, `holdout`, `kfold`, and `leaveout`.

**holdout**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'kfold', 'holdout', 'leaveout', or 'cvguchi'.

**kfold**

Number of folds for cross validation, a positive integer value greater than 1.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvguchi'.

**leaveout**

If 'on', use leave-one-out cross-validation.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvguchi'.

**nprint**

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

**Default**: 'off', meaning no printout

**Output Arguments**

**cvens**

A cross-validated classification ensemble of class `RegressionPartitionedEnsemble`. 
Examples

Create Cross-Validated Regression Model

Create a cross-validated regression model for the carsmall data, and evaluate its quality using the kfoldLoss method.

Load the carsmall data set and select acceleration, displacement, horsepower, and vehicle weight as predictors.

```matlab
load carsmall;
X = [Acceleration Displacement Horsepower Weight];
```

Train a regression ensemble.

```matlab
rens = fitrensemble(X,MPG);
```

Create a cross-validated ensemble from rens and find the cross-validation loss.

```matlab
rng(10,'twister') % For reproducibility
cvens = crossval(rens);
L = kfoldLoss(cvens)
L = 31.8744
```

Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in fitrensemble: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

See Also
RegressionPartitionedEnsemble | cvpartition | kfoldLoss
crossval

**Class:** RegressionGP

Cross-validate Gaussian process regression model

**Syntax**

```matlab
cvMdl = crossval(gprMdl)
cvmdl = crossval(gprMdl,Name,Value)
```

**Description**

`cvMdl = crossval(gprMdl)` returns the partitioned model, `cvMdl`, built from the Gaussian process regression (GPR) model, `gprMdl`, using 10-fold cross validation.

`cvmdl` is a `RegressionPartitionedModel` object, and `gprMdl` is a `RegressionGP` (full) object.

`cvmdl = crossval(gprMdl,Name,Value)` returns the partitioned model, `cvmdl`, with additional options specified by one or more `Name`, `Value` pair arguments. For example, you can specify the number of folds or the fraction of the data to use for testing.

**Input Arguments**

`gprMdl` — Gaussian process regression model
RegressionGP object

Gaussian process regression model, specified as a `RegressionGP` (full) object. You cannot call `crossval` on a compact regression object.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

32-1129
You can specify several name and value pair arguments in any order as 
Name1,Value1,...,NameN,ValueN.

**CVPartition — Random partition for a k-fold cross validation**
cvpartition object

Random partition for a k-fold cross validation, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object.

Example: 'CVPartition', cvp uses the random partition defined by cvp.

If you specify CVPartition, then you cannot specify Holdout, KFold, or LeaveOut.

**Holdout — Fraction of data to use for testing**
scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p, then crossval:
1. Randomly reserves p*100% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in cvgprMdl.Trained.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify Holdout, then you cannot specify CVPartition, KFold, or Leaveout.

Data Types: single | double

**KFold — Number of folds**
10 (default) | positive integer value greater than 1

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. Kfold must be greater than 1. If you specify 'Kfold', k then crossval:
1. Randomly partitions the data into k sets.
2. For each set, reserves the set as test data, and trains the model using the other k - 1 sets.
3. Stores the k compact, trained models in the cells of a k-by-1 cell array in cvgprMdl.Trained.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, it uses that fold as test data, and trains the model on the remaining 4 folds.
If you specify KFold, then you cannot specify CVPartition, Holdout, or Leaveout.

Data Types: single | double

**Leaveout — Indicator for leave-one-out cross-validation**

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'LeaveOut' and either 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the n observations, crossval:
1. Reserves the observation as test data, and trains the model using the other n - 1 observations.
2. Stores the n compact, trained models in the cells of a n-by-1 cell array in cvgprMdl.Trained.

Example: 'Leaveout','on'

If you specify Leaveout, then you cannot specify CVPartition, Holdout, or KFold.

**Output Arguments**

cvgprMdl — Partitioned Gaussian process regression model
RegressionPartitionedModel object

Partitioned Gaussian process regression model, returned as a RegressionPartitionedModel object.

**Examples**

**Partition Data for Cross-Validation**

Download the housing data [1], from the UCI Machine Learning Repository [4].

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);

Fit a GPR model using the squared exponential kernel function with separate length scale for each predictor. Standardize the predictor variables.

gprMdl = fitrgp(X,y,'KernelFunction','ardsquaredexponential','Standardize',1);

Create a cross-validation partition for data using predictor 4 as a grouping variable.

rng('default') % For reproducibility
cvp = cvpartition(X(:,4),'kfold',10);

Create a 10-fold cross-validated model using the partitioned data in cvp.

cvgprMdl = crossval(gprMdl,'CVPartition',cvp);

Compute the regression loss for in-fold observations using models trained on out-of-fold observations.

L = kfoldLoss(cvgprMdl)

L =
    9.5299

Predict the response for in-fold observations, i.e. observations not used for training.

ypred = kfoldPredict(cvgprMdl);

For every fold, kfoldPredict predicts responses for observations in that fold using the models trained on out-of-fold observations.

Plot the actual responses and prediction data.

plot(y,'r.');
hold on;
plot(ypred,'b--.);
axis([0 510 -15 65]);
legend('True response','GPR prediction','Location','Best');
hold off;
Train GPR Model Using 4-Fold Cross Validation

Download the abalone data [2], [3], from the UCI Machine Learning Repository [4] and save it in your current directory with the name ‘abalone.data’.

Read the data into a table.

tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);

The dataset has 4177 observations. The goal is to predict the age of abalone from 8 physical measurements.

Fit a GPR model using the subset of regressors (sr) method for parameter estimation and fully independent conditional (fic) method for prediction. Standardize the predictors and use a squared exponential kernel function with a separate length scale for each predictor.

gprMdl = fitrgp(tbl,tbl(:,end),'KernelFunction','ardsquaredexponential',... 'FitMethod','sr','PredictMethod','fic','Standardize',1);

Cross-validate the model using 4-fold cross validation. This partitions the data into 4 sets. For each set, fitrgp uses that set (25% of the data) as the test data, and trains the model on the remaining 3 sets (75% of the data).
rng('default') % For reproducibility
cvgprMdl = crossval(gprMdl,'KFold',4);

Compute the loss over individual folds.

L = kfoldLoss(cvgprMdl,'mode','individual')

L =
    4.3669
    4.6896
    4.0565
    4.3162

Compute the average cross-validated loss on over all folds. The default is the mean squared error.

L2 = kfoldLoss(cvgprMdl)

L2 =
    4.3573

This is equal to the mean loss over individual folds.

mse = mean(L)

mse =
    4.3573

Tips

- You can only use one of the name-value pair arguments at a time.
- You cannot compute the prediction intervals for a cross-validated model.

Alternatives

Alternatively, you can train a cross-validated model using the related name-value pair arguments in fitrgp.
If you supply a custom 'ActiveSet' in the call to \texttt{fitrgp}, then you cannot cross validate the GPR model.

“Train GPR Model Using Cross-Validation” on page 32-2252

**Introduced in R2015b**
crossval

Class: RegressionSVM

Cross-validated support vector machine regression model

Syntax

CVMdl = crossval(mdl)
CVMdl = crossval(mdl,Name,Value)

Description

CVMdl = crossval(mdl) returns a cross-validated (partitioned) support vector machine regression model, CVMdl, from a trained SVM regression model, mdl.

CVMdl = crossval(mdl,Name,Value) returns a cross-validated model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

mdl — Full, trained SVM regression model
RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by fitrsvm.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
CVPartition — Cross-validation partition

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

Holdout — Fraction of data for holdout validation

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1 Randomly partition the data into k sets.
For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.

Store the $k$ compact, trained models in the cells of a $k$-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold', 5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the $n$ observations (where $n$ is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
2. Store the $n$ compact, trained models in the cells of an $n$-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Output Arguments**

**CVMdl — Cross-validated SVM regression model**

RegressionPartitionedSVM model

Cross-validated SVM regression model, returned as a RegressionPartitionedSVM model.
Examples

Train Cross-Validated SVM Regression Model Using crossval

This example shows how to train a cross-validated SVM regression model using crossval.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name 'abalone.data'. Read the data into a table.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
 rng default  % for reproducibility
```

The sample data contains 4177 observations. All the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```matlab
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale',2.2,'Standardize',true);
mdl
```

`mdl` is a trained RegressionSVM regression model.

Cross validate the model using 10-fold cross validation.

```matlab
CVMdl = crossval(mdl)
CVMdl =
```

```matlab
classreg.learning.partition.RegressionPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 10
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```
Properties, Methods

CVMdl is a RegressionPartitionedSVM cross-validated regression model. The software:

1. Randomly partitions the data into 10 equally sized sets.
2. Trains an SVM regression model on nine of the 10 sets.
3. Repeats steps 1 and 2 \( k = 10 \) times. It leaves out one of the partitions each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

Calculate the resubstitution loss for the cross-validated model.

```matlab
loss = kfoldLoss(CVMdl)
loss =
    4.5712
```

Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name 'abalone.data'. Read the data into a table.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  \% for reproducibility
```

The sample data contains 4177 observations. All the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true);

mdl is a trained RegressionSVM regression model.

Cross validate the regression model by specifying a 10% holdout sample.

CVMdl = crossval(mdl,'Holdout',0.1)

CVMdl =

    classreg.learning.partition.RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
    PredictorNames: {1x8 cell}
    CategoricalPredictors: 1
    ResponseName: 'Var9'
    NumObservations: 4177
    KFold: 1
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'

Properties, Methods

CVMdl is a RegressionPartitionedSVM model object.

Calculate the resubstitution loss for the cross-validated model.

loss = kfoldLoss(CVMdl)

loss =

    5.2499

Alternatives

Instead of training an SVM regression model and then cross-validating it, you can create a cross-validated model directly by using fitrsvm and specifying any of these name-value pair arguments: 'CrossVal','CVPartition','Holdout','Leaveout', or 'KFold'.

Introduced in R2015b
crossval

Class: RegressionTree

Cross-validated decision tree

Syntax

cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)

Description

cvmodel = crossval(model) creates a partitioned model from model, a fitted regression tree. By default, crossval uses 10-fold cross validation on the training data to create cvmodel.

cvmodel = crossval(model,Name,Value) creates a partitioned model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

model

A regression model, produced using fitrtree.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
**CVPARTITION**

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: []

**Holdout**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**KFold**

Number of folds to use in a cross-validated tree, a positive integer value greater than 1.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: 10

**Leaveout**

Set to 'on' for leave-one-out cross-validation.

**Output Arguments**

cvmodel

A partitioned model of class `RegressionPartitionedModel`.

**Examples**
Cross-Validate Regression Tree

Load the carsmall data set. Consider Acceleration, Displacement, Horsepower, and Weight as predictor variables.

load carsmall
X = [Acceleration Displacement Horsepower Weight];

Grow a regression tree using the entire data set.

Mdl = fitrtree(X,MPG);

Mdl is a RegressionTree model.

Cross-validate the regression tree using 10-fold cross-validation.

CVMdl = crossval(Mdl);

CVMdl is a RegressionPartitionedModel cross-validated model. crossval stores the ten trained, compact regression trees in the Trained property of CVMdl.

Display the compact regression tree that crossval trained using all observations except those in the first fold.

CVMdl.Trained{1}

ans =
    classreg.learning.regr.CompactRegressionTree
    PredictorNames: {'x1'  'x2'  'x3'  'x4'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'

Estimate the generalization error of Mdl by computing the 10-fold cross-validated mean-squared error.

L = kfoldLoss(CVMdl)

L = 23.8065
Tips

• Assess the predictive performance of model on cross-validated data using the “kfold” methods and properties of cvmodel, such as kfoldLoss.

Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in fitrtree: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

See Also
crossval | fitrtree
cutcategories

Class: classregtree

(Removed) Cut categories

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

\[
C = \text{cutcategories}(t) \\
C = \text{cutcategories}(t,\text{nodes})
\]

Description

\(C = \text{cutcategories}(t)\) returns an \(n\)-by-2 cell array \(C\) of the categories used at branches in the decision tree \(t\), where \(n\) is the number of nodes. For each branch node \(i\) based on a categorical predictor variable \(x\), the left child is chosen if \(x\) is among the categories listed in \(C\{i,1\}\), and the right child is chosen if \(x\) is among those listed in \(C\{i,2\}\). Both columns of \(C\) are empty for branch nodes based on continuous predictors and for leaf nodes.

\(C = \text{cutcategories}(t,\text{nodes})\) takes a vector \(\text{nodes}\) of node numbers and returns the categories for the specified nodes.

References

See Also
classregtree | cutpoint | cuttype | cutvar
cutpoint

Class: classregtree

(Removed) Decision tree cut point values

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[ v = \text{cutpoint}(t) \]
\[ v = \text{cutpoint}(t,\text{nodes}) \]

**Description**

\[ v = \text{cutpoint}(t) \] returns an \( n \)-element vector \( v \) of the values used as cut points in the decision tree \( t \), where \( n \) is the number of nodes. For each branch node \( i \) based on a continuous predictor variable \( x \), the left child is chosen if \( x < v(i) \) and the right child is chosen if \( x \geq v(i) \). \( v \) is NaN for branch nodes based on categorical predictors and for leaf nodes.

\[ v = \text{cutpoint}(t,\text{nodes}) \] takes a vector \( \text{nodes} \) of node numbers and returns the cut points for the specified nodes.

**References**

**See Also**

classregtree | cutcategories | cuttype | cutvar
cuttype

**Class:** classregtree

(Removed) Cut types

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[
c = \text{cuttype}(t)
\]

\[
c = \text{cuttype}(t,nodes)
\]

**Description**

\(c = \text{cuttype}(t)\) returns an \(n\)-element cell array \(c\) indicating the type of cut at each node in the tree \(t\), where \(n\) is the number of nodes. For each node \(i\), \(c\{i\}\) is:

- **'continuous'** — If the cut is defined in the form \(x < v\) for a variable \(x\) and cut point \(v\).
- **'categorical'** — If the cut is defined by whether a variable \(x\) takes a value in a set of categories.
- **''** — If \(i\) is a leaf node.

\text{cutvar} \text{returns the cut points for 'continuous' cuts, and cutcategories returns the set of categories.}

\(c = \text{cuttype}(t,nodes)\) takes a vector \(nodes\) of node numbers and returns the cut types for the specified nodes.

classregtree | cutcategories | cutvar | numnodes
cutvar

Class: classregtree

(Removed) Cut variable names

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[ v = \text{cutvar}(t) \]
\[ v = \text{cutvar}(t, \text{nodes}) \]
\[ [v, \text{num}] = \text{cutvar}(...) \]

**Description**

\( v = \text{cutvar}(t) \) returns an \( n \)-element cell array \( v \) of the names of the variables used for branching in each node of the tree \( t \), where \( n \) is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, \( v \) contains an empty character vector.

\( v = \text{cutvar}(t, \text{nodes}) \) takes a vector \( \text{nodes} \) of node numbers and returns the cut variables for the specified nodes.

\[ [v, \text{num}] = \text{cutvar}(...) \] also returns a vector \( \text{num} \) containing the number of each variable.

32-1153
cvloss

Class: ClassificationTree

Classification error by cross validation

Syntax

E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[___] = cvloss(tree,Name,Value)

Description

E = cvloss(tree) returns the cross-validated classification error (loss) for tree, a classification tree. The cvloss method uses stratified partitioning to create cross-validated sets. That is, for each fold, each partition of the data has roughly the same class proportions as in the data used to train tree.

[E,SE] = cvloss(tree) returns the standard error of E.

[E,SE,Nleaf] = cvloss(tree) returns the number of leaves of tree.

[E,SE,Nleaf,BestLevel] = cvloss(tree) returns the optimal pruning level for tree.

[___] = cvloss(tree,Name,Value) cross validates with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.
**Input Arguments**

`tree` — Trained classification tree
ClassificationTree model object

Trained classification tree, specified as a ClassificationTree model object produced by fitctree.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Subtrees — Pruning level**

`0` (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `cvloss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`cvloss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

**TreeSize — Tree size**

`'se'` (default) | `'min'`
Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- 'se' — cvloss uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — cvloss uses the minimal cost tree.

Example: 'TreeSize','min'

**KFold — Number of cross-validation samples**

10 (default) | positive integer value greater than 1

Number of cross-validation samples, specified as the comma-separated pair consisting of KFold and a positive integer value greater than 1.

Example: 'KFold',8

**Output Arguments**

**E — Cross-validation classification error**

numeric vector | scalar value

Cross-validation classification error (loss), returned as a vector or scalar depending on the setting of the Subtrees name-value pair.

**SE — Standard error**

numeric vector | scalar value

Standard error of E, returned as a vector or scalar depending on the setting of the Subtrees name-value pair.

**Nleaf — Number of leaf nodes**

numeric vector | scalar value

Number of leaf nodes in tree, returned as a vector or scalar depending on the setting of the Subtrees name-value pair. Leaf nodes are terminal nodes, which give classifications, not splits.

**BestLevel — Best pruning level**

scalar value
Best pruning level, returned as a scalar value. By default, a scalar representing the largest pruning level that achieves a value of $E$ within $SE$ of the minimum error. If you set `TreeSize` to `'min'`, `BestLevel` is the smallest value in `Subtrees`.

**Examples**

**Compute the Cross-Validation Error**

Compute the cross-validation error for a default classification tree.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Grow a classification tree using the entire data set.

```matlab
Mdl = fitctree(X,Y);
```

Compute the cross-validation error.

```matlab
rng(1); % For reproducibility
E = cvloss(Mdl)
```

```matlab
E = 0.1111
```

$E$ is the 10-fold misclassification error.

**Find the Best Pruning Level Using Cross Validation**

Apply $k$-fold cross validation to find the best level to prune a classification tree for all of its subtrees.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Grow a classification tree using the entire data set. View the resulting tree.

```matlab
Mdl = fitctree(X,Y);
view(Mdl,'Mode','graph')
```
Compute the 5-fold cross-validation error for each subtree except for the highest pruning level. Specify to return the best pruning level over all subtrees.

```matlab
rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1
m = 7
[E,~,~,bestLevel] = cvloss(Mdl,'SubTrees',0:m,'KFold',5)
E = 8×1
```

32-1158
bestLevel = 6

Of the 7 pruning levels, the best pruning level is 6.

Prune the tree to the best level. View the resulting tree.

MdlPrune = prune(Mdl,'Level',bestLevel);
view(MdlPrune,'Mode','graph')
Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`. `kfoldLoss` also does not allow you to examine any error other than the classification error.
See Also

crossval | fitctree | kfoldLoss | loss
cvloss

**Class:** RegressionTree

Regression error by cross validation

**Syntax**

```
E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[E,...] = cvloss(tree,Name,Value)
```

**Description**

'E = cvloss(tree) returns the cross-validated regression error (loss) for tree, a regression tree.

'E,SE] = cvloss(tree) returns the standard error of E.'

'E,SE,Nleaf] = cvloss(tree) returns the number of leaves (terminal nodes) in tree.'

'E,SE,Nleaf,BestLevel] = cvloss(tree) returns the optimal pruning level for tree.'

'E,...] = cvloss(tree,Name,Value) cross validates with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.'

**Input Arguments**

*tree — Trained regression tree*

RegressionTree object
Trained regression tree, specified as a `RegressionTree` object constructed using `fitrtree`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### `Subtrees` — Pruning level

0 (default) | vector of nonnegative integers | `all`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `cvloss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`cvloss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

#### `TreeSize` — Tree size

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following:

- `'se'` — `cvloss` uses the smallest tree whose cost is within one standard error of the minimum cost.

32-1163
• 'min' — `cvloss` uses the minimal cost tree.

**KFold** — **Number of folds**
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Example: 'KFold',8

**Output Arguments**

**E** — **Mean squared error**
scalar value | numeric vector

Cross-validation mean squared error (loss), returned as a vector or scalar depending on the setting of the **Subtrees** name-value pair.

**SE** — **Standard error**
scalar value | numeric vector

Standard error of **E**, returned as vector or scalar depending on the setting of the **Subtrees** name-value pair.

**Nleaf** — **Number of leaf nodes**
vector of integer values

Number of leaf nodes in **tree**, returned as a vector or scalar depending on the setting of the **Subtrees** name-value pair. Leaf nodes are terminal nodes, which give responses, not splits.

**BestLevel** — **Best pruning level**
scalar value

Best pruning level as defined in the **TreeSize** name-value pair, returned as a scalar whose value depends on **TreeSize**:

• If **TreeSize** is 'se', then BestLevel is the largest pruning level that achieves a value of **E** within **SE** of the minimum error.
• If **TreeSize** is 'min', then BestLevel is the smallest value in **Subtrees**.

Examples

Compute the Cross-Validation Error

Compute the cross-validation error for a default regression tree.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using the entire data set.

Mdl = fitrtree(X,MPG);

Compute the cross-validation error.

rng(1); % For reproducibility
E = cvloss(Mdl)
E = 25.7383

E is the 10-fold weighted, average MSE (weighted by number of test observations in the folds).

Find the Best Pruning Level Using Cross Validation

Apply k-fold cross validation to find the best level to prune a regression tree for all of its subtrees.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

load carsmall
X = [Displacement Horsepower Weight];

Grow a regression tree using the entire data set. View the resulting tree.

Mdl = fitrtree(X,MPG);
view(Mdl,'Mode','graph')
Compute the 5-fold cross-validation error for each subtree except for the first two lowest and highest pruning level. Specify to return the best pruning level over all subtrees.

```matlab
rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1
m = 15
 [~,~,~,bestLevel] = cvloss(Mdl,'SubTrees',2:m,'KFold',5)
bestLevel = 14
```
Of the 15 pruning levels, the best pruning level is 14.

Prune the tree to the best level. View the resulting tree.

```plaintext
MdlPrune = prune(Mdl,'Level',bestLevel);
view(MdlPrune,'Mode','graph')
```
Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return SE, Nleaf, or **BestLevel**.

cvpartition class

Data partitions for cross validation

Description

An object of the cvpartition class defines a random partition on a set of data of a specified size. Use this partition to define test and training sets for validating a statistical model using cross validation.

Construction

cvpartition

Create cross-validation partition for data

Methods

disp
Display cvpartition object
display
Display cvpartition object
repartition
Repartition data for cross-validation
test
Test indices for cross-validation
training
Training indices for cross-validation
Properties

NumObservations  Number of observations (including observations with missing group values)
NumTestSets  Number of test sets
TestSize  Size of each test set
TrainSize  Size of each training set
Type  Type of partition

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes (MATLAB) in the MATLAB Object-Oriented Programming documentation.

Examples

Use a 10-fold stratified cross validation to compute the misclassification error for classify on iris data.

load('fisheriris');
CVO = cvpartition(species,'k',10);
err = zeros(CVO.NumTestSets,1);
for i = 1:CVO.NumTestSets
    trIdx = CVO.training(i);
    teIdx = CVO.test(i);
    ytest = classify(meas(teIdx,:),meas(trIdx,:),... 
        species(trIdx,:));
    err(i) = sum(~strcmp(ytest,species(teIdx)));
end
cvErr = sum(err)/sum(CVO.TestSize);

cvpartition

Class: cvpartition

Create cross-validation partition for data

Syntax

c = cvpartition(n,'KFold',k)
c = cvpartition(n,'HoldOut',p)
c = cvpartition(group,'KFold',k)
c = cvpartition(group,'KFold',k,'Stratify',stratifyOption)
c = cvpartition(group,'HoldOut',p)
c = cvpartition(group,'HoldOut',p,'Stratify',stratifyOption)
c = cvpartition(n,'LeaveOut')
c = cvpartition(n,'resubstitution')

Description

c = cvpartition(n,'KFold',k) constructs an object c of the cvpartition class on page 32-1169 defining a random nonstratified partition for k-fold cross-validation on n observations. The partition divides the observations into k disjoint subsamples (or folds), chosen randomly but with roughly equal size. The default value of k is 10.

c = cvpartition(n,'HoldOut',p) creates a random nonstratified partition for holdout validation on n observations. This partition divides the observations into a training set and a test (or holdout) set. The parameter p must be a scalar. When 0 < p < 1, cvpartition randomly selects approximately p*n observations for the test set. When p is an integer, cvpartition randomly selects p observations for the test set. The default value of p is 1/10.

c = cvpartition(group,'KFold',k) creates a random partition for a stratified k-fold cross-validation. group is a numeric vector, categorical array, character array, string
array, or cell array of character vectors indicating the class of each observation. Each subsample has roughly equal size and roughly the same class proportions as in group.

When you supply group as the first input argument to cvpartition, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in group.

c = cvpartition(group,'KFold',k,'Stratify',stratifyOption) returns an object c defining a random partition for k-fold cross-validation. When you supply group as the first input argument to cvpartition, then the function implements stratification by default. If you also specify 'Stratify',false, then the function creates nonstratified random partitions.

You can specify 'Stratify',true only if the first input argument to cvpartition is group.

\[ c = \text{cvpartition}(\text{group},'\text{HoldOut}',p) \]
randomly partitions observations into a training set and a holdout (or test) set with stratification, using the class information in group. Both the training and test sets have roughly the same class proportions as in group.

\[ c = \text{cvpartition}(\text{group},'\text{HoldOut}',p,'\text{Stratify}',\text{stratifyOption}) \]
returns an object c defining a random partition into a training set and a holdout (or test) set. When you supply group as the first input argument to cvpartition, then the function implements stratification by default. If you also specify 'Stratify',false, then the function creates nonstratified random partitions.

\[ c = \text{cvpartition}(\text{n},'\text{LeaveOut}') \]
creates a random partition for leave-one-out cross-validation on n observations. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.

\[ c = \text{cvpartition}(\text{n},'\text{resubstitution}') \]
creates an object c that does not partition the data. Both the training set and the test set contain all of the original n observations.

**Examples**

**Find Misclassification Rate for K-Fold Cross-Validation**

Use stratified 10-fold cross-validation to compute misclassification rate.
Load Fisher's iris data set.

```matlab
load fisheriris;
y = species;
X = meas;
```

Create a random partition for a stratified 10-fold cross-validation.

```matlab
c = cvpartition(y,'KFold',10);
```

Create a function that computes the number of misclassified test samples.

```matlab
fun = @(xTrain,yTrain,xTest,yTest)(sum(~strcmp(yTest,...
    classify(xTest,xTrain,yTrain))));
```

Return the estimated misclassification rate using cross-validation.

```matlab
rate = sum(crossval(fun,X,y,'partition',c))... /sum(c.TestSize)
rate = 0.0200
```

**Create Nonstratified Partition**

Find the proportion of each class in a 5-fold nonstratified partition of the `fisheriris` data.

Load Fisher's iris data set.

```matlab
load fisheriris;
```

Find the number of instances of each class in the data.

```matlab
[C,~,idx] = unique(species);
C % Unique classes
C = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }

n = accumarray(idx(:,1),1) % Number of instances for each class in species
The three classes occur in equal proportion.

Create a random, nonstratified 5-fold partition.

```matlab
cv = cvpartition(species,'KFold',5,'Stratify',false)
```

```matlab
cv = 
K-fold cross validation partition
    NumObservations: 150
    NumTestSets: 5
    TrainSize: 120  120  120  120  120
    TestSize: 30  30  30  30  30
```

Show that the three classes do not occur in equal proportion for each fold of the data set.

```matlab
for i = 1:cv.NumTestSets
    disp(['Fold ',num2str(i)])
    testClasses = species(cv.test(i));
    [C,~,idx] = unique(testClasses);
    C % Unique classes
    nCount = accumarray(idx(:),1) % Number of instances for each class in a fold
end
```

Fold 1

```matlab
C = 3x1 cell array
    {'setosa'    }
    {'versicolor' }
    {'virginica' }
```

```matlab
nCount = 3x1
     8
    13
     9
```

Fold 2
C = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }

nCount = 3x1

    10
    11
    9

Fold 3
C = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }

nCount = 3x1

    10
    8
    12

Fold 4
C = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }

nCount = 3x1

    12
    8
    10

Fold 5
C = 3x1 cell array
    {'setosa'   }
Because `cv` is a random nonstratified partition of the `fisheriris` data, the class proportions in each of the five folds are not guaranteed to be equal to the class proportions in `species`. That is, the classes do not occur equally in each fold, as they do in `species`. Cross-validation produces randomness in the results, so your number of instances for each class in a fold can vary from those shown.

Create Nonstratified Holdout Set for Tall Array

Compare the number of instances for each class in a nonstratified holdout set with a stratified holdout set of a tall array.

Create a numeric vector of two classes, where class 1 and class 2 occur in the ratio 1:10.

```matlab
group = [ones(20,1);2*ones(200,1)]
```

```plaintext
group = 220×1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
1
```

Create a tall array from `group`. 
tgroup = tall(group)
Starting parallel pool (parpool) using the 'local' profile ... connected to 12 workers.

Holdout is the only cvpartition option that is supported for tall arrays. Create a random, nonstratified holdout partition.

CV0 = cvpartition(tgroup,'Holdout',1/4,'Stratify',false)

Return the result of CV0.test to memory by using the gather function.

testIdx0 = gather(CV0.test);

Find the number of times each class occurs in the holdout set.

accumarray(group(testIdx0),1) % Number of instances for each class in the holdout set
ans = 2x1
    3
cvpartition produces randomness in the results, so your number of instances for each class can vary from those shown.

Because CV0 is a nonstratified partition, class 1 and class 2 in the holdout set are not guaranteed to occur in the same ratio that they do in tgroup. However, because of the inherent randomness in cvpartition, you can sometimes obtain a holdout set for which the classes occur in the same ratio that they do in tgroup even though you specify 'Stratify',false. A similar result can be illustrated for the training set.

Return the result of CV0.training to memory.

```
trainIdx0 = gather(CV0.training);
```

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.061 sec

Find the number of times each class occurs in the training set.

```
accumarray(group(trainIdx0),1) % Number of instances for each class in the training set
ans = 2x1
    17
   148
```

The classes in the nonstratified training set are not guaranteed to occur in the same ratio that they do in tgroup.

Create a random, stratified holdout partition.

```
CV1 = cvpartition(tgroup,'Holdout',1/4)
```

```
CV1 =
    Hold-out cross validation partition
    NumObservations: [1x1 tall]
    NumTestSets: 1
    TrainSize: [1x1 tall]
    TestSize: [1x1 tall]
```

Return the result of CV1.test to memory.
testIdx1 = gather(CV1.test);

Evaluating tall expression using the Parallel Pool 'local':
Evaluation completed in 0.079 sec

Find the number of times each class occurs in the holdout set.

accumarray(group(testIdx1),1) % Number of instances for each class in the holdout set
ans = 2×1
     5
     50

In the case of the stratified holdout partition, the class ratio in the holdout set and the class ratio in tgroup are the same (1:10).

Algorithms

- If you supply group as the first input argument to cvpartition, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in group.
- When you supply group as the first input argument to cvpartition, then the function implements stratification by default. You can specify 'Stratify',false to create nonstratified random partitions.
- You can specify 'Stratify',true only if the first input argument to cvpartition is group.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.
• When you use cvpartition with tall arrays, the first input argument must be a grouping variable, tGroup. If you specify a tall scalar as the first input argument, cvpartition gives an error.

• cvpartition supports only Holdout cross-validation for tall arrays; for example, c = cvpartition(tGroup,'HoldOut',p). By default, cvpartition randomly partitions observations into a training set and a test set with stratification, using the class information in tGroup. The parameter p is a scalar such that 0 < p < 1.

• To create nonstratified Holdout partitions, specify the value of the 'Stratify' name-value pair argument as false; for example, c = cvpartition(tGroup,'Holdout',p,'Stratify',false).

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2008a
cvshrink

Class: ClassificationDiscriminant

Cross-validate regularization of linear discriminant

Syntax

err = cvshrink(obj)
[err, gamma] = cvshrink(obj)
[err, gamma, delta] = cvshrink(obj)
[err, gamma, delta, numpred] = cvshrink(obj)
[err, ...] = cvshrink(obj, Name, Value)

Description

err = cvshrink(obj) returns a vector of cross-validated classification error values for differing values of the regularization parameter Gamma.

[err, gamma] = cvshrink(obj) also returns the vector of Gamma values.

[err, gamma, delta] = cvshrink(obj) also returns the vector of Delta values.

[err, gamma, delta, numpred] = cvshrink(obj) returns the vector of number of nonzero predictors for each setting of the parameters Gamma and Delta.

[err, ...] = cvshrink(obj, Name, Value) cross validates with additional options specified by one or more Name, Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using fitcdiscr.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

delta

- Scalar delta — cvshrink uses this value of delta with every value of gamma for regularization.
- Row vector delta — For each i and j, cvshrink uses delta(j) with gamma(i) for regularization.
- Matrix delta — The number of rows of delta must equal the number of elements in gamma. For each i and j, cvshrink uses delta(i, j) with gamma(i) for regularization.

Default: 0

gamma

Vector of Gamma values for cross-validation.

Default: 0:0.1:1

NumDelta

Number of Delta intervals for cross-validation. For every value of Gamma, cvshrink cross-validates the discriminant using NumDelta + 1 values of Delta, uniformly spaced from zero to the maximal Delta at which all predictors are eliminated for this value of Gamma. If you set delta, cvshrink ignores NumDelta.

Default: 0

NumGamma

Number of Gamma intervals for cross-validation. cvshrink cross-validates the discriminant using NumGamma + 1 values of Gamma, uniformly spaced from MinGamma to 1. If you set gamma, cvshrink ignores NumGamma.

Default: 10
verbose

Verbosity level, an integer from 0 to 2. Higher values give more progress messages.

Default: 0

Output Arguments

err

Numeric vector or matrix of errors. err is the misclassification error rate, meaning the average fraction of misclassified data over all folds.

- If delta is a scalar (default), err(i) is the misclassification error rate for obj regularized with gamma(i).
- If delta is a vector, err(i,j) is the misclassification error rate for obj regularized with gamma(i) and delta(j).
- If delta is a matrix, err(i,j) is the misclassification error rate for obj regularized with gamma(i) and delta(i,j).

gamma

Vector of Gamma values used for regularization. See “Gamma and Delta” on page 32-1187.

delta

Vector or matrix of Delta values used for regularization. See “Gamma and Delta” on page 32-1187.

- If you give a scalar for the delta name-value pair, the output delta is a row vector the same size as gamma, with entries equal to the input scalar.
- If you give a row vector for the delta name-value pair, the output delta is a matrix with the same number of columns as the row vector, and with the number of rows equal to the number of elements of gamma. The output delta(i,j) is equal to the input delta(j).
- If you give a matrix for the delta name-value pair, the output delta is the same as the input matrix. The number of rows of delta must equal the number of elements in gamma.
**numpred**

Numeric vector or matrix containing the number of predictors in the model at various regularizations. **numpred** has the same size as **err**.

- If **delta** is a scalar (default), **numpred(i)** is the number of predictors for **obj** regularized with **gamma(i)** and **delta**.
- If **delta** is a vector, **numpred(i,j)** is the number of predictors for **obj** regularized with **gamma(i)** and **delta(j)**.
- If **delta** is a matrix, **numpred(i,j)** is the number of predictors for **obj** regularized with **gamma(i)** and **delta(i,j)**.

**Examples**

**Regularize Data with Many Predictors**

Regularize a discriminant analysis classifier, and view the tradeoff between the number of predictors in the model and the classification accuracy.

Create a linear discriminant analysis classifier for the **ovariancancer** data. Set the **SaveMemory** and **FillCoeffs** options to keep the resulting model reasonably small.

```matlab
load ovariancancer
obj = fitcdiscr(obs,grp,...
    'SaveMemory','on','FillCoeffs','off');
```

Use 10 levels of **Gamma** and 10 levels of **Delta** to search for good parameters. This search is time-consuming. Set **Verbose** to 1 to view the progress.

```matlab
rng('default') % for reproducibility
[err,gamma,delta,numpred] = cvshrink(obj,...
    'NumGamma',9,'NumDelta',9,'Verbose',1);
```

Done building cross-validated model.
Processing Gamma step 1 out of 10.
Processing Gamma step 2 out of 10.
Processing Gamma step 3 out of 10.
Processing Gamma step 4 out of 10.
Processing Gamma step 5 out of 10.
Processing Gamma step 6 out of 10.
Processing Gamma step 7 out of 10.
Processing Gamma step 8 out of 10.
Processing Gamma step 9 out of 10.
Processing Gamma step 10 out of 10.

Plot the classification error rate against the number of predictors.

```matlab
plot(err,numpred,'k.'
xlabel('Error rate');
ylabel('Number of predictors');
```
Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$, that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let $\Sigma$ represent the covariance matrix of the data $X$, and let $\hat{X}$ be the centered data (the data $X$ minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T \ast \hat{X}).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma) \Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\Sigma$ is nonsingular.

Let $\mu_k$ be the mean vector for those elements of $X$ in class $k$, and let $\mu_0$ be the global mean vector (the mean of the rows of $X$). Let $C$ be the correlation matrix of the data $X$, and let $\tilde{C}$ be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma) C + \gamma I,$$

where $I$ is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point $x$ is

$$\left( x - \mu_0 \right)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[ \left( x - \mu_0 \right)^T D^{-1/2} \right] \left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter $\delta$ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller.
in magnitude than the threshold $\delta$. Therefore, for class $k$, if component $j$ is thresholded to zero, component $j$ of $x$ does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes $k$ have

$$\left| \tilde{C}^{-1}D^{-1/2}(\mu_k - \mu_0) \right| \leq \delta.$$  

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor $i$.

**Tips**

- Examine the err and numpred outputs to see the tradeoff between cross-validated error and number of predictors. When you find a satisfactory point, set the corresponding gamma and delta properties in the model using dot notation. For example, if $(i,j)$ is the location of the satisfactory point, set

  ```matlab
  obj.Gamma = gamma(i);
  obj.Delta = delta(i,j);
  ```

cvshrink

Cross validate shrinking (pruning) ensemble

Syntax

vals = cvshrink(ens)
[val, nlearn] = cvshrink(ens)
[val, nlearn] = cvshrink(ens, Name, Value)

Description

vals = cvshrink(ens) returns an L-by-T matrix with cross-validated values of the mean squared error. L is the number of lambda values in the ens.Regularization structure. T is the number of threshold values on weak learner weights. If ens does not have a Regularization property filled in by the regularize method, pass a lambda name-value pair.

[val, nlearn] = cvshrink(ens) returns an L-by-T matrix of the mean number of learners in the cross-validated ensemble.

[val, nlearn] = cvshrink(ens, Name, Value) cross validates with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Input Arguments

ens

A regression ensemble, created with fitrensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**cvpartition**

A partition created with cvpartition to use in a cross-validated tree. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**holdout**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**kfold**

Number of folds to use in a cross-validated tree, a positive integer. If you do not supply a cross-validation method, cvshrink uses 10-fold cross validation. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**Default**: 10

**lambda**

Vector of nonnegative regularization parameter values for lasso. If empty, cvshrink does not perform cross validation.

**Default**: []

**leaveout**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**threshold**

Numeric vector with lower cutoffs on weights for weak learners. cvshrink discards learners with weights below threshold in its cross-validation calculation.

**Default**: 0
Output Arguments

vals

L-by-T matrix with cross-validated values of the mean squared error. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

nlearn

L-by-T matrix with cross-validated values of the mean number of learners in the cross-validated ensemble. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

Examples

Cross-Validate Regression Ensemble

Create a regression ensemble for predicting mileage from the carsmall data. Cross-validate the ensemble.

Load the carsmall data set and select displacement, horsepower, and vehicle weight as predictors.

load carsmall
X = [Displacement Horsepower Weight];

Train an ensemble of bagged regression trees.

ens = fitrensemble(X,MPG,'Method','Bag','Learners','Tree');

Specify values for lambda and threshold. Use these values to cross-validate the ensemble.

rng(10,'twister') % For reproducibility
[valsnlearn] = cvshrink(ens,'lambda', [.01 .1 1], 'threshold', [0 .01 .1])

vals = 3x3

17.7488  17.6537  123.2749
17.7374  17.6304  123.4240
Clearly, setting a threshold of \(0.1\) leads to unacceptable errors, while a threshold of \(0.01\) gives similar errors to a threshold of \(0\). The mean number of learners with a threshold of \(0.01\) is \(11.6\), whereas the mean number is about \(13.1\) when the threshold is \(0\).

regularize | shrink
datasample
Randomly sample from data, with or without replacement

Syntax

\[
\begin{align*}
y &= \text{datasample}(\text{data},k) \\
y &= \text{datasample}(\text{data},k,\text{dim}) \\
y &= \text{datasample}(__,\text{Name},\text{Value}) \\
y &= \text{datasample}(s,\text{___}) \\
y,\text{idx} &= \text{datasample}(\text{___})
\end{align*}
\]

Description

\[
y = \text{datasample}(\text{data},k) \text{ returns } k \text{ observations sampled uniformly at random, with replacement, from the data in } \text{data}.
\]

\[
y = \text{datasample}(\text{data},k,\text{dim}) \text{ returns a sample taken along dimension } \text{dim} \text{ of } \text{data}.
\]

\[
y = \text{datasample}(\text{___},\text{Name},\text{Value}) \text{ returns a sample for any of the input arguments in the previous syntaxes, with additional options specified by one or more name-value pair arguments. For example, } '\text{Replace}', \text{false} \text{ specifies sampling without replacement.}
\]

\[
y = \text{datasample}(s,\text{___}) \text{ uses the random number stream } s \text{ to generate random numbers. The option } s \text{ can precede any of the input arguments in the previous syntaxes.}
\]

\[
[y,\text{idx}] = \text{datasample}(\text{___}) \text{ also returns an index vector indicating which values datasample sampled from data using any of the input arguments in the previous syntaxes.}
\]

Examples

Sample Unique Values from Vector

Create the random number stream for reproducibility.
s = RandStream('mlfg6331_64');

Draw five unique values from the integers 1 to 10.

\[ \text{y} = \text{datasample}(\text{s},1:10,5,'\text{Replace}',\text{false}) \]

\[ \text{y} = 1\times5 \]

\[
\begin{array}{ccccc}
9 & 8 & 3 & 6 & 2 \\
\end{array}
\]

### Generate Random Characters for Specified Probabilities

Create the random number stream for reproducibility.

\[ \text{s} = \text{RandStream('mlfg6331_64')}; \]

Generate 48 random characters from the sequence ACGT per specified probabilities.

\[ \text{seq} = \text{datasample}(\text{s},'\text{ACGT}',48,'\text{Weights}',[0.15 \ 0.35 \ 0.35 \ 0.15]) \]

\[ \text{seq} = \text{GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG} \]

### Select Random Subset of Matrix Columns

Set the random seed for reproducibility of the results.

\[ \text{rng}(10, '\text{twister}') \]

Generate a matrix with 10 rows and 1000 columns.

\[ \text{X} = \text{randn}(10,1000); \]

Create the random number stream for reproducibility within `datasample`.

\[ \text{s} = \text{RandStream('mlfg6331_64')}; \]

Randomly select five unique columns from X.

\[ \text{Y} = \text{datasample}(\text{s},\text{X},5,2,'\text{Replace}',\text{false}) \]
Create a Bootstrap Replicate Data Set

Resample observations from a dataset array to create a bootstrap replicate data set. See “Bootstrap Resampling” on page 3-15 for more information about bootstrapping.

Load the sample data set.

load hospital

Create a data set that has the same size as the hospital data set and contains random samples chosen with replacement from the hospital data set.

\[
y = \text{datasample}(\text{hospital}, \text{size(hospital,1)});\]

Sample in Parallel from Two Data Vectors

Select samples from data based on indices of a sample chosen from another vector.

Generate two random vectors.

x1 = \text{randn}(100,1);
x2 = \text{randn}(100,1);

Select a sample of 10 elements from vector \(x1\), and return the indices of the sample in vector \(idx\).
[y1,idx] = datasample(x1,10);

Select a sample of 10 elements from vector x2 using the indices in vector idx.

y2 = x2(idx);

**Input Arguments**

data — Input data
VECTOR | MATRIX | MULTIDIMENSIONAL ARRAY | TABLE | DATASET ARRAY

Input data from which to sample, specified as a vector, matrix, multidimensional array, table, or dataset array. By default, datasample samples from the first nonsingleton dimension of data. For example, if data is a matrix, then datasample samples from the rows. Change this behavior with the dim input argument.

Data Types: SINGLE | DOUBLE | LOGICAL | CHAR | STRING | TABLE

k — Number of samples
POSITIVE INTEGER

Number of samples, specified as a positive integer.

Example: datasample(data, 100) returns 100 observations sampled uniformly and at random from the data in data.

Data Types: SINGLE | DOUBLE

dim — Dimension to sample
1 (DEFAULT) | POSITIVE INTEGER

Dimension to sample, specified as a positive integer. For example, if data is a matrix and dim is 2, y contains a selection of columns in data. If data is a table or dataset array and dim is 2, y contains a selection of variables in data. Use dim to ensure sampling along a specific dimension regardless of whether data is a vector, matrix, or N-dimensional array.

Data Types: SINGLE | DOUBLE

s — Random number stream
GLOBAL STREAM (DEFAULT) | RANDSTREAM

Random number stream, specified as the global stream or RandStream. For example, s = RandStream('mlfg6331_64') creates a random number stream that uses the
multiplicative lagged Fibonacci generator algorithm. For details, see “Creating and Controlling a Random Number Stream” (MATLAB).

The `rng` function provides a simple way to control the global stream. For example, `rng(seed)` seeds the random number generator using the nonnegative integer seed. For details, see “Managing the Global Stream” (MATLAB).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'Replace',false,'Weights',ones(datasize,1) samples without replacement and with probability proportional to the elements of `Weights`, where `datasize` is the size of the dimension being sampled.

**Replace** — Indicator for sampling with replacement.

`true` (default) | `false`

Indicates whether to sample with replacement, specified as the comma-separated pair consisting of 'Replace' and either `true` or `false`.

Sample with replacement if 'Replace' is `true`, or without replacement if 'Replace' is `false`. If 'Replace' is `false`, then `k` must not be larger than the size of the dimension being sampled. For example, if `data = [1 3 Inf; 2 4 5]` and `y = datasample(data,k,'Replace',false)`, then `k` cannot be larger than 2.

Data Types: `logical`

**Weights** — Sampling weights.

`ones(datasize,1)` (default) | vector of nonnegative numeric values

Sampling weights, specified as the comma-separated pair consisting of 'Weights' and a vector of nonnegative numeric values. The vector is of size `datasize`, where `datasize` is the size of the dimension being sampled. The vector must have at least one positive value and cannot contain `NaN` values. The `datasample` function samples with probability proportional to the elements of 'Weights'.

Example: 'Weights',[0.1 0.5 0.35 0.46]

Data Types: `single` | `double`
Output Arguments

\( y \) — Sample
vector | matrix | multidimensional array | table | dataset array

Sample, returned as a vector, matrix, multidimensional array, table, or dataset array.

- If \( \text{data} \) is a vector, then \( y \) is a vector containing \( k \) elements selected from \( \text{data} \).
- If \( \text{data} \) is a matrix and \( \text{dim} = 1 \), then \( y \) is a matrix containing \( k \) rows selected from \( \text{data} \). Or, if \( \text{dim} = 2 \), then \( y \) is a matrix containing \( k \) columns selected from \( \text{data} \).
- If \( \text{data} \) is an \( N \)-dimensional array and \( \text{dim} = 1 \), then \( y \) is an \( N \)-dimensional array of samples taken along the first nonsingleton dimension of \( \text{data} \). Or, if you specify a value for the \text{dim} name-value pair argument, \text{datasample} samples along the dimension \text{dim}.
- If \( \text{data} \) is a table and \( \text{dim} = 1 \), then \( y \) is a table containing \( k \) rows selected from \( \text{data} \). Or, if \( \text{dim} = 2 \), then \( y \) is a table containing \( k \) variables selected from \( \text{data} \).
- If \( \text{data} \) is a dataset array and \( \text{dim} = 1 \), then \( y \) is a dataset array containing \( k \) rows selected from \( \text{data} \). Or, if \( \text{dim} = 2 \), then \( y \) is a dataset array containing \( k \) variables selected from \( \text{data} \).

If the input \( \text{data} \) contains missing observations that are represented as \text{NaN} values, \text{datasample} samples from the entire input, including the \text{NaN} values. For example, \( y = \text{datasample}([\text{NaN} \ 6 \ 14],2) \) can return \( y = \text{NaN} \ 14 \).

When the sample is taken with replacement (default), \( y \) can contain repeated observations from \( \text{data} \). Set the Replace name-value pair argument to \text{false} to sample without replacement.

\( \text{idx} \) — Indices
vector

Indices, returned as a vector indicating which elements \text{datasample} chooses from \( \text{data} \) to create \( y \). For example:

- If \( \text{data} \) is a vector, then \( y = \text{data}(\text{idx}) \).
- If \( \text{data} \) is a matrix and \( \text{dim} = 1 \), then \( y = \text{data}(\text{idx},:) \).
- If \( \text{data} \) is a matrix and \( \text{dim} = 2 \), then \( y = \text{data}(:,\text{idx}) \).
**Tips**

- To sample random integers with replacement from a range, use `randi`.
- To sample random integers without replacement, use `randperm` or `datasample`.
- To randomly sample from data, with or without replacement, use `datasample`.

**Algorithms**

datasample uses `randperm`, `rand`, or `randi` to generate random values. Therefore, datasample changes the state of the MATLAB global random number generator. Control the random number generator using `rng`.

For selecting weighted samples without replacement, datasample uses the algorithm of Wong and Easton [1].

**Alternative Functionality**

You can use `randi` or `randperm` to generate indices for random sampling with or without replacement, respectively. However, datasample can be more convenient to use because it samples directly from your data. datasample also allows weighted sampling.

**References**

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.
• `datasample` is useful as a precursor to plotting and fitting a random subset of a large data set. Sampling a large data set preserves trends in the data without requiring the use of all the data points. If the sample is small enough to fit in memory, then you can apply plotting and fitting functions that do not directly support tall arrays.

• `datasample` supports sampling only along the first dimension of the data.

• For tall arrays, `datasample` does not support sampling with replacement. You must specify `'Replace',false`, for example, `datasample(data,k,'Replace',false)`.

• The value of `'Weights'` must be a numeric tall array of the same height as `data`.

• For the syntax `[Y,idx] = datasample(__)`, the output `idx` is a tall logical vector of the same height as `data`. The vector indicates whether each data point is included in the sample.

• If you specify a random number stream, then the underlying generator must support multiple streams and substreams. If you do not specify a random number stream, then `datasample` uses the stream controlled by `tallrng`.

For more information, see “Tall Arrays” (MATLAB).

**Introduced in R2011b**
dataset class

Arrays for statistical data

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Description**

Dataset arrays are used to collect heterogeneous data and metadata including variable and observation names into a single container variable. Dataset arrays are suitable for storing column-oriented or tabular data that are often stored as columns in a text file or in a spreadsheet, and can accommodate variables of different types, sizes, units, etc.

Dataset arrays can contain different kinds of variables, including numeric, logical, character, string, categorical, and cell. However, a dataset array is a different class than the variables that it contains. For example, even a dataset array that contains only variables that are double arrays cannot be operated on as if it were itself a double array. However, using dot subscripting, you can operate on variable in a dataset array as if it were a workspace variable.

You can subscript dataset arrays using parentheses much like ordinary numeric arrays, but in addition to numeric and logical indices, you can use variable and observation names as indices.

**Construction**

Use the `dataset` constructor to create a dataset array from variables in the MATLAB workspace. You can also create a dataset array by reading data from a text or spreadsheet file. You can access each variable in a dataset array much like fields in a structure, using dot subscripting. See the following section for a list of operations available for dataset arrays.

**Properties**

A dataset array D has properties that store metadata (information about your data). Access or assign to a property using \( P = D.\text{Properties}.\text{PropName} \) or \( D.\text{Properties}.\text{PropName} = P \), where PropName is one of the following:

- **Description**: Character vector describing data set
- **DimNames**: Two-element cell array of character vectors giving names of dimensions of data set
- **ObsNames**: Cell array of nonempty, distinct character vectors giving names of observations in data set
- **Units**: Units of variables in data set
- **UserData**: Variable containing additional information associated with data set
- **VarDescription**: Cell array of character vectors giving descriptions of variables in data set
- **VarNames**: Cell array giving names of variables in data set

**Copy Semantics**

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes (MATLAB) in the MATLAB Object-Oriented Programming documentation.

**Examples**

Load a dataset array from a .mat file and create some simple subsets:

```matlab
load hospital
h1 = hospital(1:10,:)
h2 = hospital(:,{'LastName' 'Age' 'Sex' 'Smoker'})

% Access and modify metadata
hospital.Properties.Description
hospital.Properties.VarNames{4} = 'Wgt'

% Create a new dataset variable from an existing one
hospital.AtRisk = hospital.Smoker | (hospital.Age > 40)
```
% Use individual variables to explore the data
boxplot(hospital.Age,hospital.Sex)
h3 = hospital(hospital.Age<30,...
    {'LastName' 'Age' 'Sex' 'Smoker'})

% Sort the observations based on two variables
h4 = sortrows(hospital,{'Sex','Age'})

dataset

Class: dataset

Construct dataset array

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

A = dataset(varspec,'ParamName',Value)
A = dataset('File',filename,'ParamName',Value)
A = dataset('XLSFile',filename,'ParamName',Value)
A = dataset('XPTFile',xptfilename,'ParamName',Value)

**Description**

A = dataset(varspec,'ParamName',Value) creates dataset array A using the workspace variable input method varspec and one or more optional name/value pairs (see Parameter Name/Value Pairs).

The input method varspec can be one or more of the following:

- **VAR** — a workspace variable. dataset uses the workspace name for the variable name in A. To include multiple variables, specify VAR_1,VAR_2,...,VAR_N. Variables can be arrays of any size, but all variables must have the same number of rows. VAR can also be an expression. In this case, dataset creates a default name automatically.
- **{VAR,name]** — a workspace variable, VAR and a variable name, name. dataset uses name as the variable name. To include multiple variables and names, specify {VAR_1,name_1}, {VAR_2,name_2},..., {VAR_N,name_N}.
- **{VAR,name_1,...,name_m]** — an m-columned workspace variable, VAR. dataset uses the names name_1,...,name_m as variable names. You must include a name for every column in VAR. Each column becomes a separate variable in A.
You can combine these input methods to include as many variables and names as needed. Names must be valid, unique MATLAB identifiers. For example input combinations, see Examples. For optional name/value pairs see Inputs.

To convert numeric arrays, cell arrays, structure arrays, or tables to dataset arrays, you can also use (respectively):

- `mat2dataset`
- `cell2dataset`
- `struct2dataset`
- `table2dataset`

**Note** Dataset arrays may contain built-in types or array objects as variables. Array objects must implement each of the following:

- Standard MATLAB parenthesis indexing of the form `var(i, ...)` where `i` is a numeric or logical vector corresponding to rows of the variable
- A `size` method with a `dim` argument
- A `vertcat` method

```matlab
A = dataset('File', filename, 'ParamName', Value)
```
creates dataset array `A` from column-oriented data in the text file specified by `filename`. Variables in `A` are of type `double` if data in the corresponding column of the file, following the column header, are entirely numeric; otherwise the variables in `A` are cell arrays of character vectors. `dataset` converts empty fields to either `NaN` (for a numeric variable) or the empty character vector (for a character-valued variable). `dataset` ignores insignificant white space in the file. You cannot specify both a file and workspace variables as input. See Name/Value Pairs for more information.

```matlab
A = dataset('XLSFile', filename, 'ParamName', Value)
```
creates dataset array `A` from column-oriented data in the Excel spreadsheet specified by `filename`. Variables in `A` are of type `double` if data in the corresponding column of the spreadsheet, following the column header, are entirely numeric; otherwise the variables in `A` are cell arrays of character vectors. See Name/Value Pairs for more information.

```matlab
A = dataset('XPTFile', xptfilename, 'ParamName', Value)
```
creates a dataset array from a SAS® XPORT format file. Variable names from the XPORT format file are
preserved. Numeric data types in the XPORT format file are preserved but all other data types are converted to cell arrays of character vectors. The XPORT format allows for 28 missing data types. dataset represents these in the file by an upper case letter, '.' or '_'. dataset converts all missing data to NaN values in A. See Name/Value Pairs for more information.

**Parameter Name/Value Pairs**

Specify one or more of the following name/value pairs when constructing a dataset:

**VarNames**

A string array or cell array \{name_1,...,name_m\} naming the m variables in A with the specified variable names. Names must be valid, unique MATLAB identifiers. The number of names must equal the number of variables in A. You cannot use the VarNames parameter if you provide names for individual variables using \{VAR,name\} pairs. To specify VarNames when using a file as input, set ReadVarNames to false.

**ObsNames**

A string array or cell array \{name_1,...,name_n\} naming the n observations in A with the specified observation names. The names need not be valid MATLAB identifiers, but must be unique. The number of names must equal the number of observations (rows) in A. To specify ObsNames when using a file as input, set ReadObsNames to false.

**Name/value pairs available when using text files as inputs:**

**Delimiter**

A character vector or string scalar indicating the character separating columns in the file. Values are

- '\t' (tab, the default when no format is specified)
- ' ' (space, the default when a format is specified)
- ',' (comma)
- ';;' (semicolon)
- '|' (bar)
**Format**

A format character vector or string scalar, as accepted by `textscan`. `dataset` reads the file using `textscan`, and creates variables in `A` according to the conversion specifiers in the format character vector or string scalar. You may also provide any name/value pairs accepted by `textscan`. Using the `Format` parameter is much faster for large files. If `ReadObsNames` is `true`, then `format` should include a format specifier for the first column of the file.

**HeaderLines**

Numeric value indicating the number of lines to skip at the beginning of a file.

**Default:** 0

**TreatAsEmpty**

Specifies characters to treat as the empty character vector in a numeric column. Values may be a character array, a string array, or a cell array of character vectors. The parameter applies only to numeric columns in the file; `dataset` does not accept numeric literals such as `'99'`.

**Name/value pairs available when using text files or Excel spreadsheets as inputs:**

**ReadVarNames**

A logical value indicating whether (`true`) or not (`false`) to read variable names from the first row of the file. The default is `true`. If `ReadVarNames` is `true`, variable names in the column headers of the file or range (if using an Excel spreadsheet) cannot be empty.

**ReadObsNames**

A logical value indicating whether (`true`) or not (`false`) to read observation names from the first column of the file or range (if using an Excel spreadsheet). The default is `false`. If `ReadObsNames` and `ReadVarNames` are both `true`, `dataset` saves the header of the first column in the file or range as the name of the first dimension in `A.Properties.DimNames`.

When reading from an XPT format file, the `ReadObsNames` parameter name/value pair determines whether or not to try to use the first variable in the file as observation names. Specify as a logical value (default `false`). If the contents of the first variable are not valid observation names then `dataset` reads the variable into a variable of the dataset array and does not set the observation names.
Name/value pairs available when using Excel spreadsheets as input:

Sheet

A positive scalar value of type double indicating the sheet number, or a quoted sheet name.

Range

A character vector or string scalar of the form 'C1:C2' where C1 and C2 are the names of cells at opposing corners of a rectangular region to be read, as for xlsread. By default, the rectangular region extends to the right-most column containing data. If the spreadsheet contains empty columns between columns of data, or if the spreadsheet contains figures or other non-tabular information, specify a range that contains only data.

Examples

Create a dataset array from workspace variables, including observation names:

load cereal
cereal = dataset(Calories,Protein,Fat,Sodium,Fiber,Carbo,...
   Sugars,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:10,2);

Create a dataset array from a single, multi-columned workspace variable, designating variable names for each column:

load cities
categories = cellstr(categories);
cities = dataset({ratings,categories{:}},{},...
   'ObsNames',cellstr(names))

Load data from a text or spreadsheet file

patients = dataset('File','hospital.dat',...
   'Delimiter','','ReadObsNames',true)
patients2 = dataset('XLSFile','hospital.xls',...
   'ReadObsNames',true)

1 Load patient data from the CSV file hospital.dat and store the information in a dataset array with observation names given by the first column in the data (patient identification):
patients = dataset('file','hospital.dat', ...
   'format','%s%s%s%f%f%f%f%f%f', ...
   'Delimiter',',','ReadObsNames',true);

You can also load the data without specifying a format. dataset will automatically create dataset variables that are either double arrays or cell arrays of character vectors, depending on the contents of the file:

patients = dataset('file','hospital.dat',...
   'delimiter',',',...
   'ReadObsNames',true);

2 Make the \{0,1\}-valued variable smoke nominal, and change the labels to 'No' and 'Yes':

patients.smoke = nominal(patients.smoke,{'No','Yes'});

3 Add new levels to smoke as placeholders for more detailed histories of smokers:

patients.smoke = addlevels(patients.smoke,...
   {'0-5 Years','5-10 Years','LongTerm'});

4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

patients.smoke = setlabels(patients.smoke,'Never','No');

5 Drop the undifferentiated 'Yes' level from smoke:

patients.smoke = droplevels(patients.smoke,'Yes');

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

6 Set each smoker to one of the new levels, by observation name:

patients.smoke('YPL-320') = '5-10 Years';

dataset2cell

Class: dataset

Convert dataset array to cell array

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

\[ C = \text{dataset2cell}(D) \]

**Description**

\( C = \text{dataset2cell}(D) \) converts the dataset array \( D \) to a cell array \( C \). Each variable of \( D \) becomes a column in \( C \). If \( D \) is an \( M \)-by-\( N \) array, then \( C \) is \((M+1)\)-by-\( N \), with the variable names of \( D \) in the first row. If \( D \) contains observation names, then \( C \) is \((M+1)\)-by-\((N+1)\), with the observation names in the first column.

“Dataset Arrays” on page 2-137
dataset2struct

Class: dataset

Convert dataset array to structure

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

S = dataset2struct(D)
S = dataset2struct(D,'AsScalar',true)

Description

S = dataset2struct(D) converts a dataset array to a structure array. Each variable of D becomes a field in S. If D is an M-by-N dataset array, then S is M-by-1 and has N fields. If D contains observation names, then S contains those names in the additional field ObsNames.

S = dataset2struct(D,'AsScalar',true) converts a dataset array to a scalar structure. Each variable of D becomes a field in S. If D is an M-by-N dataset array, then S has N fields, each of which as M rows. If D contains observation names, then S contains those names in the additional field ObsNames.

Input Arguments

D

M-by-N dataset array.
Output Arguments

S

M-by-1 structure array, with N fields. If the input dataset array contains observation names, then S has an additional field ObsNames.

If you specify 'AsScalar', true, then S is a scalar structure, with N fields, each with M rows.

Examples

Convert Dataset Array to Structure Array

Load sample dataset array.

load('hospital')

Create a dataset array, D, that has only a subset of the observations and variables.

D = hospital(1:8,{'LastName','Sex','Age'});
size(D)

ans = 1x2

8 3

The dataset array D has 8 observations and 3 variables.

Convert D to a structure array.

S = dataset2struct(D)

S = 8x1 struct array with fields:
    ObsNames
    LastName
    Sex
    Age
The structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field ObsNames, since D had observation names.

Display the field data for the first element of S.

S(1)

ans = struct with fields:
    ObsNames: 'YPL-320'
    LastName: 'SMITH'
      Sex: Male
      Age: 38

This information corresponds to the first observation (row) of the dataset array.

Convert Dataset Array to Scalar Structure

Load sample dataset array.

load('hospital')

Create a dataset array, D, that has only a subset of the observations and variables.

D = hospital(1:8,{'LastName','Sex','Age'});

size(D)

ans = 1x2
     8     3

The dataset array D has 8 observations and 3 variables.

Convert D to a scalar structure array.

S = dataset2struct(D,'AsScalar',true)

S = struct with fields:
    ObsNames: {8x1 cell}
    LastName: {8x1 cell}
      Sex: [8x1 nominal]
Age: [8x1 double]

The data in the fields of the scalar structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field ObsNames, since D had observation names.

Display the data for the field LastName.

S.LastName

ans = 8x1 cell array
  {'SMITH'   }
  {'JOHNSON' }
  {'WILLIAMS'}
  {'JONES'   }
  {'BROWN'   }
  {'DAVIS'   }
  {'MILLER'  }
  {'WILSON'  }

The structure field LastName contains all of the data that was in the original dataset array variable, LastName.

dataset | dataset2cell | struct2dataset

Topics
“Dataset Arrays” on page 2-137
dataset2table

Convert dataset array to table

Syntax

t = dataset2table(ds)

Description

t = dataset2table(ds) converts a dataset array to a table.

Examples

Convert Dataset Array to Table

Load the sample data, which contains nutritional information for 77 cereals.

load cereal;

Create a dataset array containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

Calories = Calories(1:5);
Protein = Protein(1:5);
Fat = Fat(1:5);
Name = Name(1:5);

cereal = dataset(Calories, Protein, Fat, 'ObsNames', Name)

cereal =

<table>
<thead>
<tr>
<th></th>
<th>Calories</th>
<th>Protein</th>
<th>Fat</th>
</tr>
</thead>
<tbody>
<tr>
<td>100% Bran</td>
<td>70</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>100% Natural Bran</td>
<td>120</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>All-Bran</td>
<td>70</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>All-Bran with Extra Fiber</td>
<td>50</td>
<td>4</td>
<td>0</td>
</tr>
</tbody>
</table>
cereal.Properties.VarDescription = Variables(4:6,2);

Convert the dataset array to a table.

t = dataset2table(cereal)

t=5×3 table

<table>
<thead>
<tr>
<th>Calories</th>
<th>Protein</th>
<th>Fat</th>
</tr>
</thead>
<tbody>
<tr>
<td>100% Bran</td>
<td>70</td>
<td>4</td>
</tr>
<tr>
<td>100% Natural Bran</td>
<td>120</td>
<td>3</td>
</tr>
<tr>
<td>All-Bran</td>
<td>70</td>
<td>4</td>
</tr>
<tr>
<td>All-Bran with Extra Fiber</td>
<td>50</td>
<td>4</td>
</tr>
<tr>
<td>Almond Delight</td>
<td>110</td>
<td>2</td>
</tr>
</tbody>
</table>

Input Arguments

ds — Input dataset array
dataset array

Input dataset array to convert to a table, specified as a dataset array. Each variable in ds becomes a variable in the output table t.

Output Arguments

t — Output table
table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see “Tables” (MATLAB).

“Tables” (MATLAB)

Introduced in R2013b
**datasetfun**

**Class:** dataset

Apply function to dataset array variables

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

```matlab
b = datasetfun(fun,A)
[b,c,...] = datasetfun(fun,A)
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
[b,...] = datasetfun(fun,A,...,'DataVars',vars)
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)
```

**Description**

`b = datasetfun(fun,A)` applies the function specified by `fun` to each variable of the dataset array `A`, and returns the results in the vector `b`. The `i`th element of `b` is equal to `fun` applied to the `i`th dataset variable of `A`. `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called, and `datasetfun` concatenates them into the vector `b`. The outputs from `fun` must be one of the following types: numeric, logical, character, structure, or cell.

To apply functions that return results that are nonscalar or of different sizes and types, use the 'UniformOutput' or 'DatasetOutput' parameters described below.

Do not rely on the order in which `datasetfun` computes the elements of `b`, which is unspecified.
If `fun` is bound to more than one built-in function or file, (that is, if it represents a set of overloaded functions), `datasetfun` follows MATLAB dispatching rules in calling the function. (See “Function Precedence Order” (MATLAB).)

```matlab
[b,c,...] = datasetfun(fun,A), where `fun` is a function handle to a function that returns multiple outputs, returns vectors `b`, `c`, ..., each corresponding to one of the output arguments of `fun`. `datasetfun` calls `fun` each time with as many outputs as there are in the call to `datasetfun`. `fun` may return output arguments having different classes, but the class of each output must be the same each time `fun` is called.
```

```matlab
[b,...] = datasetfun(fun,A,...,'UniformOutput',false) allows you to specify a function `fun` that returns values of different sizes or types. `datasetfun` returns a cell array (or multiple cell arrays), where the `i`th cell contains the value of `fun` applied to the `i`th dataset variable of `A`. Setting 'UniformOutput' to true is equivalent to the default behavior.
```

```matlab
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true) specifies that the output(s) of `fun` are returned as variables in a dataset array (or multiple dataset arrays). `fun` must return values with the same number of rows each time it is called, but it may return values of any type. The variables in the output dataset array(s) have the same names as the variables in the input. Setting 'DatasetOutput' to false (the default) specifies that the type of the output(s) from `datasetfun` is determined by 'UniformOutput'.
```

```matlab
[b,...] = datasetfun(fun,A,...,'DataVars',vars) allows you to apply `fun` only to the dataset variables in `A` specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.
```

```matlab
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames) specifies observation names for the dataset output when 'DatasetOutput' is true.
```

```matlab
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun), where `efun` is a function handle, specifies the MATLAB function to call if the call to `fun` fails. The error-handling function is called with the following input arguments:
```

- A structure with the fields `identifier`, `message`, and `index`, respectively containing the identifier of the error that occurred, the text of the error message, and the linear index into the input array(s) at which the error occurred
- The set of input arguments at which the call to the function failed
The error-handling function should either re-throw an error, or return the same number of outputs as `fun`. These outputs are then returned as the outputs of `datasetfun`. If 'UniformOutput' is true, the outputs of the error handler must also be scalars of the same type as the outputs of `fun`. For example, the following code could be saved in a file as the error-handling function:

```matlab
function [A,B] = errorFunc(S,varargin)

warning(S.identifier,S.message);
A = NaN;
B = NaN;
```

If an error-handling function is not specified, the error from the call to `fun` is rethrown.

**Examples**

**Work With Datasets Using Function Handles**

Use function handles to compute the mean and plot a histogram of selected variables in a dataset array.

Load the sample data.

```matlab
load hospital
```

Use `datasetfun` to compute the means of the `Weight` and `BloodPressure` variables, and store the results in a dataset array.

```matlab
stats = datasetfun(@mean,hospital,...
    'DataVars',{'Weight','BloodPressure'},...
    'UniformOutput',false)
```

```matlab
stats = 1x2 cell array
    {[154]}    {1x2 double}
```

The variable `BloodPressure` contains two columns: One for the systolic measurement, and one for the diastolic measurement.

Display the mean of the blood pressure variable.

```matlab
stats{2}
```
ans = 1×2

122.7800   82.9600

Plot a histogram of the blood pressure variable.

datasetfun(@hist,hospital,...
    'DataVars','BloodPressure',...
    'UniformOutput',false);

title('{\bf Blood Pressure}')
legend('Systolic','Diastolic','Location','N')

grpstats
**daugment**

*D*-optimal augmentation

**Syntax**

\[
dCE2 = \text{daugment}(dCE, mruns)\\
[dCE2, X] = \text{daugment}(dCE, mruns)\\
[dCE2, X] = \text{daugment}(dCE, mruns, \text{model})\\
[dCE2, X] = \text{daugment}(..., \text{param1}, \text{val1}, \text{param2}, \text{val2}, ...)\]

**Description**

\(dCE2 = \text{daugment}(dCE, mruns)\) uses a coordinate-exchange algorithm to *D*-optimally add \(mruns\) runs to an existing experimental design \(dCE\) for a linear additive model.

\([dCE2, X] = \text{daugment}(dCE, mruns)\) also returns the design matrix \(X\) associated with the augmented design.

\([dCE2, X] = \text{daugment}(dCE, mruns, \text{model})\) uses the linear regression model specified in \(\text{model}\). \(\text{model}\) is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of \(X\) for a full quadratic model with \(n\) terms is:

1. The constant term
2. The linear terms in order 1, 2, ..., \(n\)
3. The interaction terms in order (1, 2), (1, 3), ..., (1, \(n\)), (2, 3), ..., (\(n-1\), \(n\))
4. The squared terms in order 1, 2, ..., \(n\)

Other models use a subset of these terms, in the same order.
Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors $X_1$, $X_2$, and $X_3$, then a row $[0 \ 1 \ 2]$ in *model* specifies the term $(X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

$$[dCE2,X] = \text{daugment(...,param1,val1,param2,val2,...)}$$

specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bounds'</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix, where nfactors is the number of factors. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>'categorical'</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>'display'</td>
<td>Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.</td>
</tr>
<tr>
<td>'excludefun'</td>
<td>Handle to a function that excludes undesirable runs. If the function is $f$, it must support the syntax $b = f(S)$, where $S$ is a matrix of treatments with nfactors columns, where nfactors is the number of factors, and $b$ is a vector of Boolean values with the same number of rows as $S$. $b(i)$ is true if the $i$th row $S$ should be excluded.</td>
</tr>
<tr>
<td>'init'</td>
<td>Initial design as an mruns-by-nfactors matrix, where nfactors is the number of factors. The default is a randomly selected set of points.</td>
</tr>

<tr>
<td></td>
<td>In that case, use a cell array the same size as the Parallel pool.</td>
</tr>
<tr>
<td>'tries'</td>
<td>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</td>
</tr>
</tbody>
</table>

**Note** The `daugment` function augments an existing design using a coordinate-exchange algorithm; the 'start' parameter of the `candexch` function provides the same functionality using a row-exchange algorithm.
Examples

The following eight-run design is adequate for estimating main effects in a four-factor model:

```matlab
dCEmain = cordexch(4,8)
dCEmain =
   1   -1   -1    1
 -1   -1    1    1
 -1    1   -1    1
  1    1    1   -1
  1    1    1    1
 -1    1   -1   -1
  1   -1   -1   -1
 -1   -1    1   -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```matlab
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
   1   -1   -1    1
 -1   -1    1    1
 -1    1   -1    1
  1    1    1   -1
  1    1    1    1
 -1    1   -1   -1
  1   -1   -1   -1
 -1   -1    1   -1
 -1     1    1    1
 -1    1   -1    1
 -1     1    1   -1
  1    1    1    1
 -1    1   -1    1
  1    1   -1    1
 -1    1    1   -1
  1    1   -1   -1
  1   -1    1    1
 -1    1    1    1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel', true)

For more information, see the 'Options' name-value pair argument.

See Also

candexch | cordexch | dcovary

Introduced before R2006a
**d covary**

*D*-optimal design with fixed covariates

**Syntax**

\[
dCV = \text{d covary}(\text{n factors}, \text{fixed})
\]

\[
[dCV, X] = \text{d covary}(\text{n factors}, \text{fixed})
\]

\[
[dCV, X] = \text{d covary}(\text{n factors}, \text{fixed}, model)
\]

\[
[dCV, X] = \text{daugment}(\ldots, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \ldots)
\]

**Description**

\(dCV = \text{d covary}(\text{n factors}, \text{fixed})\) uses a coordinate-exchange algorithm to generate a *D*-optimal design for a linear additive model with \text{n factors} factors, subject to the constraint that the model include the fixed covariate factors in \text{fixed}. The number of runs in the design is the number of rows in \text{fixed}. The design \(dCV\) augments \text{fixed} with initial columns for treatments of the model terms.

\([dCV, X] = \text{d covary}(\text{n factors}, \text{fixed})\) also returns the design matrix \(X\) associated with the design.

\([dCV, X] = \text{d covary}(\text{n factors}, \text{fixed}, model)\) uses the linear regression model specified in \text{model}. \text{model} is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of \(X\) for a full quadratic model with \(n\) terms is:

1. The constant term
2. The linear terms in order 1, 2, ..., \(n\)
3. The interaction terms in order \((1, 2), (1, 3), ..., (1, n), (2, 3), ..., (n - 1, n)\)

32-1231
The squared terms in order 1, 2, ..., \( n \)  

Other models use a subset of these terms, in the same order.

Alternatively, \( \text{model} \) can be a matrix specifying polynomial terms of arbitrary order. In this case, \( \text{model} \) should have one column for each factor and one row for each term in the model. The entries in any row of \( \text{model} \) are powers for the factors in the columns. For example, if a model has factors \( X_1, X_2, \) and \( X_3 \), then a row \([0 \ 1 \ 2]\) in \( \text{model} \) specifies the term \((X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)\). A row of all zeros in \( \text{model} \) specifies a constant term, which can be omitted.

\[
[dCV,X] = \text{daugment}(..., \text{param1,val1, param2,val2,} ...) 
\]

specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bounds'</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-( \text{n} )factors matrix. Alternatively, this value can be a cell array containing ( \text{n} )factors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>'categorical'</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>'display'</td>
<td>Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.</td>
</tr>
<tr>
<td>'excludefun'</td>
<td>Handle to a function that excludes undesirable runs. If the function is ( f ), it must support the syntax ( b = f(S) ), where ( S ) is a matrix of treatments with ( \text{n} )factors columns and ( b ) is a vector of Boolean values with the same number of rows as ( S ). ( b(i) ) is true if the ( i )th row ( S ) should be excluded.</td>
</tr>
<tr>
<td>'init'</td>
<td>Initial design as an ( \text{n} )runs-by-( \text{n} )factors matrix. The default is a randomly selected set of points.</td>
</tr>
<tr>
<td>'levels'</td>
<td>Vector of number of levels for each factor.</td>
</tr>
<tr>
<td>'maxiter'</td>
<td>Maximum number of iterations. The default is 10.</td>
</tr>
</tbody>
</table>
### Examples

#### Example 1

Suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:
time = linspace(-1,1,8)';
[dCV1,X] = dcovary(3,time,'linear')
dCV1 =
    -1.0000    1.0000    1.0000   -1.0000
    1.0000   -1.0000   -1.0000   -0.7143
    -1.0000   -1.0000   -1.0000   -0.4286
    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000   -1.0000    0.1429
    -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    0.7143
   -1.0000   -1.0000    1.0000    1.0000
X =
    1.0000   -1.0000    1.0000    1.0000   -1.0000
    1.0000    1.0000   -1.0000   -1.0000   -0.7143
    1.0000   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000    1.0000   -1.0000    0.1429
    1.0000   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    1.0000    0.7143
    1.0000   -1.0000   -1.0000    1.0000    1.0000

The column vector time is a fixed factor, normalized to values between ±1. The number of rows in the fixed factor specifies the number of runs in the design. The resulting design dCV gives factor settings for the three controlled model factors at each time.

### Example 2

The following example uses the dummyvar function to block an eight-run experiment into 4 blocks of size 2 for estimating a linear additive model with two factors:

```matlab
fixed = dummyvar([1 1 2 2 3 3 4 4]);
dCV2 = dcovary(2,fixed(:,1:3),'linear')
dCV2 =
    1   1   1   0   0
   -1  -1   1   0   0
   -1   1   0   1   0
    1  -1   0   1   0
    1   1   0   0   1
   -1  -1   0   0   1
   -1   1   0   0   0
    1  -1   0   0   0
```

The first two columns of dCV2 contain the settings for the two factors; the last three columns are dummy variable codings for the four blocks.
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced before R2006a
delete

Class: qrandstream

Delete handle object

Syntax

delete(h)

Description

delete(h) deletes the handle object h, where h is a scalar handle. The delete method deletes a handle object but does not clear the handle from the workspace. A deleted handle is no longer valid.

See Also

clear | isValid | qrandstream
dendrogram

Dendrogram plot

Syntax

dendrogram(tree)
dendrogram(tree,Name,Value)
dendrogram(tree,P)
dendrogram(tree,P,Name,Value)

H = dendrogram(__)
[H,T,outperm] = dendrogram(__)

Description

dendrogram(tree) generates a dendrogram plot of the hierarchical binary cluster tree. A dendrogram consists of many U-shaped lines that connect data points in a hierarchical tree. The height of each U represents the distance between the two data points being connected.

• If there are 30 or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.

• If there are more than 30 data points, then dendrogram collapses lower branches so that there are 30 leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

dendrogram(tree,Name,Value) uses additional options specified by one or more name-value pair arguments.

dendrogram(tree,P) generates a dendrogram plot with no more than P leaf nodes. If there are more than P data points in the original data set, then dendrogram collapses the lower branches of the tree. As a result, some leaves in the plot correspond to more than one data point.
dendrogram(tree,P,Name,Value) uses additional options specified by one or more name-value pair arguments.

H = dendrogram(___) generates a dendrogram plot and returns a vector of line handles. You can use any of the input arguments from the previous syntaxes.

[H,T,outperm] = dendrogram(___) also returns a vector containing the leaf node number for each object in the original data set, T, and a vector giving the order of the node labels of the leaves as shown in the dendrogram, outperm.

- It is useful to return T when the number of leaf nodes, P, is less than the total number of data points, so that some leaf nodes in the display correspond to multiple data points.
- The order of the node labels given in outperm is from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram.

**Examples**

**Plot Dendrogram**

Generate sample data.

rng('default') % For reproducibility
X = rand(10,3);

Create a hierarchical binary cluster tree using linkage. Then, plot the dendrogram using the default options.

tree = linkage(X,'average');
figure()
dendrogram(tree)
Specify Dendrogram Leaf Node Order

Generate sample data.

```matlab
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`.

```matlab
tree = linkage(X,'average');
```
D = pdist(X);
leafOrder = optimalleaforder(tree,D)
leafOrder = 1×10

Plot the dendrogram using an optimal leaf order.

figure()
dendrogram(tree,'Reorder',leafOrder)

The order of the leaf nodes in the dendrogram plot corresponds - from left to right - to the permutation in leafOrder.
Specify Number of Nodes in Dendrogram Plot

Generate sample data.

```matlab
rng('default') % For reproducibility
X = rand(100,2);
```

There are 100 data points in the original data set, \( X \).

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram for the complete tree (100 leaf nodes) by setting the input argument \( P \) equal to 0.

```matlab
tree = linkage(X,'average');
dendrogram(tree,0)
```
Now, plot the dendrogram with only 25 leaf nodes. Return the mapping of the original data points to the leaf nodes shown in the plot.

```matlab
figure
[~,T] = dendrogram(tree,25);
```

List the original data points that are in leaf node 7 of the dendrogram plot.

```matlab
find(T==7)
```

```
ans = 7×1

7
33
60
```
Change Dendrogram Orientation and Line Width

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram with a vertical orientation, using the default color threshold. Return handles to the lines so you can change the dendrogram line widths.

```
tree = linkage(X,'average');
H = dendrogram(tree,'Orientation','left','ColorThreshold','default');
set(H,'LineWidth',2)
```
Input Arguments

tree — Hierarchical binary cluster tree
matrix returned by linkage

Hierarchical binary cluster tree, specified as an \((M - 1)\)-by-3 matrix that you generate using `linkage`, where \(M\) is the number of data points in the original data set.

P — Maximum number of leaf nodes
30 (default) | positive integer value

Maximum number of leaf nodes to include in the dendrogram plot, specified as a positive integer value.
• If there are \( P \) or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.

• If there are more than \( P \) data points, then dendrogram collapses lower branches so that there are \( P \) leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

If you do not specify \( P \), then dendrogram uses 30 as the maximum number of leaf nodes. To display the complete tree, set \( P \) equal to 0.

Data Types: single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Orientation','left','Reorder',myOrder specifies a vertical dendrogram with leaves in the order specified by myOrder.

**Reorder — Order of leaf nodes**

vector

Order of leaf nodes in the dendrogram plot, specified as the comma-separated pair consisting of 'Reorder' and a vector giving the order of nodes in the complete tree. The order vector must be a permutation of the vector 1:M, where \( M \) is the number of data points in the original data set. Specify the order from left to right for horizontal dendrograms, and from bottom to top for vertical dendrograms.

If \( M \) is greater than the number of leaf nodes in the dendrogram plot, \( P \) (by default, \( P \) is 30), then you can only specify a permutation vector that does not separate the groups of leaves that correspond to collapsed nodes.

Data Types: single | double

**CheckCrossing — Indicator for whether to check for crossing branches**

true (default) | false

Indicator for whether to check for crossing branches in the dendrogram plot, specified as the comma-separated pair consisting of 'CheckCrossing' and either true or false. This option is only useful when you specify a value for Reorder.
When CheckCrossing has the value true, dendrogram issues a warning if the order of the leaf nodes causes crossing branches in the plot. If the dendrogram plot does not show a complete tree (because the number of data points in the original data set is greater than P), dendrogram only issues a warning when the order of the leaf nodes causes branch to cross in the dendrogram as shown in the plot. That is, there is no warning if the order causes crossing branches in the complete tree but not in the dendrogram as shown in the plot.

Data Types: logical

**ColorThreshold — Threshold for unique colors**
'default' | scalar value in the range (0,max(tree(:,3)))

Threshold for unique colors in the dendrogram plot, specified as the comma-separated pair consisting of 'ColorThreshold' and either 'default' or a scalar value in the range (0,max(tree(:,3))). If ColorThreshold has the value T, then dendrogram assigns a unique color to each group of nodes in the dendrogram whose linkage is less than T.

- If ColorThreshold has the value 'default', then the threshold, T, is 70% of the maximum linkage, 0.7*max(tree(:,3)).
- If you do not specify a value for ColorThreshold, or if you specify a threshold outside the range (0,max(tree(:,3))), then dendrogram uses only one color for the dendrogram plot.

**Orientation — Orientation of dendrogram**
'top' (default) | 'bottom' | 'left' | 'right'

Orientation of the dendrogram in the figure window, specified as the comma-separated pair consisting of 'Orientation' and one of these values:

- 'top' Top to bottom
- 'bottom' Bottom to top
- 'left' Left to right
- 'right' Right to left

**Labels — Label for each data point**
character array | string array | cell array of character vectors

Label for each data point in the original data set, specified as the comma-separated pair consisting of 'Labels' and a character array, string array or cell array of character vectors.
vectors. `dendrogram` labels any leaves in the dendrogram plot containing a single data point with that data point’s label.

**Output Arguments**

**H — Handles to lines**

vector

Handles to lines in the dendrogram plot, returned as a vector.

**T — Leaf node numbers**

column vector

Leaf node numbers for each data point in the original data set, returned as a column vector of length $M$, where $M$ is the number of data points in the original data set.

When there are fewer than $P$ data points in the original data ($P$ is 30, by default), all data points are displayed in the dendrogram, with each node containing a single data point. In this case, $T$ is the identity map, $T = (1:M)'$.

$T$ is useful when $P$ is less than the total number of data points. That is, when some leaf nodes in the dendrogram display correspond to multiple data points. For example, to find out which data points are contained in leaf node $k$ of the dendrogram plot, use `find(T==k)`.

**outperm — Permutation of node labels**

vector

Permutation of the node labels of the leaves of the dendrogram as shown in the plot, returned as a row vector. `outperm` gives the order from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram. If there are $P$ leaves in the dendrogram plot, `outperm` is a permutation of the vector $1:P$.

**Introduced before R2006a**
Description property

**Class:** dataset

Character vector describing data set

**Note** The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

**Description**

`Description` is a character vector describing the data set. The default is an empty character vector.
designecoc

Coding matrix for reducing error-correcting output code to binary

**Syntax**

\[
M = \text{designecoc}(K, \text{name}) \\
M = \text{designecoc}(K, \text{name}, \text{Name,Value})
\]

**Description**

\[
M = \text{designecoc}(K, \text{name}) \text{ returns the coding matrix } M \text{ that reduces the error-correcting output code (ECOC) design specified by name and K classes to a binary problem. } \\
M \text{ has } K \text{ rows and } L \text{ columns, with each row corresponding to a class and each column corresponding to a binary learner. name and K determine the value of } L.
\]

You can view or customize \( M \), and then specify it as the coding matrix for training an ECOC multiclass classifier using \text{fitcecoc}.

\[
M = \text{designecoc}(K, \text{name}, \text{Name,Value}) \text{ returns the coding matrix with additional options specified by one or more Name,Value pair arguments.}
\]

For example, you can specify the number of trials when generating a dense or sparse, random coding matrix.

**Examples**

**Train ECOC Classifiers Using a Custom Coding Design**

Consider the arrhythmia data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia. Train an ECOC classifier using a custom coding design specified by the description of the classes.
Load the `arrhythmia` data set.

```matlab
class1VSOrd = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VSOrd class1VSClass16 OrdVSClass16,...
          zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))];
```

Train an ECOC classifier using the custom coding design `Coding` and specify that the binary learners are decision trees.

```matlab
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learner','Tree');
```

Estimate the in-sample classification error.

```matlab
genErr = resubLoss(Mdl)
genErr = 0.1460
```
**Choose Among Several Random Coding Designs**

If you request a random coding matrix by specifying `sparserandom` or `denserandom`, then, by default, `designecoc` generates 10,000 random matrices. Then, it chooses the matrix with the largest, minimal, pair-wise row distances based on the Hamming measure. You can specify to generate more matrices to increase the chance of obtaining a better one, or you can generate several coding matrices, and then see which performs best.

Load the `arrhythmia` data set. Reserve the observations classified into class 16 (i.e., those that do not have an arrhythmia classification) as new data.

```matlab
load arrhythmia
oosIdx = Y == 16;
isIdx = ~oosIdx;
Y = categorical(Y(isIdx));
tabulate(Y)
```

<table>

<td>4</td>
<td>0.93%</td>
</tr>
<tr>
<td>15</td>
<td>5</td>
<td>1.16%</td>
</tr>
</tbody>
</table>

K = numel(unique(Y));

Generate four random coding design matrices such that the first two are dense and the second two are sparse. Specify to find the best out of 20,000 variates.

```matlab
rng(1); % For reproducibility
Coding = cell(4,1); % Preallocate for coding matrices
CodingTypes = {'denserandom','denserandom','sparserandom','sparserandom'};
for j = 1:4;
    Coding{j} = designecoc(K,CodingTypes{j},'NumTrials',2e4);
end
```
Coding is a 4-by-1 cell array, where each cell is a coding design matrix. The matrices have \( K \) rows, but the number of columns (i.e., binary learners) might vary.

Train and cross validate ECOC classifiers using the 15-fold cross validation. Specify that each ECOC classifier be trained using a classification tree, and the random coding matrix stored in Coding.

```matlab
Mdl = cell(4,1); % Preallocate for the ECOC classifiers
for j = 1:4;
    Mdl{j} = fitcecoc(X(isIdx,:),Y,'Learners','tree',...
                    'Coding',Coding{j},'KFold',15);
end
```

Warning: One or more folds do not contain points from all the groups.

Mdl is a 4-by-1 cell array of ClassificationPartitionedECOC models. Several classes have low relative frequency in the data, and so there is a chance that, during cross validation, some in-sample folds will not train using observations from those classes.

Estimate the 15-fold classification error for each classifier.

```matlab
genErr = nan(4,1);
for j = 1:4;
    genErr(j) = kfoldLoss(Mdl{j});
end
```

```
genErr
genErr = 4x1
       0.2349
       0.2140
       0.2116
       0.2279
```

Though the generalization error is still high, the best performing model, based solely on the out-of-sample classification error, is the model that used the coding design Coding{3}.
You can try to improve the generalization error by tuning some parameters of the binary learners. For example, you can specify to use the twoing rule or deviance for the split criterion, rather than the default Gini’s diversity index. You might also specify to use surrogate splits since there are missing values in the data.

**Input Arguments**

**K — Number of classes**  
positive integer

Number of classes, specified as a positive integer.  

\( K \) specifies the number of rows of the coding matrix \( M \).  

Data Types: single | double

**name — Coding design name**  
'binarycomplete' | 'denserandom' | 'onevsall' | 'onevsone' | 'sparserandom' | ...

Coding design name, specified as a value in the following table. The table summarizes the coding schemes.

<table>
<thead>
<tr>
<th>Value</th>
<th>Number of Binary Learners</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allpairs' and 'onevsone'</td>
<td>( K(K - 1)/2 )</td>
<td>For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.</td>
</tr>
<tr>
<td>Value</td>
<td>Number of Binary Learners</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'binarycomplete'</td>
<td>$2^{(K-1)} - 1$</td>
<td>This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.</td>
</tr>
<tr>
<td>'denserandom'</td>
<td>Random, but approximately $10 \log_2 K$</td>
<td>For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1795.</td>
</tr>
<tr>
<td>'onevsall'</td>
<td>$K$</td>
<td>For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.</td>
</tr>
<tr>
<td>'ordinal'</td>
<td>$K - 1$</td>
<td>For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.</td>
</tr>
<tr>
<td>Value</td>
<td>Number of Binary Learners</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'sparserandom'</td>
<td>Random, but approximately 15 $\log_2 K$</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1795.</td>
</tr>
<tr>
<td>'ternarycomplete'</td>
<td>$\left(3^K - 2^{(K+1)} + 1\right)/2$</td>
<td>This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.</td>
</tr>
</tbody>
</table>

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'NumTrials',1000 specifies to generate 1000 random matrices.

**NumTrials — Number of random coding matrices to generate**

`10000` (default) | positive integer

Number of random coding matrices to generate, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer.

The software:

- Generates `NumTrials` matrices, and selects the one with the maximal, pair-wise row distance.
- Ignores `NumTrials` for all values of name except 'denserandom' and 'sparserandom'.
Example: 'NumTrials',1000
Data Types: single | double

Output Arguments

M — Coding matrix
numeric matrix

Coding matrix that reduces an ECOC scheme to binary, returned as a numeric matrix. M has K rows and L columns, where L is the number of binary learners. Each row corresponds to a class and each column corresponds to a binary learner.

The elements of M are -1, 0, or 1, and the value corresponds to a dichotomous class assignment. This table describes the meaning of M(i,j), that is, the class that learner j assigns to observations in class i.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner j assigns observations in class i to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner j removes observations in class i from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner j assigns observations in class i to a positive class.</td>
</tr>
</tbody>
</table>

The binary learners for designs denserandom, binarycomplete, and onevsall do not assign 0 to observations in any class.

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the binarycomplete and ternarycomplete coding designs are not efficient. However:
  - If K ≤ 4, then use ternarycomplete coding design rather than sparserandom.
  - If K ≤ 5, then use binarycomplete coding design rather than denserandom.
You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use $k$-fold cross-validation (`KFold`).

## Algorithms

### Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors $u$ and $v$, $u \neq v$ and $u \neq -v$.
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
  - You can move vertically from 1 to -1 or -1 to 1.
  - You can move horizontally from a nonzero element to another nonzero element.
  - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row $i$ to row $j$ using these rules, then classes $i$ and $j$ cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix}
1 & 0 \\
-1 & 0 \\
0 & 1 \\
0 & -1
\end{bmatrix}$$
classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

**Random Coding Design Matrices**

For a given number of classes, for example, \( K \), the software generates random coding design matrices as follows.

1. The software generates one of the following:
   a. Dense random — The software assigns a 1 or -1 with equal probability to each element of the \( K \)-by-\( L_d \) coding design matrix, where \( L_d = \left\lfloor 10 \log_2 K \right\rfloor \).
   b. Sparse random — The software assigns a 1 to each element of the \( K \)-by-\( L_s \) coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where \( L_s = \left\lfloor 15 \log_2 K \right\rfloor \).

2. If a column does not contain at least one 1 and at least one -1, then the software removes that column.

3. For distinct columns \( u \) and \( v \), if \( u = v \) or \( u = -v \), then the software removes \( v \) from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

\[
\Delta(k_1,k_2) = 0.5 \sum_{l=1}^{L} |m_{k_1,l}||m_{k_2,l}||m_{k_1,l} - m_{k_2,l}|,
\]

where \( m_{k,l} \) is an element of coding design matrix \( j \).

Introduced in R2014b
**devianceTest**

Analysis of deviance

**Syntax**

```matlab
tbl = devianceTest(mdl)
```

**Description**

`tbl = devianceTest(mdl)` returns an analysis of deviance table for the `mdl` generalized linear model. `tbl` gives the result of a test of whether the fitted model fits significantly better than a constant model.

**Input Arguments**

`mdl`

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

**Output Arguments**

`tbl`

Table containing two rows and four columns.

- The first row relates to a constant model.
- The second row relates to the full model in `mdl`.
- The columns are:
| **Deviance** | Deviance is twice the difference between the log likelihoods of the corresponding model (mdl or constant) and the saturated model. The test statistic for the deviance test is twice the difference between the log likelihoods of the tested model mdl and the constant model. For more information, see Deviance on page 32-1262. |
| **DFE** | Error degrees of freedom. It is the number of observations minus the number of parameters in the corresponding model. |
| **chi2Stat** | F statistic or Chi-squared statistic, depending on whether the dispersion is estimated (F statistic) or not (Chi-squared statistic) |
| | • Chi-squared statistic is the difference between the deviance of the constant model and the deviance of the full model. |
| | • F statistic is the difference between the deviance of the constant model and the deviance of the full model, divided by the estimated dispersion. |
| **pValue** | p-value associated with the test. It is the Chi-squared statistic with (number of coefficients in the model minus one) degrees of freedom, or F statistic with (number of coefficients in the model minus one) numerator degrees of freedom, and DFE denominator degrees of freedom. |
Examples

Deviance Test

Perform a deviance test on a generalized linear model.

Construct a generalized linear model.

```matlab
rng('default') % for reproducibility
X = randn(100,5);
mu = exp(X(:,[1 4 5])*[.4;.2;.3]);
y = poissrnd(mu);
mdl = fitglm(X,y,'linear','Distribution','poisson');
```

Test whether the model differs from a constant in a statistically significant way.

```matlab
tbl = devianceTest(mdl)
```

<table>
<thead>
<tr>
<th>Deviance</th>
<th>DFE</th>
<th>chi2Stat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>log(y) ~ 1</td>
<td>128.58</td>
<td>99</td>
<td></td>
</tr>
<tr>
<td>log(y) ~ 1 + x1 + x2 + x3 + x4 + x5</td>
<td>83.726</td>
<td>94</td>
<td>44.858</td>
</tr>
</tbody>
</table>

The $P$-value is very small, indicating that the model significantly differs from a constant.

Definitions

Deviance

Deviance of a model $M_1$ is twice the difference between the loglikelihood of that model and the saturated model, $M_S$. The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are $n$ observations $y_i$, $i = 1, 2, ..., n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with $n$ parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model $M_1$ is
where $b_1$ are the estimated parameters for model $M_1$ and $b_S$ are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where $n$ is the number of parameters in the saturated model and $p$ is the number of parameters in model $M_1$.

If $M_1$ and $M_2$ are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances $D_1$ and $D_2$ of these models. The difference of the deviances is

$$D = D_2 - D_1 = -2 \left( \log L(b_2, y) - \log L(b_S, y) \right) + 2 \left( \log L(b_1, y) - \log L(b_S, y) \right)$$

$$= -2 \left( \log L(b_2, y) - \log L(b_1, y) \right).$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom $v$ equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can get the $p$-value for this test using $1 - \text{chi2cdf}(D, V)$, where $D = D_2 - D_1$.

**Topics**

“Generalized Linear Models” on page 12-12
**designMatrix**

**Class:** GeneralizedLinearMixedModel

Fixed- and random-effects design matrices

**Syntax**

```matlab
D = designMatrix(glme)
D = designMatrix(glme,'Fixed')

D = designMatrix(glme,'Random')
Dsub = designMatrix(glme,'Random',gnumbers)
[Dsub,gnames] = designMatrix(glme,'Random',gnumbers)
```

**Description**

- **D = designMatrix(glme)** or **D = designMatrix(glme,'Fixed')** returns the fixed-effects design matrix for the generalized linear mixed-effects model `glme`.

- **D = designMatrix(glme,'Random')** returns the random-effects design matrix for the generalized linear mixed-effects model `glme`.

- **Dsub = designMatrix(glme,'Random',gnumbers)** returns a subset of the random-effects design matrix for the generalized linear mixed-effects model `glme` that corresponds to the grouping variables indicated by `gnumbers`.

- **[Dsub,gnames] = designMatrix(glme,'Random',gnumbers)** also returns the grouping variable names that correspond to `gnumbers`.

**Input Arguments**

- **glme — Generalized linear mixed-effects model**
  GeneralizedLinearMixedModel object
Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**gnumbers — Grouping variable numbers**
array of integer values

Grouping variable numbers, specified as an array of integer values containing elements in the range \([1, R]\), where \(R\) is the length of the cell array that contains the grouping variables for the generalized linear mixed-effects model \(glme\).

For example, you can specify the grouping variables \(g_1, g_3,\) and \(g_r\) as \([1, 3, r]\).

Data Types: single | double

## Output Arguments

**D — Design matrix**
matrix

Design matrix of a generalized linear mixed-effects model \(glme\) returned as one of the following:

- Fixed-effects design matrix — \(n\)-by-\(p\) matrix consisting of the fixed-effects design matrix of \(glme\), where \(n\) is the number of observations and \(p\) is the number of fixed-effects terms.
- Random-effects design matrix — \(n\)-by-\(k\) matrix, consisting of the random-effects design matrix of \(glme\). Here, \(k\) is equal to \(\text{length}(B)\), where \(B\) is the random-effects coefficients vector of generalized linear mixed-effects model \(glme\). The random-effects design matrix is returned as a sparse matrix. For more information, see “Sparse Matrices“ (MATLAB).

If \(glme\) has \(R\) grouping variables \(g_1, g_2, \ldots, g_R\), with levels \(m_1, m_2, \ldots, m_R\), respectively, and if \(q_1, q_2, \ldots, q_R\) are the lengths of the random-effects vectors that are associated with \(g_1, g_2, \ldots, g_R\), respectively, then \(B\) is a column vector of length \(q_1*m_1 + q_2*m_2 + \ldots + q_R*m_R\).

\(B\) is made by concatenating the empirical Bayes predictors of random effects vectors corresponding to each level of each grouping variable as \([g_1\text{level}_1; g_1\text{level}_2; \ldots; g_1\text{level}_{m_1}; g_2\text{level}_1; g_2\text{level}_2; \ldots; g_2\text{level}_{m_2}; \ldots; g_R\text{level}_1; g_R\text{level}_2; \ldots; g_R\text{level}_{m_R}]'\).
Data Types: single | double

Dsub — Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix that corresponds to the grouping variables specified by gnumbers, returned as an \( n \)-by-\( k \) matrix, where \( k \) is length of the column vector Bsub.

Bsub contains the concatenated empirical Bayes predictors of random-effects vectors, corresponding to each level of the grouping variables, specified by gnumbers.

If, for example, gnumbers is \([1, 3, r]\), this corresponds to the grouping variables \(g_1\), \(g_3\), and \(g_r\). Then, Bsub contains the empirical Bayes predictors of random-effects vectors corresponding to each level of the grouping variables \(g_1\), \(g_3\), and \(g_r\), such as

\[
[g_1 \text{level}_1; g_1 \text{level}_2; \ldots; g_1 \text{level}_{m_1}; g_3 \text{level}_1; g_3 \text{level}_2; \ldots; g_3 \text{level}_{m_3}; \quad \\
g_r \text{level}_1; g_r \text{level}_2; \ldots; g_r \text{level}_{m_r}]'.
\]

Thus, \(Dsub^*Bsub\) represents the contribution of all random effects corresponding to grouping variables \(g_1\), \(g_3\), and \(g_r\) to the response of glme.

If gnumbers is empty, then Dsub is the full random-effects design matrix.

Data Types: single | double

gnames — Names of grouping variables

\(k\)-by-1 cell array

Names of grouping variables corresponding to the integers in gnumbers if the design type is 'Random', returned as a \(k\)-by-1 cell array. If the design type is 'Fixed', then gnames is an empty matrix [].

Data Types: cell

Examples

Obtain Fixed- and Random-Effects Design Matrices

Load the sample data.
load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}).$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i,$$

where
• $\text{defects}_{ij}$ is the number of defects observed in the batch produced by factory $i$ during batch $j$.

• $\mu_{ij}$ is the mean number of defects corresponding to factory $i$ (where $i = 1, 2, ..., 20$) during batch $j$ (where $j = 1, 2, ..., 5$).

• $\text{newprocess}_{ij}$, $\text{time\_dev}_{ij}$, and $\text{temp\_dev}_{ij}$ are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, $\text{newprocess}_{ij}$ indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• $\text{supplier\_C}_{ij}$ and $\text{supplier\_B}_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma^2_b)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme}(\text{mfr}, \text{'defects ~ 1 + newprocess + time\_dev + temp\_dev + supplier + (1|factory)'});
\]

Extract the fixed-effects design matrix and display rows 1 through 10.

\[
\text{Dfe} = \text{designMatrix}(\text{glme}, \text{'Fixed'});
\]

```matlab
disp(Dfe(1:10,:))
```

\[
\begin{array}{cccccc}
1.0000 & 0 & 0.1834 & 0.2259 & 1.0000 & 0 \\
1.0000 & 0 & 0.3035 & 0.0725 & 0 & 1.0000 \\
1.0000 & 0 & 0.0717 & 0.1630 & 1.0000 & 0 \\
1.0000 & 0 & 0.1069 & 0.0809 & -1.0000 & -1.0000 \\
1.0000 & 0 & 0.0241 & 0.0319 & 1.0000 & 0 \\
1.0000 & 0 & 0.1214 & 0.1114 & 0 & 1.0000 \\
1.0000 & 0 & 0.0033 & 0.0553 & 1.0000 & 0 \\
1.0000 & 0 & 0.2350 & 0.0616 & 1.0000 & 0 \\
1.0000 & 0 & 0.0488 & 0.0177 & 0 & 1.0000 \\
1.0000 & 0 & 0.1148 & 0.0105 & 1.0000 & 0 \\
\end{array}
\]

Column 1 of the fixed-effects design matrix $\text{Dfe}$ contains the constant term. Column 2, 3, and 4 contain the $\text{newprocess}$, $\text{time\_dev}$, and $\text{temp\_dev}$ terms, respectively. Columns 5 and 6 contain dummy variables for $\text{supplier\_C}$ and $\text{supplier\_B}$, respectively.

Extract the random-effects design matrix and display rows 1 through 10.
Dre = designMatrix(glme,'Random');
disp(Dre(1:10,:))

(1,1)   1
(2,1)   1
(3,1)   1
(4,1)   1
(5,1)   1
(6,2)   1
(7,2)   1
(8,2)   1
(9,2)   1
(10,2)  1

Convert the sparse matrix Dre to a full matrix and display rows 1 through 10.

full(Dre(1:10,:))

ans = 10×20

1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
0     1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
0     1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
0     1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
0     1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0
0     1     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0     0

Each column corresponds to a level of the grouping variable factory.

designMatrix

Class: LinearMixedModel

Fixed- and random-effects design matrices

Syntax

D = designMatrix(lme)
D = designMatrix(lme,'Fixed')

D = designMatrix(lme,'Random')
Dsub = designMatrix(lme,'Random',gnumbers)
[Dsub,gnames] = designMatrix(lme,'Random',gnumbers)

Description

D = designMatrix(lme) or D = designMatrix(lme,'Fixed') returns the fixed-effects design matrix for the linear mixed-effects model lme.

D = designMatrix(lme,'Random') returns the random-effects design matrix for the linear mixed-effects model lme.

Dsub = designMatrix(lme,'Random',gnumbers) returns a subset of the random-effects design matrix for the linear mixed-effects model lme corresponding to the grouping variables indicated by the integers in gnumbers.

[Dsub,gnames] = designMatrix(lme,'Random',gnumbers) also returns the grouping variable names corresponding to the integers in gnumbers.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object
Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

**gnumbers — Grouping variable numbers**
integer array

Grouping variable numbers, specified as an integer array, where \( R \) is the length of the cell array that contains the grouping variables for the linear mixed-effects model \( \text{lme} \).

For example, you can specify the grouping variables \( g_1, g_3, \) and \( g_r \) as follows.

Example: \([1,3,r]\)

Data Types: `double` | `single`

## Output Arguments

**D — Design matrix**
matrix

Design matrix of a linear mixed-effects model \( \text{lme} \) returned as one of the following:

- Fixed-effects design matrix — \( n \)-by-\( p \) matrix consisting of the fixed-effects design of \( \text{lme} \), where \( n \) is the number of observations and \( p \) is the number of fixed-effects terms.
- Random-effects design matrix — \( n \)-by-\( k \) matrix, consisting of the random-effects design matrix of \( \text{lme} \). Here, \( k \) is equal to `length(B)`, where \( B \) is the random-effects coefficients vector of linear mixed-effects model \( \text{lme} \).

If \( \text{lme} \) has \( R \) grouping variables \( g_1, g_2, ..., g_R \), with levels \( m_1, m_2, ..., m_R \), respectively, and if \( q_1, q_2, ..., q_R \) are the lengths of the random-effects vectors that are associated with \( g_1, g_2, ..., g_R \), respectively, then \( B \) is a column vector of length \( q_1 * m_1 + q_2 * m_2 + ... + q_R * m_R \).

\( B \) is made by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as \([g_1\text{level}_1; \newline g_1\text{level}_2; \ldots; g_1\text{level}_{m_1}; g_2\text{level}_1; g_2\text{level}_2; \ldots; g_2\text{level}_{m_2}; \ldots; \newline g_R\text{level}_1; g_R\text{level}_2; \ldots; g_R\text{level}_{m_R}]'\).

Data Types: `single` | `double`

**Dsub — Submatrix of random-effects design matrix**
matrix
Submatrix of random-effects design matrix corresponding to the grouping variables indicated by the integers in `gnumbers`, returned as an $n$-by-$k$ matrix, where $k$ is length of the column vector `Bsub`.

`Bsub` contains the concatenated best linear unbiased predictors (BLUPs) of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1,3,r]`, this corresponds to the grouping variables $g_1$, $g_3$, and $g_r$. Then, `Bsub` contains the concatenated BLUPs of random-effects vectors corresponding to each level of the grouping variables $g_1$, $g_3$, and $g_r$, such as

$$[g_1 \text{level}_1; g_1 \text{level}_2; \ldots; g_1 \text{level}_{m_1}; g_3 \text{level}_1; g_3 \text{level}_2; \ldots; g_3 \text{level}_{m_3}; g_r \text{level}_1; g_r \text{level}_2; \ldots; g_r \text{level}_{m_r}]'$$

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables $g_1$, $g_3$, and $g_r$ to the response of `lme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

Data Types: `single` | `double`

`gnames` — Names of grouping variables

$k$-by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is `'Random'`, returned as a $k$-by-1 cell array. If the design type is `'Fixed'`, then `gnames` is an empty matrix `[]`.

Data Types: `cell`

### Examples

#### Display Fixed- and Random-Effects Design Matrices

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The data shows the deviations from the target quality characteristic measured from the products that 5 operators manufacture during three different shifts, morning, evening,
and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

**Shift** and **Operator** are nominal variables.

```matlab
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```matlab
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Display the fixed-effects design matrix.

```matlab
designMatrix(lme)
```

```
ans = 15×3
   1     1     0
   1     0     0
   1     0     1
   1     1     0
   1     0     0
   1     0     1
   1     1     0
   1     0     0
   1     0     1
   1     1     0
   ⋮
```

The column of 1s represents the constant term in the model. **fitlme** takes the evening shift as the reference group and creates two dummy variables to represent the morning and night shifts, respectively.

Display the random-effects design matrix.

```matlab
designMatrix(lme,'random')
```

```
ans =
   (1,1)    1
   (2,1)    1
```
The first number, $i$, in the $(i,j)$ indices corresponds to the observation number, and $j$ corresponds to the level of the grouping variable, Operator, i.e., the operator number.

Show the full display of the random-effects design matrix.

```matlab
default('designMatrix(lme,'random')
ans = 15x5
   1    0    0    0    0
   1    0    0    0    0
   1    0    0    0    0
   0    1    0    0    0
   0    1    0    0    0
   0    1    0    0    0
   0    0    1    0    0
   0    0    1    0    0
   0    0    0    1    0
   ...```

Each column corresponds to a level of the grouping variable, Operator.

**Random-Effects Design Matrix of Multiple Grouping Variables**

Load the sample data.
The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```matlab
D = full(designMatrix(lme,'random'));
```

The first three columns of matrix `D` contain the indicator variables `fitlme` creates for the three levels (Loamy, Silty, Sandy, respectively) of the first grouping variable, `Soil`. The next 15 columns contain the indicator variables created for the second grouping variable, `|Tomato` nested under `Soil`. These are basically the elementwise products of the dummy variables representing the levels of `Soil` (Loamy, Silty, and Sandy, respectively) and the levels of `Tomato` (Cherry, Grape, Heirloom, Plum, Vine, respectively).

**Subset of the Random-Effects Design Matrix**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five
plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called ds, for practical purposes, and define Tomato, Soil, and Fertilizer as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the random-effects design matrix for the second grouping variable, and display the first 12 rows.

```matlab
[Dsub,gname] = designMatrix(lme,'random',2);
full(Dsub(1:12,:))
```

```
ans = 12×15
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0

Dsub contains the dummy variables created for the second grouping variable, that is, tomato nested under soil. These are the elementwise products of the dummy variables representing the levels of Soil (Loamy, Silty, Sandy, respectively) and the levels of Tomato (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Display the name of the grouping variable.
gname

gname = 1x1 cell array
   {'Soil:Tomato'}

LinearMixedModel | fitlmematrix | fitted
dfittool

Open Distribution Fitter app

Note The distributionFitter function was introduced in R2017a as a replacement for the dfittool function. Both functions continue to work to start the Distribution Fitter app.

This page contains programmatic syntax information for the Distribution Fitter app. For general usage information, see Distribution Fitter.

Syntax

dfittool
dfittool(y)
dfittool(y,cens)
dfittool(y,cens,freq)
dfittool(y,cens,freq,dsname)

Description

dfittool opens the Distribution Fitter app, or brings focus to the app if it is already open.

dfittool(y) opens the Distribution Fitter app populated with the data specified by the vector y.

dfittool(y,cens) uses the vector cens to specify whether each observation in y is censored.

dfittool(y,cens,freq) uses the vector freq to specify the frequency of each element of y.

dfittool(y,cens,freq,dsname) creates a data set with the name dsname, using the data vector, y, censoring indicator, cens, and frequency vector, freq.
Examples

Open Distribution Fitter App with Existing Data

Load the carsmall sample data.

load carsmall

Open the Distribution Fitter app using the MPG miles per gallon data.

dfittool(MPG)
The Distribution Fitter app opens, populated with the MPG data, and displays the density (PDF) plot. You can use the app to display different plots and fit distributions to this data.

**Open Distribution Fitter App with Censoring Data**

Load the sample data.
load(fullfile(matlabroot,'examples','stats','lightbulb.mat'))

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of lightbulb as the input data, and the third column as the censoring data. Name the data lifetime.

dfittool(lightbulb(:,1),lightbulb(:,3),[],'lifetime')

To open the Data dialog box, click Data. In the Manage data sets pane, click to highlight the lifetime data set row. Finally, to open the View Data Set dialog, click View. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.
Input Arguments

\textbf{y — Input data}
array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: single | double

\textbf{cens — Censoring indicator}
zeros(n) (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of \texttt{cens} must be equal to the length of \texttt{y}. If \texttt{y(j)} is censored, then \( \texttt{cens(j)==1} \). If \texttt{y(j)} is not
censored, then (cens(j)==0). If cens is omitted or empty, then no y values are censored.

If you have frequency data (freq) but not censoring data (cens), then you must specify empty brackets ([[]]) for cens.

Data Types: single | double

freq — Frequency data
ones(n) (default) | vector of scalar values

Frequency data, specified as a vector of scalar values. The length of freq must be equal to the length of y. If freq is omitted or empty, then all y values have a frequency of 1.

If you have frequency data (freq) but not censoring data (cens), then you must specify empty brackets ([]) for cens.

Data Types: single | double

dsname — Data set name
character vector | string scalar

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data (cens) or frequency data (freq), then you must specify empty brackets ([ ]) for both freq and cens.

Example: 'MyData'

Data Types: char | string

Dimensions property

Class: qrandset

Number of dimensions

Description

Number of dimensions in the point set. The Dimensions property of a point set contains a positive integer that indicates the number of dimensions for which the points have values. For example, a point set with Dimensions=5 produces points that each have five values.

Set this property by specifying the number of dimensions when constructing a new point set. After construction, you cannot change the value. The default number of dimensions is 2.
DimNames property

Class: dataset

Two-element cell array of character vectors giving names of dimensions of data set

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Description

A two-element cell array of character vectors giving the names of the two dimensions of the data set. The default is {'Observations' 'Variables'}. 
discardSupportVectors

Discard support vectors of linear support vector machine binary learners

**Syntax**

Mdl = discardSupportVectors(MdlSV)

**Description**

Mdl = discardSupportVectors(MdlSV) returns a trained, multiclass, error-correcting output codes (ECOC) model (Mdl) containing at least one linear, support vector machine (SVM) binary learner. Mdl is similar to the trained ECOC model MdlSV, except:

- The Alpha, SupportVectors, and SupportVectorLabels properties of all linear SVM binary learners are empty ([]).
- If you display any linear SVM binary learners stored in the cell array of trained models Mdl.BinaryLearners, the software lists the Beta property instead of Alpha.

**Input Arguments**

MdlSV — Full or compact, trained, multiclass ECOC model
ClassificationECOC model | CompactClassificationECOC model

Full or compact, trained, multiclass ECOC model containing at least one linear, SVM binary learner, specified as a ClassificationECOC or CompactClassificationECOC model.

**Output Arguments**

Mdl — Full or compact, trained, multiclass ECOC model
ClassificationECOC model | CompactClassificationECOC model
Full or compact, trained, multiclass ECOC model, returned as a ClassificationECOC or CompactClassificationECOC model. Mdl is the same type as MdlSV.

The properties Alpha, SupportVectorLabels, and SupportVectors of all linear, SVM binary learners in the cell array Mdl.BinaryLearners are empty. The software lists the property Beta when you display any linear, SVM binary learner, and does not list Alpha.

**Examples**

**Retain and Discard Support Vectors of SVM Binary Learners**

By default, fitcecoc empties the Alpha, SupportVectorLabels, and SupportVectors properties of the linear, SVM binary learners stored in the BinaryLearners property of the trained ECOC model. You can retain the support vectors and related values, and then discard them from the model.

Load Fisher's iris data set.

```matlab
load fisheriris
rng(1); % For reproducibility
```

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in the appropriate SVM template.

```matlab
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);
```

Mdl is a trained ClassificationECOC model. By default, fitcecoc uses linear, SVM binary learners. It implements a one-versus-one coding design, which requires three binary learners for three-class learning.

Access the estimated $\alpha$ values using dot notation.

```matlab
alpha = cell(3,1);
alpha{1} = MdlSV.BinaryLearners{1}.Alpha;
alpha{2} = MdlSV.BinaryLearners{2}.Alpha;
alpha{3} = MdlSV.BinaryLearners{3}.Alpha;
alpha
```

alpha =
alpha is a 3-by-1 cell array that stores the estimated values of \( \alpha \).

Discard the support vectors and related values from the ECOC model.

\[
Mdl = \text{discardSupportVectors}(MdlSV);
\]

\( Mdl \) is similar to \( MdlSV \), except that the \text{Alpha}, \text{SupportVectorLabels}, and \text{SupportVectors} of all linear SVM binary learners are empty (\text{[]}).

\[
\text{areAllEmpty} = @(x) \text{isempty}([x.\text{Alpha} x.\text{SupportVectors} x.\text{SupportVectorLabels}]);
\]
\[
\text{cellfun}(\text{areAllEmpty},Mdl.\text{BinaryLearners})
\]

\[
\text{ans} =
\]

3x1 logical array

\[
\begin{align*}
1 \\
1 \\
1
\end{align*}
\]

Compare the sizes of the two ECOC models.

\[
\text{vars} = \text{whos}('MdlSV','Mdl');
\]
\[
100*(1 - \text{vars}(1).\text{bytes}/\text{vars}(2).\text{bytes})
\]

\[
\text{ans} =
\]

5.1575

\( Mdl \) is about 5% smaller than \( MdlSV \).

Reduce your memory footprint by compacting \( Mdl \), and then clearing \( MdlSV \) and \( Mdl \) from the workspace.
CMdl = compact(Mdl);
clear MdlSV Mdl;

Predict the label for a random row of the training data using the more efficient SVM model.

idx = randsample(size(meas,1),1)
predictedLabel = predict(CMdl,meas(idx,:))
trueLabel = species(idx)

idx =

    63

predictedLabel =

    1x1 cell array
    {'versicolor'}

trueLabel =

    1x1 cell array
    {'versicolor'}

**Tip**

For linear, SVM binary learners, and for efficiency, fitcecoc empties the properties Alpha, SupportVectorLabels, and SupportVectors. fitcecoc lists Beta, rather than Alpha, in the model display.

To store Alpha, SupportVectorLabels, and SupportVectors, pass a linear, SVM template that specifies storing support vectors to fitcecoc. For example, enter:

t = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',t);
You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

**Algorithms**

For each linear, SVM binary learner in an ECOC model, predict and resubPredict estimate SVM scores \( f(x) \) using

\[
f(x) = x'\beta + b.
\]

\( \beta \) is the Beta property and \( b \) is the Bias property of the binary learners. You can access these properties for each linear, SVM binary learner in the cell array \( Mdl.BinaryLearners \). For more details on the SVM score calculation, see “Support Vector Machines for Binary Classification” on page 32-2002.

**Introduced in R2015a**
discardSupportVectors

Package: classreg.learning.classif

Discard support vectors for linear support vector machine (SVM) classifier

Syntax

Mdl = discardSupportVectors(MdlSV)

Description

Mdl = discardSupportVectors(MdlSV) returns the trained, linear support vector machine (SVM) model Mdl. Both Mdl and the trained, linear SVM model MdlSV are the same type of object. That is, they both are either ClassificationSVM objects or CompactClassificationSVM objects. However, Mdl and MdlSV differ in the following ways:

- The Alpha, SupportVectors, and SupportVectorLabels properties are empty ([]) in Mdl.
- If you display Mdl, the software lists the Beta property instead of Alpha.

Examples

Discard Support Vectors

Create a linear SVM model that is more memory-efficient by discarding support vectors and other related parameters.

Load the ionosphere data set.

load ionosphere

Train a linear SVM model using the entire data set.
MdlSV = fitcsvm(X,Y)

MdlSV = ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
        Alpha: [103x1 double]
        Bias: -3.8828
    KernelParameters: [1x1 struct]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'

Display the number of support vectors in MdlSV.

numSV = size(MdlSV.SupportVectors,1)

numSV = 103

Display the number of predictor variables in X.

p = size(X,2)

p = 34

By default, fitcsvm trains a linear SVM model for two-class learning. The software lists Alpha in the display. The model includes 103 support vectors and 34 predictors. If you discard the support vectors, the resulting model consumes less memory.

Discard the support vectors and other related parameters.

Mdl = discardSupportVectors(MdlSV)

Mdl = ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
ClassNames: {'b'  'g'}
ScoreTransform: 'none'
NumObservations: 351
    Beta: [34x1 double]
    Bias: -3.8828
KernelParameters: [1x1 struct]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'

Properties, Methods

Display the coefficients in Mdl.
Mdl.Alpha
ans =
    []

Display the support vectors in Mdl.
Mdl.SupportVectors
ans =
    []

Display the support vector class labels in Mdl.
Mdl.SupportVectorLabels
ans =
    []

The software lists Beta in the display instead of Alpha. The Alpha, SupportVectors, and SupportVectorLabels properties are empty.

Compare the sizes of the models.
vars = whos('MdlSV','Mdl');
100*(1 - vars(1).bytes-vars(2).bytes)
Reduce Memory Consumption of SVM Models

Compact an SVM model by discarding the stored support vectors and other related estimates. Predict the label for a row of the training data by using the compacted model.

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Train an SVM model using the default options.

```matlab
MdlSV = fitcsvm(X,Y);
```

MdlSV is a `ClassificationSVM` model containing nonempty values for its `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties.

Reduce the size of the SVM model by discarding the training data, support vectors, and related estimates.

```matlab
CMdlSV = compact(MdlSV); % Discard training data
CMdl = discardSupportVectors(CMdlSV); % Discard support vectors
```

CMdl is a `CompactClassificationSVM` model.

Compare the sizes of the SVM models MdlSV and CMdl.

```matlab
vars = whos('MdlSV','CMdl');
100*(1 - vars(1).bytes/vars(2).bytes)
```

ans = 97.1896

The compacted model CMdl consumes much less memory than the full model.
Predict the label for a random row of the training data by using CMdl. The predict function accepts compacted SVM models, and, for linear SVM models, does not require the Alpha, SupportVectors, and SupportVectorLabels properties to predict labels for new observations.

```matlab
idx = randsample(size(X,1),1)
idx = 147
predictedLabel = predict(CMdl,X(idx,:))
predictedLabel = 1x1 cell array
   {'b'}
```

```matlab
trueLabel = Y(idx)
trueLabel = 1x1 cell array
   {'b'}
```

### Input Arguments

**MdLSV — Trained, linear SVM model**

- `ClassificationSVM` model
- `CompactClassificationSVM` model

Trained, linear SVM model, specified as a `ClassificationSVM` or `CompactClassificationSVM` model.

If the field `MdLSV.KernelParameters.Function` is not 'linear' (that is, `MdLSV` is not a linear SVM model), the software returns an error.

### Tips

- For a trained, linear SVM model, the `SupportVectors` property is an \( n_{sv} \)-by-\( p \) matrix. \( n_{sv} \) is the number of support vectors (at most the training sample size) and \( p \) is the number of predictors, or features. The `Alpha` and `SupportVectorLabels` properties are vectors with \( n_{sv} \) elements. These properties can be large for complex data sets containing many observations or examples. The `Beta` property is a vector with \( p \) elements.
• If the trained SVM model has many support vectors, use `discardSupportVectors` to reduce the amount of space consumed by the trained, linear SVM model. You can display the size of the support vector matrix by entering `size(MdlSV.SupportVectors)`.

**Algorithms**

`predict` and `resubPredict` estimate SVM scores $f(x)$, and subsequently label and estimate posterior probabilities using

$$f(x) = x'\beta + b.$$ 

$\beta$ is `Mdl.Beta` and $b$ is `Mdl.Bias`, that is, the Beta and Bias properties of `Mdl`, respectively. For more details, see “Support Vector Machines for Binary Classification” on page 32-2002.

**See Also**

**Introduced in R2015a**
**discardSupportVectors**

Discard support vectors

**Syntax**

mdlOut = discardSupportVectors(mdl)

**Description**

mdlOut = discardSupportVectors(mdl) returns the trained, linear support vector machine (SVM) regression model mdlOut, which is similar to the trained, linear SVM regression model mdl, except:

- The Alpha and SupportVectors properties are empty ([]).
- If you display mdlOut, the software lists the Beta property instead of the Alpha property.

**Input Arguments**

mdl — Trained, linear SVM regression model

RegressionSVM model | CompactRegressionSVM model

Trained, linear SVM regression model, specified as a RegressionSVM or CompactRegressionSVM model.

If you train the model using a kernel function that is not linear (i.e., if the field mdl.KernelFunction is something other than 'linear'), the software returns an error. You can only discard support vectors for linear models.

**Output Arguments**

mdlOut — Trained, linear SVM regression model

RegressionSVM model | CompactRegressionSVM model
Trained, linear SVM regression model, returned as a RegressionSVM or CompactRegressionSVM model. mdlOut is the same type as mdl.

After discarding the support vectors, the properties Alpha and SupportVectors are empty ([]). The software lists the property Beta in its display, and does not list the property Alpha. The predict and resubPredict methods compute predicted responses using the coefficients stored in the Beta property.

**Examples**

**Discard Support Vectors for SVM Regression Model**

This model shows how to reduce the disk space used by a trained, linear SVM regression model by discarding the support vectors and other related parameters.

Load the carsmall data set. Specify Horsepower and Weight as the predictor variables (X), and MPG as the response variable (Y).

```matlab
load carsmall
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model, standardizing the data. Display the number of support vectors.

```matlab
mdl = fitrsvm(X,Y,'Standardize',true)
numSV = size(mdl.SupportVectors,1)
```

mdl =

```
RegressionSVM
   PredictorNames: {'x1'  'x2'}
   ResponseName: 'Y'
   CategoricalPredictors: []
   ResponseTransform: 'none'
   Alpha: [77x1 double]
   Bias: 22.9131
   KernelParameters: [1x1 struct]
     Mu: [109.3441 2.9625e+03]
     Sigma: [45.3545 805.9668]
   NumObservations: 93
```
By default, \texttt{fitrsvm} trains a linear SVM regression model. The software lists \texttt{Alpha} in the display. The model has 77 support vectors.

Note that the predictor and response variables contain several NaN values. When training a model, \texttt{fitrsvm} will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 93 of the 100 total observations contained in the sample data.

Discard the support vectors and other related parameters.

\begin{verbatim}
mdlOut = discardSupportVectors(mdl)
mdlOut.Alpha
mdlOut.SupportVectors
\end{verbatim}

\begin{verbatim}
mdlOut =

RegressionSVM
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Beta: [2x1 double]
    Bias: 22.9131
    KernelParameters: [1x1 struct]
        Mu: [109.3441 2.9625e+03]
        Sigma: [45.3545 805.9668]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [93x1 logical]
    Solver: 'SMO'
\end{verbatim}
Properties, Methods

ans =
  []

ans =
  []

The software lists Beta in the display instead of Alpha. The Alpha and SupportVectors properties are empty.

Compare the sizes of the models.

vars = whos('mdl','mdlOut');
[vars(1).bytes,vars(2).bytes]

ans =
  15004   13156

mdlOut consumes less memory than mdl because it does not store the support vectors.

Reduce Memory Consumption of SVM Regression Model

This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the carsmall sample data.

load carsmall
rng default  % for reproducibility

Train a linear SVM regression model using Weight as the predictor variable and MPG as the response variable. Standardize the data.

mdl = fitrsvm(Weight,MPG,'Standardize',true);
Note that MPG contains several NaN values. When training a model, fitrsvm will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.

Compact the regression model to discard the training data and some information related to the training process.

compactMdl = compact(mdl);

compactMdl is a CompactRegressionSVM model that has the same parameters, support vectors, and related estimates as mdl, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

mdlOut = discardSupportVectors(compactMdl);

mdlOut is a CompactRegressionSVM model that has the same parameters as mdl and compactMdl, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, compactMdl, mdl, and mdlOut.

vars = whos('compactMdl','mdl','mdlOut');
[vars(1).bytes,vars(2).bytes,vars(3).bytes]

ans =
3601 13727 2305

The compacted model compactMdl consumes 3601 bytes of memory, while the full model mdl consumes 13727 bytes of memory. The model mdlOut, which also discards the support vectors, consumes 2305 bytes of memory.

Tips

For a trained, linear SVM regression model, the SupportVectors property is an \( n_{sv} \)-by-\( p \) matrix. \( n_{sv} \) is the number of support vectors (at most the training sample size) and \( p \) is the number of predictor variables. If any of the predictors are categorical, then \( p \) includes the number of dummy variables necessary to account for all of the categorical predictor levels. The Alpha property is a vector with \( n_{sv} \) elements.

The SupportVectors and Alpha properties can be large for complex data sets that contain many observations or examples. However, the Beta property is a vector with \( p \)
elements, which may be considerably smaller. You can use a trained SVM regression model to predict response values even if you discard the support vectors because the predict and resubPredict methods use Beta to compute the predicted responses.

If the trained, linear SVM regression model has many support vectors, use discardSupportVectors to reduce the amount of disk space that the trained, linear SVM regression model consumes. You can display the size of the support vector matrix by entering \( \text{size(mdlIn.SupportVectors)} \).

### Algorithms

The predict and resubPredict estimate response values using the formula

\[
f(x) = \left( \frac{X}{S} \right) \beta + \beta_0,
\]

where:

- \( \beta \) is the Beta value, stored as mdl.Beta.
- \( \beta_0 \) is the bias value, stored as mdl.Bias.
- \( X \) is the training data.
- \( S \) is the kernel scale value, stored as mdl.KernelParameters.Scale.

In this way, the software can use the value of mdl.Beta to make predictions even after discarding the support vectors.

**Class:** dataset

Display dataset array

---

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

---

**Syntax**

disp(ds)

---

**Description**

`disp(ds)` prints the dataset array `ds`, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, `disp` prints the actual data using either short g, long g, or bank format, depending on the current command line setting. Otherwise, `disp` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `disp` prints quoted text. Otherwise, `disp` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `disp` prints the contents of each cell (or its size and type if too large). Otherwise, `disp` prints the size of each dataset element.

For time series variables, `disp` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `disp` prints the actual data. Otherwise, `disp` prints the size and type of each dataset element.

For other types of variables, `disp` prints the size and type of each dataset element.

Display generalized linear regression model

Syntax

disp(mdl)

Description

disp(mdl) displays the mdl linear model.

Input Arguments

mdl

Generalized linear model, specified as a full GeneralizedLinearModel object constructed using fitglm or stepwiseglm, or a compacted CompactGeneralizedLinearModel object constructed using compact.

Examples

Display a Generalized Linear Regression Model

Create and display a generalized linear regression model.

Create a generalized linear regression model of Poisson data.

```matlab
X = 2 + randn(100,1);
mu = exp(1 + X/2);
y = poissrnd(mu);
mdl = fitglm(X,y,...
    'y ~ x1','distr','poisson');
```
Display the model.

disp(mdl)

Generalized linear regression model:
  \( \log(y) \sim 1 + x1 \)
  Distribution = Poisson

**Class:** GeneralizedLinearMixedModel

Display generalized linear mixed-effects model

**Syntax**

disp(glme)

**Description**

disp(glme) displays fitted generalized linear mixed-effects model glme.

**Input Arguments**

- **glme** — Generalized linear mixed-effects model
  GeneralizedLinearMixedModel object

  Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**Examples**

**Display a Generalized Linear Mixed-Effects Model**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new
manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i, \]

where

- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
• $\mu_{ij}$ is the mean number of defects corresponding to factory $i$ (where $i = 1, 2, \ldots, 20$) during batch $j$ (where $j = 1, 2, \ldots, 5$).

• newprocess$_{ij}$, time$_{dev}$$_{ij}$, and temp$_{dev}$$_{ij}$ are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, newprocess$_{ij}$ indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• supplier$\_C$$_{ij}$ and supplier$\_B$$_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma^2_b)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme(mfr, 'defects ~ 1 + newprocess + time\_dev + temp\_dev + supplier + (1|factory)' }\]

Display the model.

disp(glme)

Generalized linear mixed-effects model fit by ML

Model information:
- Number of observations: 100
- Fixed effects coefficients: 6
- Random effects coefficients: 20
- Covariance parameters: 1
- Distribution: Poisson
- Link: Log
- FitMethod: Laplace

Formula:
- defects ~ 1 + newprocess + time\_dev + temp\_dev + supplier + (1 | factory)

Model fit statistics:
- AIC: 416.35
- BIC: 434.58
- LogLikelihood: -201.17
- Deviance: 402.35

Fixed effects coefficients (95% CIs):
'newprocess'          -0.36766     0.17755     -2.0708    94      0.041122
'time_dev'           -0.094521     0.82849    -0.11409    94       0.90941
'temp_dev'            -0.28317      0.9617    -0.29444    94       0.76907
'supplier_C'         -0.071868    0.078024     -0.9211    94       0.35936
'supplier_B'          0.071072     0.07739     0.91836    94       0.36078

-0.72019    -0.015134
-1.7395       1.5505
-2.1926       1.6263
-0.22679     0.083051
-0.082588      0.22473

Random effects covariance parameters:
Group: factory (20 Levels)
Name1                Name2                Type         Estimate
'(Intercept)'        '(Intercept)'        'std'        0.31381

Group: Error
Name                      Estimate
'sqrt(Dispersion)'        1

The Model information table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

Formula indicates the model specification using Wilkinson's notation.

The Model fit statistics table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The Fixed effects coefficients table indicates that fitglme returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the t-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and p-value that correspond to the t-
statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only factory), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, std indicates that fitglme returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by fitglme does not provide confidence intervals for the random-effects parameters. To compute and display these values, use covarianceParameters.

Definitions

Akaike and Bayesian Information Criteria

The Akaike information criterion (AIC) is \( AIC = -2 \log L_M + 2 \text{param} \).

\( \log L_M \) depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then \( \log L_M \) is the maximized log likelihood.
- If you use 'MPL', then \( \log L_M \) is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then \( \log L_M \) is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

\text{param} is the total number of parameters estimated in the model. For most GLME models, \text{param} is equal to \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance, excluding the residual variance, and \( p \) is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then \text{param} is equal to \( (nc + p) \).

The Bayesian information criterion (BIC) is \( BIC = -2 \log L_M + \ln(\text{neff}) \text{param} \).

\( \log L_M \) depends on the method used to fit the model.
If you use 'Laplace' or 'ApproximateLaplace', then log$L_M$ is the maximized log likelihood.

If you use 'MPL', then log$L_M$ is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.

If you use 'REPL', then log$L_M$ is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

\( n_{\text{eff}} \) is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then \( n_{\text{eff}} = n \), where \( n \) is the number of observations.
- If you use 'REPL', then \( n_{\text{eff}} = n - p \).

\( param \) is the total number of parameters estimated in the model. For most GLME models, \( param \) is equal to \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance, excluding the residual variance, and \( p \) is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then \( param \) is equal to \( (nc + p) \).

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, \( p \). So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REPL', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REPL' is not appropriate.

disp

**Class:** LinearMixedModel

Display linear mixed-effects model

**Syntax**

`display(lme)`

**Description**

`display(lme)` displays the fitted linear mixed-effects model `lme`.

**Input Arguments**

`lme` — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

**Examples**

**Randomized Block Design**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the
blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

**Shift and Operator** are nominal variables.

```matlab
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```matlab
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Display the model.

```matlab
disp(lme)
```

**Linear mixed-effects model fit by ML**

**Model information:**
- Number of observations: 15
- Fixed effects coefficients: 3
- Random effects coefficients: 5
- Covariance parameters: 2

**Formula:**
- QCDev ~ 1 + Shift + (1 | Operator)

**Model fit statistics:**
- AIC: 59.012
- BIC: 62.552
- LogLikelihood: -24.506
- Deviance: 49.012

**Fixed effects coefficients (95% CIs):**

This display includes the model performance statistics, “Akaike and Bayesian Information Criteria” on page 32-1320, “Akaike and Bayesian Information Criteria” on page 32-1320, loglikelihood, and “Deviance” on page 32-1321.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column SE shows the standard errors of the coefficients. The column tStat includes the t-statistic values that correspond to each coefficient. DF is the residual degrees of freedom, and the pValue is the P-value that corresponds to the corresponding t-statistic value. The columns Lower and Upper display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.

**Definitions**

**Akaike and Bayesian Information Criteria**

Akaike information criterion (AIC) is $AIC = -2 \log L_M + 2(nc + p + 1)$, where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p$
+ 1 is the number of parameters estimated in the model. \( p \) is the number of fixed-effects coefficients, and \( nc \) is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is \( \text{BIC} = -2\log L_M + \ln(n_{\text{eff}})(nc + p + 1) \), where \( \log L_M \) is the maximized log likelihood (or maximized restricted log likelihood) of the model, \( n_{\text{eff}} \) is the effective number of observations, and \( (nc + p + 1) \) is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then \( n_{\text{eff}} = n \), where \( n \) is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then \( n_{\text{eff}} = n - p \).

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, \( p \). So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

**Deviance**

`LinearMixedModel` computes the deviance of model \( M \) as minus two times the loglikelihood of that model. Let \( L_M \) denote the maximum value of the likelihood function for model \( M \). Then, the deviance of model \( M \) is

\[
-2 \log L_M.
\]

A lower value of deviance indicates a better fit. Suppose \( M_1 \) and \( M_2 \) are two different models, where \( M_1 \) is nested in \( M_2 \). Then, the fit of the models can be assessed by comparing the deviances \( \text{Dev}_1 \) and \( \text{Dev}_2 \) of these models. The difference of the deviances is

\[
\text{Dev} = \text{Dev}_1 - \text{Dev}_2 = 2(\log LM_2 - \log LM_1).
\]

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom \( v \) equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in \( M_1 \) and \( M_2 \). You can get the \( p \)-value for this test using \( 1 - \text{chi2cdf}(\text{Dev}, v) \), where \( \text{Dev} = \text{Dev}_2 - \text{Dev}_1 \).
However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

\[ H_0: \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}, \quad D \text{ is a } q\text{-by-}q \text{ symmetric positive semidefinite matrix.} \]

\[ H_1: D \text{ is a } (q+1)\text{-by-}(q+1) \text{ symmetric positive semidefinite matrix.} \]

That is, \( H_1 \) states that the last row and column of \( D \) are different from zero. Here, the bigger model \( M_2 \) has \( q + 1 \) parameters and the smaller model \( M_1 \) has \( q \) parameters. And \( \text{Dev} \) has a 50:50 mixture of \( \chi^2_q \) and \( \chi^2_{(q+1)} \) distributions (Stram and Lee, 1994).

disp

Class: NonLinearModel

Display nonlinear regression model

Syntax

disp(mdl)

Description

disp(mdl) displays the mdl nonlinear model at the command line.

Input Arguments

mdl

Nonlinear regression model, constructed by fitnlm.

Examples

Display a Nonlinear Regression Model

Create and display a nonlinear regression model.

Load the reaction data, and specify both a model function and starting values for the iterations.

load reaction
modelfun = 'rate~(b1+x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
beta0 = [1 .05 .02 .1 2];

Create a model of the data.
mdl = fitnlm(reactants,rate,modelfun,beta0);

Display the model.

disp(mdl)

Nonlinear regression model:
    rate ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)

Estimated Coefficients:
    Estimate        SE         tStat    pValue
    _____    ________    ______    _______
    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075157    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatives

Enter mdl at the command line to obtain a display, where mdl is the name of your model.

Class: classregtree

(Removed) Display classregtree object

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

display(t)
display(A)

Description

display(t) prints the classregtree object t. classregtree calls display when a you do not use a semicolon to terminate a statement.

display(A) prints the categorical array A. categorical calls display when a you do not use a semicolon to terminate a statement.

See Also

classregtree | eval | prune | test
display

Class: cvpartition

Display cvpartition object

Syntax

display(c)

Description

display(c) prints the cvpartition object c. cvpartition calls display when you do not use a semicolon to terminate a statement.

See Also

cvpartition
display

Class: dataset

Display dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

display(ds)

Description

display(ds) prints the dataset array ds, including variable names and observation names (if present). dataset calls display when a you do not use a semicolon to terminate a statement.

For numeric or categorical variables that are 2-D and have three or fewer columns, display prints the actual data. Otherwise, display prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, display prints quoted text. Otherwise, display prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, display prints the contents of each cell (or its size and type if too large). Otherwise, display prints the size of each dataset element.

For time series variables, display prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, display prints the actual data. Otherwise, display prints the size and type of each dataset element.

For other types of variables, display prints the size and type of each dataset element.

distributionFitter

Open Distribution Fitter app

This page contains programmatic syntax information for the Distribution Fitter app. For general usage information, see Distribution Fitter.

Syntax

distributionFitter

distributionFitter(y)
distributionFitter(y,cens)
distributionFitter(y,cens,freq)
distributionFitter(y,cens,freq,dsname)

Description

distributionFitter opens the Distribution Fitter app, or brings focus to the app if it is already open.

distributionFitter(y) opens the Distribution Fitter app populated with the data specified by the vector y.

distributionFitter(y,cens) uses the vector cens to specify whether each observation in y is censored.

distributionFitter(y,cens,freq) uses the vector freq to specify the frequency of each element of y.

distributionFitter(y,cens,freq,dsname) creates a data set with the name dsname, using the data vector, y, censoring indicator, cens, and frequency vector, freq.

Examples
Open Distribution Fitter App with Existing Data

Load the carsmall sample data.

```matlab
load carsmall
```

Open the Distribution Fitter app using the MPG miles per gallon data.

```matlab
distributionFitter(MPG)
```
TheDistributionFitterappopens,populatedwiththeMPGdata,anddisplaysthedensity
(PDF)plot. You can use the app to display different plots and fit distributions to this data.

**Open Distribution Fitter App with Censoring Data**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','lightbulb.mat'))
```

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of `lightbulb` as the input data, and the third column as the censoring data. Name the data `lifetime`.

```matlab
distributionFitter(lightbulb(:,1),lightbulb(:,3),[],'lifetime')
```

To open the Data dialog box, click **Data**. In the **Manage data sets** pane, click to highlight the `lifetime` data set row. Finally, to open the View Data Set dialog, click **View**. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.
Input Arguments

\( y \) — Input data
array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: single | double

\( cens \) — Censoring indicator
zeros(n) (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of \( cens \) must be equal to the length of \( y \). If \( y(j) \) is censored, then \((cens(j)==1)\). If \( y(j) \) is not
censored, then \((\text{cens}(j)==0)\). If \text{cens} is omitted or empty, then no \(y\) values are censored.

If you have frequency data \((\text{freq})\) but not censoring data \((\text{cens})\), then you must specify empty brackets \([[]]\) for \text{cens}.

Data Types: single | double

\textbf{freq — Frequency data}

\text{ones}(n) \ (\text{default}) | \text{vector of scalar values}

Frequency data, specified as a vector of scalar values. The length of \text{freq} must be equal to the length of \(y\). If \text{freq} is omitted or empty, then all \(y\) values have a frequency of 1.

If you have frequency data \((\text{freq})\) but not censoring data \((\text{cens})\), then you must specify empty brackets \([[]]\) for \text{cens}.

Data Types: single | double

\textbf{dsname — Data set name}

\text{character vector} | \text{string scalar}

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data \((\text{cens})\) or frequency data \((\text{freq})\), then you must specify empty brackets \([[]]\) for both \text{freq} and \text{cens}.

Example: 'MyData'

Data Types: char | string

“Fit a Distribution Using the Distribution Fitter App” on page 5-95
“Model Data Using the Distribution Fitter App” on page 5-68
“Working with Probability Distributions” on page 5-3
“Supported Distributions” on page 5-16
Introduced in R2017a
Probability Distribution Function

Interactive density and distribution plots

Description
The Probability Distribution Function user interface creates an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution. Explore the effects of changing parameter values on the shape of the plot, either by specifying parameter values or using interactive sliders.

Required Products
• MATLAB
• Statistics and Machine Learning Toolbox

Note: disttool does not provide printing, code generating, or data importing functionality in MATLAB Online™.

Open the Probability Distribution Function App
• At the command prompt, enter disttool.

Examples

Explore the Probability Distribution Function User Interface
This example shows how to use the Probability Distribution Function user interface to explore the shape of cdf and pdf plots for different probability distributions and parameter values.

Open the Probability Distribution Function user interface.

disttool
The interface opens with a plot of the cdf of the Normal distribution. The initial parameter settings are $\mu = 0$ and $\sigma = 1$.

Select PDF from the **Function type** drop-down menu to plot the pdf of the Normal distribution using the same parameter values.
Change the value of the location parameter \( \mu \) to 1.
As the parameter values change, the shape of the plot also changes. Also, the value of \(X\) remains the same, but the density value changes because of the new parameter value.

Use the **Distribution** drop-down menu to change the distribution type from **Normal** to **Weibull**.
The shape of the plot changes, along with the names and values of the parameters.

**Parameters**

**Distribution — Probability distribution**

Normal (default) | Exponential | Poisson | Weibull | ...
Specify the probability distribution to explore by selecting a distribution name from the drop-down list. The drop-down list includes approximately 25 probability distribution options, including Normal, Exponential, Poisson, Weibull, and more.

**Function type — Probability distribution function type**

CDF (default) | PDF

Specify the probability distribution function type as CDF (cumulative distribution function) or PDF (probability density function) by selecting the function name from the drop-down list.

**Probability — Cumulative distribution function value**

numeric value in the range [0,1]

Specify the cumulative distribution function (cdf) value of interest as a numeric value in the range [0,1]. The corresponding random variable value appears in the X field below the plot. Alternatively, you can specify a value for X, and the Probability value will update automatically.

This option only appears if Function type is CDF. If Function type is PDF, then the probability density at the specified X value displays to the left of the plot.

**X — Random variable**

numeric value

Specify the random variable of interest as a numeric value. If the Function type is CDF, then the corresponding cumulative distribution function (cdf) value appears in the Probability field to the left of the plot. Alternatively, you can specify a value for Probability, and the X value will update automatically. If the Function type is PDF, then the corresponding probability density value appears to the left of the plot.

**Parameters — Parameter boundaries and values**

numeric value

Specify the parameter boundaries and values as numeric values. Each column contains a field for the upper bound, value, and lower bound of one parameter. The name and number of available parameters changes based on the distribution specified in the Distribution drop-down list. For example, if you select the Normal distribution, then disttool enables two columns: One column for the Mu parameter and one column for the Sigma parameter. If you select the Exponential distribution, then disttool enables one column for the Mu parameter.
Tips

To change the value of X (on the y-axis), or Probability or Density (on the x-axis):

• Type the values of interest into the Probability or X fields;
• Click on the point of interest on the plot; or
• Click and drag the reference lines across the plot.

Introduced before R2006a
**double**

**Class:** dataset

Convert dataset variables to double array

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

\[ b = \text{double}(A) \]
\[ b = \text{double}(a,\text{vars}) \]

**Description**

\[ b = \text{double}(A) \] returns the contents of the dataset \( A \), converted to one double array. The classes of the variables in the dataset must support the conversion.

\[ b = \text{double}(a,\text{vars}) \] returns the contents of the dataset variables specified by \( \text{vars} \). \( \text{vars} \) is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

**See Also**

dataset | replacedata | single
droplevels

Drop levels from a nominal or ordinal array

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

B = droplevels(A)
B = droplevels(A,oldlevels)

**Description**

B = droplevels(A) drops unused levels from the nominal or ordinal array A. The array B has the same size, type, and values as A, but has a list of potential levels that includes only those present in some element of A.

B = droplevels(A,oldlevels) removes the specified levels oldlevels from A.

droplevels removes levels, but does not remove elements. Elements of B that correspond to elements of A having levels in oldlevels all have an undefined level.

**Examples**

**Drop Levels From an Ordinal Array**

Bin patient ages into ordinal levels corresponding to 10-year intervals.

```matlab
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90),'%d'),{'s'});
A = ordinal(hospital.Age,labels,[]);edges);
getlabels(A)
```
ans = 1x10 cell array
Columns 1 through 7

{'0s'}    {'10s'}    {'20s'}    {'30s'}    {'40s'}    {'50s'}    {'60s'}

Columns 8 through 10

{'70s'}    {'80s'}    {'90s'}

Drop any levels that have no patients in them.

A = droplevels(A);
gll etlabels(A)

ans = 1x4 cell array

{'20s'}    {'30s'}    {'40s'}    {'50s'}

Input Arguments

A — Nominal or ordinal array
nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

oldlevels — Levels to remove
string array | cell array of character vectors | 2-D character matrix

Levels to remove from the nominal or ordinal array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: char | string | cell

Output Arguments

B — Nominal or ordinal array
nominal array | ordinal array

Nominal or ordinal array, returned as a nominal or ordinal array object.
See Also
addlevels | mergelevels | nominal | ordinal | reorderlevels

Topics
“Add and Drop Category Levels” on page 2-24

Introduced in R2007a
**dummyvar**

Create dummy variables

**Syntax**

\[ D = \text{dummyvar}(\text{group}) \]

**Description**

\[ D = \text{dummyvar}(\text{group}) \] returns a matrix \( D \) containing zeros and ones, whose columns are dummy variables for the grouping variables on page 2-57 in \( \text{group} \). Each column of \( \text{group} \) is a single grouping variable, with values indicating category levels. The rows of \( \text{group} \) represent observations across all variables.

**Examples**

**Create Dummy Variables from Categorical Grouping Variable**

Create a column vector of categorical data specifying color types.

\[ \text{Colors} = \{\text{'Red';'Blue';'Green';'Red';'Green';'Blue'}\}; \]
\[ \text{Colors} = \text{categorical(Colors)}; \]

Create dummy variables for each color type.

\[ D = \text{dummyvar}(\text{Colors}) \]

\[ D = \begin{bmatrix} 
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0 \\
\end{bmatrix} \]
The columns in D correspond to the levels in Colors. For example, the first column of dummyvar corresponds to the first level, 'Blue', in Colors.

Display the category levels of Colors.

categories(Colors)
ans = 3x1 cell array
    {'Blue'  }
    {'Green'}
    {'Red'   }

Create Dummy Variables from Numeric Grouping Variables

Create a matrix group of data containing the effects of two machines and three operators on a process.

machine = [1 1 1 1 2 2 2 2]';
operator = [1 2 3 1 2 3 1 2]';
group = [machine operator]
group = 8×2
    1     1
    1     2
    1     3
    1     1
    2     2
    2     3
    2     1
    2     2

Create dummy variables of the data in group.

D = dummyvar(group)

D = 8×5
The first two columns of D represent observations of machine 1 and machine 2, respectively. The remaining columns represent observations of the three operators.

Create Dummy Variables from Multiple Grouping Variables

Create a cell array of phone types and a numeric vector of area codes.

```matlab
phone = {'mobile';'landline';'mobile';'mobile';'mobile';'landline';'landline'};
codes = [802 802 603 603 802 603 802]';
```

Because the area code data has two levels (rather than 802 levels corresponding to the integers 1:802), convert `codes` to a categorical vector.

```matlab
newcodes = categorical(codes);
```

Combine the `phone` and `newcodes` grouping variables into the cell array `group`.

```matlab
group = {phone,newcodes};
```

Create dummy variables for the groups in `group`.

```matlab
D = dummyvar(group)
```

```matlab
D = 7×4
    1 0 1 0
    1 0 0 1
    1 0 0 0
    0 1 0 1
    0 1 0 0
    0 1 1 0
    0 1 0 1
```
The first two columns of D correspond to the phone types, and the last two columns correspond to the area codes.

Input Arguments

group — Grouping variables
positive integer vector | categorical column vector | cell array | positive integer matrix

Grouping variables, specified as a positive integer vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables on page 2-57, or a positive integer matrix representing levels within multiple variables.

If group is a categorical vector, then the groups and their order match the output of the categories function applied to group. If group is a numeric vector, then dummyvar assumes that the groups and their order are 1:max(group). In this respect, dummyvar treats a numeric grouping variable differently from grp2idx. For information on the order of groups within grouping variables, see “Grouping Variables” on page 2-57.

Example: [2 1 1 1 2 3 3 2]'
Example: {Origin,Cylinders}

Output Arguments

D — Dummy variables
numeric matrix

Dummy variables, returned as an n-by-s numeric matrix, where n is the number of rows of group and s is the sum of the number of levels in each column of group. From left to right, the columns of D are dummy variables created from the first column of group, followed by dummy variables created from the second column of group, and so on.

Data Types: single | double
Tips

- Use dummy variables in regression analysis and ANOVA to indicate values of categorical predictors.
- `dummyvar` treats NaN values and undefined categorical levels in `group` as missing data and returns NaN values in `D`.
- If a column of ones is introduced in the matrix `D`, then the resulting matrix \( X = [\text{ones(size(D,1)},1) \ D] \) is rank deficient. If `group` has multiple columns, then the matrix `D` itself is rank deficient because dummy variables produced from any column of `group` always sum to a column of ones. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of `group`.
- If `group` is a numeric vector with levels that do not correspond exactly to the integers \( 1:\text{max(group)} \), first convert the data to a categorical vector by using `categorical`. You can then pass the result to `dummyvar`. For an example, see “Create Dummy Variables from Multiple Grouping Variables” on page 32-1350.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a
**dwtest**

Durbin-Watson test

**Syntax**

\[ p = \text{dwtest}(r,x) \]
\[ p = \text{dwtest}(r,x,\text{Name,Value}) \]
\[ [p,d] = \text{dwtest}(\text{___}) \]

**Description**

\( p = \text{dwtest}(r,x) \) returns the \( p \)-value for the Durbin-Watson test on page 32-1357 of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

\( p = \text{dwtest}(r,x,\text{Name,Value}) \) returns the \( p \)-value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the \( p \)-value using a normal approximation.

\[ [p,d] = \text{dwtest}(\text{___}) \] also returns the Durbin-Watson test statistic, \( d \), using any of the input arguments from the previous syntaxes.

**Examples**

**Test Residuals For Correlation**

Load the sample census data.

\[
\text{load census}
\]

Create a design matrix using the census date (\text{cdate}) as the predictor. Add a column of 1 values to include a constant term.

\[
n = \text{length(cdate)}; \\
x = [\text{ones}(n,1),\text{cdate}];
\]
Fit a linear regression to the data.

\[ [b, bint, r] = \text{regress}(\text{pop}, x); \]

Test the null hypothesis that there is no autocorrelation among the residuals, \( r \).

\[ [p, d] = \text{dwtest}(r, x) \]

\( p = 3.6190\times10^{-15} \)

\( d = 0.1308 \)

The returned value \( p = 3.6190\times10^{-15} \) indicates rejection of the null hypothesis at the 5% significance level.

**One-Sided Hypothesis Test**

Load the sample census data.

\[ \text{load census} \]

Create a design matrix using the census date (\( \text{cdate} \)) as the predictor. Add a column of 1 values to include a constant term.

\[ n = \text{length}(\text{cdate}); \]

\[ x = [\text{ones}(n,1), \text{cdate}]; \]

Fit a linear regression to the data.

\[ [b, bint, r] = \text{regress}(\text{pop}, x); \]

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

\[ [p, d] = \text{dwtest}(r, x, '\text{Tail}', '\text{right}') \]

\( p = 1.8095\times10^{-15} \)

\( d = 0.1308 \)

The returned value \( p = 1.8095\times10^{-15} \) indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.
Input Arguments

\( x \) — Design matrix

Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.

Data Types: single | double

\( r \) — Regression residuals

Regression residuals, specified as a vector. Obtain \( r \) by performing a linear regression using a function such as \textit{regress}, or by using the backslash operator.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: \texttt{'Tail','right','Method','approximate'} specifies a right-tailed hypothesis test and calculates the \( p \)-value using a normal approximation.

\textbf{Method — Computation method for} \textit{p-value}

\texttt{'exact' | 'approximate'}

Computation method for the \( p \)-value, specified as the comma-separated pair consisting of \texttt{'Method'} and one of the following.

\begin{itemize}
  \item \texttt{'exact'} \quad Calculate an exact \( p \)-value using the Pan algorithm. This is the default if the sample size is less than 400.
  \item \texttt{'approximate'} \quad Calculate the \( p \)-value using a normal approximation. This is the default if the sample size is 400 or larger.
\end{itemize}
**Tail — Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'both'          Test the alternate hypothesis that autocorrelation among the residuals is not zero.
- 'right'         Test the alternative hypothesis that autocorrelation among the residuals is greater than zero.
- 'left'          Test the alternative hypothesis that autocorrelation among the residuals is less than zero.

Example: 'Tail','right'

**Output Arguments**

- **p — p-value**
  scalar value in the range [0,1]

  p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

- **d — Test statistic**
  nonnegative scalar value

  Test statistic of the hypothesis test, returned as a nonnegative scalar value.

**Definitions**

**Durbin-Watson Test**

The Durbin-Watson test is used to test the null hypothesis that linear regression residuals are uncorrelated, against the alternative that autocorrelation exists.

The test statistic for the Durbin-Watson test is
where $T$ is the number of observations, and $e_t$ is the residual at time $t$.

The $p$-value of the Durbin-Watson test is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. A significantly small $p$-value casts doubt on the validity of the null hypothesis and indicates correlation among residuals. The $p$-value can be calculated exactly using the Pan algorithm. Alternatively, the $p$-value can be estimated using a normal approximation.

regress

*Introduced in R2006a*
**dwtest**

**Class:** LinearModel

Durbin-Watson test of linear model

**Syntax**

\[ P = \text{dwtest}(mdl) \]

\[ [P, DW] = \text{dwtest}(mdl) \]

\[ [P, DW] = \text{dwtest}(mdl, \text{method}) \]

\[ [P, DW] = \text{dwtest}(mdl, \text{method}, \text{tail}) \]

**Description**

\( P = \text{dwtest}(mdl) \) returns the \( p \)-value of the Durbin-Watson test on the \( mdl \) linear model.

\( [P, DW] = \text{dwtest}(mdl) \) also returns the Durbin-Watson statistic, \( DW \).

\( [P, DW] = \text{dwtest}(mdl, \text{method}) \) specifies the method \text{dwtest} uses to compute the \( p \)-value.

\( [P, DW] = \text{dwtest}(mdl, \text{method}, \text{tail}) \) specifies the alternative hypothesis.

**Input Arguments**

\( mdl \) — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a \text{LinearModel} object constructed using \text{fitlm} or \text{stepwiselm}.

\( \text{method} \) — Algorithm for computing \( p \)-value

'exact' | 'approximate'

32-1359
Algorithm for computing the $p$-value, specified as one of the following:

- `'exact'` — Calculates an exact $p$-value using Pan’s algorithm.
- `'approximate'` — Calculates the $p$-value using a normal approximation.

The default is `'exact'` when the sample size is less than 400, `'approximate'` otherwise.

**Tail** — *Alternative hypothesis to test*

- `'both'` (default) | `'right'` | `'left'`

Alternative hypothesis to test, specified as one of the following:

<table>
<thead>
<tr>
<th>Tail</th>
<th>Alternative Hypothesis</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'both'</code></td>
<td>Serial correlation is not 0.</td>
</tr>
<tr>
<td><code>'right'</code></td>
<td>Serial correlation is greater than 0 (right-tailed test).</td>
</tr>
<tr>
<td><code>'left'</code></td>
<td>Serial correlation is less than 0 (left-tailed test).</td>
</tr>
</tbody>
</table>

`dwtest` tests whether `mdl` has no serial correlation against the specified alternative hypotheses.

**Output Arguments**

**P** — *$p$-value of the test*

numeric value

$p$-value of the test, returned as a numeric value. `dwtest` tests if the residuals are uncorrelated, against the alternative that there is autocorrelation among them. Small values of `P` indicate that the residuals are correlated.

**DW** — *Durbin-Watson statistic*

numeric value

Durbin-Watson statistic, returned as a numeric value.

**Examples**
Test Residuals for Autocorrelation

Examine whether the residuals from a fitted model of census data over time have autocorrelated residuals.

Load the census data and create a linear model.

```matlab
load census
mdl = fitlm(cdate,pop);
```

Find the $p$-value of the Durbin-Watson autocorrelation test.

```matlab
P = dwtest(mdl)
```

$P = 3.6190\text{e-15}$

There is significant autocorrelation in the residuals.

Definitions

Durbin-Watson Statistic

Let $r$ be the vector of residuals (in `mdl.residuals.response`). The Durbin-Watson statistic is

$$DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^{n} r_i^2}.$$  

Algorithms

Approximate calculation of the $p$-value uses a normal approximation [1]. Exact calculation uses Pan’s algorithm [2].

**ecdf**

Empirical cumulative distribution function

**Syntax**

\[ [f, x] = ecdf(y) \]
\[ [f, x] = ecdf(y, Name, Value) \]
\[ [f, x, flo, fup] = ecdf(____) \]

ecdf(____)
ecdf(ax,____)

**Description**

\[ [f, x] = ecdf(y) \] returns the empirical cumulative distribution function (cdf), \( f \), evaluated at the points in \( x \), using the data in the vector \( y \).

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

\[ [f, x] = ecdf(y, Name, Value) \] returns the empirical function values, \( f \), evaluated at the points in \( x \), with additional options specified by one or more Name, Value pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

\[ [f, x, flo, fup] = ecdf(____) \] also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

ecdf computes the confidence bounds using Greenwood's formula on page 32-1374. They are not simultaneous confidence bounds.

ecdf(____) plots the evaluated function.

ecdf(ax,____) plots the evaluated function using axes with the handle, \( ax \), instead of the current axes returned by gca.
Examples

**Compute Empirical Cumulative Distribution Function**

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

```matlab
rng('default')  % for reproducibility
failuretime = random('wbl',3,1,15,1);
```

Compute the Kaplan-Meier estimate of the cdf for survival data.

```matlab
[f,x] = ecdf(failuretime);
[f,x]
```

```matlab
ans = 16×2

0    0.0895
0.0667    0.0895
0.1333    0.1072
0.2000    0.1303
0.2667    0.1313
0.3333    0.2718
0.4000    0.2968
0.4667    0.6147
0.5333    0.6684
0.6000    1.3749
```

Plot the estimated cdf.

```matlab
ecdf(failuretime)
```
Empirical Hazard Function of Right-Censored Data

Compute and plot the hazard function of simulated right-censored survival data.

Generate failure times from a Birnbaum-Saunders distribution.

```matlab
rng default  % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector.
\( T = 0.9; \)
\[ \text{cens} = (\text{failuretime}>\text{T}); \]

Plot the empirical hazard function for the data.

\[ \text{ecdf(failuretime,'function','cumulative hazard',...} \]
\[ \text{'censoring',cens,'bounds','on'}); \]

---

**Compare Empirical Cumulative Distribution Function (CDF) with Known CDF**

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.
Generate failure times from an exponential distribution with mean failure time of 15.

```matlab
rng default  % for reproducibility
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```matlab
d = exprnd(30,75,1);
```

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

```matlab
t = min(y,d);
```

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

```matlab
censored = (y>d);
```

Compute the empirical cdf and confidence bounds.

```matlab
[f,x,flo,fup] = ecdf(t,'censoring',censored);
```

Plot the cdf and confidence bounds.

```matlab
figure()
ecdf(t,'censoring',censored,'bounds','on');
hold on
```
Superimpose a plot of the known population cdf.

```matlab
xx = 0:.1:max(t);
yy = 1-exp(-xx/15);
plot(xx,yy,'g-','LineWidth',2)
axis([0 50 0 1])
legend('Empirical','LCB','UCB','Population',...
      'Location','SE')
hold off
```
Empirical Survivor Function with 99% Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

```matlab
rng default  % for reproducibility
R = wblrnd(100,2,100,1);
```

Plot the survivor function for the data with 99% confidence bounds.
ecdf(R,'function','survivor','alpha',0.01,'bounds','on')
hold on

Fit the Weibull survivor function.

x = 1:1:250;
wblsurv = 1-cdf('weibull',x,100,2);
plot(x,wblsurv,'g-','LineWidth',2)
legend('Empirical','LCB','UCB','Population','Location','NE')
The survivor function based on the actual distribution is within the confidence bounds.

**Input Arguments**

`y` — Input data

column vector

Input data, specified as a column vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

Data Types: `single` | `double`
**ax — Axes handle**

handle

Axes handle for the figure `ecdf` plots to, specified as a handle.

For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

Example: `ecdf(h,x)`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'censoring',c,'function','cumulative hazard','alpha',0.025,'bounds','on'` specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector `c`.

**censoring — Indicator of censored data**

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including 'censoring' and a Boolean array of the same size as `x`. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

For instance, if vector `cdata` stores the censored data information, you can enter the censoring information as follows.

Example: `'censoring',cdata`

Data Types: `logical`

**frequency — Frequency of observations**

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and a vector containing nonnegative integer counts. This vector is the same size as the vector `x`. The jth element of this vector gives the number of times the jth element of `x` was observed. Default is one observation per element of `x`. 

32-1372
For instance, if \texttt{failurefreq} is a vector of frequencies, then you can enter it as follows.

Example: \texttt{'}frequency',failurefreq\texttt{'}

Data Types: \texttt{single} | \texttt{double}

\textbf{alpha — Confidence level}

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of the evaluated function, specified as the comma-separated pair consisting of \texttt{'}alpha' and a scalar value between in the range (0,1). Default is 0.05 for 95% confidence. For a given value \texttt{alpha}, the confidence level is \(100(1-\alpha)\%\).

For instance, for a 99% confidence interval, you can specify the alpha value as follows.

Example: \texttt{'}alpha',0.01\texttt{'}

Data Types: \texttt{single} | \texttt{double}

\textbf{function — Type of function returned}

\texttt{'}cdf' (default) | 'survivor' | 'cumulative hazard'

Type of function that \texttt{ecdf} evaluates and returns, specified as the comma-separated pair consisting of \texttt{'}function' and one of the following.

<table>
<thead>
<tr>
<th>\texttt{'}function'</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{'}cdf'</td>
<td>Default. Cumulative distribution function.</td>
</tr>
<tr>
<td>\texttt{'}survivor'</td>
<td>Survivor function.</td>
</tr>
<tr>
<td>\texttt{'}cumulative hazard'</td>
<td>Cumulative hazard function.</td>
</tr>
</tbody>
</table>

Example: \texttt{'}function',\texttt{'}cumulative hazard'\texttt{'}

\textbf{bounds — Indicator for including bounds}

\texttt{'}off' (default) | \texttt{'}on' |

Indicator for including bounds, specified as the comma-separated pair consisting of \texttt{'}bounds' and one of the following.

<table>
<thead>
<tr>
<th>\texttt{'}bounds'</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{'}off'</td>
<td>Default. Specify to omit bounds.</td>
</tr>
<tr>
<td>\texttt{'}on'</td>
<td>Specify to include bounds.</td>
</tr>
</tbody>
</table>

\textbf{Note} This name-value argument is used only for plotting.
Example: 'bounds', 'on'

**Output Arguments**

**f** — Function values
column vector

Function values evaluated at the points in \( x \), returned as a column vector.

**x** — Distinct observed points
column vector

Distinct observed points in data vector \( y \), returned as a column vector.

**flo** — Lower confidence bound
column vector

Lower confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood’s formula on page 32-1374. They are not simultaneous confidence bounds.

**fup** — Upper confidence bound
column vector

Upper confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood’s formula on page 32-1374. They are not simultaneous confidence bounds.

**Definitions**

**Greenwood’s Formula**

Approximation for the variance of Kaplan-Meier estimator.

The variance estimate is given by

\[
V(S(t)) = S^2(t) \sum_{t_i < T} \frac{d_i}{n_i (r_i - d_i)},
\]
where $r_i$ is the number at risk at time $t_i$, and $d_i$ is the number of failures at time $t_i$.

ecdfhist

Histogram based on empirical cumulative distribution function

Syntax

\[ [n,c] = \text{ecdfhist}(f,x) \]
\[ [n,c] = \text{ecdfhist}(f,x,m) \]
\[ n = \text{ecdfhist}(f,x,\text{centers}) \]
\[ \text{ecdfhist}(\_\_) \]

Description

\[ [n,c] = \text{ecdfhist}(f,x) \] returns the heights, \( n \), of histogram bars for 10 equally spaced bins and the position of the bin centers, \( c \).

ecdfhist computes the bar heights from the increases in the empirical cumulative distribution function, \( f \), at evaluation points, \( x \). It normalizes the bar heights so that the area of the histogram is equal to 1. In contrast, \text{histogram} produces bars with heights representing bin counts.

\[ [n,c] = \text{ecdfhist}(f,x,m) \] returns the histogram bars using \( m \) bins.

\( n = \text{ecdfhist}(f,x,\text{centers}) \) returns the heights of the histogram bars with bin centers specified by \( \text{centers} \).

\text{ecdfhist}(\_\_) plots the histogram bars.

Examples
Return Histogram Bar Heights and Bin Centers

Compute the histogram bar heights based on the empirical cumulative distribution function.

Generate failure times from a Birnbaum-Saunders distribution.

```matlab
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```matlab
T = 0.9;
cens = (failuretime>T);
```

Compute the empirical cumulative distribution function for the data.

```matlab
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, find the bar heights of the histogram using the cumulative distribution function estimate.

```matlab
[n,c] = ecdfhist(f,x);
[n' c']
```

```
ans = 10×2
        2.3529     0.0715
        1.7647     0.1565
        1.4117     0.2415
        1.5294     0.3265

        0.2353     0.7515
        0.2353     0.8365
```
Return Bar Heights and Bin Centers for a Given Number of Bins

Compute the bar heights for six bins using the empirical cumulative distribution function and also return the bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```matlab
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```matlab
T = 0.9;
cens = (failuretime>T);
```

First, compute the empirical cumulative distribution function for the data.

```matlab
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, estimate the histogram with six bins using the cumulative distribution function estimate.

```matlab
[n,c] = ecdfhist(f,x,6);
[n' c']
```

ans = 6×2

```

0.4235  0.5248
0.7764  0.6665
0.2118  0.8081
```

Draw Histogram for Given Bin Centers

Draw the histogram of the empirical cumulative distribution histogram for specified bin centers.

Generate failure times from a Birnbaum-Saunders distribution.
rng default; % For reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

T = 0.9;
cens = (failuretime>T);

Define bin centers.

centers = 0.1:0.1:1;

Compute the empirical cumulative distribution function for the data and draw the histogram for specified bin centers.

[f,x] = ecdf(failuretime,'censoring',cens);
ecdfhist(f,x,centers)
axis([0 1 0 2.5])
Compare Histogram with Known Probability Distribution Function

Generate right-censored survival data and compare the histogram from cumulative distribution function with the known probability distribution function.

Generate failure times from an exponential distribution with mean failure time of 15.

```matlab
rng default; % For reproducibility
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.
d = exprnd(30, 75, 1);

Record the minimum of these times as the observed failure times.

\[ t = \min(y, d) \]

Generate censoring by finding the generated failure times that are greater than the drop-out times.

\[ \text{censored} = (y > d) \]

Calculate the empirical cdf and plot a histogram using the empirical cumulative distribution function.

\[
[f, x] = \text{ecdf}(t, 'censoring', \text{censored});
\]
\[
\text{ecdfhist}(f, x)
\]
\[
h = \text{findobj(gca, 'Type', 'patch');}
\]
\[
h.\text{FaceColor} = [.8 .8 1];
\]
\[
\text{hold on}
\]
Superimpose a plot of the known population pdf.

```matlab
xx = 0:.1:max(t);
yy = exp(-xx/15)/15;
plot(xx,yy,'r-','LineWidth',2)
hold off
```
Input Arguments

\textbf{f} — Empirical cdf values
vector

Empirical cdf values at given evaluation points, \textit{x}, specified as a vector.

For instance, you can use \texttt{ecdf} to obtain the empirical cdf values and enter them in \texttt{ecdfhist} as follows.

Example: \texttt{[f,x] = ecdf(failure); ecdfhist(f,x);}
Data Types: single | double

**x** — Evaluation points
vector

Evaluation points at which empirical cdf values, f, are calculated, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

Example: 
```
[f,x] = ecdf(failure); ecdfhist(f,x);
```

Data Types: single | double

**m** — Number of bins
scalar

Number of bins, specified as a scalar.

For instance, you can draw a histogram with 8 bins as follows.

Example: 
```
ecdfhist(f,x,8)
```

Data Types: single | double

**centers** — Center points of bins
vector

Center points of bins, specified as a vector.

Example: 
```
centers = 2:2:10; ecdfhist(f,x,centers);
```

Data Types: single | double

**Output Arguments**

**n** — Heights of histogram bars
row vector

Heights of histogram bars `ecdfhist` calculates based on the empirical cdf values, returned as a row vector.

**c** — Position of bin centers
row vector
Position of bin centers, returned as a row vector.

**See Also**
ecdf | histc | histogram

edge

Edge of \( k \)-nearest neighbor classifier

Syntax

\[
E = \text{edge}(\text{mdl}, \text{tbl}, \text{ResponseVarName})
\]
\[
E = \text{edge}(\text{mdl}, \text{tbl}, Y)
\]
\[
E = \text{edge}(\text{mdl}, X, Y)
\]
\[
E = \text{edge}(\_, \_,'\text{Weights}', \text{weights})
\]

Description

\( E = \text{edge}(\text{mdl}, \text{tbl}, \text{ResponseVarName}) \) returns the classification edge for \( \text{mdl} \) with data \( \text{tbl} \) and classification \( \text{tbl.\text{ResponseVarName}} \). If \( \text{tbl} \) contains the response variable used to train \( \text{mdl} \), then you do not need to specify \( \text{ResponseVarName} \).

The classification edge (\( E \)) is a scalar value that represents the mean of the classification margins on page 32-1389.

\( E = \text{edge}(\text{mdl}, \text{tbl}, Y) \) returns the classification edge for \( \text{mdl} \) with data \( \text{tbl} \) and classification \( Y \).

\( E = \text{edge}(\text{mdl}, X, Y) \) returns the classification edge for \( \text{mdl} \) with data \( X \) and classification \( Y \).

\( E = \text{edge}(\_, \_,'\text{Weights}', \text{weights}) \) computes the edge with additional observation weights \( \text{weights} \), using any of the input arguments in the previous syntaxes.

Examples

Edge Calculation

Create a \( k \)-nearest neighbor classifier for the Fisher iris data, where \( k = 5 \).
Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the edge of the classifier for minimum, mean, and maximum observations classified as 'setosa', 'versicolor', and 'virginica', respectively.

```
NewX = [min(X);mean(X);max(X)];
Y = {'setosa';'versicolor';'virginica'};
E = edge(mdl,NewX,Y)
```

```
E = 1
```

All five nearest neighbors of each NewX point classify as the corresponding Y entry.

### Input Arguments

- **mdl** — *k*-nearest neighbor classifier model
  *ClassificationKNN* object

  *k*-nearest neighbor classifier model, specified as a *ClassificationKNN* object.

- **tbl** — Sample data
table

  Sample data used to train the model, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

  If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName or Y.

  If you train mdl using sample data contained in a table, then the input data for edge must also be in a table.
Data Types: `table`

**ResponseVarName — Response variable name**
name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one variable.

Data Types: `single` | `double`

**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**weights — Observation weights**
`ones(size(X,1),1)` (default) | numeric vector | name of variable in `tbl`

Observation weights, specified as a numeric vector or the name of a variable in `tbl`.

If you specify `weights` as a numeric vector, then the size of `weights` must be equal to the number of rows in `X` or `tbl`. 

32-1388
If you specify `weights` as the name of a variable in `tbl`, then the name must be a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you specify `weights`, then the `edge` function weights the observation in each row of `X` or `tbl` with the corresponding weight in `weights`.

Example: 'Weights','w'

Data Types: single | double | char | string

Definitions

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

The classification margins form a column vector with the same number of rows as `X` or `tbl`.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-4943.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Topics
“Classification Using Nearest Neighbors” on page 18-16

Introduced in R2012a
edge

Class: ClassificationLinear
Classification edge for linear classification models

Syntax

\[ e = \text{edge}(\text{Mdl},X,Y) \]
\[ e = \text{edge}(\_\_\_,\text{Name},\text{Value}) \]

Description

\[ e = \text{edge}(\text{Mdl},X,Y) \] returns the classification edges on page 32-1399 for the binary, linear classification model \( \text{Mdl} \) using predictor data in \( X \) and corresponding class labels in \( Y \). \( e \) contains a classification edge for each regularization strength in \( \text{Mdl} \).

\[ e = \text{edge}(\_\_\_,\text{Name},\text{Value}) \] uses any of the previous syntaxes and additional options specified by one or more \text{Name,Value} pair arguments. For example, you can specify that columns in the predictor data correspond to observations or supply observation weights.

Input Arguments

\( \text{Mdl} \) — Binary, linear classification model
\text{ClassificationLinear} model object

Binary, linear classification model, specified as a \text{ClassificationLinear} model object. You can create a \text{ClassificationLinear} model object using \text{fitclinear}.

\( X \) — Predictor data
full matrix | sparse matrix

Predictor data, specified as an \( n \)-by-\( p \) full or sparse matrix. This orientation of \( X \) indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.
**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in Y must be a subset of Mdl.ClassNames.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.
Weights — Observation weights
numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, edge computes the weighted classification edge.

Let n be the number of observations in X.

- numel(Weights) must be n.
- By default, Weights is ones(n,1).

dge normalizes Weights to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Output Arguments

e — Classification edges
numeric scalar | numeric row vector

Classification edges, returned as a numeric scalar or row vector.

e is the same size as Mdl.Lambda. e(j) is the classification edge of the linear classification model trained using the regularization strength Mdl.Lambda(j).

Examples

Estimate Test-Sample Edge

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.
The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

\[
Y_{\text{stats}} = Y == '\text{stats}';
\]

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to holdout 30% of the observations. Optimize the objective function using SpaRSA.

\[
\text{rng}(1); \quad \% \text{For reproducibility}
\]

\[
\text{CVMdl} = \text{fitclinear}(X,Y_{\text{stats}},'\text{Solver}','\text{sparsa}','\text{Holdout}',0.30);
\]

\[
\text{CMdl} = \text{CVMdl.Trained}{1};
\]

\text{CVMdl} is a \text{ClassificationPartitionedLinear} model. It contains the property \text{Trained}, which is a 1-by-1 cell array holding a \text{ClassificationLinear} model that the software trained using the training set.

Extract the training and test data from the partition definition.

\[
\text{trainIdx} = \text{training(CVMdl.Partition)};
\]

\[
\text{testIdx} = \text{test(CVMdl.Partition)};
\]

Estimate the training- and test-sample edges.

\[
\text{eTrain} = \text{edge(CMdl,X(trainIdx,:),Y_{\text{stats}}(trainIdx))}
\]

\[
eTrain = 15.6660
\]

\[
\text{eTest} = \text{edge(CMdl,X(testIdx,:),Y_{\text{stats}}(testIdx))}
\]

\[
eTest = 15.4767
\]

**Feature Selection Using Test-Sample Edges**

One way to perform feature selection is to compare test-sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set.
load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages. For quicker execution time, orient the predictor data so that individual observations correspond to columns.

Ystats = Y == 'stats';
X = X';
rng(1); % For reproducibility

Create a data partition which holds out 30% of the observations for testing.

Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition); % Test-set indices
XTest = X(:,testIdx);
YTest = Ystats(testIdx);

Partition is a cvpartition object that defines the data set partition.

Randomly choose half of the predictor variables.

p = size(X,1); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));

Train two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

CVMdl = fitclinear(X,Ystats,'CVPartition',Partition,'Solver','sparsa',... 'ObservationsIn','columns');
PCVMdl = fitclinear(X(idxPart,:),Ystats,'CVPartition',Partition,'Solver','sparsa',... 'ObservationsIn','columns');

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Extract the trained ClassificationLinear models from the cross-validated models.

CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(CMdl,XTest,YTest,'ObservationsIn','columns')
fullEdge = 15.4767
partEdge = edge(PCMdl,XTest(idxPart,:),YTest,'ObservationsIn','columns')
partEdge = 13.4458
```

Based on the test-sample edges, the classifier that uses all of the predictors is the better model.

**Find Good Lasso Penalty Using Edge**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using Test-Sample Edges” on page 32-1394.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);

Lambda = logspace(-8,1,11);
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^1$.

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
                  'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
                  'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```
CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 1
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Properties, Methods

Extract the trained linear classification model.
Mdl = CVMdl.Trained{1}
Mdl =
    ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023x11 double]
    Bias: [1x11 double]
    Lambda: [1x11 double]
    Learner: 'logistic'

Properties, Methods

Mdl is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda.

Estimate the test-sample edges.
e = edge(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns')
e = 1x11
   0.9986   0.9986   0.9986   0.9986   0.9986   0.9932   0.9766   0.9202   0.8337   0.8128   0.8128

Because there are 11 regularization strengths, e is a 1-by-11 vector of edges.
Plot the test-sample edges for each regularization strength. Identify the regularization strength that maximizes the edges over the grid.

```matlab
figure;
plot(log10(Lambda),log10(e),'-o')
 [~, maxEIdx] = max(e);
 maxLambda = Lambda(maxEIdx);
 hold on
 plot(log10(maxLambda),log10(e(maxEIdx)),'ro');
 ylabel('log_{10} test-sample edge')
 xlabel('log_{10} Lambda')
 legend('Edge','Max edge')
 hold off
```
Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

\[
\text{LambdaFinal} = \text{Lambda}(5);
\]

Train a linear classification model using the entire data set and specify the regularization strength yielding the maximal edge.

\[
\text{MdlFinal} = \text{fitclinear}(X,Y\text{stats},'ObservationsIn','columns',... \\
  'Learner','logistic','Solver','sparsa','Regularization','lasso',... \\
  'Lambda',\text{LambdaFinal});
\]

To estimate labels for new observations, pass \text{MdlFinal} and the new data to \text{predict}.

**Definitions**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[
m = 2yf(x).
\]

\(x\) is an observation. If the true label of \(x\) is the positive class, then \(y\) is 1, and -1 otherwise. \(f(x)\) is the positive-class classification score for the observation \(x\). The classification margin is commonly defined as \(m = yf(x)\).
If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

For linear classification models, the raw classification score for classifying the observation $x$, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$  

For the model with regularization strength $j$, $\beta_j$ is the estimated column vector of coefficients (the model property $\text{Beta}(:,j)$) and $b_j$ is the estimated, scalar bias (the model property $\text{Bias}(j)$).

The raw classification score for classifying $x$ into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**Algorithms**

By default, observation weights are prior class probabilities. If you supply weights using Weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the normalized weights to estimate the weighted edge.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).
See Also
ClassificationLinear | fitclinear | margin | predict

Introduced in R2016a
**edge**

Classification edge

**Syntax**

\[
E = \text{edge}(\text{obj},X,Y)
\]
\[
E = \text{edge}(\text{obj},X,Y,\text{Name},\text{Value})
\]

**Description**

\(E = \text{edge}(\text{obj},X,Y)\) returns the classification edge for \(\text{obj}\) with data \(X\) and classification \(Y\).

\(E = \text{edge}(\text{obj},X,Y,\text{Name},\text{Value})\) computes the edge with additional options specified by one or more \(\text{Name},\text{Value}\) pair arguments.

**Input Arguments**

**obj**

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

**X**

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in \(X\) must equal the number of predictors in \(\text{obj}\).

**Y**

Class labels, with the same data type as exists in \(\text{obj}\). The number of elements of \(Y\) must equal the number of rows of \(X\).
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

weights

Observation weights, a numeric vector of length size(X,1). If you supply weights, edge computes the weighted classification edge.

Default: ones(size(X,1),1)

Output Arguments

E

Edge, a scalar representing the weighted average value of the margin.

Examples

Compute the classification edge and margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
E = edge(obj,X,species)

E =
   0.4980

M = margin(obj,X,species);
M(end-10:end)

ans =
   0.6551
   0.4838
   0.6551
The classifier trained on all the data is better:

```matlab
obj = fitcdiscr(meas,species);
E = edge(obj,meas,species)
```

```
E = 
0.9454
```

```matlab
M = margin(obj,meas,species);
M(end-10:end)
```

```
ans = 
0.9983 
1.0000 
0.9991 
0.9978 
1.0000 
1.0000 
0.9999 
0.9882 
0.9937 
1.0000 
0.9649
```

**Definitions**

**Edge**

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.
**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix $X$. A high value of margin indicates a more reliable prediction than a low value.

**Score (discriminant analysis)**

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-7.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**Topics**

“Discriminant Analysis Classification” on page 20-2
edge

Classification edge for multiclass, error-correcting output codes model

Syntax

e = edge(Mdl,tbl,ResponseVarName)
e = edge(Mdl,tbl,Y)
e = edge(Mdl,X,Y)
e = edge(___,Name,Value)

Description

e = edge(Mdl,tbl,ResponseVarName) returns the classification edge on page 32-1415 (e) for the error-correcting output code (ECOC) multiclass classifier Mdl using predictor data in table tbl and class labels tbl.ResponseVarName. Each row of tbl and ResponseVarName is an observation.

e = edge(Mdl,tbl,Y) returns the classification edge for the classifier Mdl using predictor data in table tbl and class labels in vector Y. Each row of tbl and Y is an observation.

e = edge(Mdl,X,Y) returns the classification edge (e) for the classifier Mdl using predictor data in matrix X and class labels in vector Y. Each row of X and Y is an observation.

e = edge(___,Name,Value) computes the classification edge with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

For example, specify a decoding scheme, binary learner loss function, or verbosity level.
Input Arguments

**Mdl — Full or compact, multiclass ECOC model**
ClassificationECOC model object | CompactClassificationECOC model object

Full or compact, multiclass ECOC model, specified as a ClassificationECOC or CompactClassificationECOC model object.

To create a full or compact ECOC model, see ClassificationECOC or CompactClassificationECOC.

**tbl — Sample data**
table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional columns for the response variable and observation weights. tbl must contain all the predictors used to train Mdl. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained Mdl using sample data contained in a table, then the input data for this method must also be in a table.

**Note** If Mdl.BinaryLearners contains linear or kernel classification models (that is, ClassificationLinear or ClassificationKernel model objects), then you cannot specify sample data in a table. Instead, pass a matrix (X) and class labels (Y).

Data Types: table

**ResponseVarName — Response variable name**
name of a variable in tbl

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored as tbl.y, then specify it as 'y'. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.
The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables composing the columns of X should be the same as the variables that trained the Mdl classifier.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

**Y — Class labels**
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**BinaryLoss — Binary learner loss function**
'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle
Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>

</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, \texttt{customFunction}, specify its function handle 'BinaryLoss', \texttt{'@customFunction'}.

\texttt{customFunction} has this form:

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \texttt{Mdl.CodingMatrix}.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.
For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

- SVMs or either linear or kernel classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by AdaboostM1 or GentleBoost, then `BinaryLoss` is 'exponential'
- Ensembles trained by LogitBoost, then `BinaryLoss` is 'binodeviance'
- Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior',1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. `Mdl.BinaryLearners` must contain linear classification models.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', you can experience a significant reduction in execution time.
Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', 1).

Verbose — Verbosity level
0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Weights — Observation weights
ones(size(X,1)) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. If you supply weights, edge computes the weighted classification edge on page 32-1415.

Weights requires the same length as the number of observations in X or tbl. The software normalizes Weights to sum up to the value of the prior probability in the respective class.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify it as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If Mdl.BinaryLearners contains linear classification models, then you must specify a vector.

Data Types: single | double | char | string
Output Arguments

**e — Classification edge**

numeric scalar | numeric vector

Classification edge on page 32-1415, returned as a numeric scalar or vector. e represents the (weighted) mean of the classification margins on page 32-1415.

If `Mdl.BinaryLearners` contains linear classification models, then `e` is a 1-by-\(L\) vector, where \(L\) is the number of regularization strengths in the linear classification models (i.e., `numel(Mdl.BinaryLearners{1}.Lambda)`). \(e(j)\) is the edge for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `e` is a scalar.

Examples

**Estimate the Test-Sample Edge of ECOC Models**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = categorical(species);  
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```matlab
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);  
CMdl = CVMdl.Trained{1};  
testInds = test(CVMdl.Partition);  
XTest = X(testInds,:);  
YTest = Y(testInds,:);  
```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.
Estimate the test-sample edge.

e = edge(CMdl,XTest,YTest)

e = 0.4573

The estimated test sample margin average is approximately 0.45.

**Estimate the Test-Sample Weighted Margin Mean of ECOC Models**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Suppose that the observations were measured sequentially, and that the last 75 observations were better quality because of a technology upgrade. One way to incorporate this advancement is to weigh the better-quality observations more than the other observations.

Define a weight vector that weights the better-quality observations two times greater than the other observations.

```matlab
n = size(X,1);
weights = [ones(n-75,1);2*ones(75,1)];
```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample and the weighting scheme. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,...
    'Weights',weights,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```
CVMdl is a trained ClassificationPartitionedECOC model. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationECOC classifier that the software trained using the training set.

Estimate the test-sample weighted edge using the weighting scheme.

```matlab
e = edge(CMdl,XTest,YTest,'Weights',wTest)
e = 0.4798
```

The test sample weighted average margin is approximately 0.48.

### Select ECOC Model Features by Comparing Test-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test-sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:
- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```matlab
fullX = X;
partX = X(:,3:4);
```
Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

CVMdl and PCVMdl are ClassificationPartitionedECOC models. They contain the property `Trained`, which is a 1-by-1 cell array holding a CompactClassificationECOC model that the software trained using the training set.

Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(CMdl,XTest,YTest)
fullEdge = 0.4573
partEdge = edge(PCMdl,XTest(:,3:4),YTest)
partEdge = 0.4839
```

PCMdl achieves an edge that resembles the more complex model CMdl.

**Definitions**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the
margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.
\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/\left[2\log(2)\right]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/\left[2\log(2)\right]$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Tip**

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using fitcecoc.

**Algorithms**

If you trained Mdl specifying to standardize the predictor data, then the software standardizes the columns of $X$ using the corresponding means and standard deviations that the software stored in $\text{Mdl.BinaryLearner}\{j\}.\text{Mu}$ and $\text{Mdl.BinaryLearner}\{j\}.\text{Sigma}$ for learner $j$. 

32-1417

Extended Capabilities

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options`, `statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

**edge**

Classification edge

**Syntax**

\[
E = \text{edge}(\text{ens}, \text{tbl}, \text{ResponseVarName}) \\
E = \text{edge}(\text{ens}, \text{tbl}, Y) \\
E = \text{edge}(\text{ens}, X, Y) \\
E = \text{edge}(\text{___}, \text{Name}, \text{Value})
\]

**Description**

\(E = \text{edge}(\text{ens}, \text{tbl}, \text{ResponseVarName})\) returns the classification edge for \(\text{ens}\) with data \(\text{tbl}\) and classification \(\text{tbl}.\text{ResponseVarName}\).

\(E = \text{edge}(\text{ens}, \text{tbl}, Y)\) returns the classification edge for \(\text{ens}\) with data \(\text{tbl}\) and classification \(Y\).

\(E = \text{edge}(\text{ens}, X, Y)\) returns the classification edge for \(\text{ens}\) with data \(X\) and classification \(Y\).

\(E = \text{edge}(\text{___}, \text{Name}, \text{Value})\) computes the edge with additional options specified by one or more \text{Name,Value} pair arguments, using any of the previous syntaxes.

**Input Arguments**

- **ens**

  A classification ensemble constructed with \texttt{fitensemble}, or a compact classification ensemble constructed with \texttt{compact}.

- **tbl**

  Sample data, specified as a table. Each row of \(\text{tbl}\) corresponds to one observation, and each column corresponds to one predictor variable. \(\text{tbl}\) must contain all of the predictors.
used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained ens using sample data contained in a table, then the input data for this method must also be in a table.

**ResponseVarName**

Response variable name, specified as the name of a variable in tbl.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable Y is stored as `tbl.Y`, then specify it as 'Y'. Otherwise, the software treats all columns of `tbl`, including Y, as predictors when training the model.

**X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

**Y**

Class labels of observations in `tbl` or `X`. Y should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or `X`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**learners**

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. edge uses only these learners for calculating loss.

**Default:** 1:NumTrained
**mode**

Meaning of the output E:

- 'ensemble' — E is a scalar value, the edge for the entire ensemble.
- 'individual' — E is a vector with one element per trained learner.
- 'cumulative' — E is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

**UseObsForLearner**

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When UseObsForLearner(i,j) is true, learner j is used in predicting the class of row i of X.

**Default:** true(N,T)

**weights**

Observation weights, a numeric vector of length size(X,1). If you supply weights, edge computes weighted classification edge.

**Default:** ones(size(X,1),1)

**Output Arguments**

**E**

The classification edge, a vector or scalar depending on the setting of the mode name-value pair. Classification edge is weighted average classification margin.
Examples

Find Classification Edge of Training Data

Find the classification edge for some of the data used to train a boosted ensemble classifier.

Load the ionosphere data set.
load ionosphere

Train an ensemble of 100 boosted classification trees using AdaBoostM1.

\[
t = \text{templateTree}('\text{MaxNumSplits}',1); \quad \% \text{Weak learner template tree object}
\]
\[
\text{ens} = \text{fitcensemble}(X,Y,'\text{Method}', '\text{AdaBoostM1}','\text{Learners}',t);
\]

Find the classification edge for the last few rows.

\[
E = \text{edge}(\text{ens},X(\text{end-10:end},:),Y(\text{end-10:end}))
\]

\[
E = 8.3310
\]

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix \(X\).

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
• Bag scores range from 0 to 1.

**Edge**

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`. If you supply weights in the `weights` name-value pair, those weights are used instead of class probabilities.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**See Also**

e|margin
**edge**

Classification edge for naive Bayes classifiers

**Syntax**

\[ e = \text{edge}(Mdl, tbl, \text{ResponseVarName}) \]
\[ e = \text{edge}(Mdl, tbl, Y) \]
\[ e = \text{edge}(Mdl, X, Y) \]
\[ e = \text{edge}(\_, \text{Name}, \text{Value}) \]

**Description**

\[ e = \text{edge}(Mdl, tbl, \text{ResponseVarName}) \] returns the classification edge on page 32-1431 (e) for the naive Bayes classifier \( Mdl \) using the predictor data in table \( tbl \) and the class labels in \( tbl.\text{ResponseVarName} \).

\[ e = \text{edge}(Mdl, tbl, Y) \] returns the classification edge (e) for the naive Bayes classifier \( Mdl \) using predictor data in table \( tbl \) and the class labels in vector \( Y \).

\[ e = \text{edge}(Mdl, X, Y) \] returns the classification edge on page 32-1431 (e) for the naive Bayes classifier \( Mdl \) using predictor data \( X \) and class labels \( Y \).

\[ e = \text{edge}(\_, \text{Name}, \text{Value}) \] computes the classification edge with additional options specified by one or more \( \text{Name}, \text{Value} \) pair arguments, using any of the previous syntaxes.

**Input Arguments**

\( Mdl \) — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model
Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

**tbl — Sample data**

`table`

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

**ResponseVarName — Response variable name**

`name of a variable in tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

**X — Predictor data**

`numeric matrix`

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.
Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of tbl or X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. The software weighs the observations in each row of X or tbl with the corresponding weight in Weights.

If you specify Weights as a vector, then the size of Weights must be equal to the number of rows of X or tbl.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify Weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you do not specify your own loss function, then the software normalizes Weights to add up to 1.

Data Types: double | char | string
Output Arguments

e — Classification edge
scalar

Classification edge on page 32-1431, returned as a scalar. If you supply Weights, then e is the weighted classification edge.

Examples

Estimate the Test Sample Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);      % For reproducibility

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1};          % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Estimate the test sample edge.

e = edge(CMdl,XTest,YTest)
e = 0.8244

The estimated test sample margin average is approximately 0.82. This indicates that, on average, the test sample difference between the estimated posterior probability for the
predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.82. This indicates that the classifier labels with high confidence.

**Estimate the Test Sample Weighted Margin Mean of Naive Bayes Classifiers**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;  % Predictors
Y = species;  % Response
rng(1);
```

Suppose that the setosa iris measurements are lower quality because they were measured with an older technology. One way to incorporate this is to weigh the setosa iris measurements less than the other observations.

Define a weight vector that weighs the better quality observations twice the other observations.

```matlab
n = size(X,1);
idx = strcmp(Y,'setosa');
weights = ones(size(X,1),1);
weights(idx) = 0.5;
```

Train a naive Bayes classifier. Specify the weighting scheme and a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```matlab
CVMdl = fitcnb(X,Y,'Weights',weights,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1};  % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
wTest = weights(testInds);
```

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.
e = edge(CMdl, XTest, YTest, 'Weights', wTest)

\[ e = 0.7893 \]

The test sample weighted average margin is approximately 0.79. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.79. This indicates that the classifier labels with high confidence.

**Select Naive Bayes Classifier Features by Comparing Test Sample Edges**

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```matlab
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```matlab
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.
FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};

FCVMdl and PCVMdl are ClassificationPartitionedModel classifiers. They contain the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

fullEdge = edge(FCMdl,XTest,YTest)
fullEdge = 0.8244

partEdge = edge(PCMdl,XTest(:,3:4),YTest)
partEdge = 0.8420

The test-sample edges of the classifiers are nearly the same. However, the model trained using two predictors (PCMdl) is less complex.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same
scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

**Posterior Probability**

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is $k$ for a given observation $(x_1,\ldots,x_P)$ is

$$
\hat{P}(Y = k \mid x_1,\ldots,x_P) = \frac{P(X_1,\ldots,X_P \mid y = k) \pi(Y = k)}{P(X_1,\ldots,X_P)},
$$

where:

- $P(X_1,\ldots,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class $k$. Mdl.DistributionNames stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. Mdl.Prior stores the prior distribution.
- $P(X_1,\ldots,X_P)$ is the joint density of the predictors. The classes are discrete, so

$$
P(X_1,\ldots,X_P) = \sum_{k=1}^{K} P(X_1,\ldots,X_P \mid y = k) \pi(Y = k).
$$

**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

**Score**

The naive Bayes score is the class posterior probability given the observation.
Extended Capabilities

edge

Package: classreg.learning.classif

Find classification edge for support vector machine (SVM) classifier

Syntax

\[ e = \text{edge}(\text{SVMModel}, \text{TBL}, \text{ResponseVarName}) \]
\[ e = \text{edge}(\text{SVMModel}, \text{TBL}, \text{Y}) \]
\[ e = \text{edge}(\text{SVMModel}, \text{X}, \text{Y}) \]
\[ e = \text{edge}(\_, \_,'\text{Weights}', \text{weights}) \]

Description

\[ e = \text{edge}(\text{SVMModel}, \text{TBL}, \text{ResponseVarName}) \] returns the classification edge on page 32-1440 (e) for the support vector machine (SVM) classifier \( \text{SVMModel} \) using the predictor data in table \( \text{TBL} \) and the class labels in \( \text{TBL.ResponseVarName} \).

The classification edge (e) is a scalar value that represents the weighted mean of the classification margins on page 32-1440.

\[ e = \text{edge}(\text{SVMModel}, \text{TBL}, \text{Y}) \] returns the classification edge on page 32-1440 (e) for the SVM classifier \( \text{SVMModel} \) using the predictor data in table \( \text{TBL} \) and the class labels in \( \text{Y} \).

\[ e = \text{edge}(\text{SVMModel}, \text{X}, \text{Y}) \] returns the classification edge for \( \text{SVMModel} \) using the predictor data in matrix \( \text{X} \) and the class labels in \( \text{Y} \).

\[ e = \text{edge}(\_, \_, '\text{Weights}', \text{weights}) \] computes the classification edge for the observation weights supplied in \( \text{weights} \) using any of the input arguments in the previous syntaxes.
Examples

Estimate Test Sample Edge of SVM Classifiers

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```matlab
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample edge.

```matlab
e = edge(CompactSVMMModel,XTest,YTest)
e = 5.0765
```

The margin average of the test sample is approximately 5.

---

Estimate Test Sample Weighted Margin Mean of SVM Classifiers

Suppose that the observations in a data set are measured sequentially, and that the last 150 observations have better quality due to a technology upgrade. Incorporate this advancement by weighing the better quality observations more than the other observations.

Load the ionosphere data set.
Define a weight vector that weighs the better quality observations two times the other observations.

\[
\text{n} = \text{size}(	ext{X},1);
\text{weights} = [\text{ones}(\text{n}-150,1);2*\text{ones}(150,1)];
\]

Train an SVM classifier. Specify the weighting scheme and a 15% holdout sample for testing. Also, standardize the data and specify that 'g' is the positive class.

\[
\text{CVSVMModel} = \text{fitcsvm}(	ext{X},\text{Y},'\text{Weights}',\text{weights},'\text{Holdout}',0.15,...
\text{',ClassNames'},'\text{b}','\text{g}','\text{Standardize}',\text{true});
\]

\[
\text{CompactSVMModel} = \text{CVSVMModel}.\text{Trained}{1};
\text{testInds} = \text{test}(\text{CVSVMModel}.\text{Partition}); \quad \% \text{Extract the test indices}
\text{XTest} = \text{X}(\text{testInds},:);
\text{YTest} = \text{Y}(\text{testInds},:);
\text{wTest} = \text{weights}(\text{testInds},:);
\]

The weighted average margin of the test sample is approximately 5.

### Select SVM Classifier Features by Comparing Test Sample Edges

Perform feature selection by comparing test sample edges from multiple models. Based solely on this comparison, the classifier with the highest edge is the best classifier.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```
Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`Partition` defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```matlab
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```matlab
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(FCSVMModel,XTest,YTest)
fullEdge = 2.8319
```

```matlab
partEdge = edge(PCSVMModel,XTest(:,end-20:end),YTest)
partEdge = 1.5540
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors is better.
Input Arguments

**SVMMModel — SVM classification model**

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

**TBL — Sample data**

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMMModel using sample data contained in a table, then the input data for edge must also be in a table.

If you set 'Standardize',true in fitcsvm when training SVMMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMMModel.Mu and the standard deviations in SVMMModel.Sigma.

Data Types: table

**X — Predictor data**

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMMModel classifier.

The length of Y and the number of rows in X must be equal.
If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: double | single

**ResponseVarName — Response variable name**

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify ResponseVarName as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.Response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of SVMModel.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y must equal the number of rows in TBL or the number of rows in X.

**weights — Observation weights**

ones(size(X,1),1) (default) | numeric vector | name of variable in TBL

Observation weights, specified as a numeric vector or the name of a variable in TBL.

If you specify weights as a numeric vector, then the size of weights must be equal to the number of rows in X or TBL.
If you specify `weights` as the name of a variable in `TBL`, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify `weights` as 'W'. Otherwise, the software treats all columns of `TBL`, including `TBL.W`, as predictors.

If you supply weights, `edge` computes the weighted classification edge on page 32-1440. The software weights the observations in each row of `X` or `TBL` with the corresponding weight in `weights`.

Example: 'Weights','W'

Data Types: `single` | `double` | `char` | `string`

**Definitions**

**Classification Edge**

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).
If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

The SVM classification score for classifying observation \( x \) is the signed distance from \( x \) to the decision boundary ranging from \(-\infty\) to \(+\infty\). A positive score for a class indicates that \( x \) is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score \( f(x) \) is the trained SVM classification function. \( f(x) \) is also the numerical, predicted response for \( x \), or the score for predicting \( x \) into the positive class.

\[
f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,
\]

where \( (\alpha_1, ..., \alpha_n, b) \) are the estimated SVM parameters, \( G(x_j, x) \) is the dot product in the predictor space between \( x \) and the support vectors, and the sum includes the training set observations. The negative class classification score for \( x \), or the score for predicting \( x \) into the negative class, is \(-f(x)\).

If \( G(x_j, x) = x_j'x \) (the linear kernel), then the score function reduces to

\[
f(x) = (x/s)'\beta + b.
\]

\( s \) is the kernel scale and \( \beta \) is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-183.

**Algorithms**

For binary classification, the software defines the margin for observation \( j \), \( m_j \), as

\[
m_j = 2y_j f(x_j),
\]
where \( y_j \in \{-1,1\} \), and \( f(x_j) \) is the predicted score of observation \( j \) for the positive class. However, \( m_j = y_j f(x_j) \) is commonly used to define the margin.

*Introduced in R2014a*
edge

Classification edge

Syntax

E = edge(tree,TBL,ResponseVarName)
E = edge(tree,X,Y)
E = edge(___,Name,Value)

Description

E = edge(tree,TBL,ResponseVarName) returns the classification edge for tree with data TBL and classification TBL.ResponseVarName.

E = edge(tree,X,Y) returns the classification edge for tree with data X and classification Y.

E = edge(___,Name,Value) computes the edge with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify observation weights.

Input Arguments

tree — Trained classification tree
ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, tree is a trained classification model returned by fitctree or compact.

TBL — Sample data
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional
columns for the response variable and observation weights. TBL must contain all the predictors used to train tree. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName or Y.

If you train tree using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Data to classify
numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train tree. X must have the same number of rows as the number of elements in Y.

Data Types: single | double

ResponseVarName — Response variable name
name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify it as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.ResponseVarName, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors
Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train tree, and its number of elements must equal the number of rows of X.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Weights — Observation weights
ones(size(X,1),1) (default) | name of a variable in TBL | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in TBL.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of rows in X or TBL.

If you specify Weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.W, then specify it as 'W'. Otherwise, the software treats all columns of TBL, including TBL.W, as predictors.

If you supply weights, edge computes the weighted classification edge on page 32-1440. The software weights the observations in each row of X or TBL with the corresponding weight in Weights.

Data Types: single | double | char | string

Output Arguments

E — Classification edge
scalar value

Classification edge, returned as a scalar representing the weighted average value of the margin.
Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```matlab
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
E = edge(tree,X,species)
E =
    0.6299

M = margin(tree,X,species);
M(end-10:end)
ans =
   0.1111
   0.1111
   0.1111
  -0.2857
   0.6364
   0.6364
   0.1111
   0.7500
   1.0000
   0.6364
   0.2000

The classification tree trained on all the data is better.

tree = fitctree(meas,species);
E = edge(tree,meas,species)
E =
    0.9384

M = margin(tree,meas,species);
M(end-10:end)
ans =
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
```
Definitions

Margin
The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix X.

Score (tree)
For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when \( X < \theta_{.15} \) or \( X > \theta_{.95} \), and X is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```
Prune the tree:

```matlab
treel = prune(tree,'Level',1);
view(treel,'Mode','Graph')
```
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range (0.95,1) instead of the expected 5 observations.

**Edge**

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

end

Class: dataset

Last index in indexing expression for dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

end(A,k,n)

Description

end(A,k,n) is called for indexing expressions involving the dataset A when end is part of the k-th index out of n indices. For example, the expression A(end-1,:) calls A's end method with end(A,1,2).

See Also

size
end

Class: qrandset

Last index in indexing expression for point set

Syntax

end(p,k,n)

Description

dend(p,k,n) is called for indexing expressions involving the point set p when end is part of the k-th index out of n indices. For example, the expression p(end-1,:) calls p's end method with end(p,1,2).

See Also

qrandset
**epsilon**

**Class:** RepeatedMeasuresModel

Epsilon adjustment for repeated measures anova

**Syntax**

```matlab
tbl = epsilon(rm)
tbl = epsilon(rm,C)
```

**Description**

`tbl = epsilon(rm)` returns the epsilon adjustment factors for repeated measures model `rm`.

`tbl = epsilon(rm,C)` returns the epsilon adjustment factors for the test based on the contrast matrix `C`.

**Input Arguments**

- **`rm` — Repeated measures model**
  RepeatedMeasuresModel object

  Repeated measures model, returned as a `RepeatedMeasuresModel` object.

  For properties and methods of this object, see `RepeatedMeasuresModel`.

- **`C` — Contrasts**
  matrix

  Contrasts, specified as a matrix. The default value of `C` is the Q factor in a QR decomposition of the matrix M, where M is defined so that Y*M is the difference between all successive pairs of columns of the repeated measures matrix Y.

  Data Types: `single` | `double`
Output Arguments

tbl — Epsilon adjustment factors
table

epsilon adjustment factors for the repeated measures model rm, returned as a table. tbl
contains four different adjustments for epsilon.

<table>
<thead>
<tr>

Data Types: table

Examples

Epsilon Corrections for Repeated Measures ANOVA

Load the sample data.

load fisheriris

The column vector, species consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...'
     'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);

Perform repeated measures analysis of variance.

ranovatbl = ranova(rm)

ranovatbl=3×8 table

<table>
<thead>
<tr>

<td>0.76409</td>
<td>0.33333</td>
</tr>
</tbody>
</table>

You can check the compound symmetry (sphericity) assumption using the `mauchly` method.

**Tips**

- The `mauchly` method tests for sphericity.
- The `ranova` method contains $p$-values based on each epsilon value.
Algorithms

ranova computes the regular $p$-value (in the pValue column of the rmanova table) using the $F$-statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, ranova uses a correction factor epsilon, $\varepsilon$, to compute the corrected $p$-values as follows:

$$p\text{-value_corrected} = 1 - \text{fcdf}(F, \varepsilon v_1, \varepsilon v_2).$$

The epsilon method returns the epsilon adjustment values.

**evcdf**

Extreme value cumulative distribution function

**Syntax**

```
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf(___,'upper')
```

**Description**

`p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies $100(1 - \alpha)\%$ confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

`[p,plo,pup] = evcdf(___,'upper')` returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$
\frac{X - \hat{\mu}}{\hat{\sigma}}
$$
and then transforming those bounds to the scale of the output \( P \). The computed bounds give approximately the desired confidence level when you estimate \( \mu, \sigma, \) and \( \text{pcov} \) from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating \( X \) and subtracting the resulting distribution values from 1. See “Extreme Value Distribution” on page B-36 for more details. If \( x \) has a Weibull distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.

**Extended Capabilities**

**Topics**
“Extreme Value Distribution” on page B-36

**Introduced before R2006a**
evfit
Extreme value parameter estimates

Syntax

parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)

Description

parmhat = evfit(data) returns maximum likelihood estimates of the parameters of
the type 1 extreme value distribution given the data in the vector data. parmhat(1) is
the location parameter, \( \mu \), and parmhat(2) is the scale parameter, \( \sigma \).

[parmhat,parmci] = evfit(data) returns 95% confidence intervals for the
parameter estimates on the \( \mu \) and \( \sigma \) parameters in the 2-by-2 matrix parmci. The first
column of the matrix of the extreme value fit contains the lower and upper confidence
bounds for the parameter \( \mu \), and the second column contains the confidence bounds for
the parameter \( \sigma \).

[parmhat,parmci] = evfit(data,alpha) returns 100(1 - alpha)% confidence
intervals for the parameter estimates, where alpha is a value in the range \([0 1]\)
specifying the width of the confidence intervals. By default, alpha is 0.05, which
corresponds to 95% confidence intervals.

[...] = evfit(data,alpha,censoring) accepts a Boolean vector, censoring, of
the same size as data, which is 1 for observations that are right-censored and 0 for
observations that are observed exactly.

[...] = evfit(data,alpha,censoring,freq) accepts a frequency vector, freq of
the same size as data. Typically, freq contains integer frequencies for the corresponding
elements in data, but can contain any nonnegative values. Pass in [] for alpha,
censoring, or freq to use their default values.

[..., ] = evfit(data, alpha, censoring, freq, options) accepts a structure,
options, that specifies control parameters for the iterative algorithm the function uses
to compute maximum likelihood estimates. You can create options using the function
statset. Enter statset('evfit') to see the names and default values of the
parameters that evfit accepts in the options structure. See the reference page for
statset for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The
version used here is suitable for modeling minima; the mirror image of this distribution
can be used to model maxima by negating X. See “Extreme Value Distribution” on page B-
36 for more details. If x has a Weibull distribution, then X = log(x) has the type 1
extreme value distribution.

Topics
“Extreme Value Distribution” on page B-36

Introduced before R2006a
evinv

Extreme value inverse cumulative distribution function

Syntax

X = evinv(P,mu,sigma)
[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)

Description

X = evinv(P,mu,sigma) returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter mu and scale parameter sigma, evaluated at the values in P. P, mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for mu and sigma are 0 and 1, respectively.

[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha) produces confidence bounds for X when the input parameters mu and sigma are estimates. pcov is the covariance matrix of the estimated parameters. alpha is a scalar that specifies 100(1 - alpha)% confidence bounds for the estimated parameters, and has a default value of 0.05. XLO and XUP are arrays of the same size as X containing the lower and upper confidence bounds.

The function evinv computes confidence bounds for P using a normal approximation to the distribution of the estimate

\[ \hat{\mu} + \hat{\sigma} q \]

where q is the Pth quantile from an extreme value distribution with parameters \( \mu = 0 \) and \( \sigma = 1 \). The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pcov from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution
can be used to model maxima by negating $X$. See “Extreme Value Distribution” on page B-36 for more details. If $x$ has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

**Extended Capabilities**

*Introduced before R2006a*
eq

Class: qrandstream

Test handle equality

Syntax

h1 == h2
tf = eq(h1, h2)

Description

h1 == h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = eq(h1, h2) stores the result in a logical array of the same dimensions.

error

Class: CompactTreeBagger

Error (misclassification probability or MSE)

Syntax

err = error(B,TBLnew,Ynew)
err = error(B,Xnew,Ynew)
err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)

Description

err = error(B,TBLnew,Ynew) computes the misclassification probability for
classification trees or mean squared error (MSE) for regression trees for each tree, for
the predictors contained in the table TBLnew given true response Ynew. You can omit
Ynew if TBLnew contains the response variable. If you trained B using sample data
contained in a table, then the input data for this method must also be in a table.

err = error(B,Xnew,Ynew) computes the misclassification probability for
classification trees or mean squared error (MSE) for regression trees for each tree, the
for predictors contained in the matrix Xnew given true response Ynew. If you trained B
using sample data contained in a matrix, then the input data for this method must also be
in a matrix.

For classification, Ynew can be a numeric vector, character matrix, string array, cell array
of character vectors, categorical vector, or logical vector. For regression, Y must be a
numeric vector. err is a vector with one error measure for each of the NTrees trees in
the ensemble B.

err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...) or err =
error(B,Xnew,Ynew,'param1',val1,'param2',val2,...) specifies optional
parameter name-value pairs:
'Mode'
Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.

'Weights'
Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.

'Trees'
Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.

'TreeWeights'
Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.

'UseInstanceForTree'
Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

### Algorithms

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
  - The error for individual trees in the ensemble
• The cumulative error over all trees
• The error for the entire ensemble
• Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
• Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
• Using the 'Weights' name-value pair argument, you can attribute each observation with a weight. For the formulae that follow, w_j is the weight of observation j.
• Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

For regression problems, error estimates the weighted MSE of the ensemble of bagged regression trees for predicting Y given X using selected trees and observations.

1 error predicts responses for selected observations in X using the selected regression trees in the ensemble.

2 The MSE estimate depends on the value of 'Mode'.

• If you specify 'Mode','Individual', then the weighted MSE for tree t is

\[
MSE_t = \frac{1}{n} \sum_{j=1}^{n} w_j (y_j - \hat{y}_{tj})^2.
\]

\(\hat{y}_{tj}\) is the predicted response of observation j from selected regression tree t. error sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

• If you specify 'Mode','Cumulative', then the weighted MSE is a vector of size \(T^*\) containing cumulative, weighted MSEs over the \(T^* \leq T\) selected trees. error follows these steps to estimate \(MSE_t^*\), the cumulative, weighted MSE using the first t selected trees.

a For selected observation \(j, j = 1,...,n\), error estimates \(\hat{y}_{bag,tj}\), the weighted average of the predictions among the first t selected trees (for details, see predict). For this computation, error uses the tree weights.
error estimates the cumulative, weighted MSE through tree \( t \).

\[
\text{MSE}_{t}^{*} = \frac{1}{n} \sum_{j=1}^{n} w_{j} \left( y_{j} - \hat{y}_{\text{bag},tj} \right)^{2}.
\]

error sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, error estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting \( Y \) given \( X \) using selected trees and observations.

- If you specify 'Mode', 'Individual', then the weighted misclassification rate for tree \( t \) is

\[
e_{t} = \frac{1}{n} \sum_{j=1}^{n} w_{j} I(y_{j} \neq \hat{y}_{tj}).
\]

\( \hat{y}_{tj} \) is the predicted class for selected observation \( j \) using from selected classification tree \( t \). error sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular.

- If you specify 'Mode', 'Cumulative' then the weighted misclassification rate is a vector of size \( T \) containing cumulative, weighted misclassification rates over the \( T \leq T^{*} \) selected trees. error follows these steps to estimate \( e_{t}^{*} \), the cumulative, weighted misclassification rate using the first \( t \) selected trees.

1 For selected observation \( j, j = 1, \ldots, n \), error estimates \( \hat{y}_{\text{bag},tj} \), the weighted, most popular class among the first \( t \) selected trees (for details, see predict). For this computation, error uses the tree weights.
error estimates the cumulative, weighted misclassification rate through tree $t$.

$$e_t^* = \frac{1}{n} \sum_{j=1}^{n} w_j I(y_j \neq \hat{y}_{\text{bag},tj}).$$

error sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular.

- If you specify 'Mode','Ensemble', then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

**error**

**Class:** TreeBagger

Error (misclassification probability or MSE)

**Syntax**

```matlab
err = error(B,TBLnew,Ynew)
err = error(B,Xnew,Ynew)
err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

**Description**

`err = error(B,TBLnew,Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`err = error(B,Xnew,Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, the for predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

For classification, `Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:
'Mode' | Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.

'Weights' | Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.

'Trees' | Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.

'TreeWeights' | Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.

'UseInstanceForTree' | Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

### Algorithms

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
  - The error for individual trees in the ensemble
• The cumulative error over all trees
• The error for the entire ensemble
• Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
• Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
• Using the 'Weights' name-value pair argument, you can attribute each observation with a weight. For the formulae that follow, \( w_j \) is the weight of observation \( j \).
• Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

For regression problems, \( \text{error} \) estimates the weighted MSE of the ensemble of bagged regression trees for predicting \( Y \) given \( X \) using selected trees and observations.

1 \( \text{error} \) predicts responses for selected observations in \( X \) using the selected regression trees in the ensemble.
2 The MSE estimate depends on the value of 'Mode'.
   • If you specify 'Mode','Individual', then the weighted MSE for tree \( t \) is

\[
MSE_t = \frac{1}{n} \sum_{j=1}^{n} w_j (y_j - \hat{y}_{tj})^2.
\]

\( \hat{y}_{tj} \) is the predicted response of observation \( j \) from selected regression tree \( t \). \( \text{error} \) sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

• If you specify 'Mode','Cumulative', then the weighted MSE is a vector of size \( T^* \) containing cumulative, weighted MSEs over the \( T^* \leq T \) selected trees. \( \text{error} \) follows these steps to estimate \( MSE_t^* \), the cumulative, weighted MSE using the first \( t \) selected trees.

\[ a \]
   For selected observation \( j, j = 1,...,n, \text{error} \) estimates \( \hat{y}_{\text{bag}, tj} \), the weighted average of the predictions among the first \( t \) selected trees (for details, see predict). For this computation, \( \text{error} \) uses the tree weights.
error estimates the cumulative, weighted MSE through tree $t$.

$$\text{MSE}_t^* = \frac{1}{n} \sum_{j=1}^{n} w_j \left( y_j - \hat{y}_{\text{bag},tj} \right)^2.$$  

error sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode','Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, error estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting $Y$ given $X$ using selected trees and observations.

- If you specify 'Mode','Individual', then the weighted misclassification rate for tree $t$ is

$$e_t = \frac{1}{n} \sum_{j=1}^{n} w_j I(y_j \neq \hat{y}_{tj}).$$

$\hat{y}_{tj}$ is the predicted class for selected observation $j$ using from selected classification tree $t$. error sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular.

- If you specify 'Mode','Cumulative' then the weighted misclassification rate is a vector of size $T^*$ containing cumulative, weighted misclassification rates over the $T^* \leq T$ selected trees. error follows these steps to estimate $e_t^*$, the cumulative, weighted misclassification rate using the first $t$ selected trees.

For selected observation $j$, $j = 1,...,n$, error estimates $\hat{y}_{\text{bag},tj}$, the weighted, most popular class among the first $t$ selected trees (for details, see predict). For this computation, error uses the tree weights.
error estimates the cumulative, weighted misclassification rate through tree \( t \).

\[
e_t^* = \frac{1}{n} \sum_{j=1}^{n} w_j I(y_j \neq \hat{y}_{\text{bag},tj}).
\]

error sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular.

- If you specify 'Mode', 'Ensemble', then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

eval

**Class:** classregtree

(Removed) Predicted responses

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[
yfit = \text{eval}(t,X)
\]

\[
yfit = \text{eval}(t,X,s)
\]

\[
[yfit,nodes] = \text{eval}(...)
\]

\[
[yfit,nodes,cnums] = \text{eval}(...)
\]

\[
[...] = t(X)
\]

\[
[...] = t(X,s)
\]

**Description**

\[
yfit = \text{eval}(t,X)\] takes a classification or regression tree \(t\) and a matrix \(X\) of predictors, and produces a vector \(yfit\) of predicted response values. For a regression tree, \(yfit(i)\) is the fitted response value for a point having the predictor values \(X(i,:)\). For a classification tree, \(yfit(i)\) is the class into which the tree assigns the point with data \(X(i,:}\).

\[
yfit = \text{eval}(t,X,s)\] takes an additional vector \(s\) of pruning levels, with 0 representing the full, unpruned tree. \(t\) must include a pruning sequence as created by classregtree or by prune. If \(s\) has \(k\) elements and \(X\) has \(n\) rows, the output \(yfit\) is an \(n\)-by-\(k\) matrix, with the \(j\)th column containing the fitted values produced by the \(s(j)\) subtree. \(s\) must be sorted in ascending order.

To compute fitted values for a tree that is not part of the optimal pruning sequence, first use prune to prune the tree.
[yfit, nodes] = eval(...) also returns a vector nodes the same size as yfit containing the node number assigned to each row of X. Use view to display the node numbers for any node you select.

[yfit, nodes, cnums] = eval(...) is valid only for classification trees. It returns a vector cnum containing the predicted class numbers.

NaN values in X are treated as missing. If eval encounters a missing value when it attempts to evaluate the split rule at a branch node, it cannot determine whether to proceed to the left or right child node. Instead, it sets the corresponding fitted value equal to the fitted value assigned to the branch node.

[...] = t(X) or [...] = t(X,s) also invoke eval.

**evalclusters**

Evaluate clustering solutions

**Syntax**

`eva = evalclusters(x,clust,criterion)`  
`eva = evalclusters(x,clust,criterion,Name,Value)`

**Description**

`eva = evalclusters(x,clust,criterion)` creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

`eva = evalclusters(x,clust,criterion,Name,Value)` creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

**Examples**

**Evaluate the Clustering Solution Using Calinski-Harabasz Criterion**

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```matlab
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using `kmeans`. 
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])

eva =
    CalinskiHarabaszEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
    OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

**Evaluate a Matrix of Clustering Solutions**

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

Load the sample data.

load fisheriris;

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use kmeans to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

clust = zeros(size(meas,1),6);
for i=1:6
    clust(:,i) = kmeans(meas,i,'emptyaction','singleton',
                           'replicate',5);
end

Each row of clust corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

eva = evalclusters(meas,clust,'CalinskiHarabasz')
eva = 
    CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
    OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Specify Clustering Algorithm with a Function Handle

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

load fisheriris;

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton','
        'replicate',5));

Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

eva = evalclusters(meas,myfunc,'CalinskiHarabasz',...
    'klist',[1:6])

eva = 
    CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

**Input Arguments**

x — Input data matrix

Input data, specified as an N-by-P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans' Cluster the data in x using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.

'linkage' Cluster the data in x using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.

'gmdistribution' Cluster the data in x using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form C = clustfun(DATA,K), where DATA is the data to be clustered, and K is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in DATA. There must be K unique values in this vector.
A numeric $n$-by-$K$ matrix of score for $n$ observations and $K$ classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a $n$-by-$K$ matrix containing the proposed clustering solutions. $n$ is the number of observations in the sample data, and $K$ is the number of proposed clustering solutions. Column $j$ contains the cluster indices for each of the $N$ points in the $j$th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

criterion — Clustering evaluation criterion

'CalinskiHarabasz' | 'DaviesBouldin' | 'gap' | 'silhouette'

Clustering evaluation criterion, specified as one of the following.

'CalinskiHarabasz' Create a `CalinskiHarabaszEvaluation` clustering evaluation object containing Calinski-Harabasz index values.

'DaviesBouldin' Create a `DaviesBouldinEvaluation` cluster evaluation object containing Davies-Bouldin index values.

gap Create a `GapEvaluation` cluster evaluation object containing gap criterion values.

'silhouette' Create a `SilhouetteEvaluation` cluster evaluation object containing silhouette values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.
**For All Criteria**

**KList — List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when clust is a clustering algorithm name or a function handle. When criterion is 'gap', clust must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]

Data Types: single | double

**For Silhouette and Gap**

**Distance — Distance metric**

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

- 'sqEuclidean' Squared Euclidean distance
- 'Euclidean' Euclidean distance. This option is not valid for the kmeans clustering algorithm.
- 'cityblock' Sum of absolute differences
- 'cosine' One minus the cosine of the included angle between points (treated as vectors)
- 'correlation' One minus the sample correlation between points (treated as sequences of values)
- 'Hamming' Percentage of coordinates that differ. This option is only valid for the Silhouette criterion.
- 'Jaccard' Percentage of nonzero coordinates that differ. This option is only valid for the Silhouette criterion.

For detailed information about each distance metric, see pdist.

You can also specify a function for the distance metric using a function handle (MATLAB). The distance function must be of the form d2 = distfun(XI,XJ), where XI is a 1-by-n vector corresponding to a single row of the input matrix X, and XJ is an m_2-by-n matrix.
corresponding to multiple rows of \( X \). \( \text{distfun} \) must return an \( m_2 \)-by-1 vector of distances \( d_2 \), whose \( k \)th element is the distance between \( X_I \) and \( X_J(k,:) \).

\textbf{Distance} only accepts a function handle if the clustering algorithm \( \text{clust} \) accepts a function handle as the distance metric. For example, the \( \text{kmeans} \) clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the \( \text{kmeans} \) algorithm and then specify a function handle for \( \text{Distance} \), the software errors.

- If \( \text{criterion} \) is 'silhouette', you can also specify \( \text{Distance} \) as the output vector created by the function \( \text{pdist} \).
- When \( \text{clust} \) is 'kmeans' or 'gmdistribution', \( \text{evalclusters} \) uses the distance metric specified for \( \text{Distance} \) to cluster the data.
- If \( \text{clust} \) is 'linkage', and \( \text{Distance} \) is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If \( \text{clust} \) is 'linkage' and \( \text{Distance} \) is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for \( \text{Distance} \) must match the distance metric used in the clustering algorithm to obtain meaningful results.

\textbf{Example}: 'Distance','Euclidean'

\textbf{Data Types:} single | double | char | string | function_handle

\textbf{For Silhouette Only}

\textbf{ClusterPriors — Prior probabilities for each cluster}

'\text{empirical}' (default) | 'equal'

Prior probabilities for each cluster, specified as the comma-separated pair consisting of 'ClusterPriors' and one of the following.

- 'empirical' Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
- 'equal' Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.
Example: 'ClusterPriors','empirical'

**For Gap Only**

**B — Number of reference data sets**

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B',150

Data Types: single | double

**ReferenceDistribution — Reference data generation method**

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

- 'PCA' Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x.
- 'uniform' Generate reference data uniformly over the range of each feature in the data matrix x.

Example: 'ReferenceDistribution','uniform'

**SearchMethod — Method for selecting optimal number of clusters**

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.
Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}), \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, \( \text{GAPMAX} \) is the largest gap value, and \( \text{SE}(\text{GAPMAX}) \) is the standard error corresponding to the largest gap value.

Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1), \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, and \( \text{SE}(K + 1) \) is the standard error of the clustering solution with \( K + 1 \) clusters.

Example: 'SearchMethod','globalMaxSE'

**Output Arguments**

**eva** — Clustering evaluation data  
clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

evlike

Extreme value negative log-likelihood

Syntax

nlogL = evlike(params,data)  
[nlogL,AVAR] = evlike(params,data)  
[...] = evlike(params,data,censoring)  
[...] = evlike(params,data,censoring,freq)

Description

nlogL = evlike(params,data) returns the negative of the log-likelihood for the type 1 extreme value distribution. params(1) is the tail location parameter, mu, and params(2) is the scale parameter, sigma. nlogL is a scalar.

[nlogL,AVAR] = evlike(params,data) returns the inverse of Fisher's information matrix, AVAR. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of AVAR are their asymptotic variances. AVAR is based on the observed Fisher's information, not the expected information.

[...] = evlike(params,data,censoring) accepts a Boolean vector of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

[...] = evlike(params,data,censoring,freq) accepts a frequency vector of the same size as data. freq typically contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for censoring to use its default value.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating data. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then X = log(x) has the type 1 extreme value distribution.
Extended Capabilities

GPU Arrays

evpdf

Extreme value probability density function

Syntax

Y = evpdf(X,mu,sigma)

Description

Y = evpdf(X,mu,sigma) returns the pdf of the type 1 extreme value distribution with location parameter mu and scale parameter sigma, evaluated at the values in X. X, mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for mu and sigma are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating X. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then X = log(x) has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

evrnd

Extreme value random numbers

Syntax

\[ R = \text{evrnd}(\mu, \sigma) \]
\[ R = \text{evrnd}(\mu, \sigma, m, n, \ldots) \]
\[ R = \text{evrnd}(\mu, \sigma, [m, n, \ldots]) \]

Description

\[ R = \text{evrnd}(\mu, \sigma) \] generates random numbers from the extreme value distribution with parameters specified by location parameter \( \mu \) and scale parameter \( \sigma \). \( \mu \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \( R \). A scalar input for \( \mu \) or \( \sigma \) is expanded to a constant array with the same dimensions as the other input.

\[ R = \text{evrnd}(\mu, \sigma, m, n, \ldots) \] or \[ R = \text{evrnd}(\mu, \sigma, [m, n, \ldots]) \] generates an \( m \)-by-\( n \)-by-\( \ldots \) array containing random numbers from the extreme value distribution with parameters \( \mu \) and \( \sigma \). \( \mu \) and \( \sigma \) can each be scalars or arrays of the same size as \( R \).

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating \( R \). See “Extreme Value Distribution” on page B-36 for more details. If \( x \) has a Weibull distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.
Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

evstat

Extreme value mean and variance

Syntax

\[ [M,V] = \text{evstat}(\mu,\sigma) \]

Description

\[ [M,V] = \text{evstat}(\mu,\sigma) \]

returns the mean of and variance for the type 1 extreme value distribution with location parameter \( \mu \) and scale parameter \( \sigma \). \( \mu \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input. The default values for \( \mu \) and \( \sigma \) are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima. See “Extreme Value Distribution” on page B-36 for more details. If \( x \) has a Weibull distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.

Extended Capabilities

“Extreme Value Distribution” on page B-36

Introduced before R2006a
expcdf

Exponential cumulative distribution function

Syntax

\[ p = \text{expcdf}(x, \mu) \]
\[ [p, plo, pup] = \text{expcdf}(x, \mu, \text{pcov}, \alpha) \]
\[ [p, plo, pup] = \text{expcdf}(\_, \text{',} 'upper') \]

Description

\[ p = \text{expcdf}(x, \mu) \] computes the exponential cdf at each of the values in \( x \) using the corresponding mean parameter \( \mu \). \( x \) and \( \mu \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( \mu \) must be positive.

\[ [p, plo, pup] = \text{expcdf}(x, \mu, \text{pcov}, \alpha) \] produces confidence bounds for \( p \) when the input mean parameter \( \mu \) is an estimate. \( \text{pcov} \) is the variance of the estimated \( \mu \). \( \alpha \) specifies \( 100(1 - \alpha)\% \) confidence bounds. The default value of \( \alpha \) is 0.05. \( plo \) and \( pup \) are arrays of the same size as \( p \) containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of \( \mu \). If you estimate \( \mu \) from a set of data, you can get a more accurate set of bounds by applying \text{expfit} to the data to get a confidence interval for \( \mu \), and then evaluating \text{expinv} at the lower and upper endpoints of that interval.

\[ [p, plo, pup] = \text{expcdf}(\_, \text{',} 'upper') \] returns the complement of the exponential cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the prior syntaxes.

The exponential cdf is

\[ p = F(x \mid \mu) = \int_0^x \frac{-t}{\mu} e^{-\mu} dt = 1 - e^{-\frac{x}{\mu}} \]
The result, \( p \), is the probability that a single observation from an exponential distribution will fall in the interval \( [0 \ x] \).

**Examples**

**Compute the Exponential CDF**

The following code shows that the median of the exponential distribution is \( \mu \log(2) \).

```matlab
mu = 10:10:60;
p = expcdf(log(2)*mu,mu)
p = 1×6
    0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
```

What is the probability that an exponential random variable is less than or equal to the mean, \( \mu \)?

```matlab
mu = 1:6;
x = mu;
p = expcdf(x,mu)
p = 1×6
    0.6321    0.6321    0.6321    0.6321    0.6321    0.6321
```

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.
GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

**expfit**

Exponential parameter estimates

**Syntax**

muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)

**Description**

muhat = expfit(data) estimates the mean of an exponentially distributed sample data. Each entry of muhat corresponds to the data in a column of data.

[muhat,muci] = expfit(data) returns 95% confidence intervals for the mean parameter estimates in matrix muci. The first row of muci contains the lower bounds of the confidence intervals, and the second row contains the upper bounds.

[muhat,muci] = expfit(data,alpha) returns 100(1 - alpha)% confidence intervals for the parameter estimates, where alpha is a value in the range [0 1] specifying the width of the confidence intervals. By default, alpha is 0.05, which corresponds to 95% confidence intervals.

[...] = expfit(data,alpha,censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. data must be a vector in order to pass in the argument censoring.

[...] = expfit(data,alpha,censoring,freq) accepts a frequency vector, freq of the same size as data. Typically, freq contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for alpha, censoring, or freq to use their default values.
Examples

The following estimates the mean \( \mu \) of exponentially distributed data, and returns a 95% confidence interval for the estimate:

\[
\mu = 3; \\
data = exprnd(\mu,100,1); \quad \text{% Simulated data}
\]

\[
[muhat,muci] = \text{expfit}(\text{data})
\]

\[
\begin{align*}
\text{muhat} &= \\
&= 2.7511 \\
\text{muci} &= \\
&= 2.2826 \\
&= 3.3813
\end{align*}
\]

Extended Capabilities

Introduced before R2006a
ExhaustiveSearcher

Create exhaustive nearest neighbor searcher

Description

ExhaustiveSearcher model objects store the training data, distance metric, and parameter values of the distance metric for an exhaustive nearest neighbor search. The exhaustive search algorithm finds the distance from each query observation to all \( n \) observations in the training data, which is an \( n \)-by-\( K \) numeric matrix.

Once you create an ExhaustiveSearcher model object, find neighboring points in the training data to the query data by performing a nearest neighbor search using knnsearch or a radius search using rangesearch. The exhaustive search algorithm is more efficient than the Kd-tree algorithm when \( K \) is large (that is, \( K > 10 \)), and it is more flexible than the Kd-tree algorithm with respect to distance metric choices. The ExhaustiveSearcher model object also supports sparse data.

Creation

Use either the createns function or the ExhaustiveSearcher function (described here) to create an ExhaustiveSearcher object. Both functions use the same syntax except that the createns function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The createns function also creates a KDTreeSearcher object. Specify 'NSMethod','exhaustive' to create an ExhaustiveSearcher object. The default is 'exhaustive' if \( K > 10 \), the training data is sparse, or the distance metric is not the Euclidean, city block, Chebychev, or Minkowski.

Syntax

Mdl = ExhaustiveSearcher(X)
Mdl = ExhaustiveSearcher(X,Name,Value)
Description

Mdl = ExhaustiveSearcher(X) creates an exhaustive nearest neighbor searcher object (Mdl) using the $n$-by-$K$ numeric matrix of training data ($X$).

Mdl = ExhaustiveSearcher(X,Name,Value) specifies additional options using one or more name-value pair arguments. You can specify the distance metric and set the distance metric parameter (DistParameter) property. For example, ExhaustiveSearcher(X,'Distance','chebychev') creates an exhaustive nearest neighbor searcher object that uses the Chebychev distance. To specify DistParameter, use the Cov, P, or Scale name-value pair argument.

Input Arguments

X — Training data
numeric matrix

Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. $X$ has $n$ rows, each corresponding to an observation (that is, an instance or example), and $K$ columns, each corresponding to a predictor (that is, a feature).

Data Types: single | double

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','mahalanobis','Cov',eye(3) specifies to use the Mahalanobis distance when searching for nearest neighbors and a 3-by-3 identity matrix for the covariance matrix in the Mahalanobis distance metric.

Distance — Distance metric
'euclidean' (default) | character vector | string scalar | custom distance function

Distance metric used when you call knnsearch or rangesearch to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and a character vector, string scalar, or function handle.

This table describes the supported distance metrics specified as character vectors or string scalars.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as row vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the 'Scale' name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>

For more details, see “Distance Metrics” on page 18-16.

You can specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form function D2 = distfun(ZI, ZJ).
- Take as arguments:
  - A 1-by-\( K \) vector ZI containing a single row from X or from the query points Y, where \( K \) is the number of columns in X.
• An \( m \)-by-\( K \) matrix \( ZJ \) containing multiple rows of \( X \) or \( Y \), where \( m \) is a positive integer.

• Return an \( m \)-by-1 vector of distance \( D2 \), where \( D2(j) \) is the distance between the observations \( ZI \) and \( ZJ(j,:) \).

The software does not use the distance metric for creating an ExhaustiveSearcher model object, so you can alter the distance metric by using dot notation after creating the object.

Example: 'Distance','mahalanobis'

\( \textbf{Cov} \) — Covariance matrix for Mahalanobis distance metric

\texttt{nan	ext{c}ov(X)} (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a \( K \)-by-\( K \) positive definite matrix, where \( K \) is the number of columns in \( X \). This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov',\texttt{eye(3)}

Data Types: single | double

\( \textbf{P} \) — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

\( \textbf{Scale} \) — Scale parameter value for standardized Euclidean distance metric

\texttt{nan	ext{std}(X)} (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length \( K \), where \( K \) is the number of columns in \( X \). The software scales each difference between the training and query data using the corresponding element of Scale. This argument is valid only if 'Distance' is 'seuclidean'.

Example: 'Scale',\texttt{quantile(X,0.75) - quantile(X,0.25)}

Data Types: single | double
Properties

**X — Training data**
numeric matrix

This property is read-only.

Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. X has $n$ rows, each corresponding to an observation (that is, an instance or example), and $K$ columns, each corresponding to a predictor (that is, a feature).

The input argument X of createns or ExhaustiveSearcher sets this property.

Data Types: single | double

**Distance — Distance metric**

character vector | string scalar | custom distance function

Distance metric used when you call knnsearch or rangesearch to find nearest neighbors for future query points, specified as a character vector or string scalar ('chebychev', 'cityblock', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'minkowski', 'mahalanobis', 'seuclidean', or 'spearman'), or a function handle.

The 'Distance' name-value pair argument of createns or ExhaustiveSearcher sets this property.

The software does not use the distance metric for creating an ExhaustiveSearcher model object, so you can alter it by using dot notation.

**DistParameter — Distance metric parameter values**

[] | positive scalar

Distance metric parameter values, specified as empty ([ ]) or a positive scalar.

This table describes the distance parameters of the supported distance metrics.
<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mahalanobis'</td>
<td>A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. By default, the software sets the covariance using <code>nancov(Mdl.X)</code>. The 'Cov' name-value pair argument of <code>createns</code> or <code>ExhaustiveSearcher</code> sets this property. You can alter <code>DistParameter</code> by using dot notation, for example, <code>Mdl.DistParameter = CovNew</code>, where <code>CovNew</code> is a K-by-K positive definite numeric matrix.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>A positive scalar indicating the exponent of the Minkowski distance. By default, the exponent is 2. The 'P' name-value pair argument of <code>createns</code> or <code>ExhaustiveSearcher</code> sets this property. You can alter <code>DistParameter</code> by using dot notation, for example, <code>Mdl.DistParameter = PNew</code>, where <code>PNew</code> is a positive scalar.</td>
</tr>
</tbody>
</table>
| 'seuclidean'    | A positive numeric vector indicating the values used by the software to scale the predictors when computing the standardized Euclidean distance. By default, the software:  
1. Estimates the standard deviation of each predictor (column) of `X` using `scale = nanstd(Mdl.X)`  
2. Scales each coordinate difference between the rows in `X` and the query matrix by dividing by the corresponding element of `scale`  
The 'Scale' name-value pair argument of `createns` or `ExhaustiveSearcher` sets this property. You can alter `DistParameter` by using dot notation, for example, `Mdl.DistParameter = sNew`, where `sNew` is a K-dimensional positive numeric vector. |

If `Mdl.Distance` is not one of the parameters listed in this table, then `Mdl.DistParameter` is `[]`, which means that the specified distance metric formula has no parameters.
Data Types: single | double

Object Functions

knnsearch    Find k-nearest neighbors using object
rangesearch   Find all neighbors within specified distance using object

Examples

Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

load fisheriris
X = meas;
[n,k] = size(X)
n = 150
k = 4

X has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.

Mdl1 = ExhaustiveSearcher(X)

Mdl1 =
    ExhaustiveSearcher with properties:

    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]

Mdl1 is an ExhaustiveSearcher model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.
Alternatively, you can prepare an exhaustive nearest neighbor searcher by using `createns` and specifying 'exhaustive' as the search method.

```matlab
Mdl2 = createns(X,'NSMethod','exhaustive')
```

```
Mdl2 =  
  ExhaustiveSearcher with properties:  
    Distance: 'euclidean'  
    DistParameter: []  
    X: [150x4 double]
```

Mdl2 is also an `ExhaustiveSearcher` model object, and it is equivalent to `Mdl1`.

To search `X` for the nearest neighbors to a batch of query data, pass the `ExhaustiveSearcher` model object and the query data to `knnsearch` or `rangesearch`.

### Specify the Mahalanobis Distance for Nearest Neighbor Search

Load Fisher's iris data set. Focus on the petal dimensions.

```matlab
load fisheriris
X = meas(:,[3 4]);  % Predictors
```

Prepare an exhaustive nearest neighbor searcher. Specify the Mahalanobis distance metric.

```matlab
Mdl = createns(X,'Distance','mahalanobis')
```

```
Mdl =  
  ExhaustiveSearcher with properties:  
    Distance: 'mahalanobis'  
    DistParameter: [2x2 double]  
    X: [150x2 double]
```

Because the distance metric is Mahalanobis, `createns` creates an `ExhaustiveSearcher` model object by default.

Access properties of `Mdl` by using dot notation. For example, use `Mdl.DistParameter` to access the Mahalanobis covariance parameter.
Mdl.DistParameter
ans = 2×2
     3.1163    1.2956
     1.2956    0.5810

You can pass query data and Mdl to:

- `knnsearch` to find indices and distances of nearest neighbors
- `rangesearch` to find indices of all nearest neighbors within a distance that you specify

**Alter Properties of ExhaustiveSearcher Model**

Create an `ExhaustiveSearcher` model object and alter the `Distance` property by using dot notation.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
```

Train a default exhaustive searcher algorithm using the entire data set as training data.

```matlab
Mdl = ExhaustiveSearcher(X)
```

```matlab
Mdl = ExhaustiveSearcher with properties:

    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]
```

Specify that the neighbor searcher use the Mahalanobis metric to compute the distances between the training and query data.

```matlab
Mdl.Distance = 'mahalanobis'
```

```matlab
Mdl = ExhaustiveSearcher with properties:

    Distance: 'mahalanobis'
    DistParameter: []
    X: [150x4 double]
```
You can pass Mdl and the query data to either knnsearch or rangesearch to find the nearest neighbors to the points in the query data based on the Mahalanobis distance.

**Search for Nearest Neighbors of Query Data Using Mahalanobis Distance**

Create an exhaustive searcher object by using the createns function. Pass the object and query data to the knnsearch function to find $k$-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default'); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','mahalanobis')
```

```
Mdl = 
    ExhaustiveSearcher with properties:
        Distance: 'mahalanobis'
        DistParameter: [4x4 double]
        X: [145x4 double]
```

Because the distance metric is Mahalanobis, createns creates an ExhaustiveSearcher model object by default.
The software uses the covariance matrix of the predictors (columns) in the training data for computing the Mahalanobis distance. To display this value, use `Mdl.DistParameter`.

Mdl.DistParameter

```
ans = 4x4
     0.6547   -0.0368    1.2320    0.5026
-0.0368     0.1914   -0.3227   -0.1193
 1.2320   -0.3227    3.0671    1.2842
 0.5026   -0.1193    1.2842    0.5800
```

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Y`).

```
IdxNN = knnsearch(Mdl,Y,'K',2)
```

```
IdxNN = 5x2
     5     6
    98    95
   104   128
   135    65
   102   115
```

Each row of `IdxNN` corresponds to a query data observation. The column order corresponds to the order of the nearest neighbors with respect to ascending distance. For example, based on the Mahalanobis metric, the second nearest neighbor of `Y(3,:)` is `X(128,:)`.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The knnsearch and rangesearch functions support code generation.
• When you train an ExhaustiveSearcher model object, the value of the 'Distance' name-value pair argument cannot be a custom distance function.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Introduced in R2010a
**expinv**

Exponential inverse cumulative distribution function

**Syntax**

```
X = expinv(P,mu)
[X,XLO,XUP] = expinv(P,mu,pcov,alpha)
```

**Description**

\( X = \text{expinv}(P,\mu) \) computes the inverse of the exponential cdf with parameters specified by mean parameter \( \mu \) for the corresponding probabilities in \( P \). \( P \) and \( \mu \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( \mu \) must be positive and the values in \( P \) must lie on the interval \([0, 1]\).

\( [X,XLO,XUP] = \text{expinv}(P,\mu,pcov,alpha) \) produces confidence bounds for \( X \) when the input mean parameter \( \mu \) is an estimate. \( pcov \) is the variance of the estimated \( \mu \). \( alpha \) specifies \( 100(1 - alpha)\% \) confidence bounds. The default value of \( alpha \) is 0.05. \( XLO \) and \( XUP \) are arrays of the same size as \( X \) containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of \( \mu \). If you estimate \( \mu \) from a set of data, you can get a more accurate set of bounds by applying \( \text{expfit} \) to the data to get a confidence interval for \( \mu \), and then evaluating \( \text{expinv} \) at the lower and upper end points of that interval.

The inverse of the exponential cdf is

\[
x = F^{-1}(p \mid \mu) = -\mu \ln(1 - p)
\]

The result, \( x \), is the value such that an observation from an exponential distribution with parameter \( \mu \) will fall in the range \([0, x]\) with probability \( p \).
Examples

Let the lifetime of light bulbs be exponentially distributed with $\mu = 700$ hours. What is the median lifetime of a bulb?

```matlab
expinv(0.50, 700)
ans =
   485.2030
```

Suppose you buy a box of “700 hour” light bulbs. If 700 hours is the mean life of the bulbs, half of them will burn out in less than 500 hours.

Extended Capabilities

explike

Exponential negative log-likelihood

Syntax

\[ \text{nlogL} = \text{explike}(\text{param}, \text{data}) \]
\[ [\text{nlogL}, \text{avar}] = \text{explike}(\text{param}, \text{data}) \]
\[ [...] = \text{explike}(\text{param}, \text{data}, \text{censoring}) \]
\[ [...] = \text{explike}(\text{param}, \text{data}, \text{censoring}, \text{freq}) \]

Description

\[ \text{nlogL} = \text{explike}(\text{param}, \text{data}) \] returns the negative of the log-likelihood for the exponential distribution. \( \text{param} \) is the mean parameter, \( \mu \). \( \text{nlogL} \) is a scalar.

\[ [\text{nlogL}, \text{avar}] = \text{explike}(\text{param}, \text{data}) \] returns the inverse of Fisher's information, \( \text{avar} \), a scalar. If the input parameter value in \( \text{param} \) is the maximum likelihood estimate, \( \text{avar} \) is its asymptotic variance. \( \text{avar} \) is based on the observed Fisher's information, not the expected information.

\[ [...] = \text{explike}(\text{param}, \text{data}, \text{censoring}) \] accepts a Boolean vector, \( \text{censoring} \), of the same size as \( \text{data} \), which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

\[ [...] = \text{explike}(\text{param}, \text{data}, \text{censoring}, \text{freq}) \] accepts a frequency vector, \( \text{freq} \), of the same size as \( \text{data} \). The vector \( \text{freq} \) typically contains integer frequencies for the corresponding elements in \( \text{data} \), but can contain any nonnegative values. Pass in \([\,]\) for \( \text{censoring} \) to use its default value.
Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Introduced before R2006a
export

Class: dataset

Write dataset array to file

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

export(DS,'file',filename)
export(DS)
export(DS,'file',filename,'Delimiter',delim)
export(DS,'XLSfile',filename)
export(DS,'XPTFile',filename)
export(DS,...,'WriteVarNames',false)
export(DS,...,'WriteObsNames',false)

Description

export(DS,'file',filename) writes the dataset array DS to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, 'Observations'). export overwrites any existing file named filename.

export(DS) writes to a text file whose default name is the name of the dataset array DS appended by '.txt'. If export cannot construct the file name from the dataset array input, it writes to the file 'dataset.txt'. export overwrites any existing file.

export(DS,'file',filename,'Delimiter',delim) writes the dataset array DS to a text file using the delimiter delim. delim must be one of the following:
export(DS,'XLSfile',filename) writes the dataset array DS to a Microsoft® Excel spreadsheet file, including variable names and observation names (if present). You can specify the 'Sheet' and 'Range' parameter name/value pairs, with parameter values as accepted by the xlsread function. Since export uses the xlswrite function internally, this syntax is only compatible with Microsoft Excel for Windows, and does not work on a Mac. For more information, see xlswrite.

export(DS,'XPTFile',filename) writes the dataset array DS to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. export saves observation names to a variable called obsnames, unless the WriteObsNames parameter described below is false. The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

export(DS,...,'WriteVarNames',false) does not write the variable names to the text file. export(DS,...,'WriteVarNames',true) is the default, writing the names as column headings in the first line of the file.

export(DS,...,'WriteObsNames',false) does not write the observation names to the text file. export(DS,...,'WriteObsNames',true) is the default, writing the names as the first column of the file.

In some cases, export creates a text file that does not represent A exactly, as described below. If you use dataset to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save A as a MAT-file if you need to import it again as a dataset array.

export writes out numeric variables using long g format, and categorical or character variables as unquoted text.

For non-character variables with more than one column, export writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

export writes out variables that have more than two dimensions as a single empty field in each line of the file.
For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a `.mat` file.

**Examples**

Move data between external text files and dataset arrays in the MATLAB workspace:

```matlab
A = dataset('file','sat2.dat','delimiter','','
A =
    Test     Gender     Score
     'Verbal'     'Male'     470
     'Verbal'     'Female'    530
     'Quantitative'     'Male'     520
     'Quantitative'     'Female'    480

export(A(A.Score > 500,:),'file','HighScores.txt')

B = dataset('file','HighScores.txt','delimiter','	')
B =
    Test     Gender     Score
     'Verbal'     'Female'    530
     'Quantitative'     'Male'     520

See Also
dataset
exppdf

Exponential probability density function

Syntax

Y = exppdf(X,mu)

Description

Y = exppdf(X,mu) returns the pdf of the exponential distribution with mean parameter mu, evaluated at the values in X. X and mu can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in mu must be positive.

The exponential pdf is

\[ y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}} \]

The exponential pdf is the gamma pdf with its first parameter equal to 1.

The exponential distribution is appropriate for modeling waiting times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

Examples

y = exppdf(5,1:5)
y =
0.0067  0.0410  0.0630  0.0716  0.0736

y = exppdf(1:5,1:5)
\[ y = 0.3679 \ 0.1839 \ 0.1226 \ 0.0920 \ 0.0736 \]

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
exprnd

Exponential random numbers

Syntax

\[ R = \text{exprnd}(\mu) \]
\[ R = \text{exprnd}(\mu,m,n,\ldots) \]
\[ R = \text{exprnd}(\mu,[m,n,\ldots]) \]

Description

\( R = \text{exprnd}(\mu) \) generates random numbers from the exponential distribution with mean parameter \( \mu \). \( \mu \) can be a vector, a matrix, or a multidimensional array. The size of \( R \) is the size of \( \mu \).

\( R = \text{exprnd}(\mu,m,n,\ldots) \) or \( R = \text{exprnd}(\mu,[m,n,\ldots]) \) generates an \( m \)-by-\( n \)-by-\( \ldots \) array containing random numbers from the exponential distribution with mean parameter \( \mu \). \( \mu \) can be a scalar or an array of the same size as \( R \).

Examples

\[ n1 = \text{exprnd}(5:10) \]
\[
\begin{array}{cccccccc}
 7.5943 & 18.3400 & 2.7113 & 3.0936 & 0.6078 & 9.5841 \\
\end{array}
\]

\[ n2 = \text{exprnd}(5:10,[1 6]) \]
\[
\begin{array}{ccccccc}
 3.2752 & 1.1110 & 23.5530 & 23.4303 & 5.7190 & 3.9876 \\
\end{array}
\]

\[ n3 = \text{exprnd}(5,2,3) \]
\[
\begin{array}{cccc}
 24.3339 & 13.5271 & 1.8788 & 4.7932 \\
 4.3675 & 2.6468 \\
\end{array}
\]
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

expstat

Exponential mean and variance

Syntax

[m,v] = expstat(mu)

Description

[m,v] = expstat(mu) returns the mean of and variance for the exponential
distribution with parameters mu. mu can be a vectors, matrix, or multidimensional array.
The mean of the exponential distribution is µ, and the variance is µ².

Examples

[m,v] = expstat([1 10 100 1000])
m = 
   1    10   100   1000
v = 
   1   100  10000 1000000

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.
This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
factoran

Factor analysis

Syntax

lambda = factoran(X,m)
[lambda,psi] = factoran(X,m)
[lambda,psi,T] = factoran(X,m)
[lambda,psi,T,stats] = factoran(X,m)
[lambda,psi,T,stats,F] = factoran(X,m)
[...] = factoran(...,param1,val1,param2,val2,...)

Description

lambda = factoran(X,m) returns the maximum likelihood estimate, lambda, of the factor loadings matrix, in a common factor analysis model with m common factors. X is an n-by-d matrix where each row is an observation of d variables. The (i,j)th element of the d-by-m matrix lambda is the coefficient, or loading, of the jth factor for the ith variable. By default, factoran calls the function rotatefactors to rotate the estimated factor loadings using the 'varimax' option.

[lambda,psi] = factoran(X,m) also returns maximum likelihood estimates of the specific variances as a column vector psi of length d.

[lambda,psi,T] = factoran(X,m) also returns the m-by-m factor loadings rotation matrix T.

[lambda,psi,T,stats] = factoran(X,m) also returns a structure stats containing information relating to the null hypothesis, H_0, that the number of common factors is m. stats includes the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loglike</td>
<td>Maximized log-likelihood value</td>
</tr>
<tr>
<td>dfe</td>
<td>Error degrees of freedom = ((d-m)^2 - (d+m))/2</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>chisq</td>
<td>Approximate chi-squared statistic for the null hypothesis</td>
</tr>
<tr>
<td>p</td>
<td>Right-tail significance level for the null hypothesis</td>
</tr>
</tbody>
</table>

`factoran` does not compute the chisq and p fields unless `dfe` is positive and all the specific variance estimates in `psi` are positive (see “Heywood Case” on page 32-1535 below). If `X` is a covariance matrix, then you must also specify the `'nobs'` parameter if you want `factoran` to compute the chisq and p fields.

```plaintext
[lambda,psi,T,stats,F] = factoran(X,m) also returns, in F, predictions of the common factors, known as factor scores. F is an n-by-m matrix where each row is a prediction of m common factors. If X is a covariance matrix, `factoran` cannot compute F. `factoran` rotates F using the same criterion as for lambda.

[...] = factoran(...,param1,val1,param2,val2,...) enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'xtype'</td>
<td>Type of input in the matrix X. 'xtype' can be one of:</td>
</tr>
<tr>
<td></td>
<td>'data' Raw data (default)</td>
</tr>
<tr>
<td></td>
<td>'covariance' Positive definite covariance or correlation matrix</td>
</tr>
<tr>
<td>'scores'</td>
<td>Method for predicting factor scores. 'scores' is ignored if X is not raw data.</td>
</tr>
<tr>
<td></td>
<td>'wls' Synonyms for a weighted least-squares estimate that treats F as fixed (default)</td>

</table>
| **Function** | Function handle to rotation function of the form 
\[ B, T \] = 
myrotation(A,...) 
where \( A \) is a \( d \)-by-\( m \) matrix of unrotated factor loadings, \( B \) is a \( d \)-by-\( m \) matrix of rotated loadings, and \( T \) is the corresponding \( m \)-by-\( m \) rotation matrix. Use the factoran parameter 'userargs' to pass additional arguments to this rotation function. See “User-Defined Rotation Function” on page 32-1533. |
| **'coeff'** | Coefficient, often denoted as \( \gamma \), defining the specific 'orthomax' criterion. Must be from 0 to 1. The value 0 corresponds to quartimax, and 1 corresponds to varimax. Default is 1. |
| **'normalize'** | Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for 'orthomax' or 'varimax' rotation. Default is 1. |
| **'reltol'** | Relative convergence tolerance for 'orthomax' or 'varimax' rotation. Default is \( \text{sqrt(eps)} \). |
| **'maxit'** | Iteration limit for 'orthomax' or 'varimax' rotation. Default is 250. |
| **'target'** | Target factor loading matrix for 'procrustes' rotation. Required for 'procrustes' rotation. No default value. |
| **'type'** | Type of 'procrustes' rotation. Can be 'oblique' (default) or 'orthogonal'. |
| **'power'** | Exponent for creating the target matrix in the 'promax' rotation. Must be ≥ 1. Default is 4. |
| **'userargs'** | Denotes the beginning of additional input values for a user-defined rotation function. factoran appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix \( A \). See “User-Defined Rotation Function” on page 32-1533. |
Estimate and Plot Factor Loadings

Load the sample data.

load carbig

Define the variable matrix.

X = [Acceleration Displacement Horsepower MPG Weight];
X = X(all(~isnan(X),2),:);

Estimate the factor loadings using a minimum mean squared error prediction for a factor analysis with two common factors.

[Lambda,Psi,T,stats,F] = factoran(X,2,'scores','regression');
inv(T'*T); % Estimated correlation matrix of F, == eye(2)
Lambda*Lambda' + diag(Psi); % Estimated correlation matrix
Lambda*inv(T); % Unrotate the loadings
F*T'; % Unrotate the factor scores

Create biplot of two factors.
Estimate the factor loadings using the covariance (or correlation) matrix.

\[
[\text{Lambda}, \text{Psi}, \text{T}] = \text{factoran}(\text{cov}(X), 2, 'xtype', 'cov')
\]

\[
\text{Lambda} = 5 \times 2
\]

\[
\begin{bmatrix}

-0.4167   0.9328   0.8647  -0.8326   1.0000

Plot the unrotated variables with oblique axes superimposed.
invT = inv(T); 
Lambda0 = Lambda*invT; 
figure();
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...
     [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ... 
     'Color','r','linewidth',2)
grid on
hold on
biplot(Lambda0,'LineWidth',2,'MarkerSize',20)
xlabel('Loadings for unrotated Factor 1')
ylabel('Loadings for unrotated Factor 2')

Plot the rotated variables against the oblique axes.
User-Defined Rotation Function

Syntax for passing additional arguments to a user-defined rotation function:
[Lambda,Psi,T] = ...
    factoran(X,2,'rotate',@myrotation,'userargs',1,'two');

Definitions

Factor Analysis Model

`factoran` computes the maximum likelihood estimate (MLE) of the factor loadings matrix `Lambda` in the factor analysis model

\[ x = \mu + \Lambda f + e \]

where \( x \) is a vector of observed variables, \( \mu \) is a constant vector of means, \( \Lambda \) is a constant \( d \)-by-\( m \) matrix of factor loadings, \( f \) is a vector of independent, standardized common factors, and \( e \) is a vector of independent specific factors. \( x, \mu, \) and \( e \) are of length \( d \). \( f \) is of length \( m \).

Alternatively, the factor analysis model can be specified as

\[ \text{cov}(x) = \Lambda \Lambda^T + \Psi \]

where \( \Psi = \text{cov}(e) \) is a \( d \)-by-\( d \) diagonal matrix of specific variances.

Tips

Observed Data Variables

The variables in the observed data matrix \( X \) must be linearly independent, i.e., \( \text{cov}(X) \) must have full rank, for maximum likelihood estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

`factoran` standardizes the observed data \( X \) to zero mean and unit variance before estimating the loadings \( \text{lambda} \). This does not affect the model fit, because MLEs in this model are invariant to scale. However, \( \text{lambda} \) and \( \text{psi} \) are returned in terms of the standardized variables, i.e., \( \text{lambda}' \cdot \text{lambda} + \text{diag(psi)} \) is an estimate of the correlation matrix of the original data \( X \) (although not after an oblique rotation). See
Heywood Case

If elements of psi are equal to the value of the 'delta' parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e., m is too large), but can also be the result of underfitting.

Rotation of Factor Loadings and Scores

Unless you explicitly specify no rotation using the 'rotate' parameter, factoran rotates the estimated factor loadings, lambda, and the factor scores, F. The output matrix T is used to rotate the loadings, i.e., lambda = lambda0*T, where lambda0 is the initial (unrotated) MLE of the loadings. T is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of T is known as the primary axis rotation matrix, while T itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

factoran computes factor scores that have been rotated by inv(T'), i.e., F = F0 * inv(T'), where F0 contains the unrotated predictions. The estimated covariance of F is inv(T'*T), which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

`pcacov` and `factoran` do not work directly on tall arrays. Instead, use `C = gather(cov(X))` to compute the covariance matrix of a tall array. Then, you can use `pcacov` or `factoran` on the in-memory covariance matrix. Alternatively, you can use `pca` directly on a tall array.

For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a
**fcdf**

*F* cumulative distribution function

**Syntax**

\[
p = \text{fcdf}(x,v1,v2)
\]

\[
p = \text{fcdf}(x,v1,v2,\text{'upper'})
\]

**Description**

\[p = \text{fcdf}(x,v1,v2)\] computes the *F* cdf at each of the values in \(x\) using the corresponding numerator degrees of freedom \(v1\) and denominator degrees of freedom \(v2\). \(x, v1,\) and \(v2\) can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs. \(v1\) and \(v2\) parameters must contain real positive values, and the values in \(x\) must lie on the interval \([0 \ Inf]\).

\[p = \text{fcdf}(x,v1,v2,\text{'upper'})\] returns the complement of the *F* cdf at each value in \(x\), using an algorithm that more accurately computes the extreme upper tail probabilities.

The *F* cdf is

\[
p = F(x | v1,v2) = \int_0^x \frac{\Gamma \left( \frac{v1 + v2}{2} \right)}{\Gamma \left( \frac{v1}{2} \right) \Gamma \left( \frac{v2}{2} \right)} \left( \frac{v1}{v2} \right)^{v1/2} \left( \frac{v2}{t^2} \right)^{v2/2} \left[ 1 + \left( \frac{v1}{v2} \right) t \right]^{-v1-v2/2} \, dt
\]

The result, \(p\), is the probability that a single observation from an *F* distribution with parameters \(v1\) and \(v2\) will fall in the interval \([0 \ x]\).

**Examples**

32-1538
Compute F Distribution CDF

The following illustrates a useful mathematical identity for the F distribution.

\[
\begin{align*}
\text{nu1} &= 1:5; \\
\text{nu2} &= 6:10; \\
\text{x} &= 2:6; \\
\text{F1} &= \text{fcdf(x,nu1,nu2)} \\
F1 &= 1\times5 \\
&= \begin{bmatrix} 0.7930 & 0.8854 & 0.9481 & 0.9788 & 0.9919 \end{bmatrix} \\
\text{F2} &= 1 - \text{fcdf(1/x,nu2,nu1)} \\
F2 &= 1\times5 \\
&= \begin{bmatrix} 0.7930 & 0.8854 & 0.9481 & 0.9788 & 0.9919 \end{bmatrix}
\end{align*}
\]

Introduced before R2006a
feval

Evaluate generalized linear regression model prediction

Syntax

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)

Description

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn) returns the predicted response of mdl to the input [Xnew1,Xnew_2,...,Xnewn].

Input Arguments

mdl

Generalized linear model, specified as a full GeneralizedLinearModel object constructed using fitglm or stepwiseglm, or a compacted CompactGeneralizedLinearModel object constructed using compact.

Xnew1,Xnew2,...,Xnewn

Predictor components. Xnewi can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one Xnew array, Xnew can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.
Output Arguments

ypred

Predicted mean values at Xnew. ypred is the same size as each component of Xnew.

For binomial models, feval uses 1 as the BinomialSize parameter, so ypred is predicted probabilities.

For models with an offset, feval uses 0 as the offset value.

Examples

Predict Responses Using feval

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors X(1) and X(2).

rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

Create a generalized linear regression model of Poisson data.

mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');

Generate a range of values for X(1) and X(2), and plot the model predictions at those values.

[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
Tips

- `feval` allows you to easily evaluate predictions of a model when the model was fitted using a table or dataset array. `predict` requires a table or dataset array with the same predictor names, but you can use simple arrays of scalars with `feval`.

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.
random predicts with added noise.

“Generalized Linear Models” on page 12-12
feval

Class: CompactLinearModel

Evaluate linear regression model prediction

Syntax

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)

Description

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn) returns the predicted response of mdl to the new input predictors [Xnew1,Xnew2,...,Xnewn].

Input Arguments

mdl — Linear model object
LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using fitlm or stepwiselm, or a compacted CompactLinearModel object constructed using compact.

Xnew1,Xnew2,...,Xnewn — New predictor values
scalar value | numeric vector

New predictor values, specified as a scalar value, numeric vector, or numeric array. You can specify multiple components for this argument. Each vector component must have the same number of elements in each dimension (in other words, each vector must be same size).

If you pass just one Xnew array, then Xnew can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.
**Output Arguments**

**ypred — Predicted mean values**

scalar value | numeric vector

Predicted mean values at \(X_{new1}, X_{new2}, \ldots, X_{newn}\), returned as a scalar value or numeric vector. \(ypred\) is the same size as each component of \(X_{new1}, X_{new2}, \ldots, X_{newn}\).

For models with an offset, `feval` uses 0 as the offset value.

**Examples**

**Plot Different Categorical Levels for Linear Model**

Fit a mileage model to the `carsmall` data, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data and fit a model.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a scatter plot of the mileage versus weight.

```matlab
gscatter(tbl.Weight,tbl.MPG,tbl.Year);
```
Use `feval` to plot curves of the model predictions for the various years and weights.

```matlab
w = linspace(min(tbl.Weight),max(tbl.Weight))';
line(w,feval(mdl,w,'70'),'Color','r')
line(w,feval(mdl,w,'76'),'Color','g')
line(w,feval(mdl,w,'82'),'Color','b')
```
Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

feval

Class: NonLinearModel

Evaluate nonlinear regression model prediction

Syntax

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)

Description

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn) returns the predicted response of mdl to the input [Xnew1,Xnew2,...,Xnewn].

Input Arguments

mdl

Nonlinear regression model, constructed by fitnlm.

Xnew1,Xnew2,...,Xnewn

 Predictor components. Xnewi can be one of:

• Scalar
• Vector
• Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one Xnew array, Xnew can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.
Output Arguments

ypred

Predicted mean values at Xnew. ypred is the same size as each component of Xnew.

Examples

Predict a Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the carbig data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using nanmean.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew = 21.8073
```

Alternatives

predict gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. predict also gives confidence intervals on its predictions.

random predicts with added noise.

**ff2n**

Two-level full factorial design

**Syntax**

\[dFF2 = ff2n(n)\]

**Description**

dFF2 = ff2n(n) gives factor settings dFF2 for a two-level full factorial design with n factors. dFF2 is m-by-n, where m is the number of treatments in the full-factorial design. Each row of dFF2 corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

**Examples**

\[
dFF2 = ff2n(3)
dFF2 =
\begin{array}{ccc}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0 \\
0 & 1 & 1 \\
1 & 0 & 0 \\
1 & 0 & 1 \\
1 & 1 & 0 \\
1 & 1 & 1 \\
\end{array}
\]

*Introduced before R2006a*
fillprox

Class: TreeBagger

Proximity matrix for training data

Syntax

B = fillprox(B)
B = fillprox(B,'param1',val1,'param2',val2,...)

Description

B = fillprox(B) computes a proximity matrix for the training data and stores it in the Properties field of B.

B = fillprox(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Trees' Either 'all' or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is 'all'.

'NumPrint' Number of training cycles (grown trees) after which TreeBagger displays a diagnostic message showing training progress. Default is no diagnostic messages.

See Also

CompactTreeBagger.outlierMeasure | CompactTreeBagger.proximity
findobj

**Class:** qrandstream

Find objects matching specified conditions

**Syntax**

hm = findobj(h, 'conditions')

**Description**

The `findobj` method of the handle class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

hm = findobj(h, 'conditions') searches the handle object array h and returns an array of handle objects matching the specified conditions. Only the public members of the objects of h are considered when evaluating the conditions.

**See Also**

`findobj` | `qrandstream`
findprop

Class: qrandstream

Find property of MATLAB handle object

Syntax

\[ p = \text{findprop}(h,'\text{propname}') \]

Description

\[ p = \text{findprop}(h,'\text{propname}') \] finds and returns the meta.property object associated with property name propname of scalar handle object h. propname must be a character vector. It can be the name of a property defined by the class of h or a dynamic property added to scalar object h.

If no property named propname exists for object h, an empty meta.property array is returned.

See Also

dynamicprops | findobj | meta.property | qrandstream
**finv**

*F* inverse cumulative distribution function

**Syntax**

\[ X = \text{finv}(P, V1, V2) \]

**Description**

\( X = \text{finv}(P, V1, V2) \) computes the inverse of the *F* cdf with numerator degrees of freedom \( V1 \) and denominator degrees of freedom \( V2 \) for the corresponding probabilities in \( P \). \( P, V1, \) and \( V2 \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. \( V1 \) and \( V2 \) parameters must contain real positive values, and the values in \( P \) must lie on the interval \([0 1]\).

The *F* inverse function is defined in terms of the *F* cdf as

\[
x = F^{-1} (p \mid v_1,v_2) = \{ x : F(x \mid v_1,v_2) = p \}
\]

where

\[
p = F(x \mid v_1,v_2) = \int_0^x \Gamma \left( \frac{v_1 + v_2}{2} \right) \left( \frac{v_1}{v_2} \right)^{v_1/2} \frac{v_1 - 2}{t^{v_2/2}} \left[ 1 + \left( \frac{v_1}{v_2} \right) t \right]^{v_1+v_2/2} dt
\]

**Examples**

Find a value that should exceed 95% of the samples from an *F* distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.
x = finv(0.95,5,10)
x =
    3.3258

You would observe values greater than 3.3258 only 5% of the time by chance.

Introduced before R2006a
**fishertest**

Fisher’s exact test

**Syntax**

```matlab
h = fishertest(x)
[h,p,stats] = fishertest(x)
[___] = fishertest(x,Name,Value)
```

**Description**

`h = fishertest(x)` returns a test decision for Fisher’s exact test of the null hypothesis that there are no nonrandom associations between the two categorical variables in `x`, against the alternative that there is a nonrandom association. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`[h,p,stats] = fishertest(x)` also returns the significance level `p` of the test and a structure `stats` containing additional test results, including the odds ratio and its asymptotic confidence interval.

`[___] = fishertest(x,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test or conduct a one-sided test.

**Examples**

**Conduct Fisher's Exact Test**

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu this winter. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.
Create a 2-by-2 contingency table containing the survey data. Row 1 contains data for the individuals who did not receive a flu shot, and row 2 contains data for the individuals who received a flu shot. Column 1 contains the number of individuals who got the flu, and column 2 contains the number of individuals who did not.

\[
x = \text{table}([3;1],[6;7],\text{'}VariableNames\text{'}\{\text{'Flu','NoFlu'}\},\text{'}RowNames\text{'}\{\text{'NoShot','Shot'}\})
\]

\[
x=2\times2 \text{ table}
\]

<table>
<thead>
<tr>
<th></th>
<th>Flu</th>
<th>NoFlu</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoShot</td>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>Shot</td>
<td>1</td>
<td>7</td>
</tr>
</tbody>
</table>

Use Fisher's exact test to determine if there is a nonrandom association between receiving a flu shot and getting the flu.

\[
h = \text{fishertest}(x)
\]

\[
h = \text{logical}
\]

\[
h = 0
\]

The returned test decision \(h = 0\) indicates that \text{fishertest} does not reject the null hypothesis of no nonrandom association between the categorical variables at the default 5% significance level. Therefore, based on the test results, individuals who do not get a flu shot do not have different odds of getting the flu than those who got the flu shot.

**Conduct a One-Sided Fisher's Exact Test**

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

\[
x = [3,6;1,7];
\]

Use a right-tailed Fisher's exact test to determine if the odds of getting the flu is higher for individuals who did not receive a flu shot than for individuals who did. Conduct the test at the 1% significance level.
[h,p,stats] = fishertest(x,'Tail','right','Alpha',0.01)

h = logical
0

p = 0.3353

stats = struct with fields:
    OddsRatio: 3.5000
    ConfidenceInterval: [0.1289 95.0408]

The returned test decision \( h = 0 \) indicates that \texttt{fishertest} does not reject the null hypothesis of no nonrandom association between the categorical variables at the 1% significance level. Since this is a right-tailed hypothesis test, the conclusion is that individuals who do not get a flu shot do not have greater odds of getting the flu than those who got the flu shot.

**Generate a Contingency Table Using crosstab**

Load the hospital data.

load hospital

The \texttt{hospital} dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine if smoking status is independent of gender, use \texttt{crosstab} to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender:

[tbl,chi2,p,labels] = crosstab(hospital.Sex,hospital.Smoker)

tbl = 2x2

\[
\begin{array}{cc}
40 & 13 \\
26 & 21
\end{array}
\]

chi2 = 4.5083

p = 0.0337
labels = 2x2 cell array
    {'Female'}    {'0'}
    {'Male'   }    {'1'}

The rows of the resulting contingency table tbl correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result chi2 = 4.5083 is the value of the chi-squared test statistic for a chi-squared test of independence. The returned value p = 0.0337 is an approximate P-value based on the chi-squared distribution.

Use the contingency table generated by crosstab to perform Fisher's exact test on the data.

[h,p,stats] = fishertest(tbl)

h = logical
   1

p = 0.0375

stats = struct with fields:
    OddsRatio: 2.4852
    ConfidenceInterval: [1.0624 5.8135]

The result h = 1 indicates that fishertest rejects the null hypothesis of nonassociation between smoking status and gender at the 5% significance level. In other words, there is an association between gender and smoking status. The odds ratio indicates that the male patients have about 2.5 times greater odds of being smokers than the female patients.

The returned P-value of the test, p = 0.0375, is close to, but not exactly the same as, the result obtained by crosstab. This is because fishertest computes an exact P-value using the sample data, while crosstab uses a chi-squared approximation to compute the P-value.
Input Arguments

**x — Contingency table**  
2-by-2 matrix of nonnegative integer values | 2-by-2 table of nonnegative integer values

Contingency table, specified as a 2-by-2 matrix or table containing nonnegative integer values. A contingency table contains the frequency distribution of the variables in the sample data. You can use `crosstab` to generate a contingency table from sample data.

Example: `[4,0;0,4]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Tail','right'` specifies a right-tailed hypothesis test at the 1% significance level.

**Alpha — Significance level**  
0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

**Tail — Type of alternative hypothesis**  
'both' (default) | 'right' | 'left'

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.
'both'

Two-tailed test. The alternative hypothesis is that there is a nonrandom association between the two variables in x, and the odds ratio is not equal to 1.

'right'

Right-tailed test. The alternative hypothesis is that the odds ratio is greater than 1.

'left'

Left-tailed test. The alternative hypothesis is that the odds ratio is less than 1.

Example: 'Tail','right'

Output Arguments

h — Hypothesis test result
1 | 0

Hypothesis test result, returned as a logical value.
- If h is 1, then fishertest rejects the null hypothesis at the Alpha significance level.
- If h is 0, then fishertest fails to reject the null hypothesis at the Alpha significance level.

p — p-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test data
structure

Test data, returned as a structure with the following fields:
- OddsRatio — A measure of association between the two variables.
- ConfidenceInterval — Asymptotic confidence interval for the odds ratio. If any of the cell frequencies in x are 0, then fishertest does not compute a confidence interval and instead displays [-Inf Inf].
Definitions

Fisher’s Exact Test

Fisher’s exact test is a nonparametric statistical test used to test the null hypothesis that no nonrandom associations exist between two categorical variables, against the alternative that there is a nonrandom association between the variables.

Fisher’s exact test provides an alternative to the chi-squared test for small samples, or samples with very uneven marginal distributions. Unlike the chi-squared test, Fisher’s exact test does not depend on large-sample distribution assumptions, and instead calculates an exact $p$-value based on the sample data. Although Fisher’s exact test is valid for samples of any size, it is not recommended for large samples because it is computationally intensive. If all of the frequency counts in the contingency table are greater than or equal to 1e7, then fishertest errors. For contingency tables that contain large count values or are well-balanced, use crosstab or chi2gof instead.

fishertest accepts a 2-by-2 contingency table as input, and computes the $p$-value of the test as follows:

1. Calculate the sums for each row, column, and total number of observations in the contingency table.
2. Using a multivariate generalization of the hypergeometric probability function, calculate the conditional probability of observing the exact result in the contingency table if the null hypothesis were true, given its row and column sums. The conditional probability is

$$P_{cutoff} = \frac{(R_1!R_2!)(C_1!C_2!)}{N! \prod_{i,j} n_{ij}!},$$

where $R_1$ and $R_2$ are the row sums, $C_1$ and $C_2$ are the column sums, $N$ is the total number of observations in the contingency table, and $n_{ij}$ is the value in the $i$th row and $j$th column of the table.
3. Find all possible matrices of nonnegative integers consistent with the row and column sums. For each matrix, calculate the associated conditional probability using the equation for $P_{cutoff}$.
4. Use these values to calculate the $p$-value of the test, based on the alternative hypothesis of interest.
• For a two-sided test, sum all of the conditional probabilities less than or equal to $P_{cutoff}$ for the observed contingency table. This represents the probability of observing a result as extreme as, or more extreme than, the actual outcome if the null hypothesis were true. Small $p$-values cast doubt on the validity of the null hypothesis, in favor of the alternative hypothesis of association between the variables.

• For a left-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency less than or equal to $n_{11}$.

• For a right-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency greater than or equal to $n_{11}$ in the observed contingency table.

The odds ratio is

$$OR = \frac{n_{11}n_{22}}{n_{21}n_{12}}.$$

The null hypothesis of conditional independence is equivalent to the hypothesis that the odds ratio equals 1. The left-sided alternative is equivalent to an odds ratio less than 1, and the right-sided alternative is equivalent to an odds ratio greater than 1.

The asymptotic 100(1 - $\alpha$)% confidence interval for the odds ratio is

$$CI = \left[ \exp \left( L - \Phi^{-1} \left( \frac{1 - \alpha}{2} \right) SE \right), \exp \left( L + \Phi^{-1} \left( \frac{1 - \alpha}{2} \right) SE \right) \right],$$

where $L$ is the log odds ratio, $\Phi^{-1}(\cdot)$ is the inverse of the normal inverse cumulative distribution function, and $SE$ is the standard error for the log odds ratio. If the 100(1 - $\alpha$) % confidence interval does not contain the value 1, then the association is significant at the $\alpha$ significance level. If any of the four cell frequencies are 0, then fishertest does not compute the confidence interval and instead displays [-Inf Inf].

fishertest only accepts 2-by-2 contingency tables as input. To test the independence of categorical variables with more than two levels, use the chi-squared test provided by crosstab.

chi2gof | crosstab
Introduced in R2014b
ClassificationDiscriminant.fit

Class: ClassificationDiscriminant

Fit discriminant analysis classifier (to be removed)

Note ClassificationDiscriminant.fit will be removed in a future release. Use fitcdiscr instead.

Syntax

obj = ClassificationDiscriminant.fit(x,y)
obj = ClassificationDiscriminant.fit(x,y,Name,Value)

Description

obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.

obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name,Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.

Input Arguments

x — Predictor values
matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.
ClassificationDiscriminant.fit considers `NaN` values in `x` as missing values. ClassificationDiscriminant.fit does not use observations with missing values for `x` in the fit.

Data Types: `single` | `double`

**y — Classification values**

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of character vectors. Each row of `y` represents the classification of the corresponding row of `x`.

ClassificationDiscriminant.fit considers `NaN` values in `y` to be missing values. ClassificationDiscriminant.fit does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `logical` | `char` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**ClassNames — Class names**

array

Class names, specified as the comma-separated pair consisting of `ClassNames` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

Data Types: `single` | `double` | `logical` | `char`

**Cost — Cost of misclassification**

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `Cost` and a square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames`
containing the group names as a variable of the same type as \( y \), and \( S.ClassificationCosts \) containing the cost matrix.

The default is \( \text{Cost}(i,j)=1 \) if \( i\neq j \), and \( \text{Cost}(i,j)=0 \) if \( i=j \).

Data Types: \text{single} | \text{double} | \text{struct}

**CrossVal — Cross-validation flag**

\( 'off' \) (default) | \( 'on' \)

Cross-validation flag, specified as the comma-separated pair consisting of \( 'Crossval' \) and \( 'on' \) or \( 'off' \).

If you specify \( 'on' \), then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: \( \text{CVPartition} \), \( \text{Holdout} \), \( \text{KFold} \), or \( \text{Leaveout} \). To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing \( \text{Mdl} \) to \( \text{crossval} \).

Example: \( 'CrossVal','on' \)

**CVPartition — Cross-validated model partition**

\( \text{cvpartition} \) object

Cross-validated model partition, specified as the comma-separated pair consisting of \( 'CVPartition' \) and an object created using \( \text{cvpartition} \).

To create a cross-validated model, you can use one of these four name-value pair arguments only: \( \text{CVPartition} \), \( \text{Holdout} \), \( \text{KFold} \), or \( \text{Leaveout} \).

**Delta — Linear coefficient threshold**

\( 0 \) (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of \( 'Delta' \) and a nonnegative scalar value. If a coefficient of \( \text{Mdl} \) has magnitude smaller than \( \text{Delta} \), \( \text{Mdl} \) sets this coefficient to \( 0 \), and you can eliminate the corresponding predictor from the model. Set \( \text{Delta} \) to a higher value to eliminate more predictors.

\( \text{Delta} \) must be \( 0 \) for quadratic discriminant models.

Data Types: \text{single} | \text{double}
**DiscrimType — Discriminant type**

<table>
<thead>

</tr>
<tr>
<td>'pseudoquadratic'</td>
<td>QDA</td>
<td>The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.</td>
</tr>
</tbody>
</table>
**Note** To use regularization, you must specify 'linear'. To specify the amount of regularization, use the Gamma name-value pair argument.

Example: 'DiscrimType','quadratic'

**FillCoeffs — Coeffs property flag**
'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs','off'

**Gamma — Amount of regularization**
scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than DiscrimType.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering Mdl.Gamma at the command line.

- For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.

- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets DiscrimType to 'linear'.

- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set DiscrimType to 'diagLinear' or 'diagQuadratic' for diagonal covariance matrices.
Example: 'Gamma',1
Data Types: single | double

**Holdout — Fraction of data for holdout validation**
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1. Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1
Data Types: double | single

**KFold — Number of folds**
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', $k$, then the software:

1. Randomly partitions the data into $k$ sets
2. For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
3. Stores the $k$ compact, trained models in the cells of a $k$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold', 8
Data Types: single | double
Leaveout — Leave-one-out cross-validation flag
'B off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the \( n \) observations, where \( n \) is size(Mdl.X,1), the software:

1. Reserves the observation as validation data, and trains the model using the other \( n - 1 \) observations.
2. Stores the \( n \) compact, trained models in the cells of a \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout','on'

PredictorNames — Predictor variable names
{'X1','X2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in \( X \).

Data Types: cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- 'empirical' determines class probabilities from class frequencies in \( y \). If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure \( S \) with two fields:
  - \( S.ClassNames \) containing the class names as a variable of the same type as \( y \)
  - \( S.ClassProbs \) containing a vector of corresponding probabilities

Example: 'Prior','uniform'
Data Types: single | double | char | struct

**ResponseName — Response variable name**

'S' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable y.

Example: 'ResponseName','Response'

Data Types: char

**SaveMemory — Flag to save covariance matrix**

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then fitcdiscr does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then fitcdiscr computes and stores the full covariance matrix in Mdl.

Specify SaveMemory as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory','on'

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector or function handle.

This table summarizes the available character vectors.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
</tbody>
</table>
For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | function_handle

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in X. fitcdiscr normalizes the weights to sum to 1.

Data Types: single | double

### Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.
Otherwise, obj is of class ClassificationDiscriminant, and you can use the predict method to predict the response of new data.

Examples

Construct a Discriminant Analysis Classifier

Load the sample data.

load fisheriris

Construct a discriminant analysis classifier using the sample data.

obj = ClassificationDiscriminant.fit(meas,species)

obj = ClassificationDiscriminant
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DiscrimType: 'linear'
    Mu: [3x4 double]
    Coefs: [3x3 struct]

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (gmdistribution).
• For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
• For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

\[
\hat{y} = \arg \min_{y=1,\ldots,K} \sum_{k=1}^{K} \hat{P}(k \mid x)C(y \mid k),
\]

where

• \(\hat{y}\) is the predicted classification.
• \(K\) is the number of classes.
• \(\hat{P}(k \mid x)\) is the posterior probability on page 20-7 of class \(k\) for observation \(x\).
• \(C(y \mid k)\) is the cost on page 20-8 of classifying an observation as \(y\) when its true class is \(k\).

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.

**Alternatives**

The classify function also performs discriminant analysis. classify is usually more awkward to use:

• classify requires you to fit the classifier every time you make a new prediction.
• classify does not perform cross validation.
• classify requires you to fit the classifier when changing prior probabilities.

ClassificationDiscriminant
Topics
“Discriminant Analysis Classification” on page 20-2
ClassificationKNN.fit

Fit k-nearest neighbor classifier (to be removed)

**Note** ClassificationKNN.fit will be removed in a future release. Use fitcknn instead.

**Syntax**

mdl = ClassificationKNN.fit(X,y)
mdl = ClassificationKNN.fit(X,y,Name,Value)

**Description**

mdl = ClassificationKNN.fit(X,y) returns a classification model based on the input variables (also known as predictors, features, or attributes) X and output (response) y.

mdl = ClassificationKNN.fit(X,y,Name,Value) fits a model with additional options specified by one or more Name,Value pair arguments.

If you use one of these options, mdl is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, mdl is of class ClassificationKNN.

**Input Arguments**

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

The length of Y and the number of observations in X must be equal.
To specify the names of the predictors in the order of their appearance in \( X \), use the \texttt{PredictorNames} name-value pair argument.

Data Types: \texttt{single} | \texttt{double}

\textbf{Y — Classification values}

\begin{verbatim}
numeric vector | categorical vector | logical vector | character array | cell array of character vectors
\end{verbatim}

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors, with the same number of rows as \( X \). Each row of \( Y \) represents the classification of the corresponding row of \( X \).

Data Types: \texttt{single} | \texttt{double} | \texttt{cell} | \texttt{logical} | \texttt{char}

\textbf{Name-Value Pair Arguments}

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

\textbf{BreakTies — Tie-breaking algorithm}

\begin{verbatim}
'smallest' (default) | 'nearest' | 'random'
\end{verbatim}
