Tie-breaking algorithm used by the \texttt{predict} method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of \texttt{'BreakTies'} and one of the following:

- \texttt{'smallest'} — Use the smallest index among tied groups.
- \texttt{'nearest'} — Use the class with the nearest neighbor among tied groups.
- \texttt{'random'} — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the \( K \) nearest neighbors.

Example: \texttt{('BreakTies','nearest')}

\textbf{BucketSize — Maximum data points in node}

\begin{verbatim}
50 (default) | positive integer value
\end{verbatim}
Maximum number of data points in the leaf node of the \( k \)-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when \( \text{NSMethod} \) is 'kdtree'.

Example: 'BucketSize',40

Data Types: single | double

**CategoricalPredictors — Categorical predictor flag**

\[
\text{[]} \quad \text{(default)} \quad \text{'}\text{all}'
\]

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- \( \text{[]} \) — No predictors are categorical.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

Example: 'CategoricalPredictors','all'

**ClassNames — Class names**

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in \( y \).

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names in \( y \).

Data Types: single | double | char | logical | cell

**Cost — Cost of misclassification**

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \) (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
• Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~j, and Cost(i,j)=0 if i=j.

Data Types: single | double | struct

**Cov — Covariance matrix**

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If 'on', fitcknn creates a cross-validated model with 10 folds. Use the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross validate mdl later using the crossval method.

Example: 'Crossval','on'

**CVPartition — Cross-validated model partition**

cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition. You can only use one of these four options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Distance — Distance metric**

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | 'hamming' | function handle | ...
Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

<table>
<thead>
<tr>
<th>NSMethod</th>
<th>Distance Metric Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>exhaustive</td>
<td>Any distance metric of ExhaustiveSearcher</td>
</tr>
<tr>
<td>kdtree</td>
<td>'cityblock', 'chebychev', 'euclidean', or 'minkowski'</td>
</tr>
</tbody>
</table>

This table includes valid distance metrics of ExhaustiveSearcher.

<table>
<thead>
<tr>
<th>Distance Metric Names</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by nancov(X). To specify a different value for C, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, S = nanstd(X). To specify another value for S, use the Scale name-value pair argument.</td>
</tr>
</tbody>
</table>
Distance Metric Names | Description
--- | ---
'spearman' | One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@distfun | Distance function handle. distfun has the form

```matlab
function D2 = distfun(ZI,ZJ)
% calculation of distance
...
```

where

- ZI is a 1-by-N vector containing one row of X or Y.
- ZJ is an M2-by-N matrix containing multiple rows of X or Y.
- D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance','minkowski'

Data Types: char | function_handle

**DistanceWeight — Distance weighting function**

Value | Description
--- | ---
'equal' (default) | No weighting
'inverse' | Weight is 1/distance
'squaredinverse' | Weight is 1/distance$^2$

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.
@fcn

*fcn* is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight','inverse'

Data Types: char | function_handle

**Exponent — Minkowski distance exponent**

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

**Holdout — Fraction of data for holdout validation**

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

**IncludeTies — Tie inclusion flag**

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies',true
Data Types: logical

**KFold — Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

**NSMethod — Nearest neighbor search method**

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a kd-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebychev'

- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point xnew, the software computes the distance values from all points in X to xnew to find nearest neighbors.
The default is 'kdtree' when \( X \) has 10 or fewer columns, \( X \) is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod','exhaustive'

**NumNeighbors — Number of nearest neighbors to find**

1 (default) | positive integer value

Number of nearest neighbors in \( X \) to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3

Data Types: single | double

**PredictorNames — Predictor variable names**

\{'x1','x2',...\} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in \( X \).

If you specify the predictors as a table (tbl), then PredictorNames must be a subset of the variable names in tbl. In this case, the software uses only the variables in PredictorNames to train the model. If you use formula to specify the model, then you cannot use the PredictorNames name-value pair.

Example: 'PredictorNames',{'PedalWidth','PedalLength'}

Data Types: cell

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in ( Y ).</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to $1/K$, where $K$ is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Data Types: char | single | double | struct

**ResponseName — Response variable name**

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable Y.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName','Response'

Data Types: char

**Scale — Distance scale**
nanstd(X) (default) | vector of nonnegative scalar values
Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weighs the observations in each row of X or tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or tbl.

If you specify the input data as a table tbl, then Weights can be the name of a variable in tbl that contains a numeric vector. In this case, you must specify Weights as a character vector containing the variable name. For example, if the weights vector w is stored as tbl.w, then specify it as 'w'. Otherwise, the software treats all columns of tbl, including w, as predictors when training the model.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

Output Arguments

mdl — k-nearest neighbor classifier model
ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

Examples
**Train k-Nearest Neighbor Classifier**

Train a $k$-nearest neighbor classifier for Fisher's iris data, where $k$, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```matlab
load fisheriris
X = meas;
Y = species;
```

$X$ is a numeric matrix that contains four petal measurements for 150 irises. $Y$ is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```matlab
Mdl = ClassificationKNN
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    Distance: 'euclidean'
    NumNeighbors: 5
```

**Properties, Methods**

`Mdl` is a trained `ClassificationKNN` classifier, and some of its properties appear in the Command Window.

To access the properties of `Mdl`, use dot notation.

```matlab
Mdl.ClassNames
```

```matlab
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```
Mdl.Prior
ans = 1x3
    0.3333    0.3333    0.3333

Mdl.Prior contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in fitcknn. The order of the class prior probabilities corresponds to the order of the classes in Mdl.ClassNames. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

Mdl.Prior = [0.5 0.2 0.3];

You can pass Mdl to predict to label new measurements or crossval to cross-validate the classifier.

### Train a k-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
              'NSMethod','exhaustive','Distance','minkowski',...
              'Standardize',1);
```

Mdl is a ClassificationKNN classifier.
You can examine the properties of \texttt{Mdl} by double-clicking \texttt{Mdl} in the Workspace window. This opens the Variable Editor.
Definitions

Prediction

ClassificationKNN predicts the classification of a point \( x_{\text{new}} \) using a procedure equivalent to this:

1. Find the \( \text{NumNeighbors} \) points in the training set \( X \) that are nearest to \( x_{\text{new}} \).
2. Find the \( \text{NumNeighbors} \) response values \( Y \) to those nearest points.
3. Assign the classification label \( y_{\text{new}} \) that has the largest posterior probability among the values in \( Y \).

For details, see “Posterior Probability” on page 32-4943 in the predict documentation.

ClassificationTree.fit

Class: ClassificationTree

Fit classification tree (to be removed)

Note ClassificationTree.fit will be removed in a future release. Use fitctree instead.

Syntax

tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)

Description

tree = ClassificationTree.fit(x,y) returns a classification tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree, where each branching node is split based on the values of a column of x.

tree = ClassificationTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.
**Input Arguments**

**x** — Predictor values
matrix of floating point values

Predictor values, specified as a matrix of floating point values.

`ClassificationTree.fit` considers NaN values in x as missing values. `ClassificationTree.fit` does not use observations with all missing values for x in the fit. `ClassificationTree.fit` uses observations with some missing values for x to find splits on variables for which these observations have valid values.

Data Types: single | double

**y** — predictor values
numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

Each row of y represents the classification of the corresponding row of x. For numeric y, consider using `fitrtree` instead. `ClassificationTree.fit` considers NaN values in y to be missing values.

`ClassificationTree.fit` does not use observations with missing values for y in the fit.

Data Types: single | double | char | logical | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**AlgorithmForCategorical** — Algorithm for best split on categorical predictor

Valid values are:

- `'Exact'`
- `'PullLeft'`
- `'PCA'`
- `'OVAbyClass'`
Algorithm to find the best split on a categorical predictor with $L$ levels for data with $K \geq 3$ classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

- 'Exact' Consider all $2^{L-1} - 1$ combinations
- 'PullLeft' Pull left by purity
- 'PCA' Principal component-based partition
- 'OVAbyClass' One versus all by class

`ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `ClassificationTree.fit` always performs the exact search.

Example: 'AlgorithmForCategorical','PCA'

**CategoricalPredictors — Categorical predictors list**

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to $p$, where $p$ is the number of columns of $x$.
- A logical vector of length $p$, where a true entry means that the corresponding column of $x$ is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in PredictorNames values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in PredictorNames values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: 'CategoricalPredictors','all'

Data Types: single | double | char

**ClassNames — Class names**

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in $y$. 

32-1597
Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names that exist in `y`.

Data Types: `single` | `double` | `char` | `logical` | `cell`

**Cost — Cost of misclassification**

Square matrix | Structure

Cost of misclassification a point, specified as the comma-separated pair consisting of 'Cost' and one of the following.

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i≠j`, and `Cost(i,j)=0` if `i=j`

Data Types: `single` | `double` | `struct`

**CrossVal — Flag to grow cross-validated tree**

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: 'CrossVal','on'

**CVPartition — Partition for cross-validation tree**

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`. 
Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout** — Fraction of data for holdout validation

1 (default) | scalar value in the range (0,1]  

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1  

Data Types: single | double

**KFold** — Number of folds  

10 (default) | positive integer value  

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8  

Data Types: single | double

**Leaveout** — Leave-one-out cross validation flag  

'off' (default) | 'on'  

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

**MaxCat** — Maximum category levels  

10 (default) | nonnegative scalar value
Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. ClassificationTree.fit splits a categorical predictor using the exact search algorithm if the predictor has at most MaxCat levels in the split node. Otherwise, ClassificationTree.fit finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

Example: 'MaxCat',8

MergeLeaves — Leaf merge flag
'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', ClassificationTree.fit merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', ClassificationTree.fit does not merge leaves.

Example: 'MergeLeaves','off'

MinLeaf — Minimum number of leaf node observations
1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Example: 'MinLeaf',3

Data Types: single | double

MinParent — Minimum number of branch node observations
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).
Example: 'MinParent', 8
Data Types: single | double

**NVarToSample — Number of predictors for split**
'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.
Example: 'NVarToSample', 3
Data Types: single | double

**PredictorNames — Predictor variable names**
{'}x1', 'x2', ...'} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in x.

**Prior — Prior probabilities**
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- 'empirical' determines class probabilities from class frequencies in y. If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as y
  - S.ClassProbs containing a vector of corresponding probabilities

If you set values for both weights and prior, the weights are renormalized to add up to the value of the prior probability in the respective class.
Example: 'Prior', 'uniform'
Prune — Pruning flag
'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', ClassificationTree.fit grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' ClassificationTree.fit grows the classification tree without pruning.

Example: 'Prune','off'

PruneCriterion — Pruning criterion
'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

Example: 'PruneCriterion','impurity'

ResponseName — Response variable name
'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable y.

Example: 'ResponseName','Response'

ScoreTransform — Score transform function
'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following values representing a built-in transformation function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'             | -1 for $x < 0$  
                      | 0 for $x = 0$  
                      | 1 for $x > 0$                                      |
| 'symmetric'        | $2x - 1$                                                                   |
| 'symmetricismax'   | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$ |
| 'symmetriclogit'   | $2/(1 + e^{-x}) - 1$                                                        |

Example: 'ScoreTransform','logit'

**SplitCriterion — Split criterion**

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion','deviance'

**Surrogate — Surrogate decision splits flag**

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', ClassificationTree.fit finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, ClassificationTree.fit finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', ClassificationTree.fit finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.
Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate','on'

**Weights — Observation weights**

ones(size(x,1),1) (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is equal to the number of rows in x. ClassificationTree.fit normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

**Output Arguments**

**tree — Classification tree**

classification tree object

Classification tree object, returned as a classification tree object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method. Instead, use kfoldpredict to predict responses for observations not used for training.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

**Examples**

**Construct a Classification Tree**

Construct a classification tree for the data in ionosphere.mat.
load ionosphere
tc = ClassificationTree.fit(X,Y)

tc =
    ClassificationTree
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    NumObservations: 351

Properties, Methods

Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is

\[ 1 - \sum_i p^2(i), \]

where the sum is over the classes \( i \) at the node, and \( p(i) \) is the observed fraction of classes with class \( i \) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With \( p(i) \) defined the same as for the Gini index, the deviance of a node is

\[ -\sum_i p(i) \log_2 p(i). \]
A pure node has deviance $\theta$; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class $i$ in the left child node after a split, and $R(i)$ denote the fraction of members of class $i$ in the right child node after a split. Choose the split criterion to maximize

$$P(L) P(R) \left( \sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If $j$ is the class with the largest number of training samples at a node, the node error is

$$1 - \frac{1}{p(j)}.$$

ClassificationTree | fitctree | kfoldpredict | predict
GeneralizedLinearModel.fit

Class: GeneralizedLinearModel

Create generalized linear regression model

Note GeneralizedLinearModel.fit will be removed in a future release. Use fitglm instead.

Syntax

mdl = GeneralizedLinearModel.fit(tbl)
mdl = GeneralizedLinearModel.fit(X,y)
mdl = GeneralizedLinearModel.fit(...,modelspec)
mdl = GeneralizedLinearModel.fit(...,Name,Value)
mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)

Description

mdl = GeneralizedLinearModel.fit(tbl) creates a generalized linear model of a table or dataset array tbl.

mdl = GeneralizedLinearModel.fit(X,y) creates a generalized linear model of the responses y to a data matrix X.

mdl = GeneralizedLinearModel.fit(...,modelspec) creates a generalized linear model as specified by modelspec.

mdl = GeneralizedLinearModel.fit(...,Name,Value) or mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value) creates a generalized linear model with additional options specified by one or more Name,Value pair arguments.
Input Arguments

tbl — Input data
table | dataset array

Input data, specified as a table or dataset array. When modelspec is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-57).

To set a different column as the response variable, use the ResponseVar name-value pair argument. To use a subset of the columns as predictors, use the PredictorVars name-value pair argument.

X — Predictor variables
matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

Data Types: single | double | logical

y — Response variable
vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X.

modelspec — Model specification
character vector or string scalar specifying the model | t-by-(p+1) terms matrix | character vector or string scalar of the form 'Y ~ terms'

Model specification, specified as one of the following:

- Character vector or string scalar specifying the type of model.
### Value-Model Type

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear terms for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept, linear terms, and squared terms.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept, linear terms, interactions, and squared terms.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.</td>
</tr>
</tbody>
</table>

- $t$-by-$(p+1)$ matrix, namely terms matrix on page 32-1616, specifying terms to include in model, where $t$ is the number of terms and $p$ is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-1619 in the form

  ```
  'Y ~ terms',
  ```

  where the terms are in “Wilkinson Notation” on page 32-1620.

**Example:** 'quadratic'

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

- **BinomialSize — Number of trials for binomial distribution**
  1 (default) | scalar value | vector
Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter \( n \) for the fitted binomial distribution. **BinomialSize** applies only when the **Distribution** parameter is 'binomial'.

If **BinomialSize** is a scalar value, that means all observations have the same number of trials.

As an alternative to **BinomialSize**, you can specify the response as a two-column vector with counts in column 1 and **BinomialSize** in column 2.

Data Types: single | double

### CategoricalVars — Categorical variable list

*string array | cell array of character vectors | logical or numeric index vector*

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array tbl, then, by default, `GeneralizedLinearModel.fit` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix \( X \), then the default value of 'CategoricalVars' is an empty matrix \([]\). That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars',[2,3]
Example: 'CategoricalVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

### DispersionFlag — Indicator to compute dispersion parameter

*false for 'binomial' and 'poisson' distributions (default) | true*

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.
**true** Estimate a dispersion parameter when computing standard errors  
**false** Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag',true

**Distribution — Distribution of the response variable**

<table>
<thead>
<tr>
<th>'normal' (default)</th>
<th>'binomial'</th>
<th>'poisson'</th>
<th>'gamma'</th>
<th>'inverse gaussian'</th>
</tr>
</thead>
</table>

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

Example: 'Distribution','gamma'

**Exclude — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]  
Example: 'Exclude',logical([0 1 1 0 0 0])  
Data Types: single | double | logical

**Intercept — Indicator for constant term**

true (default) | false

32-1611
Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

**Link — Link function**

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

<table>
<thead>
<tr>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>( f(\mu) = \mu )</td>
<td>( \mu = Xb )</td>
</tr>
<tr>
<td>'log'</td>
<td>( f(\mu) = \log(\mu) )</td>
<td>( \mu = \exp(Xb) )</td>
</tr>
<tr>
<td>'logit'</td>
<td>( f(\mu) = \log(\mu/(1-\mu)) )</td>
<td>( \mu = \exp(Xb) / (1 + \exp(Xb)) )</td>
</tr>
<tr>
<td>'probit'</td>
<td>( f(\mu) = \Phi^{-1}(\mu) )</td>
<td>( \mu = \Phi(Xb) )</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>( f(\mu) = \log(-\log(1 - \mu)) )</td>
<td>( \mu = 1 - \exp(-\exp(Xb)) )</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>( f(\mu) = 1/\mu )</td>
<td>( \mu = 1/(Xb) )</td>
</tr>
<tr>
<td>p (a number)</td>
<td>( f(\mu) = \mu^p )</td>
<td>( \mu = Xb^{1/p} )</td>
</tr>
<tr>
<td>S (a structure)</td>
<td>( f(\mu) = S.Link(\mu) )</td>
<td>( \mu = S.Inverse(Xb) )</td>
</tr>
</tbody>
</table>

with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:

- **S.Link** — The link function
- **S.Inverse** — The inverse link function
- **S.Derivative** — The derivative of the link function
The link function defines the relationship $f(\mu) = X*b$ between the mean response $\mu$ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see Definitions.

Example: 'Link','probit'

Data Types: char | string | single | double | struct

**Offset — Offset variable**

[ ] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

fitglm and stepwiseglm use Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor $A$. By using the log link function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char | string

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.
Example: 'PredictorVars', [2,3]
Example: 'PredictorVars', logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**
last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.
Example: 'ResponseVar', 'yield'
Example: 'ResponseVar', [4]
Example: 'ResponseVar', logical([0 0 0 1 0 0])
Data Types: single | double | logical | char | string

**VarNames — Names of variables**
{'x1', 'x2', ..., 'xn', 'y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.
Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
Data Types: string | cell
Weights — Observation weights
ones(n,1) (default) | n-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Generalized linear model
GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

load hospital
ds = hospital; % just to use the ds name

Specify the model using a formula that allows up to two-way interactions.

modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';

Create the generalized linear model.

mdl = fitglm(ds,modelspec,'Distribution','binomial')

mdl =
Generalized linear regression model:
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight  
Distribution = Binomial

Estimated Coefficients:

<td>0.0038964</td>
<td>-0.18468</td>
<td>0.85348</td>
</tr>
</tbody>
</table>

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large p-value indicates the model might not differ statistically from a constant.

**Definitions**

**Terms Matrix**

A terms matrix is a \( t \)-by-(\( p + 1 \)) matrix specifying terms in a model, where \( t \) is the number of terms, \( p \) is the number of predictor variables, and plus one is for the response variable.

The value of \( T(i, j) \) is the exponent of variable \( j \) in term \( i \). Suppose there are three predictor variables A, B, and C:

\[
\begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
2 & 0 & 0 & 0 \\
0 & 1 & 2 & 0 \\
\end{bmatrix}
\]

<table>
<thead>
<tr>
<th>0 0 0 0</th>
<th>% Constant term or intercept</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 0 0</td>
<td>% B; equivalently, ( A^0 ) * ( B^1 ) * ( C^0 )</td>
</tr>
<tr>
<td>1 0 1 0</td>
<td>% ( A^*C )</td>
</tr>
<tr>
<td>2 0 0 0</td>
<td>% ( A^2 )</td>
</tr>
<tr>
<td>0 1 2 0</td>
<td>% ( B^*(C^2) )</td>
</tr>
</tbody>
</table>

The 0 at the end of each term represents the response variable. In general,
• If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this using a table.

Load the sample data and define a table.

```matlab
load hospital
dsa = table(hospital.Sex,hospital.BloodPressure(:,1), ...
            hospital.Age,hospital.Smoker,'VariableNames', ...
            {'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of 0s for the response variable.

```matlab
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
T =
```

```matlab
0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1
```

Redefine the table.

```matlab
dsa = table(hospital.BloodPressure(:,1),hospital.Sex, ...
            hospital.Age,hospital.Smoker,'VariableNames', ...
            {'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the table. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```matlab
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
T =
```

```matlab
0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

• If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.
Load the sample data and define the matrix of predictors.

```matlab
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```matlab
T = [0 0 0;1 0 0;1 0;1 1 0;0 2 0]
T =

0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```matlab
mdl = fitlm(X,MPG,T)
mdl =
```

```
Linear regression model:
    y ~ 1 + x1*x2 + x2^2

Estimated Coefficients:
                          Estimate       SE            tStat      pValue
    (Intercept)         48.906        12.589     3.8847    0.00019665
    x1                 0.54418       0.57125    0.95261       0.34337
    x2               -0.012781     0.0060312    -2.1192      0.036857
    x1:x2          -0.00010892    0.00017925    -0.6076         0.545
    x2^2            9.7518e-07    7.5389e-07     1.2935       0.19917
```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 4.1
R-squared: 0.751, Adjusted R-Squared 0.739
F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.
Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

\[
T = \begin{bmatrix} 0 & 0 & 0; 1 & 0 & 0; 0 & 1 & 0; 1 & 1 & 0 \end{bmatrix};
\]

\[
mdl = \text{stepwiselm}(X, \text{MPG}, [0 \ 0 \ 0], 'upper', T);
\]

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:
\[
y ~ 1 + x2
\]

<td>1.6434e-28</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of \text{fitlm} in the previous step.

**Formula**

A formula for model specification is a character vector or string scalar of the form 'Y ~ terms'

where

- \(Y\) is the response name.
- \(terms\) contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - * defines an interaction and all lower-order terms
• ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
• ( ) groups terms

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.
'Y ~ A + B + C - 1' is a three-variable linear model without intercept.
'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.
'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.
'Y ~ A + B + C + A:B' includes an A*B term.
'Y ~ A*B + C' is the same as the previous example because A*B = A + B + A:B.
'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.
'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

**Wilkinson Notation**

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>
Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

### Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

#### Canonical Link Functions for Generalized Linear Models

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>

<td>'identity'</td>
<td>$f(\mu) = \mu$</td>
<td>$\mu = Xb$</td>
</tr>
<tr>
<td>'binomial'</td>
<td>'logit'</td>
<td>$f(\mu) = \log(\mu/(1-\mu))$</td>
<td>$\mu = \exp(Xb) / (1 + \exp(Xb))$</td>
</tr>
<tr>
<td>'poisson'</td>
<td>'log'</td>
<td>$f(\mu) = \log(\mu)$</td>
<td>$\mu = \exp(Xb)$</td>
</tr>
<tr>
<td>'gamma'</td>
<td>-1</td>
<td>$f(\mu) = 1/\mu$</td>
<td>$\mu = 1/(Xb)$</td>
</tr>
<tr>
<td>'inverse gaussian'</td>
<td>-2</td>
<td>$f(\mu) = 1/\mu^2$</td>
<td>$\mu = (Xb)^{-1/2}$</td>
</tr>
</tbody>
</table>

### Tips

- The generalized linear model mdl is a standard linear model unless you specify otherwise with the Distribution name-value pair.
- For other methods such as devianceTest, or properties of the GeneralizedLinearModel object, see GeneralizedLinearModel.

### Alternatives

You can also construct a generalized linear model using fitglm.

Use stepwiseglm to select a model specification automatically. Use step, addTerms, or removeTerms to adjust a fitted model.

“Generalized Linear Model Workflow” on page 12-40
“Generalized Linear Models” on page 12-12
gmdistribution.fit

Gaussian mixture parameter estimates

Note  fit will be removed in a future release. Use fitgmdist instead.

Syntax

obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1,val1,param2,val2,...)

Description

obj = gmdistribution.fit(X,k) uses an Expectation Maximization (EM) algorithm to construct an object obj of the gmdistribution class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with k components for data in the n-by-m matrix X, where n is the number of observations and m is the dimension of the data.

gmdistribution treats NaN values as missing data. Rows of X with NaN values are excluded from the fit.

obj = gmdistribution.fit(...,param1,val1,param2,val2,...) provides control over the iterative EM algorithm. Parameters and values are listed below.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Start'</td>
<td>Method used to choose initial component parameters. One of the following:</td>
</tr>
<tr>
<td></td>
<td>• 'randSample' — To select k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j). This is the default.</td>
</tr>
<tr>
<td></td>
<td>• 'plus' — The software selects k observations from X using the kmeans++ algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j).</td>
</tr>
<tr>
<td></td>
<td>• S — A structure array with fields mu, Sigma, and PComponents. See gmdistribution for descriptions of values.</td>
</tr>
<tr>
<td></td>
<td>• s — A vector of length n containing an initial guess of the component index for each point.</td>
</tr>
<tr>
<td>'Replicates'</td>
<td>A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.</td>
</tr>
<tr>
<td>'CovType'</td>
<td>'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.</td>
</tr>
<tr>
<td>'SharedCov'</td>
<td>Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.</td>
</tr>
<tr>
<td>'Regularize'</td>
<td>A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.</td>
</tr>
<tr>
<td>'Options'</td>
<td>Options structure for the iterative EM algorithm, as created by statset. gmdistribution.fit uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of 1e-6.</td>
</tr>
</tbody>
</table>

In some cases, gmdistribution may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:
• The number of dimension of your data is relatively high and there are not enough observations.
• Some of the features (variables) of your data are highly correlated.
• Some or all the features are discrete.
• You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

• Pre-process your data to remove correlated features.
• Set 'SharedCov' to true to use an equal covariance matrix for every component.
• Set 'CovType' to 'diagonal'.
• Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
• Try another set of initial values.

In other cases gmdistribution may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

**Examples**

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```matlab
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
scatter(X(:,1),X(:,2),10,'.')
hold on
```

Examples
Next, fit a two-component Gaussian mixture model:

```matlab
options = statset('Display','final');
obj = gmdistribution.fit(X,2,'Options',options);
10 iterations, log-likelihood = -7046.78

h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```
Among the properties of the fit are the parameter estimates:

ComponentMeans = obj.mu
ComponentMeans =
    0.9391    2.0322
   -2.9823   -4.9737

ComponentCovariances = obj.Sigma
ComponentCovariances(:,:,1) =
    1.7786   -0.0528
   -0.0528    0.5312
ComponentCovariances(:,:,2) =
    1.0491   -0.0150
   -0.0150    0.9816
MixtureProportions = obj.PComponents
MixtureProportions =
    0.5000    0.5000

The Akaike information is minimized by the two-component model:

AIC = zeros(1,4);
obj = cell(1,4);
for k = 1:4
    obj{k} = gmdistribution.fit(X,k);
    AIC(k) = obj{k}.AIC;
end

[minAIC,numComponents] = min(AIC);
numComponents
numComponents =
    2

model = obj{2}
model =
Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
    Mixing proportion: 0.500000
    Mean:      0.9391    2.0322
Component 2:
    Mixing proportion: 0.500000
    Mean:     -2.9823   -4.9737

Both the Akaike and Bayes information are negative log-likelihoods for the data with
penalty terms for the number of estimated parameters. They are often used to determine
an appropriate number of components for a model when the number of components is
unspecified.

LinearModel.fit

Class: LinearModel

Create linear regression model

Note LinearModel.fit will be removed in a future release. Use fitlm instead.

Syntax

mdl = LinearModel.fit(tbl)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit(___,modelspec)
mdl = LinearModel.fit(___,Name,Value)
mdl = LinearModel.fit(___,modelspec,Name,Value)

Description

mdl = LinearModel.fit(tbl) creates a linear model of a table or dataset array tbl.

mdl = LinearModel.fit(X,y) creates a linear model of the responses y to a data matrix X.

mdl = LinearModel.fit(___,modelspec) creates a linear model of the type specified by modelspec, using any of the previous syntaxes.

mdl = LinearModel.fit(___,Name,Value) or mdl = LinearModel.fit(___, modelspec,Name,Value) creates a linear model with additional options specified by one or more Name,Value pair arguments. For example, you can specify which predictor variables to include in the fit or include observation weights.

Input Arguments

tbl — Input data
table | dataset array
Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-57). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

-X — Predictor variables

Predictor variables, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables. Each column of \( X \) represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in \( X \).

Data Types: `single` | `double` | `logical`

-y — Response variable

Response variable, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations. Each entry in \( y \) is the response for the corresponding row of \( X \).

Data Types: `single` | `double` | `logical`

-`modelspec` — Model specification

character vector or string scalar naming the model | \( t \)-by-(\( p + 1 \)) terms matrix | character vector or string scalar of the form `'Y ~ terms'`

Model specification, specified as one of the following.

- A character vector or string scalar naming the model.
<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear terms for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept, linear terms, and squared terms.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept, linear terms, interactions, and squared terms.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.</td>
</tr>
</tbody>
</table>

- $t$-by-($p + 1$) matrix, namely terms matrix on page 32-1641, specifying terms to include in the model, where $t$ is the number of terms and $p$ is the number of predictor variables, and plus 1 is for the response variable.

- A character vector or string scalar representing a formula on page 32-1644 in the form

  \[
  'Y \sim \text{terms}',
  \]

  where the terms are specified using Wilkinson Notation on page 32-1645.

Example: 'quadratic'
Example: 'y ~ X1 + X2^2 + X1:X2'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
CategoricalVars — Categorical variable list
string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array tbl, then, by default, LinearModel.fit treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix X, then the default value of 'CategoricalVars' is an empty matrix []. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.
Example: 'CategoricalVars',[2,3]
Example: 'CategoricalVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

Exclude — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.
Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])
Data Types: single | double | logical

Intercept — Indicator for constant term
true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.
Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**

last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 0 1 0 0])
Data Types: single | double | logical | char | string

Robust0pts — Indicator of robust fitting type
'off' (default) | 'on' | character vector | string scalar | structure with character vector, string scalar, or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'Robust0pts' and one of the following.

- 'off' — No robust fitting. fitlm uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- Character vector or string scalar — Name of the robust fitting weight function from the following table. fitlm uses the corresponding default tuning constant in the table.
- Structure with the character vector or string scalar RobustWgtFun containing the name of the robust fitting weight function from the following table and optional scalar Tune fields — fitlm uses the RobustWgtFun weight function and Tune tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a Tune field, the fitting function uses the corresponding default tuning constant.

<table>
<thead>
<tr>
<th>Weight Function</th>
<th>Equation</th>
<th>Default Tuning Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>'andrews'</td>
<td>[w = (\text{abs}(r) &lt; \pi) \cdot \sin(r) \cdot \frac{1}{r}]</td>
<td>1.339</td>
</tr>
<tr>
<td>'bisquare'</td>
<td>[w = (\text{abs}(r) &lt; 1) \cdot (1 - r^2)^2]</td>
<td>4.685</td>
</tr>
<tr>
<td>'cauchy'</td>
<td>[w = \frac{1}{1 + r^2}]</td>
<td>2.385</td>
</tr>
<tr>
<td>'fair'</td>
<td>[w = \frac{1}{1 + \text{abs}(r)}]</td>
<td>1.400</td>
</tr>
<tr>
<td>'huber'</td>
<td>[w = \frac{1}{\max(1, \text{abs}(r))}]</td>
<td>1.345</td>
</tr>
<tr>
<td>'logistic'</td>
<td>[w = \tanh(r) \cdot \frac{1}{r}]</td>
<td>1.205</td>
</tr>
<tr>
<td>'ols'</td>
<td>Ordinary least squares (no weighting function)</td>
<td>None</td>
</tr>
<tr>
<td>'talwar'</td>
<td>[w = 1 \cdot (\text{abs}(r) &lt; 1)]</td>
<td>2.795</td>
</tr>
<tr>
<td>'welsch'</td>
<td>[w = \exp(-(r^2))]</td>
<td>2.985</td>
</tr>
</tbody>
</table>

The value \( r \) in the weight functions is

32-1635
\[ r = \frac{\text{resid}}{(\text{tune} \times s \times \sqrt{1-h})}, \]

where resid is the vector of residuals from the previous iteration, h is the vector of leverage values from a least-squares fit, and s is an estimate of the standard deviation of the error term given by

\[ s = \frac{\text{MAD}}{0.6745}. \]

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are \( p \) columns in \( X \), the smallest \( p \) absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle RobustWgtFun and optional scalar Tune fields —
  You can specify a custom weight function. fitlm uses the RobustWgtFun weight function and Tune tuning constant from the structure. Specify RobustWgtFun as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: 'Robust0pts', 'andrews'

**VarNames — Names of variables**

\{'x1', 'x2', ..., 'xn', 'y'\} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of \( X \) first, and the name for the response variable \( y \) last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

32-1636
Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: string | cell

**Weights — Observation weights**

`ones(n,1)` (default) | `n`-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an `n`-by-1 vector of nonnegative scalar values, where `n` is the number of observations.

Data Types: single | double

**Output Arguments**

**mdl — Linear model**

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not `{}` or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, see the `LinearModel` class page.

**Examples**

**Linear Regression Model of Matrix Data**

Fit a linear model of the Hald data.

Load the data.

```matlab
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a default linear model to the data.

```matlab
mdl = fitlm(X,y)
```
mdl =
Linear regression model:
  y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
       Estimate      SE        tStat       pValue
________________    _______    ________    ________
(Intercept)      62.405     70.071      0.8906     0.39913
x1               1.5511    0.74477      2.0827    0.070822
x2              0.51017    0.72379     0.70486      0.5009
x3              0.10191    0.75471     0.13503     0.89592
x4             -0.14406    0.70905    -0.20317     0.84407

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982,  Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the carsmall data.

load carsmall

Construct a table containing continuous predictor variable Weight, categorical predictor variable Year, and response variable MPG.

tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);

Create a fitted model of MPG as a function of Year, Weight, and Weight^2. You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight^2. The fitlm function includes Weight automatically.

mdl = fitlm(tbl,'MPG ~ Year + Weight^2')

mdl =
Linear regression model:
\[
\text{MPG} \sim 1 + \text{Weight} + \text{Year} + \text{Weight}^2
\]

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>

<td>1.5573e-06</td>
<td>4.9454e-07</td>
<td>3.149</td>
<td>0.0022303</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41

\text{fitlm} \text{ creates two dummy (indicator) variables for the categorical variate, } \text{Year}. \text{ The dummy variable } \text{Year}_76 \text{ takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable } \text{Year}_82 \text{ takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is}

\[
\hat{\text{MPG}} = 54.206 - 0.016404\text{Weight} + 2.0887\text{Year}_76 + 8.1864\text{Year}_82 + 1.5573 \cdot 10^{-06}\text{Weight}^2.
\]

**Specify Response and Predictor Variables for Linear Model**

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

load hospital

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.
The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

**Fit a Robust Linear Regression Model**

Fit a linear regression model using a robust fitting method.

Load the sample data.

```
load hald
```

The hald data measures the effect of cement composition on its hardening heat. The matrix ingredients contains the percent composition of four chemicals present in the cement. The array heat contains the heat of hardening after 180 days for each cement sample.
Fit a robust linear model to the data.

```matlab
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```
mdl = 
Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                        Estimate       SE      tStat       pValue
(Intercept)            60.09    75.818    0.79256      0.4509
x1                    1.5753    0.80585    1.9548    0.086346
x2                    0.5322    0.78315    0.67957     0.51596
x3                  0.13346    0.8166     0.16343     0.87424
x4                -0.12052    0.7672    -0.15709     0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,  Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

**Definitions**

**Terms Matrix**

A terms matrix is a $t$-by-$(p + 1)$ matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and plus one is for the response variable.

The value of $T(i,j)$ is the exponent of variable $j$ in term $i$. Suppose there are three predictor variables $A$, $B$, and $C$:

```
[0 0 0 0] % Constant term or intercept  
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0 
[1 0 1 0] % A*C                                       
[2 0 0 0] % A^2                                    
[0 1 2 0] % B*(C^2)                                    
```

The 0 at the end of each term represents the response variable. In general,
If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this using a table.

Load the sample data and define a table.

```matlab
load hospital
dsa = table(hospital.Sex,hospital.BloodPressure(:,1), ... hospital.Age,hospital.Smoker,'VariableNames', ... {'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of 0s for the response variable.

```matlab
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
T =

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the table.

```matlab
dsa = table(hospital.BloodPressure(:,1),hospital.Sex, ... hospital.Age,hospital.Smoker,'VariableNames', ... {'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the table. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```matlab
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
T =

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1
```

If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.
Load the sample data and define the matrix of predictors.

```matlab
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```matlab
T = [0 0 0;1 0 0;1 0;1 1 0;0 2 0]
```

Fit a linear model.

```matlab
mdl = fitlm(X,MPG,T)
```

```matlab
mdl =
```

```
Linear regression model:
  y ~ 1 + x1*x2 + x2^2

Estimated Coefficients:

<table>
<thead>
<tr>
<th>Estimate</th>

```

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 4.1
R-squared: 0.751, Adjusted R-Squared 0.739
F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.
Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

\[ T = \begin{bmatrix} 0 & 0 & 0; 1 & 0 & 0; 0 & 1 & 0; 1 & 1 & 0 \end{bmatrix}; \]

mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:
\[ y \sim 1 + x2 \]

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>49.238</td>

<td>-16.103</td>
<td>1.6434e-28</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of fitlm in the previous step.

**Formula**

A formula for model specification is a character vector or string scalar of the form 'Y ~ terms'

where

- Y is the response name.
- terms contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - * defines an interaction and all lower-order terms
• ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
• ( ) groups terms

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.
'Y ~ A + B + C - 1' is a three-variable linear model without intercept.
'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.
'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.
'Y ~ A + B + C + A:B' includes an A*B term.
'Y ~ A*B + C' is the same as the previous example because A*B = A + B + A*B.
'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.
'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

**Wilkinson Notation**

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>
Wilkinson Notation | Factors in Standard Notation
--- | ---

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Tips
- Use robust fitting (`RobustOpts` name-value pair) to reduce the effect of outliers automatically.
- Do not use robust fitting when you want to subsequently adjust a model using `step`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Algorithms
The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives
You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

LinearMixedModel.fit

Class: LinearMixedModel

Fit linear mixed-effects model using tables

Note  LinearMixedModel.fit will be removed in a future release. Use fitlme instead.

Syntax

lme = LinearMixedModel.fit(tbl,formula)
lme = LinearMixedModel.fit(tbl,formula,Name,Value)

Description

lme = LinearMixedModel.fit(tbl,formula) returns a linear mixed-effects model, specified by formula, fitted to the variables in the table or dataset array tbl.

lme = LinearMixedModel.fit(tbl,formula,Name,Value) returns a linear mixed-effects model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Input Arguments

tbl — Input data

 table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using formula.
Data Types: `table`

**formula — Formula for model specification**
character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For full description, see “Formula” on page 32-1669.

Example: `'y ~ treatment +(1|block)'`
Data Types: `char` | `string`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**CovariancePattern — Pattern of covariance matrix**

Default: `'FullCholesky'`

Character vector or string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are `R` random-effects terms, then the value of `'CovariancePattern'` must be a string array or cell array of length `R`, where each element `r` of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the `r`th random-effects term. The options for each element follow.

- `'FullCholesky'` Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

\[
\begin{pmatrix}
\sigma_{b1}^2 & 0 & 0 \\
0 & \sigma_{b2}^2 & 0 \\
0 & 0 & \sigma_{b3}^2
\end{pmatrix}
\]

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_b^2 & 0 & 0 \\
0 & \sigma_b^2 & 0 \\
0 & 0 & \sigma_b^2
\end{pmatrix}
\]

where $\sigma_b^2$ is the common variance of the random-effects terms.
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_b^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_b^2 & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_b^2
\end{pmatrix}
\]

where \( \sigma_b^2 \) is the common variance of the random-effects terms and \( \sigma_{b1,b2} \) is the common covariance between any two random-effects term.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \( \text{PAT}(a,b) = \text{false} \), then the \( (a,b) \) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern',{"Full","Diagonal"}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters
'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML' Default. Maximum likelihood estimation
'REML' Restricted maximum likelihood estimation

Example: 'FitMethod','REML'
Weights — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude
use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.
'quasinewton'  Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using statset('LinearMixedModel'). If you don’t specify the options, then LinearMixedModel uses the default options of statset('LinearMixedModel').

'fminunc'  You must have Optimization Toolbox to specify this option. Change the options of the algorithm using optimoptions('fminunc'). If you don’t specify the options, then LinearMixedModel uses the default options of optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

**OptimizerOptions — Options for optimization algorithm**
structure returned by statset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by statset('LinearMixedModel') or an object returned by optimoptions('fminunc').

- If 'Optimizer' is 'fminunc', then use optimoptions('fminunc') to change the options of the optimization algorithm. See optimoptions for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for LinearMixedModel is the default options created by optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use statset('LinearMixedModel') to change the optimization parameters. If you don’t change the optimization parameters, then LinearMixedModel uses the default options created by statset('LinearMixedModel').

The 'quasinewton' optimizer uses the following fields in the structure created by statset('LinearMixedModel').
**TolFun — Relative tolerance on gradient of objective function**
1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**
1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**
10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**
'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**
'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**
false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true
CheckHessian — Indicator to check positive definiteness of Hessian
false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Examples

Random-Intercept Model

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable FluRate, the nominal variable Region that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Fit a linear mixed-effects model with the nationwide a random intercept that varies by Date. The model corresponds to

\[ y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma^2_b), \]

and the error term has the distribution,

\[ \epsilon_{im} \sim N(0, \sigma^2). \]

lme = LinearMixedModel.fit(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
lme =
Linear mixed-effects model fit by ML

Model information:
  Number of observations        468
  Fixed effects coefficients    2
  Random effects coefficients   52
  Covariance parameters         2

Formula:
  FluRate ~ 1 + WtdILI + (1 | Date)

Model fit statistics:
  AIC       BIC       LogLikelihood    Deviance
  286.24    302.83    -139.12          278.24

  Fixed effects coefficients (95% CIs):

<table>
<thead>
<tr>
<th>Name</th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>DF</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>'(Intercept)'</td>
<td>0.16385</td>
<td>0.057525</td>
<td>2.8484</td>
<td>466</td>
<td>0.0045885</td>
</tr>
</tbody>
</table>
The confidence limits for the standard deviation of the random-effects term, $\sigma_b$, do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the compare method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\hat{y}_{28} = \hat{\beta}_0 \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005}$$

$$= 0.1639 + 0.7236 \times (1.343) + 0.3318$$

$$= 1.46749,$$

where $\hat{b}$ is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```matlab
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```
You can display the fitted value using the `fitted` method.

```matlab
F = fitted(lme);
F(28)
ans = 1.4674
```

**Randomized-Block Design**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'));
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a fixed effects design matrix to describe the effect of Shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

- `Shift_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}`

- `Shift_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}`
The model corresponds to

\[
\begin{align*}
\text{Morning Shift:} & \quad \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + e_{im}, \\
\text{Evening Shift:} & \quad \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + e_{im}, \\
\text{Night Shift:} & \quad \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + e_{im},
\end{align*}
\]

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, \ldots, 15 \), and \( m = 1, 2, \ldots, 5 \). The random effects and the observation error have the following distributions:

\[ b_{0m} \sim N(0, \sigma^2_b) \]

and

\[ e_{im} \sim N(0, \sigma^2). \]

```matlab
lme = LinearMixedModel.fit(shift,'QCDev ~ Shift + (1|Operator)',...
    'FitMethod','REML','DummyVarCoding','effects')
```

```
lme =
Linear mixed-effects model fit by REML

Model information:
  Number of observations    15
  Fixed effects coefficients  3
  Random effects coefficients  5

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[
\mathbf{B} = \text{randomEffects}(\text{lme})
\]

\[
\mathbf{B} = 5\times1
\]

\[
\begin{align*}
0.5775 \\
1.1757 \\
-2.1715 \\
2.3655 \\
-1.9472
\end{align*}
\]

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

\[
\hat{y}_{\text{Evening,Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift}_\text{Evening} + \hat{b}_{03}
\]

\[
= 3.6525 - 0.53293 - 2.1715
\]

\[
= 0.94807.
\]

You can also display this value as follows.
\[
\hat{y}_{\text{Morning,Operator3}} = \hat{\beta}_0 + \hat{\beta}_2 \text{Shift Morning} + \hat{b}_{03}
\]
\[
= 3.6525 - 0.91973 - 2.1715
\]
\[
= 0.56127.
\]

You can also display this value in the following way.

\[
\text{F(shift.Shift=='}\text{Morning}' \& \text{ shift.Operator=='}3'\text{'})
\]
\[
\text{ans} = 0.5613
\]

The operator tends to make a smaller magnitude of error in the morning shift.

**Split-Plot Experiment**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```
Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

\[
y_{ijk} = \beta_0 + \sum_{m=2}^{4} \beta_{1m} I[F]_{im} + \sum_{j=2}^{5} \beta_{2j} I[T]_{ij} + \sum_{j=2}^{5} \sum_{m=2}^{4} \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S \ast T)_{jk} + e_{imjk},
\]

where \( i = 1, 2, ..., 60 \), the index \( m \) corresponds to the fertilizer types, \( j \) corresponds to the tomato types, and \( k = 1, 2, 3 \) corresponds to the blocks (soil). \( S_k \) represents the kth soil type, and \( (S \ast T)_{jk} \) represents the jth tomato type nested in the kth soil type. \( I[F]_{im} \) is the dummy variable representing level \( m \) of the fertilizer. Similarly, \( I[T]_{ij} \) is the dummy variable representing the level \( j \) of the tomato type.

The random effects and observation error have the following prior distributions:

\[
\begin{align*}
b_{0k} & \sim N(0, \sigma_S^2) \\
b_{0jk} & \sim N(0, \sigma_{S*T}^2) \\
e_{imjk} & \sim N(0, \sigma^2)
\end{align*}
\]

\[
lme = \text{LinearMixedModel.fit}(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
\]

\[
lme =
\]

The P-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the anova method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms ($\sigma_s^2$), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term Tomato:Fertilizer and the random-effects term (1 | Soil).

32-1665
You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

**Longitudinal Study with a Covariate**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'));
weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables $I[.]$. Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

```
Upper 16.509
Group: Error
  Name    Estimate  Lower  Upper
'Res Std'    12.325  10.024  15.153
```
where $i = 1, 2, ..., 120$, and $m = 1, 2, ..., 20$. $\beta_j$ are the fixed-effects coefficients, $j = 0, 1, ..., 8$, and $b_{0m}$ and $b_{1m}$ are random effects. $\text{IW}$ stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```matlab
lme = LinearMixedModel.fit(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme = Linear mixed-effects model fit by ML

Model information:
  Number of observations     120
  Fixed effects coefficients  9
  Random effects coefficients 40
  Covariance parameters      4

Formula:
  y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)

Model fit statistics:
  AIC    BIC    LogLikelihood    Deviance

Fixed effects coefficients (95% CIs):
  Name            Estimate    SE      tStat    DF
  '(Intercept)'   0.66105    0.25892  2.5531  111
  'InitialWeight' 0.0031879  0.0013814 2.3078  111
```

\[ y_{im} = \beta_0 + \beta_1 \text{IW}_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\
+ \beta_6 (\text{Week}_i \ast I[\text{PB}]_i) + \beta_7 (\text{Week}_i \ast I[\text{PC}]_i) + \beta_8 (\text{Week}_i \ast I[\text{PD}]_i) \\
+ b_{0m} + b_{1m} \text{Week}_{im} + \epsilon_{im}. \]
The $p$-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include
0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

## Definitions

### Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `X_j`, which can be continuous or grouping variables
- Grouping variables, `g_1, g_2, ..., g_R`

where the grouping variables in `X_j` and `g_r` can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form `'y ~ fixed + (random_1|g_1) + ... + (random_R|g_R)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random_1` is a specification of the random-effects design matrix `Z_1` corresponding to grouping variable `g_1`, and similarly `random_R` is a specification of the random-effects design matrix `Z_R` corresponding to grouping variable `g_R`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td><code>X^k</code>, where <code>k</code> is a positive integer</td>
<td><code>X</code>, <code>X^2</code>, ..., <code>X^k</code></td>
</tr>
<tr>
<td><code>X1 + X2</code></td>
<td><code>X1</code>, <code>X2</code></td>
</tr>
</tbody>
</table>
### Wilkinson Notation vs. Standard Notation

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1.*X2 only</td>
</tr>
<tr>
<td>- X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

### Examples:

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>

<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (X1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>Formula</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>( y \sim 1 + (1 \mid g_1) + (1 \mid g_2) + (1 \mid g_1:g_2) )</td>
<td>Random intercept model with independent main effects for ( g_1 ) and ( g_2 ), plus an independent interaction effect.</td>
</tr>
</tbody>
</table>

**Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[
b \sim N\left(0, \sigma^2 D(\theta)\right),
\]

where \( D \) is a \( q \)-by-\( q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the observation error variance. Since the covariance matrix of the random effects, \( D \), is symmetric, it has \( q(q+1)/2 \) free parameters. Suppose \( L \) is the lower triangular Cholesky factor of \( D(\theta) \) such that

\[
D(\theta) = L(\theta) L(\theta)^T,
\]

then the \( q(q+1)/2 \)-by-1 unconstrained parameter vector \( \theta \) is formed from elements in the lower triangular part of \( L \).

For example, if

\[
L = \begin{bmatrix}
L_{11} & 0 & 0 \\
L_{21} & L_{22} & 0 \\
L_{31} & L_{32} & L_{33}
\end{bmatrix},
\]

then
\[
\theta = \begin{bmatrix}
L_{11} \\
L_{21} \\
L_{31} \\
L_{22} \\
L_{32} \\
L_{33}
\end{bmatrix}.
\]

**Log-Cholesky Parameterization**

When the diagonal elements of \( L \) in Cholesky parameterization are constrained to be positive, then the solution for \( L \) is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of \( L \) are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing \( L_{ii} \geq 0 \),

\[
\theta = \begin{bmatrix}
\log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33})
\end{bmatrix}.
\]

**Tips**

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmatrix`.

**Alternatives**

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmatrix`.

**NonLinearModel.fit**

**Class:** NonLinearModel

Fit nonlinear regression model

**Note** NonLinearModel.fit will be removed in a future release. Use fitnlm instead.

**Syntax**

\[
\text{mdl} = \text{NonLinearModel.fit}(\text{tbl}, \text{modelfun}, \text{beta0}) \\
\text{mdl} = \text{NonLinearModel.fit}(\text{X}, \text{y}, \text{modelfun}, \text{beta0}) \\
\text{mdl} = \text{NonLinearModel.fit}(\ldots, \text{modelfun}, \text{beta0}, \text{Name, Value})
\]

**Description**

\[
\text{mdl} = \text{NonLinearModel.fit}(\text{tbl}, \text{modelfun}, \text{beta0}) \text{ fits the model specified by modelfun to variables in the table or dataset array tbl, and returns the nonlinear modelmdl. NonLinearModel.fit estimates model coefficients using an iterative procedure starting from the initial values in beta0.}
\]

\[
\text{mdl} = \text{NonLinearModel.fit}(\text{X}, \text{y}, \text{modelfun}, \text{beta0}) \text{ fits a nonlinear regression model using the column vector y as a response variable and the columns of the matrix X as predictor variables.}
\]

\[
\text{mdl} = \text{NonLinearModel.fit}(\ldots, \text{modelfun}, \text{beta0}, \text{Name, Value}) \text{ fits a nonlinear regression model with additional options specified by one or more Name, Value pair arguments.}
\]

**Input Arguments**

- **tbl** — Input data
  
  table | dataset array
Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the ResponseVar name-value pair argument. To use a subset of the columns as predictors, use the PredictorVars name-value pair argument.

Data Types: single | double | logical

**X — Predictor variables**

matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

Data Types: single | double | logical

**y — Response variable**

vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X.

Data Types: single | double | logical

**modelfun — Functional form of the model**

function handle | character vector or string scalar of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'

Functional form of the model, specified as either of the following.

- Function handle @modelfun or @(b,x)modelfun, where
  - b is a coefficient vector with the same number of elements as beta0.
  - x is a matrix with the same number of columns as X or the number of predictor variable columns of tbl.
modelfun(b,x) returns a column vector that contains the same number of rows as x. Each row of the vector is the result of evaluating modelfun on the corresponding row of x. In other words, modelfun is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. modelfun should return real numbers to obtain meaningful coefficients.

- Character vector or string scalar of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)', where f represents a scalar function of the scalar coefficient variables b1,...,bj and the scalar data variables x1,...,xk.

Data Types: function_handle | char | string

beta0 — Coefficients
numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

CoefficientNames — Names of the model coefficients
{'b1','b2',...,'bk'} (default) | character vector | string array | cell array of character vectors

Names of the model coefficients, specified as a character vector, string array, or cell array of character vectors.

Data Types: char | string | cell

ErrorModel — Form of the error variance model
'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b.
The only allowed error model when using Weights is 'constant'.

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

**ErrorParameters** — Initial estimates of the error model parameters
numeric array

Initial estimates of the error model parameters for the chosen ErrorModel, specified as a numeric array.

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>$a$</td>
<td>1</td>
</tr>
<tr>
<td>'proportional'</td>
<td>$b$</td>
<td>1</td>
</tr>
<tr>
<td>'combined'</td>
<td>$a, b$</td>
<td>[1, 1]</td>
</tr>
</tbody>
</table>

You can only use the 'constant' error model when using Weights.

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for $a$ and the starting value 2 for $b$ as follows.

Example: 'ErrorParameters',[1, 2]

**Exclude** — Observations to exclude
logical or numeric index vector
Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Options — Options for controlling the iterative fitting procedure**

[ ] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>DerivStep</td>
<td>Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.</td>
<td>eps^(1/3)</td>
</tr>
<tr>
<td>Display</td>
<td>Amount of information displayed by the fitting algorithm.</td>
<td>'off'</td>
</tr>
<tr>
<td>FunValCheck</td>
<td>Character vector or string scalar indicating to check for invalid values, such as NaN or Inf, from the model function.</td>
<td>'on'</td>
</tr>
<tr>

<td>Maximum number of iterations allowed. Positive integer.</td>
<td>200</td>
</tr>
<tr>
<td>Option</td>
<td>Meaning</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>RobustWgtFun</td>
<td>Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-2408</td>
<td>[]</td>
</tr>
<tr>
<td>Tune</td>
<td>Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.</td>
<td>See “Robust Options” on page 32-2408 for the default, which depends on RobustWgtFun.</td>
</tr>
<tr>
<td>TolFun</td>
<td>Termination tolerance for the objective function value. Positive scalar.</td>
<td>1e-8</td>
</tr>
<tr>
<td>TolX</td>
<td>Termination tolerance for the parameters. Positive scalar.</td>
<td>1e-8</td>
</tr>
</tbody>
</table>

Data Types: struct

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell
**ResponseVar — Response variable**
last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char | string

**VarNames — Names of variables**
{'x1','x2',...,'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: string | cell

**Weights — Observation weights**
ones(n,1) (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.
• If you specify a vector, then it must have \( n \) elements, where \( n \) is the number of rows in \( \text{tbl} \) or \( y \).

• If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, \( W \), \texttt{NonLinearModel} estimates the error variance at observation \( i \) by \( \text{MSE} \times (1/W(i)) \), where MSE is the mean squared error.

Data Types: \texttt{single} | \texttt{double} | \texttt{function_handle}

### Output Arguments

\( \texttt{mdl} \) — Nonlinear model
NonLinearModel object

Nonlinear model representing a least-squares fit of the response to the data, returned as a \texttt{NonLinearModel} object.

If the \texttt{Options} structure contains a nonempty \texttt{RobustWgtFun} field, the model is not a least-squares fit, but uses the \texttt{RobustWgtFun} robust fitting function.

For properties and methods of the nonlinear model object, \( \texttt{mdl} \), see the \texttt{NonLinearModel} class page.

### Examples

**Nonlinear Model from a Table**

Create a nonlinear model for auto mileage based on the \texttt{carbig} data.

Load the data and create a nonlinear model.

```matlab
clear all
load \texttt{carbig}
tbl = \texttt{table(Horsepower,Weight,MPG)};
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = \texttt{NonLinearModel.fit(tbl,modelfun,beta0)}
```

32-1681
mdl =
Nonlinear regression model:
  MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>b1</td>
<td>-49.383</td>
<td>119.97</td>
<td>-0.41164</td>
<td>0.68083</td>
</tr>
<tr>
<td>b2</td>
<td>376.43</td>
<td>567.05</td>
<td>0.66384</td>
<td>0.50719</td>
</tr>
<tr>
<td>b3</td>
<td>-0.78193</td>
<td>0.47168</td>
<td>-1.6578</td>
<td>0.098177</td>
</tr>
<tr>
<td>b4</td>
<td>422.37</td>
<td>776.02</td>
<td>0.54428</td>
<td>0.58656</td>
</tr>
<tr>
<td>b5</td>
<td>-0.24127</td>
<td>0.48325</td>
<td>-0.49926</td>
<td>0.61788</td>
</tr>
</tbody>
</table>

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

### Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```matlab
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
             b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
```

mdl =
Nonlinear regression model:
  y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>b1</td>
<td>-49.383</td>
<td>119.97</td>
<td>-0.41164</td>
<td>0.68083</td>
</tr>
<tr>
<td>b2</td>
<td>376.43</td>
<td>567.05</td>
<td>0.66384</td>
<td>0.50719</td>
</tr>
<tr>
<td>b3</td>
<td>-0.78193</td>
<td>0.47168</td>
<td>-1.6578</td>
<td>0.098177</td>
</tr>
<tr>
<td>b4</td>
<td>422.37</td>
<td>776.02</td>
<td>0.54428</td>
<td>0.58656</td>
</tr>
<tr>
<td>b5</td>
<td>-0.24127</td>
<td>0.48325</td>
<td>-0.49926</td>
<td>0.61788</td>
</tr>
</tbody>
</table>
Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the carbig data. Strive for more accuracy by lowering the TolFun option, and observe the iterations by setting the Display option.

Load the data and create a nonlinear model.

```matlab
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...;
b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower TolFun and to report iterative display, and create a model using the options.

```matlab
opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

Specify Nonlinear Regression Using Model Character Vector

Specify a nonlinear regression model for estimation using a function handle or character vector.

Load sample data.
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Use a function handle to specify the Hougen-Watson model for the rate data.

mdl = NonLinearModel.fit(X,y,@hougen,beta0)

mdl = Nonlinear regression model:
    y ~ hougen(b,X)

Estimated Coefficients:
    Estimate    SE       tStat     pValue
    ______    ________    ______    _______
    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075157    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a character vector to specify the Hougen-Watson model for the rate data.

myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)

mdl2 = Nonlinear regression model:
    y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)

Estimated Coefficients:
    Estimate    SE       tStat     pValue
    ______    ________    ______    _______
    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

\[ y = b_1 + b_2 \exp[-b_3 x] + \epsilon, \]

where \( b_1, b_2, \) and \( b_3 \) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);

Set robust fitting options.

opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';

Fit the nonlinear model using the robust fitting options. Here, use a character vector to specify the model.

b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)
mdl =
Nonlinear regression model (robust fit):
Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```matlab
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```matlab
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```matlab
mdl =
Nonlinear regression model:
  y ~ hougen(b,X)

Estimated Coefficients:
  Estimate      SE       tStat       pValue
  ______    _______    ______    __________
  b1    1.0218     0.07202    14.188    2.1344e-25
  b2    3.6619     0.25429    14.401     7.974e-26
  b3    2.9732     0.38496    7.7232    1.0346e-11
```

Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35
Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
Nonlinear regression model:
y ~ hougen(b,X)
```

```
Estimated Coefficients:
  Estimate     SE       tStat    pValue
  ______     ______    ______    ______
    b1      1.2526     0.86702    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075158    1.4957    0.17309
    b5      1.1914     0.83671    1.4239    0.1923
```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 1.27
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Algorithms

NonLinearModel.fit uses the same fitting algorithm as nlinfit.

Alternatives

You can also construct a nonlinear model using fitnlm.

RegressionTree.fit

Class: RegressionTree

Binary decision tree for regression (to be removed)

Note RegressionTree.fit will be removed in a future release. Use fitrtree instead.

Syntax

```
tree = RegressionTree.fit(x,y)
tree = RegressionTree.fit(x,y,Name,Value)
```

Description

```
tree = RegressionTree.fit(x,y) returns a regression tree based on the input
variables (also known as predictors, features, or attributes) x and output (response) y.
tree is a binary tree where each branching node is split based on the values of a column
of x.

```
tree = RegressionTree.fit(x,y,Name,Value) fits a tree with additional options
specified by one or more Name,Value pair arguments. You can specify several name-
value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You
cannot use a partitioned tree for prediction, so this kind of tree does not have a predict
method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to
make predictions.
```
**Input Arguments**

**x — Predictor values**
matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of x represents one variable, and each row represents one observation.

RegressionTree.fit considers NaN values in x as missing values. RegressionTree.fit does not use observations with all missing values for x the fit. RegressionTree.fit uses observations with some missing values for x to find splits on variables for which these observations have valid values.

Data Types: single | double

**y — Response values**
vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as x. Each entry in y is the response to the data in the corresponding row of x.

RegressionTree.fit considers NaN values in y to be missing values. RegressionTree.fit does not use observations with missing values for y in the fit.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**CategoricalPredictors — Categorical predictors list**
numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to p, where p is the number of columns of x.
- A logical vector of length p, where a true entry means that the corresponding column of x is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: 'CategoricalPredictors','all'

Data Types: `single` | `double` | `logical` | `char` | `struct` | `cell`

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: 'CrossVal','on'

**CVPartition — Partition for cross-validation tree**

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout — Fraction of data for holdout validation**

scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.
Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

**KFold — Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold', 8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

**MergeLeaves — Leaf merge flag**

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', `RegressionTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `RegressionTree.fit` does not merge leaves.

Example: 'MergeLeaves', 'off'

**MinLeaf — Minimum number of leaf node observations**

1 (default) | positive integer value
Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Example: 'MinLeaf',3

Data Types: single | double

MinParent — Minimum number of branch node observations
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Example: 'MinParent',8

Data Types: single | double

NVarToSample — Number of predictors for split
'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NVarToSample',3

Data Types: single | double

PredictorNames — Predictor variable names
{'x1','x2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in x.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PedalLength','PedalWidth'}

Data Types: cell
**Prune — Pruning flag**
'off' (default) | 'on'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', RegressionTree.fit computes the full tree and the optimal sequence of pruned subtrees. When 'off', RegressionTree.fit computes the full tree without pruning.

Example: 'Prune','off'

**PruneCriterion — Pruning criterion**
'mse' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

Example: 'PruneCriterion','mse'

**QEToler — Quadratic error tolerance**
1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below QEToler*QED, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: 'QEToler',1e4

**ResponseName — Response variable name**
'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable in y.

Example: 'ResponseName','Response'

Data Types: char

**ResponseTransform — Response transform function**
'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle...
or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector 'none' means @(x)x, or no transformation.

Add or change a ResponseTransform function using dot notation:

tree.ResponseTransform = @function

Example: 'ResponseTransform','none'
Data Types: function_handle

**SplitCriterion — Split criterion**

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion','MSE'

**Surrogate — Surrogate decision splits flag**

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

• When 'on', RegressionTree.fit finds at most 10 surrogate splits at each branch node.
• When set to a positive integer value, RegressionTree.fit finds at most the specified number of surrogate splits at each branch node.
• When set to 'all', RegressionTree.fit finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate','on'
Data Types: single | double

**Weights — Observation weights**

ones(size(X,1),1) (default) | vector of scalar values
Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x.

Data Types: single | double

Output Arguments

tree — Regression tree
regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

Examples

Predict Values Using a Regression Tree

Load the sample data.

load carsmall

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

```
tree = RegressionTree.fit([Weight, Cylinders],MPG,...
    'MinParent',20,...
    'PredictorNames',{"W","C"})
```

```
tree = RegressionTree
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
```
Predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```matlab
predict(tree,[2200,4])
```

ans = 29.6111

### Topics

“Splitting Categorical Predictors” on page 19-31

**fitcdiscr**

Fit discriminant analysis classifier

**Syntax**

```
Mdl = fitcdiscr(Tbl,ResponseVarName)
Mdl = fitcdiscr(Tbl,formula)
Mdl = fitcdiscr(Tbl,Y)
Mdl = fitcdiscr(X,Y)
Mdl = fitcdiscr(___,Name,Value)
```

**Description**

`Mdl = fitcdiscr(Tbl,ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl,formula)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl,Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X,Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr(___,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can optimize hyperparameters to minimize the model's cross-validation loss, or specify the cost of misclassification, the prior probabilities for each class, or the observation weights.
Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

load fisheriris

Train a discriminant analysis model using the entire data set.

Mdl = fitcdiscr(meas,species)

Mdl = ClassificationDiscriminant
   ResponseName: 'Y'
   CategoricalPredictors: []
   ClassNames: {'setosa' 'versicolor' 'virginica'}
   ScoreTransform: 'none'
   NumObservations: 150
   DiscrimType: 'linear'
   Mu: [3x4 double]
   Coeffs: [3x3 struct]

Properties, Methods

Mdl is a ClassificationDiscriminant model. To access its properties, use dot notation. For example, display the group means for each predictor.

Mdl.Mu

ans = 3x4

5.0060  3.4280  1.4620  0.2460
5.9360  2.7700  4.2600  1.3260
6.5880  2.9740  5.5520  2.0260

To predict labels for new observations, pass Mdl and predictor data to predict.
Optimize Discriminant Analysis Model

This example shows how to optimize hyperparameters automatically using `fitcdiscr`. The example uses Fisher's iris data.

Load the data.

```matlab
load fisheriris
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng(1)
Mdl = fitcdiscr(meas,species,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods

The fit achieved about 2% loss for the default 5-fold cross validation.

**Optimize Discriminant Analysis Model on Tall Array**

This example shows how to optimize hyperparameters of a discriminant analysis model automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat 'NA' values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
    'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table

tt =

M×7 tall table

    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    Distance    DepDelay
    _____    __________    _________    _______    ________    ________    ________
    10       21            3          642          8         308          12
    10       26            1         1021          8         296           1
    10       23            5         2055         21         480          20
    10       23            5         1332         13         296          12
    10       22            4          629          4         373          -1
    10       28            3         1446         59         308          63

    10       10            6          859         11         954          -1
    :        :             :           :          :           :           :
    :        :             :           :          :           :           :

When you execute calculations on tall arrays, the default execution environment uses
either the local MATLAB session or a local parallel pool (if you have Parallel Computing
Toolbox™). You can use the mapreducer function to change the execution environment.

Determine the flights that are late by 10 minutes or more by defining a logical variable
that is true for a late flight. This variable contains the class labels. A preview of this
variable includes the first few rows.

Y = tt.DepDelay > 10 % Class labels

Y =

M×1 tall logical array

Create a tall array for the predictor data.

```matlab
X = tt{:,1:end-1} % Predictor data
X = 
```

```
Mx6 tall double matrix
```

```
10 21 3 642 8 308
10 26 1 1021 8 296
10 23 5 2055 21 480
10 23 5 1332 13 296
10 22 4 629 4 373
10 28 3 1446 59 308
10 8 4 928 3 447
10 10 6 859 11 954
: : : : : :
: : : : : :
: : : : : :
```

Remove rows in X and Y that contain missing data.

```matlab
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Standardize the predictor variables.

```matlab
Z = zscore(X);
```

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'DiscrimType' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'DiscrimType'.) For reproducibility, set the random seed for tall arrays and use the 'expected-improvement-plus' acquisition function.

```matlab
rng('default') % For reproducibility
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(Z,Y,...
'OptimizeHyperparameters','auto',...
'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
'AcquisitionFunctionName','expected-improvement-plus'))
```

**Input Arguments**

**Tbl — Sample data**

table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the ClassNames name-value pair argument.

Data Types: char | string

formula — Explanatory model of response and subset of predictor variables
character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in Tbl (Tbl.Properties.VariableNames).

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char | string
**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

The software considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: categorical | char | string | logical | single | double | cell

**X — Predictor data**
numeric matrix

Predictor values, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

fitcdiscr considers NaN values in X as missing values. fitcdiscr does not use observations with missing values for X in the fit.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'DiscrimType','quadratic','SaveMemory','on' specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.
Model Parameters

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.
The default is $\text{Cost}(i,j) = 1$ if $i \neq j$, and $\text{Cost}(i,j) = 0$ if $i = j$.

Data Types: single | double | struct

**FillCoeffs — Coeffs property flag**

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs','off'

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcdiscr uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.
Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar
Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

SaveMemory — Flag to save covariance matrix
'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then fitcdiscr does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then fitcdiscr computes and stores the full covariance matrix in Mdl.

Specify SaveMemory as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory','on'

ScoreTransform — Score transformation
'none' (default)| 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>1/(1 + e^{-2x})</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>log(x / (1-x))</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>1/(1 + e^{-x})</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'             | -1 for $x < 0$
|                    | 0 for $x = 0$
|                    | 1 for $x > 0$                                    |
| 'symmetric'        | $2x - 1$                                         |
| 'symmetricismax'   | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$ |
| 'symmetriclogit'   | $2/(1 + e^{-x}) - 1$                            |

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of $X$ or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of $X$ or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector $W$ is stored as Tbl.$W$, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including $W$, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones($n$,1), where $n$ is the number of observations in $X$ or Tbl.

Data Types: double | single | char | string
Cross-Validation

**CrossVal — Cross-validation flag**

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal','on'`

**CVPartition — Cross-validation partition**

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `'CVPartition', 'Holdout', 'KFold', or 'Leaveout'`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

Scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the **Trained** property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: **CVPartition**, **Holdout**, **KFold**, or **Leaveout**.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps.

1 Randomly partition the data into k sets.
2 For each set, reserve the set as validation data, and train the model using the other k – 1 sets.
3 Store the k compact, trained models in the cells of a k-by-1 cell vector in the **Trained** property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: **CVPartition**, **Holdout**, **KFold**, or **Leaveout**.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the **NumObservations** property of the model), the software completes these steps:

1 Reserve the observation as validation data, and train the model using the other n - 1 observations.
2 Store the n compact, trained models in the cells of an n-by-1 cell vector in the **Trained** property of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

Hyperparameter Optimization

**Delta — Linear coefficient threshold**

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of Mdl has magnitude smaller than Delta, Mdl sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Data Types: single | double

**DiscrimType — Discriminant type**

'linear' (default) | 'quadratic' | 'diaglinear' | 'diagquadratic' | 'pseudolinear' | 'pseudoquadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector or string scalar in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Predictor Covariance Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>'linear'</td>
<td>Regularized linear discriminant analysis (LDA)</td>
<td>• All classes have the same covariance matrix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• $\hat{\Sigma} = (1 - \gamma) \hat{\Sigma} + \gamma \text{diag}(\hat{\Sigma})$.</td>
</tr>
<tr>
<td></td>
<td></td>

<td>Description</td>
<td>Predictor Covariance Treatment</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'pseudolinear'</td>
<td>LDA</td>
<td>All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic discriminant analysis (QDA)</td>
<td>The covariance matrices can vary among classes.</td>
</tr>
<tr>
<td>'diagquadratic'</td>
<td>QDA</td>
<td>The covariance matrices are diagonal and can vary among classes.</td>
</tr>
<tr>
<td>'pseudoquadratic'</td>
<td>QDA</td>
<td>The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.</td>
</tr>
</tbody>
</table>

**Note** To use regularization, you must specify 'linear'. To specify the amount of regularization, use the Gamma name-value pair argument.

Example: 'DiscrimType','quadratic'

**Gamma — Amount of regularization**

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than DiscrimType.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the
covariance matrix. You can display the chosen regularization amount by entering 
`Mdl.Gamma` at the command line.

- For quadratic discriminant analysis, if at least one class has an empirical 
covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear 
discriminant analysis, otherwise the software throws an error. Consequently, the 
software sets `DiscrimType` to `'linear'`.
- If you specify 1, then the software uses maximum regularization for covariance matrix 
estimation. That is, the software restricts the covariance matrix to be diagonal. 
Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for 
diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single` | `double`

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter 

names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 
`'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{`'Delta',`'Gamma'`}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcdiscr` by 
varying the parameters. For information about cross-validation loss (albeit in a different 
context), see “Classification Loss” on page 32-3215. To control the cross-validation type 
and other aspects of the optimization, use the `HyperparameterOptimizationOptions` 
name-value pair.

**Note** `'OptimizeHyperparameters'` values override any values you set using other 
name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to 
`'auto'` causes the `'auto'` values to apply.
The eligible parameters for fitcdiscr are:

- **Delta** — fitcdiscr searches among positive values, by default log-scaled in the range \([1e-6, 1e3]\).

- **DiscrimType** — fitcdiscr searches among 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'.

- **Gamma** — fitcdiscr searches among real values in the range \([0, 1]\).

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcdiscr', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \(\log(1 + \text{cross-validation loss})\) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Discriminant Analysis Model” on page 32-1703.

Example: 'auto'

`HyperparameterOptimizationOptions — Options for optimization structure`

<tr>
<td>Kfold</td>
<td>An integer greater than 1.</td>
<td></td>
</tr>
</tbody>
</table>

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

### Output Arguments

**Mdl — Trained discriminant analysis classification model**

ClassificationDiscriminant model object | ClassificationPartitionedModel cross-validated model object

Trained discriminant analysis classification model, returned as a ClassificationDiscriminant model object or a ClassificationPartitionedModel cross-validated model object.
If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationDiscriminant model object.

To reference properties of Mdl, use dot notation. For example, to display the estimated component means at the Command Window, enter Mdl.Mu.

**Definitions**

**Discriminant Classification**

The model for discriminant analysis is:

- Each class \( Y \) generates data \( X \) using a multivariate normal distribution. That is, the model assumes \( X \) has a Gaussian mixture distribution (gmdistribution).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

\[
\hat{y} = \arg \min \sum_{y=1}^{K} \hat{P}(k \mid x) C(y \mid k),
\]

where

- \( \hat{y} \) is the predicted classification.
- \( K \) is the number of classes.
- \( \hat{P}(k \mid x) \) is the posterior probability on page 20-7 of class \( k \) for observation \( x \).
- \( C(y \mid k) \) is the cost on page 20-8 of classifying an observation as \( y \) when its true class is \( k \).

For details, see “Prediction Using Discriminant Analysis Models” on page 20-7.
**Tips**

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Alternative Functionality**

**Functions**

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross-validation or hyperparameter optimization.
- `classify` requires you to fit the classifier when changing prior probabilities.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- Supported syntaxes for tall arrays return the additional output arguments `FitInfo` and `HyperparameterOptimizationResults`. The supported syntaxes are:
  - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(Tbl,Y)
  - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(X,Y)
  - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(___,Name,Value)`
The **FitInfo** output argument is an empty structure array currently reserved for possible future use.

The **HyperparameterOptimizationResults** output argument is a **BayesianOptimization** object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

'**HyperparameterOptimizationResults**' is nonempty when the '**OptimizeHyperparameters**' name-value pair argument is nonempty at the time you create the model. The values in '**HyperparameterOptimizationResults**' depend on the value you specify for the '**HyperparameterOptimizationOptions**' name-value pair argument when you create the model.

- If you specify 'bayesopt' (default), then
  **HyperparameterOptimizationResults** is an object of class **BayesianOptimization**.
- If you specify 'gridsearch' or 'randomsearch', then
  **HyperparameterOptimizationResults** is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

- Supported name-value pair arguments, and any differences, are:
  - '**ClassNames**'
  - '**Cost**'
  - '**DiscrimType**'
  - '**HyperparameterOptimizationOptions**' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitcdiscr(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
  - '**OptimizeHyperparameters**' — The only eligible parameter to optimize is 'DiscrimType'. Specifying 'auto' uses 'DiscrimType'.
  - '**PredictorNames**'
  - '**Prior**'
  - '**ResponseName**'
  - '**ScoreTransform**'
  - '**Weights**'

For tall arrays and tall tables, `fitcdiscr` returns a **CompactClassificationDiscriminant** object, which contains most of the same
properties as a ClassificationDiscriminant object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these ClassificationDiscriminant properties:

- ModelParameters
- NumObservations
- HyperparameterOptimizationResults
- RowsUsed
- XCentered
- W
- X
- Y

Additionally, the compact object does not support these ClassificationDiscriminant methods:

- compact
- crossval
- cvshrink
- resubEdge
- resubLoss
- resubMargin
- resubPredict

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.
For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

Topics
“Discriminant Analysis Classification” on page 20-2

Introduced in R2014a
**fitcecoc**

Fit multiclass models for support vector machines or other classifiers

**Syntax**

```plaintext
Mdl = fitcecoc(Tbl,ResponseVarName)
Mdl = fitcecoc(Tbl,formula)
Mdl = fitcecoc(Tbl,Y)
Mdl = fitcecoc(X,Y)
Mdl = fitcecoc(___,Name,Value)
[Mdl,HyperparameterOptimizationResults] = fitcecoc(___,Name,Value)
```

**Description**

`Mdl = fitcecoc(Tbl,ResponseVarName)` returns a full, trained, multiclass, error-correcting output codes (ECOC) model on page 32-1791 using the predictors in table `Tbl` and the class labels in `Tbl.ResponseVarName`. `fitcecoc` uses $K(K - 1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design on page 32-1788, where $K$ is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(Tbl,formula)` returns an ECOC model using the predictors in table `Tbl` and the class labels. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcecoc(Tbl,Y)` returns an ECOC model using the predictors in table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcecoc(X,Y)` returns a trained ECOC model using the predictors `X` and the class labels `Y`.

`Mdl = fitcecoc(___,Name,Value)` returns an ECOC model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.
For example, specify different binary learners, a different coding design, or to cross-validate. It is good practice to cross-validate using the Kfold Name,Value pair argument. The cross-validation results determine how well the model generalizes.

\[
[Mdl,\text{HyperparameterOptimizationResults}] = \text{fitcecoc}(__,\text{Name,Value})
\]
also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair with Learners = 'linear'. For other Learners, the HyperparameterOptimizationResults property of Mdl contains the results. Hyperparameter optimization is not available for kernel binary learners.

## Examples

### Train Multiclass Model Using SVM Learners

Train an error-correcting output codes (ECOC) multiclass model using support vector machine (SVM) binary learners.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

Train an ECOC multiclass model using the default options.

```matlab
Mdl = fitcecoc(X,Y)
```

```matlab
Mdl = 
    ClassificationECOC
        ResponseName: 'Y'
        CategoricalPredictors: []
            ClassNames: {'setosa'  'versicolor'  'virginica'}
        ScoreTransform: 'none'
        BinaryLearners: {3x1 cell}
            CodingName: 'onevsone'
```

Properties, Methods
Mdl is a ClassificationECOC model. By default, fitcecoc uses SVM binary learners, and uses a one-versus-one coding design. You can access Mdl properties using dot notation.

Display the coding design matrix.

Mdl.ClassNames
ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

CodingMat = Mdl.CodingMatrix

CodingMat = 3×3
    1     1     0
   -1    0     1
    0    -1    -1

A one-versus-one coding design on three classes yields three binary learners. Columns of CodingMat correspond to learners, and rows correspond to classes. The class order corresponds to the order in Mdl.ClassNames. For example, CodingMat(:,1) is [1; -1; 0] and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Since 'setosa' corresponds to 1, it is the positive class, and since 'versicolor' corresponds to -1, it is the negative class.

You can access each binary learner using cell indexing and dot notation.

Mdl.BinaryLearners{1} % The first binary learner

ans =
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: [-1 1]
    ScoreTransform: 'none'
    Beta: [4x1 double]
    Bias: 1.4505
    KernelParameters: [1x1 struct]
Properties, Methods

Compute the in-sample classification error.

```matlab
isLoss = resubLoss(Mdl)
```

```matlab
isLoss = 0.0067
```

The classification error is small, but the classifier might have been overfit. You can cross-validate the classifier using `crossval`.

**Cross-Validate ECOC Classifier**

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```matlab
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```matlab
t = templateSVM('Standardize',1)
t =
```

Fit template for classification SVM.

```matlab
    Alpha: [0x1 double]
    BoxConstraint: []
    CacheSize: []
    CachingMethod: ''
    ClipAlphas: []
    DeltaGradientTolerance: []
    Epsilon: []
    GapTolerance: []
    KKTTLerance: []
    IterationLimit: []
    KernelFunction: ''
    KernelScale: []
    KernelOffset: []
```
t is an SVM template. Most of the template object's properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});

Mdl is a ClassificationECOC classifier. You can access its properties using dot notation.

Cross-validate Mdl using 10-fold cross-validation.

CVMdl = crossval(Mdl);

CVMdl is a ClassificationPartitionedECOC cross-validated ECOC classifier.

Estimate the classification error.

loss = kfoldLoss(CVMdl)

loss = 0.0400

The classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.
Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```matlab
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```matlab
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Display diagnostic messages during the training using the 'Verbose' name-value pair argument. It is good practice to specify the class order.

```matlab
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1

Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1

Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2

Fitting posterior probabilities for learner 3 (SVM).
Md1 is a ClassificationECOC model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the 'Verbose' name-value pair argument.

[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
Mdl.BinaryLoss

Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...

ans =

'quadratic'

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

idx = randsample(size(X,1),10,1);
Mdl.ClassNames

table(Y(idx),label(idx),Posterior(idx,:),...
     'VariableNames',{'TrueLabel','PredLabel','Posterior'})

ans =

3x1 cell array

    {'setosa'    }
    {'versicolor'}
    {'virginica' }

ans =

10x3 table
<table>
<thead>

<tr>
<td>'setosa'</td>
<td>'setosa'</td>
<td>0.999</td>
</tr>
</tbody>
</table>

The columns of Posterior correspond to the class order of Mdl.ClassNames.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```matlab
xMax = max(X); xMin = min(X); x1Pts = linspace(xMin(1),xMax(1)); x2Pts = linspace(xMin(2),xMax(2)); [x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts); [~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```matlab
figure; contourf(x1Grid,x2Grid,... reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2))); h = colorbar; h.YLabel.String = 'Maximum posterior'; h.YLabel.FontSize = 15; hold on gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8); gh(2).LineWidth = 2; gh(3).LineWidth = 2; title 'Iris Petal Measurements and Maximum Posterior';
```
Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

load nlpdata
$X$ is a sparse matrix of predictor data, and $Y$ is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```matlab
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 32-6478 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```matlab
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```matlab
Mdl =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
    CodingMatrix: [13x78 double]
```

Alternatively, you can train an ECOC model composed of default linear classification models using 'Learners','Linear'.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

**Train ECOC Classifiers Using Ensembles and Parallel Computing**

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. Estimate the classification error using 10-fold cross-validation.
Load and inspect the arrhythmia data set.

```matlab
load arrhythmia
[n,p] = size(X)

n = 452
p = 279

isLabels = unique(Y);
numLabels = numel(isLabels)

numLabels = 13

tabulate(categorical(Y))
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>245</td>
<td>54.20%</td>
</tr>
<tr>
<td>2</td>
<td>44</td>
<td>9.73%</td>
</tr>
<tr>
<td>3</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>4</td>
<td>15</td>
<td>3.32%</td>
</tr>
<tr>
<td>5</td>
<td>13</td>
<td>2.88%</td>
</tr>
<tr>
<td>6</td>
<td>25</td>
<td>5.53%</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>0.66%</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>0.44%</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>1.99%</td>
</tr>
<tr>
<td>10</td>
<td>50</td>
<td>11.06%</td>
</tr>
<tr>
<td>14</td>
<td>4</td>
<td>0.88%</td>
</tr>
<tr>
<td>15</td>
<td>5</td>
<td>1.11%</td>
</tr>
<tr>
<td>16</td>
<td>22</td>
<td>4.87%</td>
</tr>
</tbody>
</table>

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```matlab
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.
Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. (The number of workers depends on your system configuration.) Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```matlab
pool = parpool; % Invoke workers
Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','Options',options);
```

Mdl is a ClassificationECOC model.

Cross-validate the ECOC classifier using 10-fold cross-validation.

```matlab
CVMdl = crossval(Mdl,'Options',options);
Warning: One or more folds do not contain points from all the groups.
```

CVMdl is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```matlab
oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```
Optimize ECOC Classifier

This example shows how to optimize hyperparameters automatically using `fitcecoc`. The example uses Fisher's iris data.

Load the data.

```matlab
load fisheriris
X = meas;
Y = species;
```
Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng default
Mdl = fitcecoc(X,Y,'OptimizeHyperparameters','auto',
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Train Multiclass ECOC Model with SVMs and Tall Arrays

Create two multiclass ECOC models trained on tall data. Use linear binary learners for one of the models and kernel binary learners for the other. Compare the resubstitution classification error of the two models.

In general, you can perform multiclass classification of tall data by using fitcecoc with linear or kernel binary learners. When you use fitcecoc to train a model on tall arrays, you cannot use SVM binary learners directly. However, you can use either linear or kernel binary classification models that use SVMs.
Create a datastore that references the folder containing Fisher's iris data set. Specify 'NA' values as missing data so that datastore replaces them with NaN values. Create tall versions of the predictor and response data.

```matlab
ds = datastore('fisheriris.csv','TreatAsMissing','NA');
tall(ds);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

```matlab
X = [t.SepalLength t.SepalWidth t.PetalLength t.PetalWidth];
Y = t.Species;
```

Standardize the predictor data.

```matlab
Z = zscore(X);
```

Train a multiclass ECOC model that uses tall data and linear binary learners. By default, when you pass tall arrays to fitcecoc, the software trains linear binary learners that use SVMs. Because the response data contains only three unique classes, change the coding scheme from one-versus-all (which is the default when you use tall data) to one-versus-one (which is the default when you use in-memory data).

```matlab
rng('default') % For reproducibility
mdlLinear = fitcecoc(Z,Y,'Coding','onevsone')
```

Training binary learner 1 (Linear) out of 3.
Training binary learner 2 (Linear) out of 3.
Training binary learner 3 (Linear) out of 3.

```matlab
mdlLinear =
    classreg.learning.classif.CompactClassificationECOC
        ResponseName: 'Y'
            ClassNames: {'setosa'  'versicolor' 'virginica'}
        ScoreTransform: 'none'
        BinaryLearners: {3×1 cell}
            CodingMatrix: [3×3 double]
```

Properties, Methods

```
mdlLinear is a CompactClassificationECOC model composed of three binary learners.
```
Train a multiclass ECOC model that uses tall data and kernel binary learners. First, create a `templateKernel` object to specify the properties of the kernel binary learners; in particular, increase the number of expansion dimensions to \(2^{16}\).

```matlab
tKernel = templateKernel('NumExpansionDimensions',2^16)
tKernel =
Fit template for classification Kernel.

    BetaTolerance: []
    BlockSize: []
    BoxConstraint: []
    Epsilon: []
    NumExpansionDimensions: 65536
    GradientTolerance: []
    HessianHistorySize: []
    IterationLimit: []
    KernelScale: []
    Lambda: []
    Learner: 'svm'
    LossFunction: []
    Stream: []
    VerbosityLevel: []
    Version: 1
    Method: 'Kernel'
    Type: 'classification'
```

By default, the kernel binary learners use SVMs.

Pass the `templateKernel` object to `fitcecoc` and change the coding scheme to one-versus-one.

```matlab
mdlKernel = fitcecoc(Z,Y,'Learners',tKernel,'Coding','onevsone')

Training binary learner 1 (Kernel) out of 3.
Training binary learner 2 (Kernel) out of 3.
Training binary learner 3 (Kernel) out of 3.
```

```matlab
mdlKernel =
classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
```
mdlKernel is also a CompactClassificationECOC model composed of three binary learners.

Compare the resubstitution classification error of the two models.

```matlab
errorLinear = gather(loss(mdlLinear,Z,Y))
```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.7 sec
Evaluation completed in 2 sec

```matlab
errorLinear = 0.0333
```

```matlab
errorKernel = gather(loss(mdlKernel,Z,Y))
```

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 17 sec
Evaluation completed in 17 sec

```matlab
errorKernel = 0.0067
```

mdlKernel misclassifies a smaller percentage of the training data than mdlLinear.

---

**Input Arguments**

**Tbl — Sample data**

table

Sample data, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable using `ResponseVarName`. 
If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of response variable and the number of `Tbl` rows must be equal.

**Note** For training linear or kernel classification models, `fitcecoc` does not support tables. That is, if `Learners` is `'linear'` or `'kernel'`, contains a linear classification model learner template (see `templateLinear`), or contains a kernel classification learner template (see `templateKernel`), you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a matrix of predictor data (`X`) and an array of responses (`Y`) instead.

Data Types: `table`

**ResponseVarName — Response variable name**

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

**formula — Explanatory model of response and subset of predictor variables**

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).
To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, then each element must correspond to one row of the array.

The length of Y and the number of rows of Tbl or X must be equal.

It is good practice to specify the class order using the ClassNames name-value pair argument.

Data Types: categorical | char | string | logical | single | double | cell

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as a full or sparse matrix.

The length of Y and the number of observations in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Note

- For linear classification learners, if you orient X so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient X so that observations correspond to rows.
- fitcecoc supports sparse matrices for training linear classification models only.

Data Types: double | single
Note The software treats NaN, empty character vector (''), empty string ('"'), <missing>, and <undefined> elements as missing data. The software removes rows of X corresponding to missing values in Y. However, the treatment of missing values in X varies among binary learners. For details, see the training functions for your binary learners: fitcdiscr, fitckernel, fitcknn, fitclinear, fitcnb, fitcsvm, fitctree, or fitcensemble. Removing observations decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'Learners','tree','Coding','onevsone','CrossVal','on' specifies to use decision trees for all binary learners, a one-versus-one coding design, and to implement 10-fold cross-validation.

ECOC Classifier Options

Coding — Coding design

'onevsone' (default) | 'allpairs' | 'binarycomplete' | 'denserandom' | 'onevsall' | 'ordinal' | 'sparserandom' | 'ternarycomplete' | numeric matrix

Coding design name, specified as the comma-separated pair consisting of 'Coding' and a numeric matrix or a value in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Number of Binary Learners</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allpairs' and 'onevsone'</td>
<td>$K(K - 1)/2$</td>
<td>For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.</td>
</tr>
<tr>
<td>'binarycomplete'</td>
<td>$2^{(K-1)} - 1$</td>
<td>This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.</td>
</tr>
<tr>
<td>'denserandom'</td>
<td>Random, but approximately $10 \log_2 K$</td>
<td>For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1795.</td>
</tr>
<tr>
<td>'onevsall'</td>
<td>$K$</td>
<td>For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.</td>
</tr>
<tr>
<td>'ordinal'</td>
<td>$K - 1$</td>
<td>For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.</td>
</tr>
<tr>
<td>Value</td>
<td>Number of Binary Learners</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'sparserandom'</td>
<td>Random, but approximately 15 log₂(K)</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1795.</td>
</tr>
<tr>
<td>'ternarycomplete'</td>
<td>(\frac{3^K - 2^{(K+1)} + 1}{2})</td>
<td>This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.</td>
</tr>
</tbody>
</table>

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a \(K\)-by-\(L\) matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in ClassNames. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of Coding\((i,j)\), that is, the class that learner \(j\) assigns to observations in class \(i\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner (j) assigns observations in class (i) to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner (j) removes observations in class (i) from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner (j) assigns observations in class (i) to a positive class.</td>
</tr>
</tbody>
</table>

- Every column must contain at least one -1 or 1.
For all column indices $i, j$ such that $i \neq j$, $\text{Coding}(:, i)$ cannot equal $\text{Coding}(:, j)$ and $\text{Coding}(:, i)$ cannot equal $-\text{Coding}(:, j)$.

- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 32-1793.

Example: 'Coding', 'ternarycomplete'

Data Types: char | string | double | single | int16 | int32 | int64 | int8

**FitPosterior** — Flag indicating whether to transform scores to posterior probabilities

false or 0 (default) | true or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of 'FitPosterior' and a true (1) or false (0).

If **FitPosterior** is true, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using kfoldPredict, predict, or resubPredict.

**fitcecoc** does not support fitting posterior probabilities if:

- The ensemble method is AdaBoostM2, LPBoost, RUSBoost, RobustBoost, or TotalBoost.
- The binary learners (Learners) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: 'FitPosterior', true

Data Types: logical

**Learners** — Binary learner templates

'svm' (default) | 'discriminant' | 'kernel' | 'knn' | 'linear' | 'naivebayes' | 'tree' | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of 'Learners' and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use GentleBoost, LogitBoost, and RobustBoost, to solve multiclass problems. However, **fitcecoc** also supports multiclass models as binary classifiers.
• If **Learners** is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'discriminant'</td>
<td>Discriminant analysis. For default options, see <code>templateDiscriminant</code>.</td>
</tr>
<tr>
<td>'kernel'</td>
<td>Kernel classification model. For default options, see <code>templateKernel</code>.</td>
</tr>
<tr>
<td>'knn'</td>
<td>k-nearest neighbors. For default options, see <code>templateKNN</code>.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear classification model. For default options, see <code>templateLinear</code>.</td>
</tr>
<tr>
<td>'naivebayes'</td>
<td>Naive Bayes. For default options, see <code>templateNaiveBayes</code>.</td>
</tr>
<tr>
<td>'svm'</td>
<td>SVM. For default options, see <code>templateSVM</code>.</td>
</tr>
<tr>
<td>'tree'</td>
<td>Classification trees. For default options, see <code>templateTree</code>.</td>
</tr>
</tbody>
</table>

• If **Learners** is a template object, then each binary learner trains according to the stored options. You can create a template object using:

  • `templateDiscriminant`, for discriminant analysis.
  • `templateEnsemble`, for ensemble learning. You must at least specify the learning method (**Method**), the number of learners (**NLearn**), and the type of learner (**Learners**). You cannot use the **AdaBoostM2** ensemble method for binary learning.
  • `templateKernel`, for kernel classification.
  • `templateKNN`, for k-nearest neighbors.
  • `templateLinear`, for linear classification.
  • `templateNaiveBayes`, for naive Bayes.
  • `templateSVM`, for SVM.
  • `templateTree`, for classification trees.

• If **Learners** is a cell vector of template objects, then:
• Cell $j$ corresponds to binary learner $j$ (in other words, column $j$ of the coding design matrix), and the cell vector must have length $L$. $L$ is the number of columns in the coding design matrix. For details, see Coding.

• To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as predict and loss.

• You cannot specify linear classification model learner templates with any other template.

• Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: 'Learners','tree'

**NumConcurrent — Number of binary learners concurrently trained**

1 (default) | positive integer scalar

Number of binary learners concurrently trained, specified as the comma-separated pair consisting of 'NumConcurrent' and a positive integer scalar. The default value is 1, which means fitcecoc trains the binary learners sequentially.

**Note** This option applies only when you use fitcecoc on tall arrays. See “Tall Arrays” on page 32-1797 for more information.

Data Types: single | double

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note**
• For linear classification learners, if you orient X so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you can experience a significant reduction in optimization-execution time.

• For all other learners, orient X so that observations correspond to rows.

Example: 'ObservationsIn', 'columns'

Verbose — Verbosity level
0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. Verbose controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages every time it trains a new binary learner.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays extra diagnostic messages every time it trains a new binary learner.</td>
</tr>
</tbody>
</table>

Each binary learner has its own verbosity level that is independent of this name-value pair argument. To change the verbosity level of a binary learner, create a template object and specify the 'Verbose' name-value pair argument. Then, pass the template object to fitcecoc by using the 'Learners' name-value pair argument.

Example: 'Verbose', 1

Data Types: double | single

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier
'off' (default) | 'on'
Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the CVPartition, Holdout, KFold, or Leaveout name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'Crossval', 'on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1  Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
2  Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.
Example: 'Holdout', 0.1
Data Types: double | single

**KFold — Number of folds**
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', \( k \), then the software completes these steps.

1. Randomly partition the data into \( k \) sets.
2. For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.
3. Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold', 5
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**
'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the \( n \) observations, where \( n \) is `size(Mdl.X, 1)`,

1. Reserves the observation as validation data, and trains the model using the other \( n - 1 \) observations
2. Stores the \( n \) compact, trained models in the cells of a \( n \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

**Note** Leave-one-out is not recommended for cross-validating ECOC models composed of linear or kernel classification model learners.
Example: 'Leaveout', 'on'

Other Classification Options

CategoricalPredictors — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

Specification of CategoricalPredictors is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, SVM, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is kNN.

If you specify CategoricalPredictors for any other learner, then the software warns that it cannot train that binary learner. For example, the software cannot train linear or kernel classification model learners using categorical predictors.

By default, if the predictor data is in a table (Tbl), fitcecoc assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), fitcecoc assumes all predictors
are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

ClassNames — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

• Order the classes during training.
• Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
• Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

• The square matrix Cost, then Cost(i,j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding
rows and columns of Cost, additionally specify the ClassNames name-value pair argument.

- The structure S, then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as Y
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default is \texttt{ones}(K) - \texttt{eye}(K), where $K$ is the number of distinct classes.

Example: 'Cost',[0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

**Options — Parallel computing options**

[] (default) | structure array returned by statset

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. These options require Parallel Computing Toolbox. fitcecoc uses 'Streams', 'UseParallel', and 'UseSubstreams' fields.

This table summarizes the available options.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'Streams'   | A RandStream object or cell array of such objects. If you do not specify Streams, the software uses the default stream or streams. If you specify Streams, use a single object except when the following are true:  
  • You have an open parallel pool.  
  • UseParallel is true.  
  • UseSubstreams is false.  
  In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and Streams must supply a single random number stream. |
| 'UseParallel' | If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting 'UseParallel', true.                                                                                          |
| 'UseSubstreams' | Set to true to compute in parallel using the stream specified by 'Streams'. Default is false. For example, set Streams to a type allowing substreams, such as 'mlfg6331_64' or 'mrg32k3a'.                                      |

A best practice to ensure more predictable results is to use parpool and explicitly create a parallel pool before you invoke parallel computing using fitcecoc.

Example: 'Options', statset('UseParallel', true)

Data Types: struct

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character
vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcecoc uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{ 'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure <code>S</code> with two fields:</td>
</tr>
<tr>
<td></td>
<td>- <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>.</td>
</tr>
<tr>
<td></td>
<td>- <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 32-1794.

Example: `struct('ClassNames',{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `single` | `double` | `char` | `string` | `struct`

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply `Y`, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: `char` | `string`

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...
Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'               | -1 for $x < 0$
|                      | 0 for $x = 0$
|                      | 1 for $x > 0$                                                              |
| 'symmetric'          | $2x - 1$                                                                   |
| 'symmetricismax'     | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$ |
| 'symmetriclogit'     | $2/(1 + e^{-x}) - 1$                                                       |

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a
character vector or string scalar. For example, if the weights vector \( W \) is stored as \( Tbl.W \), then specify it as \( 'W' \). Otherwise, the software treats all columns of \( Tbl \), including \( W \), as predictors or the response when training the model.

The software normalizes \( Weights \) to sum up to the value of the prior probability in the respective class.

By default, \( Weights \) is \( \text{ones}(n,1) \), where \( n \) is the number of observations in \( X \) or \( Tbl \).

Data Types: double | single | char | string

### Hyperparameter Optimization

**OptimizeHyperparameters — Parameters to optimize**

- 'none' (default)  
- 'auto'  
- 'all'  
- string array or cell array of eligible parameter names  
- vector of \( \text{optimizableVariable} \) objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use \{ 'Coding' \} along with the default parameters for the specified Learners:
  - Learners = 'svm' (default) — \{ 'BoxConstraint', 'KernelScale' \}
  - Learners = 'discriminant' — \{ 'Delta', 'Gamma' \}
  - Learners = 'knn' — \{ 'Distance', 'NumNeighbors' \}
  - Learners = 'linear' — \{ 'Lambda', 'Learner' \}
  - Learners = 'naivebayes' — \{ 'DistributionNames', 'Width' \}
  - Learners = 'tree' — \{ 'MinLeafSize' \}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of \( \text{optimizableVariable} \) objects, typically the output of \text{hyperparameters}

The optimization attempts to minimize the cross-validation loss (error) for \text{fitcecoc} by varying the parameters. For information about cross-validation loss in a different context, see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the \text{HyperparameterOptimizationOptions} name-value pair.
Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcecoc are:

- **Coding** — fitcecoc searches among 'onevsall' and 'onevsone'.
- **The eligible hyperparameters for the chosen Learners:**

</table>
Alternatively, use hyperparameters with your chosen Learners, such as

```matlab
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcecoc',meas,species,'svm');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcecoc',meas,species,'svm');
params(2).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize ECOC Classifier” on page 32-1753.

Example: 'auto'

**HyperparameterOptimizationOptions — Options for optimization structure**

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>

<tr>
<td>Verbose</td>
<td>Display to the command line.</td>
<td>1</td>
</tr>
</tbody>
</table>

For details, see the bayesopt Verbose name-value pair argument.
UseParallel
Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-9.
false

Repartition
Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization.
true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations.
false

Use no more than one of the following three field names.

CVPartition
A cvpartition object, as created by cvpartition.

Holdout
A scalar in the range (0,1) representing the holdout fraction.

Kfold
An integer greater than 1.

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

**HyperparameterOptimizationResults** — Description of the cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. Nonempty when the OptimizeHyperparameters name-value pair was nonempty and Learners was 'linear'. Value depends on the setting of the HyperparameterOptimizationOptions name-value pair:

- 'bayesopt' (default) — Object of class BayesianOptimization.
'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observation from smallest (best) to highest (worst).

Data Types: table

Limitations

- For training linear or kernel classification models, fitcecoc does not support tables. That is, if Learners is 'linear' or 'kernel', contains a linear classification model learner template (see templateLinear), or contains a kernel classification model learner template (see templateKernel), then you cannot supply Tbl, ResponseVarName, or formula. Supply a matrix of predictor data (X) and an array of responses (Y) instead.
- fitcecoc supports sparse matrices for training linear classification models only. For all other models, supply a full matrix of predictor data instead.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,
\[ \hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j). \]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[ \hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}. \]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j,s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty,\infty))</td>
<td>( \log[1 + \exp(-2y_js_j)]/\left[2\log(2)\right] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty,\infty))</td>
<td>( \exp(-y_js_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty,\infty))</td>
<td>( [1 - \text{sign}(y_js_j)]/2 )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty,\infty))</td>
<td>( \max(0,1 - y_js_j)/2 )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty,\infty))</td>
<td>( (1 - y_js_j)/2 )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty,\infty))</td>
<td>( \log[1 + \exp(-y_js_j)]/\left[2\log(2)\right] )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j(2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.
Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design (adopted by the software), for a particular column (or binary learner):

- Rows containing a 1 indicate to the binary learner to group all observations in the corresponding classes into a positive class.
- Rows containing a -1 indicate to the binary learner to group all observations in the corresponding classes into a negative class.
- Rows containing a 0 indicate to the binary learner to ignore all observations in the corresponding classes.

Coding matrices with large, minimal, pair-wise row distances based on the Hamming measure are desirable. For details on the pair-wise row distance, see “Random Coding Design Matrices” on page 32-1795 and [4].

This table describes popular coding designs. For the example, suppose $K$ (the number of distinct classes) is 3.

<table>
<thead>
<tr>
<th>Coding Design</th>
<th>Description</th>

<td>Variable</td>
</tr>
</tbody>
</table>

This plot compares the number of binary learners for the coding designs with increasing $K$. 

32-1790
Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classifiers.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Suppose that:

• There are three classes.
- The coding design is one-versus-one.
- The decoding scheme uses loss $g$.
- The learners are SVMs.

To build this classification model, ECOC follows these steps.

1. A one-versus-one coding design is

   \[
   \begin{array}{ccc}
   \text{Learner 1} & \text{Learner 2} & \text{Learner 3} \\
   \text{Class 1} & 1 & 1 & 0 \\
   \text{Class 2} & -1 & 0 & 1 \\
   \text{Class 3} & 0 & -1 & -1 \\
   \end{array}
   \]

   Learner 1 trains on observations having Class 1 and Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly. Let $M$ be the coding design matrix with elements $m_{kl}$, and $s_l$ be the predicted classification score for the positive class of learner $l$.

2. A new observation is assigned to the class ($\hat{k}$) that minimizes the aggregation of the losses for the $L$ binary learners. That is,

   \[
   \hat{k} = \arg\min_k \sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l) / \sum_{l=1}^L |m_{kl}|.
   \]

ECOC models can improve classification accuracy, even compared to other multiclass models [2].

**Tips**

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
  - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparsereandom`.  

32-1792
• If $K \leq 5$, then use binarycomplete coding design rather than denserandom.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

• You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).

• Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use $k$-fold cross-validation (`KFold`).

• After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

### Algorithms

#### Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

• Every element is -1, 0, or 1.
• Every column contains at least one -1 and one 1.
• For all distinct column vectors $u$ and $v$, $u \neq v$ and $u \neq -v$.
• All rows vectors are unique.
• The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
  • You can move vertically from 1 to -1 or -1 to 1.
  • You can move horizontally from a nonzero element to another nonzero element.
  • You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row $i$ to row $j$ using these rules, then classes $i$ and $j$ cannot be separated by the design. For example, in the coding design
classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

**Parallel Computing**

If you use parallel computing (see Options), then fitcecoc trains binary learners in parallel.

**Prior Probabilities and Cost**

- Prior probabilities — The software normalizes the specified class prior probabilities (Prior) for each binary learner. Let $M$ be the coding design matrix and $I(A,c)$ be an indicator matrix. The indicator matrix has the same dimensions as $A$. If the corresponding element of $A$ is $c$, then the indicator matrix has elements equaling one, and zero otherwise. Let $M_{+1}$ and $M_{-1}$ be $K$-by-$L$ matrices such that:
  
  - $M_{+1} = M \circ I(M,1)$, where $\circ$ is element-wise multiplication (that is, $M_{+1} = M \ast (M == 1)$). Also, let $m_{l}^{(+1)}$ be column vector $l$ of $M_{+1}$.
  
  - $M_{-1} = -M \circ I(M,-1)$ (that is, $M_{-1} = -M \ast (M == -1)$). Also, let $m_{l}^{(-1)}$ be column vector $l$ of $M_{-1}$.

Let $\pi_{l}^{+1} = m_{l}^{(+1)} \circ \pi$ and $\pi_{l}^{-1} = m_{l}^{(-1)} \circ \pi$, where $\pi$ is the vector of specified, class prior probabilities (Prior).

Then, the positive and negative, scalar class prior probabilities for binary learner $l$ are

$$\hat{\pi}_{l}^{(j)} = \frac{\|\pi_{l}^{(j)}\|_1}{\|\pi_{l}^{(+1)}\|_1 + \|\pi_{l}^{(-1)}\|_1},$$
where \( j = \{-1, 1\} \) and \( \|a\|_1 \) is the one-norm of \( a \).

- **Cost** — The software normalizes the \( K \)-by-\( K \) cost matrix \( C(\text{Cost}) \) for each binary learner. For binary learner \( l \), the cost of classifying a negative-class observation into the positive class is

\[
c_l^{+-} = \left( \pi_l^{(-1)} \right) C \pi_l^{(+1)}.
\]

Similarly, the cost of classifying a positive-class observation into the negative class is

\[
c_l^{+-} = \left( \pi_l^{(+1)} \right) C \pi_l^{(-1)}.
\]

The cost matrix for binary learner \( l \) is

\[
C_l = \begin{bmatrix}
0 & c_l^{+-} \\
\overline{c_l}^{+-} & 0
\end{bmatrix}.
\]

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify \texttt{Prior} and \texttt{Cost}, then the software adjusts the class prior probabilities as follows:

\[
\overline{\pi}_l^{-1} = \frac{c_l^{+-} \pi_l^{-1}}{c_l^{+-} \pi_l^{-1} + c^{+-} \pi_l^{+1}}
\]

\[
\overline{\pi}_l^{+1} = \frac{c_l^{+-} \pi_l^{+1}}{c_l^{+-} \pi_l^{-1} + c^{+-} \pi_l^{+1}}.
\]

**Random Coding Design Matrices**

For a given number of classes, for example, \( K \), the software generates random coding design matrices as follows.

1. The software generates one of the following:
   a. **Dense random** — The software assigns a 1 or -1 with equal probability to each element of the \( K \)-by-\( L_d \) coding design matrix, where \( L_d \approx \lceil 10 \log_2 K \rceil \).
**Sparse random** — The software assigns a 1 to each element of the $K$-by-$L_s$ coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s = \lceil 15 \log_2 K \rceil$.

2. If a column does not contain at least one 1 and at least one -1, then the software removes that column.

3. For distinct columns $u$ and $v$, if $u = v$ or $u = -v$, then the software removes $v$ from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$
\Delta(k_1,k_2) = 0.5 \sum_{l=1}^{L} |m_{k_1,l}||m_{k_2,l}| |m_{k_1,l} - m_{k_2,l}|,
$$

where $m_{k,l}$ is an element of coding design matrix $j$.

### Support Vector Storage

For linear, SVM binary learners, and for efficiency, fitcecoc empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. fitcecoc lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to fitcecoc. For example, enter:

```matlab
t = templateSVM('SaveSupportVectors','on')
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

### References

### Extended Capabilities

#### Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- Supported syntaxes are:
  - `Mdl = fitcecoc(X,Y)`
  - `Mdl = fitcecoc(___,Name,Value)`
- Options related to cross-validation and hyperparameter optimization are not supported. The supported name-value pair arguments are:
  - `'ClassNames'`
  - `'Cost'`
  - `'Coding'` — Default value is 'onevsall'.
  - `'Learners'` — Default value is 'linear'. Only linear and kernel binary classifiers are supported.
  - `'Prior'`
  - `'Verbose'` — Default value is 1.
  - `'Weights'`
- This additional name-value pair argument is specific to tall arrays:
  - `'NumConcurrent'` — A positive integer scalar specifying the number of binary learners that are trained concurrently by combining file I/O operations. The default value for 'NumConcurrent' is 1, which means fitcecoc trains the binary
learners sequentially. 'NumConcurrent' is most beneficial when the input arrays cannot fit into the distributed cluster memory. Otherwise, the input arrays can be cached and speedup is negligible.

If you run your code on Apache Spark, NumConcurrent is upper bounded by the memory available for communications. Check the 'spark.executor.memory' and 'spark.driver.memory' properties in your Apache Spark configuration. See parallel.cluster.Hadoop for more details. For more information on Apache Spark and other execution environments that control where your code runs, see “Extend Tall Arrays with Other Products” (MATLAB).

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true in one of these ways:

- Set the 'UseParallel',true name-value pair argument in the call to this function.
- To perform parallel hyperparameter optimization, use the 'HyperparameterOptions',struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

Introduced in R2014b
**fitcensemble**

Fit ensemble of learners for classification

**Syntax**

Mdl = fitcensemble(Tbl,ResponseVarName)
Mdl = fitcensemble(Tbl,formula)
Mdl = fitcensemble(Tbl,Y)
Mdl = fitcensemble(X,Y)
Mdl = fitcensemble(___,Name,Value)

**Description**

Mdl = fitcensemble(Tbl,ResponseVarName) returns the trained classification ensemble model object (Mdl) that contains the results of boosting 100 classification trees and the predictor and response data in the table Tbl. ResponseVarName is the name of the response variable in Tbl. By default, fitcensemble uses LogitBoost for binary classification and AdaBoostM2 for multiclass classification.

Mdl = fitcensemble(Tbl,formula) applies formula to fit the model to the predictor and response data in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl. For example, 'Y~X1+X2+X3' fits the response variable Tbl.Y as a function of the predictor variables Tbl.X1, Tbl.X2, and Tbl.X3.

Mdl = fitcensemble(Tbl,Y) treats all variables in the table Tbl as predictor variables. Y is the array of class labels that is not in Tbl.

Mdl = fitcensemble(X,Y) uses the predictor data in the matrix X and the array of class labels in Y.

Mdl = fitcensemble(___,Name,Value) uses additional options specified by one or more Name,Value pair arguments and any of the input arguments in the previous
syntaxes. For example, you can specify the number of learning cycles, the ensemble-aggregation method, or to implement 10-fold cross-validation.

**Examples**

**Train Classification Ensemble**

Create a predictive classification ensemble using all available predictor variables in the data. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the census1994 data set.

```matlab
load census1994
```

Train an ensemble of classification models using the entire data set and default options.

```matlab
Mdl1 = fitcensemble(adultdata,'salary')
Mdl1 =
    classreg.learning.classif.ClassificationEnsemble
        PredictorNames: {1x14 cell}
        ResponseName: 'salary'
        CategoricalPredictors: [2 4 6 7 8 9 10 14]
        ClassNames: [<=50K    >50K]
        ScoreTransform: 'none'
        NumObservations: 32561
        NumTrained: 100
        Method: 'LogitBoost'
        LearnerNames: {'Tree'}
        ReasonForTermination: 'Terminated normally after completing the requested number of training cycles.'
        FitInfo: [100x1 double]
        FitInfoDescription: {2x1 cell}
```

**Properties, Methods**

*Mdl* is a `ClassificationEnsemble` model. Some notable characteristics of *Mdl* are:

- Because two classes are represented in the data, LogitBoost is the ensemble-aggregation algorithm.
Because the ensemble-aggregation method is a boosting algorithm, classification trees that allow a maximum of 10 splits compose the ensemble.

One hundred trees compose the ensemble.

Use the classification ensemble to predict the labels of a random set of five observations from the data. Compare the predicted labels with their true values.

```matlab
rng(1) % For reproducibility
[pX,pIdx] = datasample(adultdata,5);
label = predict(Mdl1,pX);
table(label,adultdata.salary(pIdx),'VariableNames',{'Predicted','Truth'})
```

```
ans=5×2 table
    Predicted    Truth
      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
```

Train a new ensemble using age and education only.

```matlab
Mdl2 = fitcensemble(adultdata,'salary ~ age + education');
```

Compare the resubstitution losses between Mdl1 and Mdl2.

```matlab
rsLoss1 = resubLoss(Mdl1)
rsLoss1 = 0.1077
rsLoss2 = resubLoss(Mdl2)
rsLoss2 = 0.2037
```

The in-sample misclassification rate for the ensemble that uses all predictors is lower.

**Estimate Generalization Error of Boosting Ensemble**

Estimate the generalization error of ensemble of boosted classification trees.
Load the ionosphere data set.

load ionosphere

Cross-validate an ensemble of classification trees using AdaBoostM1 and 10-fold cross-validation. Specify that each tree should be split a maximum of five times using a decision tree template.

rng(5); % For reproducibility
t = templateTree('MaxNumSplits',5);
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t,'CrossVal','on');

Mdl is a ClassificationPartitionedEnsemble model.

Plot the cumulative, 10-fold cross-validated, misclassification rate. Display the estimated generalization error of the ensemble.

kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold Misclassification rate');
xlabel('Learning cycle');
estGenError = kflc(end)
estGenError = 0.0684

kfoldLoss returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves a misclassification rate of around 0.06 after accumulating about 50 weak learners. Then, the misclassification rate increase slightly as more weak learners enter the ensemble.
If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters, such as the maximum number of decision splits per tree and the number of learning cycles.

**Optimize Classification Ensemble**

This example shows how to optimize hyperparameters automatically using `fitcensemble`. The example uses the ionosphere data.

Load the data.

```matlab
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng default
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto',
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',
    'expected-improvement-plus'))
```

Properties, Methods
The optimization searched over the methods for binary classification, over `NumLearningCycles`, over the `LearnRate` for applicable methods, and over the tree learner `MinLeafSize`. The output is the ensemble classifier with the minimum estimated cross-validation loss.

**Create Predictive Ensemble Using Cross-Validation**

One way to create an ensemble of boosted classification trees that has satisfactory predictive performance is by tuning the decision tree-complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.
Load the `ionosphere` data set.

```matlab
load ionosphere
```

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most \( n - 1 \) splits. \( n \) is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.

2. Estimate the cross-validated misclassification rate of each ensemble.

3. For tree-complexity level \( j, j = 1 \ldots J \), compare the cumulative, cross-validated misclassification rate of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.

4. Choose the curve that achieves the minimal misclassification rate, and note the corresponding learning cycle and learning rate.

Cross-validate a deep classification tree and a stump. These classification trees serve as benchmarks.

```matlab
rng(1); % For reproducibility
MdlDeep = fitctree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1);
MdlStump = fitctree(X,Y,'MaxNumSplits',1,'CrossVal','on');
```

Cross-validate an ensemble of 150 boosted classification trees using 5-fold cross-validation. Using a tree template, vary the maximum number of splits using the values in the sequence \( \{3^0, 3^1, \ldots, 3^m\} \). \( m \) is such that \( 2^m \) is no greater than \( n - 1 \). For each variant, adjust the learning rate using each value in the set \{0.1, 0.25, 0.5, 1\}.

```matlab
n = size(X,1);
m = floor(log(n - 1)/log(3));
learnRate = [0.1 0.25 0.5 1];
umLR = numel(learnRate);
maxNumSplits = 3.^(0:m);
umMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);
for k = 1:numLR;
    for j = 1:numMNS;
        t = templateTree('MaxNumSplits',maxNumSplits(j));
        Mdl{j,k} = fitcensemble(X,Y,'NumLearningCycles',numTrees,...
```

' Learners', 
'KFold', 5, 'LearnRate', learnRate(k));

end;
end;

Estimate the cumulative, cross-validated misclassification rate for each ensemble and the classification trees serving as benchmarks.

kflAll = @(x)kfoldLoss(x, 'Mode', 'cumulative');
errorCell = cellfun(kflAll, Mdl, 'Uniform', false);
error = reshape(cell2mat(errorCell), [numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

Plot how the cross-validated misclassification rate behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2, 2, k);
    plot(squeeze(error(:, mnsPlot(k), :)), 'LineWidth', 2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim, [errorDeep errorDeep], '--b', 'LineWidth', 2);
    plot(h.XLim, [errorStump errorStump], '--r', 'LineWidth', 2);
    plot(h.XLim, min(min(error(:, mnsPlot(k), :))).*[1 1], '--k');
    h.YLim = [0 0.2];
    xlabel 'Number of trees';
    ylabel 'Cross-validated misclass. rate';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;

hL = legend([cellstr(num2str(learnRate, 'Learning Rate = %0.2f')); ...
    'Deep Tree'; 'Stump'; 'Min. misclass. rate']);
hL.Position(1) = 0.6;
Each curve contains a minimum cross-validated misclassification rate occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest misclassification rate overall.

```matlab
[minErr, minErrIdxLin] = min(error(:));
[idxNumTrees, idxMNS, idxLR] = ind2sub(size(error), minErrIdxLin);
fprintf('
Min. misclass. rate = %0.5f', minErr);
fprintf('
Optimal Parameter Values:
Num. Trees = %d', idxNumTrees);
fprintf('
MaxNumSplits = %d
Learning Rate = %0.2f
', maxNumSplits(idxMNS), learnRate(idxLR))
```
Min. misclass. rate = 0.05413
Optimal Parameter Values:
Num. Trees = 47
MaxNumSplits = 3
Learning Rate = 0.25

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS));
MdlFinal = fitcensemble(X,Y,'NumLearningCycles',idxNumTrees,...
   'Learners',tFinal,'LearnRate',learnRate(idxFR))

MdlFinal =

    classreg.learning.classif.ClassificationEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    NumTrained: 47
    Method: 'LogitBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training cycles.'
    FitInfo: [47×1 double]
    FitInfoDescription: {2×1 cell}

MdlFinal is a ClassificationEnsemble. To predict whether a radar return is good given predictor data, pass the predictor data and MdlFinal to predict.

**Input Arguments**

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain
one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If \( Tbl \) contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using \( \text{ResponseVarName} \).
- If \( Tbl \) contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using \( \text{formula} \).
- If \( Tbl \) does not contain the response variable, then specify the response data using \( Y \). The length of response variable and the number of rows of \( Tbl \) must be equal.

**Note** To save memory and execution time, supply \( X \) and \( Y \) instead of \( Tbl \).

Data Types: \text{table}

**ResponseVarName — Response variable name**

name of response variable in \( Tbl \)

Response variable name, specified as the name of the response variable in \( Tbl \).

You must specify \( \text{ResponseVarName} \) as a character vector or string scalar. For example, if \( Tbl.Y \) is the response variable, then specify \( \text{ResponseVarName} \) as ' \( Y \)'. Otherwise, \( \text{fitcensemble} \) treats all columns of \( Tbl \) as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the \( \text{ClassNames} \) name-value pair argument. Otherwise, \( \text{fitcensemble} \) determines the class order, and stores it in the \( \text{Mdl.ClassNames} \).

Data Types: \text{char} \mid \text{string}

**formula — Explanatory model of response and subset of predictor variables**

character vector \mid string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of ' \( Y \sim X1+X2+X3 \)'. In this form, \( Y \) represents the response variable, and \( X1, X2, \) and \( X3 \) represent the predictor variables. The variables must be variable names in \( Tbl \) (\( Tbl.Properties.VariableNames \)).
To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char | string

**X — Predictor data**
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

**Y — Response data**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each entry in Y is the response to or label for the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

You can specify the order of the classes using the ClassNames name-value pair argument. Otherwise, fitensemble determines the class order, and stores it in the Mdl.ClassNames.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'CrossVal','on','LearnRate',0.05 specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

**General Ensemble Options**

**Method — Ensemble-aggregation method**

<table>
<thead>

</tbody>
</table>

For binary classification problems, the default is 'LogitBoost'. Otherwise, the default is 'AdaBoostM2'.

Example: 'Method','Bag'

**NumLearningCycles — Number of ensemble learning cycles**

100 (default) | positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles*numel(Learners) learners.
- If you specify 'AllPredictorCombinations', then set Method to 'Subspace' and specify one learner only for Learners. With these settings, the software trains learners for all possible combinations of predictors taken NPredToSample at a time. Consequently, the software trains nchoosek(size(X,2),NPredToSample) leaners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-1837.

Example: 'NumLearningCycles',500

Data Types: single | double | char | string

**Learners — Weak learners to use in ensemble**

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell vector of weak-learner template objects.
### Weak Learner

<table>
<thead>
<tr>
<th>Weak Learner</th>
<th>Weak-Learner Name</th>
<th>Template Object Creation Function</th>
<th>Method Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discriminant analysis</td>
<td>'discriminant'</td>
<td>templateDiscriminant</td>
<td>Recommended for 'Subspace'</td>
</tr>
<tr>
<td>k nearest neighbors</td>
<td>'knn'</td>
<td>templateKNN</td>
<td>For 'Subspace' only</td>
</tr>
<tr>
<td>Decision tree</td>
<td>'tree'</td>
<td>templateTree</td>
<td>All methods except 'Subspace'</td>
</tr>
</tbody>
</table>

The defaults are:

- 'knn' if 'Method' is 'Subspace'
- 'tree' if 'Method' is 'Bag'
- `templateTree('MaxNumSplits',10)` if 'Method' is any boosting method

`fitcensemble` sets the maximum number of splits for decision tree weak learners to 10 when both of these conditions occur:

- You do not set a value for the 'MaxNumSplits' property of the decision tree weak learners.
- You use a boosting algorithm as the ensemble-aggregation method for `fitcensemble`.

For example, if you specify 'Learners', `templateTree()` and 'Method','AdaBoostM1', then `fitcensemble` sets the maximum number of splits of the decision tree weak learners to 10.

Otherwise, `fitcensemble` defers to the corresponding template object to choose any required default values for the 'Learners' name-value pair argument.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 32-1837.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where t1 and t2 are classification tree templates.

**NPrint — Printout frequency**

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.
To track the number of weak learners or folds that fitensemble trained so far, specify a positive integer. That is, if you specify the positive integer $m$:

- Without also specifying any cross-validation option (for example, CrossVal), then fitensemble displays a message to the command line every time it completes training $m$ weak learners.
- And a cross-validation option, then fitensemble displays a message to the command line every time it finishes training $m$ folds.

If you specify 'off', then fitensemble does not display a message when it completes training weak learners.

**Tip** When training an ensemble of many weak learners on a large data set, specify a positive integer for NPrint.

Example: 'NPrint',5

Data Types: single | double | char | string

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>String array or cell array of character</td>
<td>Each element in the array is the name of a predictor variable. The names</td>
</tr>
<tr>
<td>vectors</td>
<td>must match the entries in <code>PredictorNames</code>.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

Specification of `CategoricalPredictors` is appropriate if:

- 'Learners' is 'tree'.
- 'Learners' is 'knn' when all predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcensemble` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcensemble` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is {'x1','x2',...}.
- If you supply `Tbl`, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitcensemble` uses only the predictor variables in `PredictorNames` and the response variable in training.
- **PredictorNames** must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
- By default, **PredictorNames** contains the names of all predictor variables.
- It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**ResponseName** — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply `Y`, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**Cross-Validation Options**

**CrossVal** — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: 'Crossval','on'
**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using 
\[
\text{cvp} = \text{cvpartition(500,'KFold',5)}
\]
Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout — Fraction of data for holdout validation**

Scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', P, then the software completes these steps:

1. Randomly select and reserve P*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps.

1. Randomly partition the data into k sets.
2 For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.

3 Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1 Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.

2 Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

Other Classification Options

ClassNames — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.
Use **ClassNames** to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use **ClassNames** to specify the order of the dimensions of **Cost** or the column order of classification scores returned by **predict**.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in **Y** is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for **ClassNames** is the set of all distinct class names in **Y**.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Misclassification cost**

Square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of **Cost** and a square matrix or structure. If you specify:

- The square matrix **Cost**, then **Cost(i,j)** is the cost of classifying a point into class **j** if its true class is **i**. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of **Cost**, also specify the **ClassNames** name-value pair argument.
- The structure **S**, then it must have two fields:
  - **S.ClassNames**, which contains the class names as a variable of the same data type as **Y**
  - **S.ClassificationCosts**, which contains the cost matrix with rows and columns ordered as in **S.ClassNames**

The default is ones**(K)** - eye**(K)**, where **K** is the number of distinct classes.

**Note** fitcensemble uses **Cost** to adjust the prior class probabilities specified in **Prior**. Then, fitcensemble uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost',[0 1 2; 1 0 2; 2 2 0]
Data Types: double | single | struct

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to $1/K$, where $K$ is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>
| structure array    | A structure S with two fields:
  - S.ClassNames contains the class names as a variable of the same type as Y.
  - S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1. |

fitcensemble normalizes the prior probabilities in Prior to sum to 1.

Example: struct({'ClassNames',
{'setosa','versicolor','virginica'}},'ClassProbs',1:3)

Data Types: char | string | double | single | struct

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...
Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'             | -1 for \( x < 0 \)  
|                    | 0 for \( x = 0 \)  
|                    | 1 for \( x > 0 \)                                                          |
| 'symmetric'        | \( 2x - 1 \)                                                               |
| 'symmetricismax'   | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to \(-1\) |
| 'symmetriclogit'   | \( \frac{2}{1 + e^{-x}} - 1 \)                                             |

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a
character vector or string scalar. For example, if the weights vector \( W \) is stored as \( Tbl.W \), then specify it as 'W'. Otherwise, the software treats all columns of \( Tbl \), including \( W \), as predictors or the response when training the model.

The software normalizes \( Weights \) to sum up to the value of the prior probability in the respective class.

By default, \( Weights \) is \( \text{ones}(n,1) \), where \( n \) is the number of observations in \( X \) or \( Tbl \).

Data Types: double | single | char | string

**Sampling Options for Boosting Methods and Bagging**

\( F\text{Resample} \) — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample', 0.75

Data Types: single | double

\( \text{Replace} \) — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace', 'off'

\( \text{Resample} \) — Flag indicating to resample

'off' | 'on'
Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is any boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off' specifies to reweight observations at every learning iteration. This setting is the default.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

**AdaBoostM1, AdaBoostM2, LogitBoost, and GentleBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**RUSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double
**RatioToSmallest — Sampling proportion with respect to lowest-represented class**

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are $K$ classes in the training data and the lowest-represented class has $m$ observations in the training data.

- If you specify the positive numeric scalar $s$, then fitcensemble samples $s \times m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2388.
- If you specify the numeric vector $[s_1, s_2, \ldots, s_K]$, then fitcensemble samples $s_i \times m$ observations from class $i$, $i = 1, \ldots, K$. The elements of RatioToSmallest correspond to the order of the class names specified using ClassNames (see “Tips” on page 32-2386).

The default value is $\text{ones}(K,1)$, which specifies to sample $m$ observations from each class.

Example: 'RatioToSmallest',[2,1]

Data Types: single | double

**LPBoost and TotalBoost Method Options**

**MarginPrecision — Margin precision to control convergence speed**

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of 'MarginPrecision' and a numeric scalar in the interval [0,1]. MarginPrecision affects the number of boosting iterations required for convergence.

**Tip** To train an ensemble using many learners, specify a small value for MarginPrecision. For training using a few learners, specify a large value.

Example: 'MarginPrecision',0.5

Data Types: single | double
RobustBoost Method Options

**RobustErrorGoal — Target classification error**

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of 'RobustErrorGoal' and a nonnegative numeric scalar. The upper bound on possible values depends on the values of RobustMarginSigma and RobustMaxMargin. However, the upper bound cannot exceed 1.

**Tip** For a particular training set, usually there is an optimal range for RobustErrorGoal. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: 'RobustErrorGoal',0.05
Data Types: single | double

**RobustMarginSigma — Classification margin distribution spread**

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar. Before specifying RobustMarginSigma, consult the literature on RobustBoost, for example, [19].

Example: 'RobustMarginSigma',0.5
Data Types: single | double

**RobustMaxMargin — Maximal classification margin**

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of 'RobustMaxMargin' and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below RobustMaxMargin.

Example: 'RobustMaxMargin',1
Data Types: single | double
Random Subspace Method Options

**NPredToSample — Number of predictors to sample**

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of 'NPredToSample' and a positive integer in the interval 1,...,p, where p is the number of predictor variables (size(X,2) or size(Tbl, 2)).

Data Types: single | double

Hyperparameter Optimization

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Method','NumLearningCycles','LearnRate'} along with the default parameters for the specified Learners:
  - Learners = 'tree' (default) — {'MinLeafSize'}
  - Learners = 'discriminant' — {'Delta','Gamma'}
  - Learners = 'knn' — {'Distance','NumNeighbors'}

**Note** For hyperparameter optimization, Learners must be a single argument, not a string array or cell array.

- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitcensemble by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.
Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcensemble are:

- **Method** — Depends on the number of classes.
  - Two classes — Eligible methods are 'Bag', 'GentleBoost', 'LogitBoost', 'AdaBoostM1', and 'RUSBoost'.
  - Three or more classes — Eligible methods are 'Bag', 'AdaBoostM2', and 'RUSBoost'.
- **NumLearningCycles** — fitcensemble searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — fitcensemble searches among positive reals, by default log-scaled with range [1e-3,1].
- The eligible hyperparameters for the chosen Learners:

<table>
<thead>
<tr>

</tbody>
</table>

Alternatively, use `hyperparameters` with your chosen `Learners`.

```matlab
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcensemble', meas, species, 'Tree');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcensemble', meas, species, 'Tree');
params(4).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the
'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Classification Ensemble” on page 32-1805.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>

</table>
Field Name | Values | Default  
--- | --- | ---  
Repartition | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false  

Use no more than one of the following three field names.

| Field Name | Values | Default  
--- | --- | ---  
CVPartition | A cvpartition object, as created by cvpartition. | 'Kfold',5 if you do not specify any cross-validation field  
Holdout | A scalar in the range (0,1) representing the holdout fraction. |  
Kfold | An integer greater than 1. |  

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct  

### Output Arguments

**Md1 — Trained classification ensemble model**

| Model Object | Specify Any Cross-Validation Options? | Method Setting | Resample Setting  
--- | --- | --- | ---  
ClassificationBaggedEnsemble | No | 'Bag' | 'on'  
ClassificationEnsemble |  
ClassificationPartitionedEnsemble |  

Trained ensemble model, returned as one of the model objects in this table.
The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

### Tips

- **NumLearningCycles** can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

- If the ensemble-aggregation method (Method) is 'bag' and:
  - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
  - The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.
For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using Cost or a less skewed prior probability vector using Prior.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the ClassNames name-value pair argument.

- To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for ClassNames. For example, suppose the response variable (Y) is a cell array of labels. This code specifies the class order in the variable classNames.

  ```matlab
  Ycat = categorical(Y);
 classNames = categories(Ycat)
  ```

  categorical assigns <undefined> to unclassified observations and categories excludes <undefined> from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to ClassNames. Following from the previous example, this code specifies the class order from lowest- to most-represented in classNamesLH.

  ```matlab
  Ycat = categorical(Y);
  classNames = categories(Ycat);
  freq = countcats(Ycat);
  [~,idx] = sort(freq);
  classNamesLH = classNames(idx);
  ```

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.
Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-50.
- If you specify Method to be a boosting algorithm and Learners to be decision trees, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using templateTree.
- fitcensemble generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble-aggregation method (Method), the name-value pair argument RatioToSmallest specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: A and B. A have 100 observations and B have 10 observations. and that the lowest-represented class has m observations in the training data.
  - If you set 'RatioToSmallest',2, then s*m = 2*10 = 20. Consequently, fitcensemble trains every learner using 20 observations from class A and 20 observations from class B. If you set 'RatioToSmallest',[2 2], then you obtain the same result.
  - If you set 'RatioToSmallest',[2,1], then s1*m = 2*10 = 20 and s2*m = 1*10 = 10. Consequently, fitcensemble trains every learner using 20 observations from class A and 10 observations from class B.

fitcknn

Fit k-nearest neighbor classifier

Syntax

Mdl = fitcknn(Tbl,ResponseVarName)
Mdl = fitcknn(Tbl,formula)
Mdl = fitcknn(Tbl,Y)
Mdl = fitcknn(X,Y)
Mdl = fitcknn(___,Name,Value)

Description

Mdl = fitcknn(Tbl,ResponseVarName) returns a k-nearest neighbor classification model based on the input variables (also known as predictors, features, or attributes) in the table Tbl and output (response) Tbl.ResponseVarName.

Mdl = fitcknn(Tbl,formula) returns a k-nearest neighbor classification model based on the input variables in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl.

Mdl = fitcknn(Tbl,Y) returns a k-nearest neighbor classification model based on the predictor variables in the table Tbl and response array Y.

Mdl = fitcknn(X,Y) returns a k-nearest neighbor classification model based on the predictor data X and response Y.

Mdl = fitcknn(___,Name,Value) fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples
Train $k$-Nearest Neighbor Classifier

Train a $k$-nearest neighbor classifier for Fisher's iris data, where $k$, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```matlab
load fisheriris
X = meas;
Y = species;
```

$X$ is a numeric matrix that contains four petal measurements for 150 irises. $Y$ is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```matlab
Mdl = ClassificationKNN
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    Distance: 'euclidean'
    NumNeighbors: 5
```

Properties, Methods

$Mdl$ is a trained ClassificationKNN classifier, and some of its properties appear in the Command Window.

To access the properties of $Mdl$, use dot notation.

```matlab
Mdl.ClassNames
ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```
Mdl.Prior

ans = 1x3

0.3333 0.3333 0.3333

Mdl.Prior contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in fitcknn. The order of the class prior probabilities corresponds to the order of the classes in Mdl.ClassNames. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

Mdl.Prior = [0.5 0.2 0.3];

You can pass Mdl to predict to label new measurements or crossval to cross-validate the classifier.

**Train a k-Nearest Neighbor Classifier Using the Minkowski Metric**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

Mdl is a ClassificationKNN classifier.
You can examine the properties of Mdl by double-clicking Mdl in the Workspace window. This opens the Variable Editor.
**Train a k-Nearest Neighbor Classifier Using a Custom Distance Metric**

Train a $k$-nearest neighbor classifier using the chi-square distance.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between $j$-dimensional points $x$ and $z$ is

$$
\chi(x, z) = \sqrt{\sum_{j=1}^{J} w_j (x_j - z_j)^2},
$$

where $w_j$ is a weight associated with dimension $j$.

Specify the chi-square distance function. The distance function must:

- Take one row of $X$, e.g., $x$, and the matrix $Z$.
- Compare $x$ to each row of $Z$.
- Return a vector $D$ of length $n_z$, where $n_z$ is the number of rows of $Z$. Each element of $D$ is the distance between the observation corresponding to $x$ and the observations corresponding to each row of $Z$.

```matlab
chiSqrDist = @(x,Z,wt)sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```matlab
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

$KNNMdl$ is a ClassificationKNN classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)

classError = 0.0600

CVKNNMdl is a ClassificationPartitionedModel classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

w2 = [0.2; 0.2; 0.3; 0.3];
CVKNNMdl2 = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w2),...
    'NumNeighbors',k,'KFold',10,'Standardize',1);
classError2 = kfoldLoss(CVKNNMdl2)

classError2 = 0.0400

The second weighting scheme yields a classifier that has better out-of-sample performance.

Optimize Fitted KNN Classifier

This example shows how to optimize hyperparameters automatically using fitcknn. The example uses the Fisher iris data.

Load the data.
load fisheriris
X = meas;
Y = species;

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

rng(1)
Md1 = fitcknn(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))

Properties, Methods

### Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.
If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

**ResponseVarName — Response variable name**

Name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

**formula — Explanatory model of response and subset of predictor variables**

Character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Data Types: `categorical` | `char` | `string`
Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of \(Y\) represents the classification of the corresponding row of \(X\).

The software considers NaN, '' (empty character vector), '"' (empty string), <missing>, and <undefined> values in \(Y\) to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: categorical | char | string | logical | single | double | cell

\(X\) — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of \(Y\) and the number of rows of \(X\) must be equal.

To specify the names of the predictors in the order of their appearance in \(X\), use the \texttt{PredictorNames} name-value pair argument.

Data Types: double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

\textbf{Note} You cannot use any cross-validation name-value pair argument along with the \texttt{'OptimizeHyperparameters'} name-value pair argument. You can modify the cross-validation for \texttt{'OptimizeHyperparameters'} only by using the \texttt{'HyperparameterOptimizationOptions'} name-value pair argument.

Example: 'NumNeighbors', 3,'NSMethod','exhaustive','Distance','minkowski' specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.
**Model Parameters**

**BreakTies — Tie-breaking algorithm**

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of 'BreakTies' and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

Example: 'BreakTies','nearest'

**BucketSize — Maximum data points in node**

50 (default) | positive integer value

Maximum number of data points in the leaf node of the kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when `NSMethod` is 'kdtree'.

Example: 'BucketSize',40

Data Types: `single` | `double`

**CategoricalPredictors — Categorical predictor flag**

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set `CategoricalPredictors` to 'all', the default `Distance` is 'hamming'.

Example: 'CategoricalPredictors','all'
**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. *ClassNames* must have the same data type as *Y*.

If *ClassNames* is a character array, then each element must correspond to one row of the array.

Use *ClassNames* to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use *ClassNames* to specify the order of the dimensions of *Cost* or the column order of classification scores returned by *predict*.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in *Y* is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for *ClassNames* is the set of all distinct class names in *Y*.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where *Cost(i,j)* is the cost of classifying a point into class *j* if its true class is *i* (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of *Cost*, additionally specify the *ClassNames* name-value pair argument.
- Structure *S* having two fields: *S.ClassNames* containing the group names as a variable of the same type as *Y*, and *S.ClassificationCosts* containing the cost matrix.

The default is *Cost(i,j)=1* if *i~=j*, and *Cost(i,j)=0* if *i=j*. 
Data Types: single | double | struct

**Cov — Covariance matrix**
nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

**IncludeTies — Tie inclusion flag**
false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: logical

**NSMethod — Nearest neighbor search method**
'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a kd-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebychev'
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point xnew, the software computes the distance values from all points in X to xnew to find nearest neighbors.
The default is 'kdtree' when \(X\) has 10 or fewer columns, \(X\) is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod','exhaustive'

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply \(X\) and \(Y\), then you can use 'PredictorNames' to give the predictor variables in \(X\) names.
  - The order of the names in PredictorNames must correspond to the column order of \(X\). That is, PredictorNames{1} is the name of \(X(:,1)\), PredictorNames{2} is the name of \(X(:,2)\), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply \(Tbl\), then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcknn uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in $Y$.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to $1/K$, where $K$ is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to $Mdl.ClassNames$ or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure $S$ with two fields:</td>
</tr>
<tr>
<td></td>
<td>• $S.ClassNames$ contains the class names as a variable of the same type as $Y$.</td>
</tr>
<tr>
<td></td>
<td>• $S.ClassProbs$ contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply $Y$, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string
Scale — Distance scale
nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

ScoreTransform — Score transformation
'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for $x &lt; 0$</td>
</tr>
<tr>
<td></td>
<td>0 for $x = 0$</td>
</tr>
<tr>
<td></td>
<td>1 for $x &gt; 0$</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>$2x - 1$</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>$2/(1 + e^{-x}) - 1$</td>
</tr>
</tbody>
</table>
For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

Weights — Observation weights
numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

Cross Validation

CrossVal — Cross-validation flag
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.
Example: 'CrossVal','on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', $p$, then the software completes these steps:

1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', $k$, then the software completes these steps.
1 Randomly partition the data into \( k \) sets.

2 For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.

3 Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1 Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.

2 Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

**Hyperparameter Optimization**

**Distance — Distance metric**

`'cityblock'` | `'chebychev'` | `'correlation'` | `'cosine'` | `'euclidean'` | `'hamming'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see `NSMethod`).
### NSMethod and Distance Metric Names

<table>
<thead>
<tr>
<th>NSMethod</th>
<th>Distance Metric Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>exhaustive</td>
<td>Any distance metric of ExhaustiveSearcher</td>
</tr>
<tr>
<td>kdtree</td>
<td>'cityblock', 'chebychev', 'euclidean', or 'minkowski'</td>
</tr>
</tbody>
</table>

This table includes valid distance metrics of ExhaustiveSearcher.

<table>
<thead>
<tr>
<th>Distance Metric Names</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix $C$. The default value of $C$ is the sample covariance matrix of $X$, as computed by nancov($X$). To specify a different value for $C$, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between $X$ and a query point is scaled, meaning divided by a scale value $S$. The default value of $S$ is the standard deviation computed from $X$, $S = \text{nansd}(X)$. To specify another value for $S$, use the Scale name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>
Distance Metric Names | Description
--- | ---
@distfun | Distance function handle. distfun has the form

```matlab
function D2 = distfun(ZI,ZJ)
% calculation of distance
...
```
where

- ZI is a 1-by-N vector containing one row of X or Y.
- ZJ is an M2-by-N matrix containing multiple rows of X or Y.
- D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance','minkowski'

Data Types: char | string | function_handle

**DistanceWeight — Distance weighting function**

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'equal'</td>
<td>No weighting</td>
</tr>
<tr>
<td>'inverse'</td>
<td>Weight is 1/distance</td>
</tr>
<tr>
<td>'squaredinverse'</td>
<td>Weight is 1/distance(^2)</td>
</tr>
<tr>
<td>@fcn</td>
<td>fcn is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).</td>
</tr>
</tbody>
</table>

Example: 'DistanceWeight','inverse'
Data Types: char | string | function_handle

**Exponent — Minkowski distance exponent**
2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

**NumNeighbors — Number of nearest neighbors to find**
1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3

Data Types: single | double

**Standardize — Flag to standardize predictors**
false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize',1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize',true

Data Types: logical
**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Distance','NumNeighbors'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitcknn by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcknn are:

- **Distance** — fitcknn searches among 'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'.
- **DistanceWeight** — fitcknn searches among 'equal', 'inverse', and 'squaredinverse'.
- **Exponent** — fitcknn searches among positive real values, by default in the range [0.5,3].
- **NumNeighbors** — fitcknn searches among positive integer values, by default log-scaled in the range [1, max(2, round(NumObservations/2))].
- **Standardize** — fitcknn searches among the values 'true' and 'false'.

32-1866
Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcknn',meas,species);
params(1).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Fitted KNN Classifier” on page 32-1847.

Example: 'auto'

**HyperparameterOptimizationOptions — Options for optimization**

structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| Optimizer             | 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt.  
|                       | 'gridsearch' — Use grid search with NumGridDivisions values per dimension.  
|                       | 'randomsearch' — Search at random among MaxObjectiveEvaluations points.  
|                       | 'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command sortrows(Mdl.HyperparameterOptimizationResults).  
| AcquisitionFunctionName | 'expected-improvement-per-second-plus'  
|                       | 'expected-improvement'  
|                       | 'expected-improvement-plus'  
|                       | 'expected-improvement-per-second'  
|                       | 'lower-confidence-bound'  
|                       | 'probability-of-improvement'  
|                       | For details, see the bayesopt AcquisitionFunctionName name-value pair argument, or “Acquisition Function Types” on page 10-4.  
| MaxObjectiveEvaluations | Maximum number of objective function evaluations.  
|                       | 30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'  

<table>

</table>

Example:

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

Md1 — Trained k-nearest neighbor classification model
ClassificationKNN model object | ClassificationPartitionedModel cross-validated model object

Trained k-nearest neighbor classification model, returned as a ClassificationKNN model object or a ClassificationPartitionedModel cross-validated model object.
If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationKNN model object.

To reference properties of Mdl, use dot notation. For example, to display the distance metric at the Command Window, enter Mdl.Distance.

**Definitions**

**Prediction**

ClassificationKNN predicts the classification of a point \( x_{\text{new}} \) using a procedure equivalent to this:

1. Find the NumNeighbors points in the training set \( X \) that are nearest to \( x_{\text{new}} \).
2. Find the NumNeighbors response values \( Y \) to those nearest points.
3. Assign the classification label \( y_{\text{new}} \) that has the largest posterior probability among the values in \( Y \).

For details, see “Posterior Probability” on page 32-4943 in the predict documentation.

**Tips**

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

- NaNs or <undefined>s indicate missing observations. The following describes the behavior of fitcknn when the data set or weights contain missing observations.
  
  - If any value of \( Y \) or any weight is missing, then fitcknn removes those values from \( Y \), the weights, and the corresponding rows of \( X \) from the data. The software renormalizes the weights to sum to 1.
• If you specify to standardize predictors ('Standardize', 1) or the standardized Euclidean distance ('Distance', 'seuclidean') without a scale, then fitcknn removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements nanmean and nanstd on each predictor.

• If you specify the Mahalanobis distance ('Distance', 'mahalanobis') without its covariance matrix, then fitcknn removes rows of X that contain at least one missing value. In other words, the software implements nancov on the predictor matrix X.

• Suppose that you set 'Standardize', 1.

• If you also specify Prior or Weights, then the software takes the observation weights into account. Specifically, the weighted mean of predictor \( j \) is

\[
\bar{x}_j = \sum_{B_j} w_k x_{jk}
\]

and the weighted standard deviation is

\[
s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j),
\]

where \( B_j \) is the set of indices \( k \) for which \( x_{jk} \) and \( w_k \) are not missing.

• If you also set 'Distance', 'mahalanobis' or 'Distance', 'seuclidean', then you cannot specify Scale or Cov. Instead, the software:

1. Computes the means and standard deviations of each predictor
2. Standardizes the data using the results of step 1
3. Computes the distance parameter values using their respective default.

• If you specify Scale and either of Prior or Weights, then the software scales observed distances by the weighted standard deviations.

• If you specify Cov and either of Prior or Weights, then the software applies the weighted covariance matrix to the distances. In other words,
\[
\text{Cov} = \frac{\sum_{B} w_j}{\left(\sum_{B} w_j\right)^2} \sum_{B} w_j (x_j - \bar{x}) (x_j - \bar{x}),
\]

where \(B\) is the set of indices \(j\) for which the observation \(x_j\) does not have any missing values and \(w_j\) is not missing.

**Alternatives**

Although \texttt{fitcknn} can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using \texttt{fitcecoc}.

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

“Modify KNN Classifier” on page 18-38
“Classification Using Nearest Neighbors” on page 18-16

Introduced in R2014a
**fitclinear**

Fit linear classification model to high-dimensional data

**fitclinear** trains linear classification models for two-class (binary) learning with high-dimensional, full or sparse predictor data. Available linear classification models include regularized support vector machines (SVM) and logistic regression models. **fitclinear** minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

A high-dimensional data set includes many predictor variables. Although such a data set can consume a significant fraction of memory, it must fit in the MATLAB Workspace. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 32-1916.

To train a linear classification model for multiclass learning by combining SVM or logistic regression binary classifiers using error-correcting output codes, see **fitcecoc**.

**Syntax**

```matlab
Mdl = fitclinear(X,Y)
Mdl = fitclinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitclinear(__)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(__)
```

**Description**

**Mdl = fitclinear(X,Y)** returns a trained linear classification model object that contains the results of fitting a binary support vector machine to the predictors X and class labels Y.

**Mdl = fitclinear(X,Y,Name,Value)** returns a trained linear classification model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that the columns of the predictor matrix correspond to observations, implement logistic regression, or specify to cross-validate. It is good practice to cross-validate using the `Kfold Name,Value` pair argument. The cross-validation results determine how well the model generalizes.
[Mdl,FitInfo] = fitclinear(___) also returns optimization details using any of the previous syntaxes. You cannot request FitInfo for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(___) also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair.

**Examples**

**Train Linear Classification Model**

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

rng(1); % For reproducibility
[Mdl,FitInfo] = fitclinear(X,Ystats)

Mdl =  
ClassificationLinear  
    ResponseName: 'Y'  
    ClassNames: [0 1]  
    ScoreTransform: 'none'  
    Beta: [34023x1 double]  
    Bias: -1.0059
Properties, Methods

FitInfo = struct with fields:
  - Lambda: 3.1674e-05
  - Objective: 5.3783e-04
  - PassLimit: 10
  - NumPasses: 10
  - BatchLimit: []
  - NumIterations: 238561
  - GradientNorm: NaN
  - GradientTolerance: 0
  - RelativeChangeInBeta: 0.0562
  - BetaTolerance: 1.0000e-04
  - DeltaGradient: 1.4582
  - DeltaGradientTolerance: 1
  - TerminationCode: 0
  - TerminationStatus: {'Iteration limit exceeded.'}
  - Alpha: [31572x1 double]
  - History: []
  - FitTime: 0.1901
  - Solver: {'dual'}

Mdl is a ClassificationLinear model. You can pass Mdl and the training or new data to loss to inspect the in-sample classification error. Or, you can pass Mdl and new predictor data to predict to predict class labels for new observations.

FitInfo is a structure array containing, among other things, the termination status (TerminationStatus) and how long the solver took to fit the model to the data (FitTime). It is good practice to use FitInfo to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like DeltaGradient.
Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

Lambda = logspace(-6,-0.5,11);

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

X = X';
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
Properties, Methods

numCLModels = numel(CVMdl.Trained)
numCLModels = 5

CVMdl is a ClassificationPartitionedLinear model. Because fitclinear implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models that the software trains on each fold.

Display the first trained linear classification model.

Mdl1 = CVMdl.Trained{1}

Mdl1 = ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023×11 double]
    Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.0071 0.0251 0.0891 0.3162]
    Learner: 'logistic'

Properties, Methods

Mdl1 is a ClassificationLinear model object. fitclinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

ce = kfoldLoss(CVMdl);

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the
entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```matlab
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...'
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...'
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```matlab
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```
Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

idxFinal = 7;

Select the model from Mdl with the chosen regularization strength.

MdlFinal = selectModels(Mdl,idxFinal);

MdlFinal is a ClassificationLinear model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to predict.
Optimize Linear Classifier

This example shows how to minimize the cross-validation error in a linear classifier using \texttt{fitclinear}. The example uses the NLP data set.

Load the NLP data set.

\begin{verbatim}
load nlpdata
\end{verbatim}

\(X\) is a sparse matrix of predictor data, and \(Y\) is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. Identify the relevant labels.

\begin{verbatim}
X = X';
Ystats = Y == 'stats';
\end{verbatim}

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

\begin{verbatim}
rng default
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns','Solver','sparsa',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
\end{verbatim}

Mdl =
    ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023×1 double]
    Bias: -10.1723
    Lambda: 7.4324e-08
    Learner: 'logistic'

Properties, Methods
Min objective vs. Number of function evaluations

- Min observed objective
- Estimated min objective
Input Arguments

X — Predictor data
defull matrix | sparse matrix

Predictor data, specified as an $n$-by-$p$ full or sparse matrix.

The length of $Y$ and the number of observations in $X$ must be equal.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in optimization-execution time.

Data Types: `single` | `double`

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the classification model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- **fitclinear** only supports binary classification. Either $Y$ must contain exactly two distinct classes, or you must specify two classes for training using the `'ClassNames'` name-value pair argument. For multiclass learning, see **fitcecoc**.
- If $Y$ is a character array, then each element must correspond to one row of the array.
- The length of $Y$ and the number of observations in $X$ must be equal.
- It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `char` | `string` | `cell` | `categorical` | `logical` | `single` | `double`

**Note** **fitclinear** removes missing observations, that is, observations with any of these characteristics:

- NaN, empty character vector (``), empty string (""), `<missing>`, and `<undefined>` elements in the response ($Y$ or `ValidationData{2}`)
• At least one NaN value in a predictor observation (row in X or ValidationData{1})
• NaN value or 0 weight (Weights or ValidationData{3})

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example:
'ObservationsIn','columns','Learner','logistic','CrossVal','on'
specifies that the columns of the predictor matrix corresponds to observations, to implement logistic regression, to implement 10-fold cross-validation.

**Linear Classification Options**

**Lambda — Regularization term strength**

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

• For 'auto', Lambda = 1/n.
  • If you specify a cross-validation, name-value pair argument (e.g., CrossVal), then n is the number of in-fold observations.
  • Otherwise, n is the training sample size.
  • For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in Lambda in ascending order.
If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-1916 for the next optimization iteration. Otherwise, the software uses warm starts.

If Regularization is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in Lambda.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda',10.^(-(10:-2:2))

Data Types: char | string | double | single

**Learner — Linear classification model type**

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In this table, \( f(x) = x\beta + b \).

- \( \beta \) is a vector of \( p \) coefficients.
- \( x \) is an observation from \( p \) predictor variables.
- \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Algorithm</th>
<th>Response Range</th>
<th>Loss Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'svm'</td>
<td>Support vector machine</td>
<td>( y \in {-1,1}; 1 ) for the positive class and -1 otherwise</td>
<td>Hinge: ( \ell[y, f(x)] = \max[0,1 - yf(x)] )</td>
</tr>
<tr>
<td>'logistic'</td>
<td>Logistic regression</td>
<td>Same as 'svm'</td>
<td>Deviance (logistic): ( \ell[y, f(x)] = \log[1 + \exp[-yf(x)]] )</td>
</tr>
</tbody>
</table>

Example: 'Learner', 'logistic'

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

32-1889
Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in optimization-execution time.

Regularization — Complexity penalty type
'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'lasso'</td>
<td>Lasso (L1) penalty: ( \lambda \sum_{j=1}^{p}</td>
</tr>
<tr>
<td>'ridge'</td>
<td>Ridge (L2) penalty: ( \frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2 )</td>
</tr>
</tbody>
</table>

To specify the regularization term strength, which is \( \lambda \) in the expressions, use Lambda.

The software excludes the bias term (\( \beta_0 \)) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

Tip
- For predictor variable selection, specify 'lasso'.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization','lasso'
**Solver — Objective function minimization technique**

'Sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sgd'</td>
<td>Stochastic gradient descent (SGD) [5][3]</td>
<td></td>
</tr>
<tr>
<td>'asgd'</td>
<td>Average stochastic gradient descent (ASGD) [8]</td>
<td></td>
</tr>
<tr>
<td>'dual'</td>
<td>Dual SGD for SVM [2][7]</td>
<td>Regularization must be 'ridge' and Learner must be 'svm'.</td>
</tr>
<tr>
<td>'bfgs'</td>
<td>Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]</td>
<td>Inefficient if X is very high-dimensional.</td>
</tr>
<tr>
<td>'lbfgs'</td>
<td>Limited-memory BFGS (LBFGS) [4]</td>
<td>Regularization must be 'ridge'.</td>
</tr>
<tr>
<td>'sparsa'</td>
<td>Sparse Reconstruction by Separable Approximation (SpaRSA) [6]</td>
<td>Regularization must be 'lasso'.</td>
</tr>
</tbody>
</table>

If you specify:

- A ridge penalty (see Regularization) and X contains 100 or fewer predictor variables, then the default solver is 'bfgs'.
- An SVM model (see Learner), a ridge penalty, and X contains more than 100 predictor variables, then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each Lambda.
For more details on which solver to choose, see “Tips” on page 32-1917.

Example: 'Solver', {'sgd', 'lbfgs'}

**Beta — Initial linear coefficient estimates**

Zeroes matrix ($p, 1$) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates ($\beta$), specified as the comma-separated pair consisting of 'Beta' and a $p$-dimensional numeric vector or a $p$-by-$L$ numeric matrix. $p$ is the number of predictor variables in $X$ and $L$ is the number of regularization-strength values (for more details, see Lambda).

- **Beta**

  - If you specify a $p$-dimensional vector, then the software optimizes the objective function $L$ times using this process.
    
    1. The software optimizes using Beta as the initial value and the minimum value of Lambda as the regularization strength.
    
    2. The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-1916, and the next smallest value in Lambda as the regularization strength.
    
    3. The software implements step 2 until it exhausts all values in Lambda.

- If you specify a $p$-by-$L$ matrix, then the software optimizes the objective function $L$ times. At iteration $j$, the software uses Beta(:, $j$) as the initial value and, after it sorts Lambda in ascending order, uses Lambda($j$) as the regularization strength.

If you set 'Solver', 'dual', then the software ignores Beta.

Data Types: `single` | `double`

**Bias — Initial intercept estimate**

Numeric scalar | numeric matrix

Initial intercept estimate ($b$), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an $L$-dimensional numeric vector. $L$ is the number of regularization-strength values (for more details, see Lambda).

- **Bias**

  - If you specify a scalar, then the software optimizes the objective function $L$ times using this process.
    
    1. The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
2. The software implements step 2 until it exhausts all values in \( \text{Lambda} \).
   - If you specify an \( L \)-dimensional vector, then the software optimizes the objective function \( L \) times. At iteration \( j \), the software uses \( \text{Bias}(j) \) as the initial value and, after it sorts \( \text{Lambda} \) in ascending order, uses \( \text{Lambda}(j) \) as the regularization strength.
   - By default:
     - If \( \text{Learner} \) is 'logistic', then let \( g_j \) be 1 if \( Y(j) \) is the positive class, and -1 otherwise. \( \text{Bias} \) is the weighted average of the \( g \) for training or, for cross-validation, in-fold observations.
     - If \( \text{Learner} \) is 'svm', then \( \text{Bias} \) is 0.

Data Types: single | double

**FitBias — Linear model intercept inclusion flag**
true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The software includes the bias term ( b ) in the linear model, and then estimates it.</td>
</tr>
<tr>
<td>false</td>
<td>The software sets ( b = 0 ) during estimation.</td>
</tr>
</tbody>
</table>

Example: 'FitBias',false
Data Types: logical

**PostFitBias — Flag to fit linear model intercept after optimization**
false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>The software estimates the bias term ( b ) and the coefficients ( \beta ) during optimization.</td>
</tr>
<tr>
<td>true</td>
<td>To estimate ( b ), the software:</td>
</tr>
<tr>
<td></td>
<td>1 Estimates ( \beta ) and ( b ) using the model</td>
</tr>
<tr>
<td></td>
<td>2 Estimates classification scores</td>
</tr>
<tr>
<td></td>
<td>3 Refits ( b ) by placing the threshold on the classification scores that attains maximum accuracy</td>
</tr>
</tbody>
</table>

If you specify true, then `FitBias` must be true.

Example: `'PostFitBias',true`

Data Types: logical

**Verbose — Verbosity level**

\( 0 \) (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitclinear` displays at the command line.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>fitclinear</code> does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td><code>fitclinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
<tr>
<td>Any other positive integer</td>
<td><code>fitclinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
</tbody>
</table>

Example: `'Verbose',1`

Data Types: `double` | `single`
SGD and ASGD Solver Options

**BatchSize — Mini-batch size**

Positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is max([10, ceil(sqrt(ff))]), where $ff = \text{numel}(X)/\text{nnz}(X)$ (the fullness factor of X).

Example: 'BatchSize', 100

Data Types: `single` | `double`

**LearnRate — Learning rate**

Positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate $\gamma_0$. The software determines the learning rate for iteration $t$, $\gamma_t$, using

$$
\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.
$$

- $\lambda$ is the value of Lambda.
- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then $c$ is 0.75 [7].
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/sqrt(1+\max((\text{sum}(X.^2,\text{obsDim}))))$, where obsDim is 1 if the observations compose the columns of the predictor data X, and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: `single` | `double`
**OptimizeLearnRate** — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:

1. For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate',true

Data Types: logical

**TruncationPeriod** — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing \( k = \text{TruncationPeriod} \) mini-batches, the software truncates the estimated coefficient \( j \) using

\[
\hat{\beta}_j^* = \begin{cases} 
\hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t, \\
0 & \text{if } |\hat{\beta}_j| \leq u_t, \\
\hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t.
\end{cases}
\]

- For SGD, \( \hat{\beta}_j \) is the estimate of coefficient \( j \) after processing \( k \) mini-batches. \( u_t = k \gamma_t \lambda \). \( \gamma_t \) is the learning rate at iteration \( t \). \( \lambda \) is the value of Lambda.
- For ASGD, \( \hat{\beta}_j \) is the averaged estimate coefficient \( j \) after processing \( k \) mini-batches, \( u_t = k \lambda \).
If Regularization is 'ridge', then the software ignores TruncationPeriod.
Example: 'TruncationPeriod',100
Data Types: single | double

Other Classification Options

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.
Example: 'ClassNames',{'b','g'}
Data Types: categorical | char | string | logical | single | double | cell

**Cost — Misclassification cost**
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure.

- If you specify the square matrix cost ('Cost',cost), then cost(i,j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class
order for the corresponding rows and columns of \texttt{cost}, use the \texttt{ClassNames} name-value pair argument.

- If you specify the structure \( S ('Cost',S) \), then it must have two fields:
  - \( S.\text{ClassNames} \), which contains the class names as a variable of the same data type as \( Y \)
  - \( S.\text{ClassificationCosts} \), which contains the cost matrix with rows and columns ordered as in \( S.\text{ClassNames} \)

The default value for \texttt{Cost} is \( \text{ones}(K) \) – \( \text{eye}(K) \), where \( K \) is the number of distinct classes.

\texttt{fitclinear} uses \texttt{Cost} to adjust the prior class probabilities specified in \texttt{Prior}. Then, \texttt{fitclinear} uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost',[0 2; 1 0]

Data Types: single | double | struct

\textbf{Prior — Prior probabilities}

'\textit{empirical}' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and '\textit{empirical}', 'uniform', a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'\textit{empirical}'</td>
<td>The class prior probabilities are the class relative frequencies in ( Y ).</td>
</tr>
<tr>
<td>'\textit{uniform}'</td>
<td>All class prior probabilities are equal to ( 1/K ), where ( K ) is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to their order in ( Y ). If you specify the order using the 'ClassNames' name-value pair argument, then order the elements accordingly.</td>
</tr>
</tbody>
</table>
Value | Description
---|---
structure array | A structure S with two fields:
  - S.ClassNames contains the class names as a variable of the same type as Y.
  - S.ClassProbs contains a vector of corresponding prior probabilities.

`fitclinear` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `'Prior', struct('ClassNames', {{'setosa', 'versicolor'}}, 'ClassProbs', 1:2)

Data Types: char | string | double | single | struct

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'       | -1 for $x < 0$
                | 0 for $x = 0$
<pre><code>            | 1 for $x &gt; 0$                  |
</code></pre>
<p>| 'symmetric'  | $2x - 1$                              |</p>
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{-x}} - 1 )</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Weights — Observation weights**
numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. fitclinear weighs the observations in \( X \) with the corresponding value in Weights. The size of Weights must equal the number of observations in \( X \).

fitclinear normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(\( n,1 \)), where \( n \) is the number of observations in \( X \).

Data Types: double | single

**Cross-Validation Options**

**CrossVal — Cross-validation flag**
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, or KFold. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.
Example: 'Crossval','on'

**CVPartition — Cross-validation partition**

[](default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software:

1. Randomly reserves p*100% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k, then the software:

1. Randomly partitions the data into k sets
2. For each set, reserves the set as validation data, and trains the model using the other k – 1 sets
3 Stores the $k$ compact, trained models in the cells of a $k$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold', 8

Data Types: single | double

**SGD and ASGD Convergence Controls**

**BatchLimit — Maximal number of batches**

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes BatchLimit batches, it terminates optimization.

- By default:
  - The software passes through the data PassLimit times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is ceil(1e6/BatchSize). BatchSize is the value of the 'BatchSize' name-value pair argument.
  - If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
  - If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit', 100

Data Types: single | double

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.
Let \( B_t = \left[ \beta_t \ b_t \right] \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \left\| B_t - B_{t-1} \right\|_2 < \text{BetaTolerance} \), then optimization terminates.

If the software converges for the last solver specified in \texttt{Solver}, then optimization terminates. Otherwise, the software uses the next solver specified in \texttt{Solver}.

Example: \texttt{'}BetaTolerance', 1e-6

\textbf{Data Types:} single | double

\textbf{NumCheckConvergence} — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of \texttt{'}NumCheckConvergence'} and a positive integer.

To specify the batch size, see \texttt{BatchSize}.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: \texttt{'}NumCheckConvergence', 100

\textbf{Data Types:} single | double

\textbf{PassLimit} — Maximal number of passes
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of \texttt{'}PassLimit'} and a positive integer.

\texttt{fitclinear} processes all observations when it completes one pass through the data.

When \texttt{fitclinear} passes through the data \texttt{PassLimit} times, it terminates optimization.

If you specify \texttt{'}BatchLimit'} and \texttt{'}PassLimit'}, then \texttt{fitclinear} chooses the argument that results in processing the fewest observations.

Example: \texttt{'}PassLimit', 5
Data Types: single | double

**ValidationData** — Validation data for optimization convergence detection
cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1918. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- **ValidationData(1)** must contain an $m$-by-$p$ or $p$-by-$m$ full or sparse matrix of predictor data that has the same orientation as $X$. The predictor variables in the training data $X$ and ValidationData{1} must correspond. The number of observations in both sets can vary.
- **ValidationData{2}** and $Y$ must be the same data type. The set of all distinct labels of ValidationData{2} must be a subset of all distinct labels of $Y$.
- Optionally, **ValidationData(3)** can contain an $m$-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**Dual SGD Convergence Controls**

**BetaTolerance** — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.
Let \( B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix} \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If 
\[
\left\| B_t - B_{t-1} \right\|_2 < \text{BetaTolerance}
\]
then optimization terminates.

If you also specify \( \text{DeltaGradientTolerance} \), then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in \( \text{Solver} \), then optimization terminates. Otherwise, the software uses the next solver specified in \( \text{Solver} \).

Example: 'BetaTolerance',1e-6
Data Types: single | double

**DeltaGradientTolerance — Gradient-difference tolerance**

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2001 violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

- If the magnitude of the KKT violators is less than \( \text{DeltaGradientTolerance} \), then the software terminates optimization.
- If the software converges for the last solver specified in \( \text{Solver} \), then optimization terminates. Otherwise, the software uses the next solver specified in \( \text{Solver} \).

Example: 'DeltaGapTolerance',1e-2
Data Types: double | single

**NumCheckConvergence — Number of passes through entire data set to process before next convergence check**

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence',100
Data Types: single | double
PassLimit — Maximal number of passes
10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data PassLimit times, it terminates optimization.

Example: 'PassLimit',5

Data Types: single | double

ValidationData — Validation data for optimization convergence detection
cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1918. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an \( m \)-by-\( p \) or \( p \)-by-\( m \) full or sparse matrix of predictor data that has the same orientation as \( X \). The predictor variables in the training data \( X \) and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData{2} and \( Y \) must be the same data type. The set of all distinct labels of ValidationData{2} must be a subset of all distinct labels of \( Y \).
- Optionally, ValidationData(3) can contain an \( m \)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.
**BFGS, LBFGS, and SpaRSA Convergence Controls**

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let \( B_t = \begin{bmatrix} \beta_t & b_t \end{bmatrix} \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \frac{\| B_t - B_{t-1} \|_2}{B_t} < \text{BetaTolerance} \), then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

**GradientTolerance — Absolute gradient tolerance**

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let \( \nabla L_t \) be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration \( t \). If \( \| \nabla L_t \|_\infty = \max |\nabla L_t| < \text{GradientTolerance} \), then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'GradientTolerance',1e-5
Data Types: single | double

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize',10

Data Types: single | double

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500

Data Types: single | double

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1918. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData{(1)} must contain an $m$-by-$p$ or $p$-by-$m$ full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{(1)} must correspond. The number of observations in both sets can vary.
- ValidationData{(2)} and Y must be the same data type. The set of all distinct labels of ValidationData{(2)} must be a subset of all distinct labels of Y.
• Optionally, ValidationData(3) can contain an \( m \)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none' (default)</td>
<td>Do not optimize.</td>
</tr>
<tr>
<td>'auto'</td>
<td>Use {'Lambda','Learner'}.</td>
</tr>
<tr>
<td>'all'</td>
<td>Optimize all eligible parameters.</td>
</tr>
<tr>
<td>Array of string</td>
<td>Array of eligible parameter names.</td>
</tr>
<tr>
<td>Vector of object</td>
<td>Vector of optimizableVariable objects.</td>
</tr>
</tbody>
</table>

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Lambda','Learner'}.
- 'all' — Optimize all eligible parameters.
- Array of string names of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitclinear by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitclinear are:
• **Lambda** — `fitclinear` searches among positive values, by default log-scaled in the range $[1e^{-5}/\text{NumObservations}, 1e5/\text{NumObservations}]$.

• **Learner** — `fitclinear` searches among 'svm' and 'logistic'.

• **Regularization** — `fitclinear` searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitclinear', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Linear Classifier” on page 32-1881.

Example: 'OptimizeHyperparameters', 'auto'

**HyperparameterOptimizationOptions — Options for optimization**

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

Mdl — Trained linear classification model

ClassificationLinear model object | ClassificationPartitionedLinear cross-validated model object

Trained linear classification model, returned as a ClassificationLinear model object or ClassificationPartitionedLinear cross-validated model object.
If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedLinear cross-validated model object. Otherwise, Mdl is a ClassificationLinear model object.

To reference properties of Mdl, use dot notation. For example, enter Mdl.Beta in the Command Window to display the vector or matrix of estimated coefficients.

**Note** Unlike other classification models, and for economical memory usage, ClassificationLinear and ClassificationPartitionedLinear model objects do not store the training data or training process details (for example, convergence history).

**FitInfo — Optimization details**
structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, **Objective** is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of **Lambda** and columns correspond to values of **Solver**.

This table describes some notable fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TerminationStatus</td>
<td>• Reason for optimization termination</td>
</tr>
<tr>
<td></td>
<td>• Corresponds to a value in TerminationCode</td>
</tr>
<tr>

</tr>
<tr>
<td>4</td>
<td>LBFGS</td>
</tr>
<tr>
<td>5</td>
<td>BFGS</td>
</tr>
<tr>
<td>6</td>
<td>SpaRSA</td>
</tr>
</tbody>
</table>

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

**HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters**

BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the `Optimizer` field value of the 'HyperparameterOptimizationOptions' name-value pair argument:

<table>
<thead>
<tr>
<th>Value of Optimizer Field</th>
<th>Value of HyperparameterOptimizationResults</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bayesopt' (default)</td>
<td>Object of class BayesianOptimization</td>
</tr>
<tr>
<td>'gridsearch' or 'randomsearch'</td>
<td>Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)</td>
</tr>
</tbody>
</table>
Definitions

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

### Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify 'ObservationsIn', 'columns'. As a result, you can experience a significant reduction in optimization-execution time.

- For better optimization accuracy if \(X\) is high-dimensional and Regularization is 'ridge', set any of these combinations for Solver:
  - 'sgd'
  - 'asgd'
  - 'dual' if Learner is 'svm'
  - {'sgd','lbfgs'}
  - {'asgd','lbfgs'}
  - {'dual','lbfgs'} if Learner is 'svm'

  Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if \(X\) is moderate- through low-dimensional and Regularization is 'ridge', set Solver to 'bfgs'.

- If Regularization is 'lasso', set any of these combinations for Solver:
  - 'sgd'
  - 'asgd'
  - 'sparsa'
  - {'sgd','sparsa'}
• {'asgd','sparsa'}
• When choosing between SGD and ASGD, consider that:
  • SGD takes less time per iteration, but requires more iterations to converge.
  • ASGD requires fewer iterations to converge, but takes more time per iteration.
• If X has few observations, but many predictor variables, then:
  • Specify 'PostFitBias',true.
  • For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
• For SGD and ASGD solvers, BatchSize affects the rate of convergence.
  • If BatchSize is too small, then fitclinear achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  • If BatchSize is too large, then fitclinear achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
• Large learning rates (see LearnRate) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
• When using lasso penalties, experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.
• For efficiency, fitclinear does not standardize predictor data. To standardize X, enter

\[ X = \text{bsxfun}@rdivide, \text{bsxfun}@minus(X, \text{mean}(X,2)), \text{std}(X,0,2)); \]

The code requires that you orient the predictors and observations as the rows and columns of X, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.
• After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

• If you specify ValidationData, then, during objective-function optimization:
• *fitclinear* estimates the validation loss of *ValidationData* periodically using the current model, and tracks the minimal estimate.

• When *fitclinear* estimates a validation loss, it compares the estimate to the minimal estimate.

• When subsequent, validation loss estimates exceed the minimal estimate five times, *fitclinear* terminates optimization.

• If you specify *ValidationData* and to implement a cross-validation routine (*CrossVal*, *CVPartition*, *Holdout*, or *KFold*), then:

1. *fitclinear* randomly partitions *X* and *Y* according to the cross-validation routine that you choose.

2. *fitclinear* trains the model using the training-data partition. During objective-function optimization, *fitclinear* uses *ValidationData* as another possible way to terminate optimization (for details, see the previous bullet).

3. Once *fitclinear* satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.

   a. If you implement *k*-fold cross-validation, and *fitclinear* has not exhausted all training-set folds, then *fitclinear* returns to Step 2 to train using the next training-set fold.

   b. Otherwise, *fitclinear* terminates training, and then returns the cross-validated model.

4. You can determine the quality of the cross-validated model. For example:

   • To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to *kfoldLoss*.

   • To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to *kfoldPredict*.

References

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitations:

- Some name-value pair arguments have different defaults compared to the in-memory `fitclinear` function. Supported name-value pair arguments, and any differences, are:
  - 'ObservationsIn' — Supports only 'rows'.
  - 'Lambda' — Can be 'auto' (default) or a scalar.
  - 'Learner'
  - 'Regularization' — Supports only 'ridge'.
  - 'Solver' — Supports only 'lbfgs'.
  - 'FitBias' — Supports only true.
  - 'Verbose' — Default value is 1.
  - 'Beta'
• 'Bias'
• 'ClassNames'
• 'Cost'
• 'Prior'
• 'Weights' — Value must be a tall array.
• 'HessianHistorySize'
• 'BetaTolerance' — Default value is relaxed to 1e-3.
• 'GradientTolerance' — Default value is relaxed to 1e-3.
• 'IterationLimit' — Default value is relaxed to 20.
• 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
• 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitclinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).

For tall arrays, fitclinear implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for Beta and Bias are not given, fitclinear refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

Introduced in R2016a
**fitcnb**

Train multiclass naive Bayes model

**Syntax**

Mdl = fitcnb(Tbl,ResponseVarName)
Mdl = fitcnb(Tbl,formula)
Mdl = fitcnb(Tbl,Y)
Mdl = fitcnb(X,Y)
Mdl = fitcnb(___,Name,Value)

**Description**

Mdl = fitcnb(Tbl,ResponseVarName) returns a multiclass naive Bayes model (Mdl), trained by the predictors in table Tbl and class labels in the variable Tbl.ResponseVarName.

Mdl = fitcnb(Tbl,formula) returns a multiclass naive Bayes model (Mdl), trained by the predictors in table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl.

Mdl = fitcnb(Tbl,Y) returns a multiclass naive Bayes model (Mdl), trained by the predictors in the table Tbl and class labels in the array Y.

Mdl = fitcnb(X,Y) returns a multiclass naive Bayes model (Mdl), trained by predictors X and class labels Y.

Mdl = fitcnb(___,Name,Value) returns a naive Bayes classifier with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.
Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

    load fisheriris
    X = meas(:,3:4);
    Y = species;
    tabulate(Y)

<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>setosa</td>
<td>50</td>
<td>33.33%</td>
</tr>
<tr>
<td>versicolor</td>
<td>50</td>
<td>33.33%</td>
</tr>
<tr>
<td>virginica</td>
<td>50</td>
<td>33.33%</td>
</tr>
</tbody>
</table>

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier. It is good practice to specify the class order.

    Mdl = fitcnb(X,Y,...
                   'ClassNames',
                   {'setosa','versicolor','virginica'})

Mdl = ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal' 'normal'}
    DistributionParameters: {3x2 cell}

Properties, Methods

Mdl is a trained ClassificationNaiveBayes classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within setosa.
setosaIndex = strcmp(Mdl.ClassNames,'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}
estimates = 2×1
1.4620
0.1737

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
cxlim = h.XLim;
cylim = h.YLim;
hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)).^2; % Create diagonal covariance matrix
    xlim = Mu(j,1) + 4*[1 -1]*sqrt(Sigma(1,1,j));
    ylim = Mu(j,2) + 4*[1 -1]*sqrt(Sigma(2,2,j));
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),[xlim ylim])
    % Draw contours for the multivariate normal distributions
end
h.XLim = cxlim;
h.YLim = cylim;
title('Naive Bayes Classifier -- Fisher''s Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
hold off
You can change the default distribution using the name-value pair argument 'DistributionNames'. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using 'DistributionNames','mvmn'.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'}; % Class order

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set, which in this case is 33% for each species. However, suppose you know that in the population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

prior = [0.5 0.2 0.3];
Mdl = fitcnb(X,Y,'ClassNames',classNames,'Prior',prior)

Mdl = ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal'  'normal'  'normal'  'normal'}
    DistributionParameters: {3x4 cell}

Mdl is a trained ClassificationNaiveBayes classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses prior.
Create a new naive Bayes model based on Mdl, and specify that the prior class probability distribution is an empirical class distribution.

```matlab
defaultPriorMdl = Mdl;
FreqDist = cell2table(tabulate(Y));
defaultPriorMdl.Prior = FreqDist{:,3};
```

The software normalizes the prior class probabilities to sum to 1.

Estimate the cross-validation error for both models using 10-fold cross-validation.

```matlab
rng(1); % For reproducibility
defaultCVMdl = crossval(defaultPriorMdl);
defaultLoss = kfoldLoss(defaultCVMdl)
defaultLoss = 0.0533
CVMdl = crossval(Mdl);
Loss = kfoldLoss(CVMdl)
Loss = 0.0340
```

Mdl performs better than defaultPriorMdl.

**Specify Predictor Distributions for Naive Bayes Classifiers**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```matlab
Mdl1 = fitcnb(X,Y,...
    'ClassNames',{setosa',versicolor',virginica'})
```

```matlab
Mdl1 =
    ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
```
ScoreTransform: 'none'
NumObservations: 150
DistributionNames: {'normal' 'normal' 'normal' 'normal'}
DistributionParameters: {3x4 cell}

Properties, Methods

Mdl1.DistributionParameters
ans = 3x4 cell array
{2x1 double}  {2x1 double}  {2x1 double}  {2x1 double}
{2x1 double}  {2x1 double}  {2x1 double}  {2x1 double}
{2x1 double}  {2x1 double}  {2x1 double}  {2x1 double}
{2x1 double}  {2x1 double}  {2x1 double}  {2x1 double}

Mdl1.DistributionParameters{1,2}
ans = 2x1

3.4280
0.3791

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in Mdl1.DistributionParameters corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for Mdl1.

isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionmat(Y,isLabels1)
ConfusionMat1 = 3x3

50 0 0
0 47 3
0 3 47

Element (j, k) of ConfusionMat1 represents the number of observations that the software classifies as k, but are truly in class j according to the data.
Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```matlab
Mdl2 = fitcnb(X,Y,...
    'DistributionNames',{'normal','normal','kernel','kernel'},...
    'ClassNames',{'setosa','versicolor','virginica'});
Mdl2.DistributionParameters{1,2}
an = 2x1
    3.4280
    0.3791
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the 'Width' name-value pair argument.

Estimate the confusion matrix for Mdl2.

```matlab
isLabels2 = resubPredict(Mdl2);
ConfusionMat2 = confusionmat(Y,isLabels2)
```

```
ConfusionMat2 = 3x3

50     0     0
0    47     3
0     3    47
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

**Compare Classifiers Using Cross-Validation**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```
Train and cross-validate a naive Bayes classifier using the default options and k-fold cross-validation. It is good practice to specify the class order.

CVMdl1 = fitcnb(X,Y,...
  'ClassNames',{'setosa','versicolor','virginica'},...
  'CrossVal','on');

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. CVMdl1 is a ClassificationPartitionedModel model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.

t = templateNaiveBayes();
CVMdl2 = fitcecoc(X,Y,'CrossVal','on','Learners',t);

CVMdl2 is a ClassificationPartitionedECOC model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for fitcnb.

Compare the out-of-sample k-fold classification error (proportion of misclassified observations).

classErr1 = kfoldLoss(CVMdl1,'LossFun','ClassifErr')
classErr1 = 0.0533

classErr2 = kfoldLoss(CVMdl2,'LossFun','ClassifErr')
classErr2 = 0.0467

Mdl2 has a lower generalization error.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.
Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to $y$ for each email.

```matlab
n = 1000;                       % Sample size
rng(1);                         % For reproducibility
Y = randsample([-1 1],n,true);  % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```matlab
tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
0.4 0.1 0.3 0.05 0.15];             % Token relative frequencies
tokensPerEmail = 20;                    % Fixed for convenience
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```matlab
Mdl = fitcnb(X,Y,'DistributionNames','mn');
```

$\text{Mdl}$ is a trained $\text{ClassificationNaiveBayes}$ classifier.

Assess the in-sample performance of $\text{Mdl}$ by estimating the misclassification error.

```matlab
isGenRate = resubLoss(Mdl,'LossFun','ClassifErr')
isGenRate = 0.0200
```

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

```matlab
newN = 500;
newY = randsample([-1 1],newN,true);
newX = zeros(newN,5);
newX(newY == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier Mdl, and determine whether the algorithm generalizes.

```matlab
oosGenRate = loss(Mdl,newX,newY)
oosGenRate = 0.0261
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Optimize Naive Bayes Classifier

This example shows how to use the OptimizeHyperparameters name-value pair to minimize cross-validation loss in a naive Bayes classifier using fitcnb. The example uses Fisher's iris data.

Load Fisher's iris data.

```matlab
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'};
```

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng default
Mdl = fitcnb(X,Y,'ClassNames',classNames,'OptimizeHyperparameters','auto',...
'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...'expected-improvement-plus'))
```

Warning: It is recommended that you first standardize all numeric predictors when optimizing.
Min objective vs. Number of function evaluations

Properties, Methods

**Input Arguments**

**Tbl — Sample data**

Table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName — Response variable name`  
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

`formula — Explanatory model of response and subset of predictor variables`  
character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`
**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each element of Y defines the class membership of the corresponding row of X. Y supports K class levels.

If Y is a character array, then each row must correspond to one class label.

The length of Y and the number of rows of X must be equivalent.

Data Types: categorical | char | string | logical | single | double | cell

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equivalent.

Data Types: double

---

**Note:** The software treats NaN, empty character vector (' '), empty string ('""'), <missing>, and <undefined> elements as missing data values.

- If Y contains missing values, then the software removes them and the corresponding rows of X.
- If X contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of Y.
- If X contains missing values and you set 'DistributionNames','mn', then the software removes those rows of X and the corresponding elements of Y.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'DistributionNames','mn','Prior','uniform','KSWidth',0.5 specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

**Naive Bayes Options**

**DistributionNames — Data distributions**

`'kernel'` | `'mn'` | `'mvmn'` | `'normal'` | string array | cell array of character vectors

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `DistributionNames` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'kernel'</code></td>
<td>Kernel smoothing density estimate.</td>
</tr>
<tr>
<td><code>'mn'</code></td>
<td>Multinomial distribution. If you specify mn, then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 32-1957.</td>
</tr>
<tr>
<td><code>'mvmn'</code></td>
<td>Multivariate multinomial distribution. For details, see “Algorithms” on page 32-1957.</td>
</tr>
<tr>
<td><code>'normal'</code></td>
<td>Normal (Gaussian) distribution.</td>
</tr>
</tbody>
</table>
If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by-\(P\) string array or cell array of character vectors, then the software models feature \(j\) using the distribution in element \(j\) of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvnm'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'DistributionNames','mn'
Example: 'DistributionNames',{'kernel','normal','kernel'}

**Kernel — Kernel smoother type**

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let \(I\{u\}\) denote the indicator function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Kernel</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'box'</td>
<td>Box (uniform)</td>
<td>(f(x) = 0.5I{</td>
</tr>
<tr>
<td>'epanechnikov'</td>
<td>Epanechnikov</td>
<td>(f(x) = 0.75(1 - x^2)I{</td>
</tr>
<tr>
<td>'normal'</td>
<td>Gaussian</td>
<td>(f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2))</td>
</tr>
<tr>
<td>'triangle'</td>
<td>Triangular</td>
<td>(f(x) = (1 -</td>
</tr>
</tbody>
</table>

If you specify a 1-by-\(P\) string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element \(j\) for feature \(j\) in \(X\). The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

32-1941
You must specify that at least one predictor has distribution 'kernel' to additionally specify Kernel, Support, or Width.

Example: 'Kernel',{ 'epanechnikov', 'normal' }

**Support — Kernel smoothing density support**

' unbounded' (default) | 'positive' | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'Support' and 'positive', 'unbounded', a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-by-2 numeric row vector</td>
<td>For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.</td>
</tr>
<tr>
<td>'positive'</td>
<td>The density support is all positive real values.</td>
</tr>
<tr>
<td>'unbounded'</td>
<td>The density support is all real values.</td>
</tr>
</tbody>
</table>

If you specify a 1-by-\( P \) string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software trains the classifier using the kernel support in element \( j \) for feature \( j \) in \( X \). The software ignores elements of Kernel not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify Kernel, Support, or Width.

Example: 'KSSupport',{ [-10,20], 'unbounded' }

Data Types: char | string | cell | double

**Width — Kernel smoothing window width**

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.
Suppose there are $K$ class levels and $P$ predictors. This table summarizes the available options for setting the kernel smoothing window width.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$K$-by-$P$ matrix of numeric values</td>
<td>Element $(k,j)$ specifies the width for predictor $j$ in class $k$.</td>
</tr>
<tr>
<td>$K$-by-1 numeric column vector</td>
<td>Element $k$ specifies the width for all predictors in class $k$.</td>
</tr>
<tr>
<td>1-by-$P$ numeric row vector</td>
<td>Element $j$ specifies the width in all class levels for predictor $j$.</td>
</tr>
<tr>
<td>scalar</td>
<td>Specifies the bandwidth for all features in all classes.</td>
</tr>
</tbody>
</table>

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify $\text{Width}$ and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution 'kernel' to additionally specify $\text{Kernel}$, $\text{Support}$, or $\text{Width}$.

Example: 'Width',[NaN NaN]

Data Types: double | struct

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'CrossVal','on'
CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1 Randomly partition the data into k sets.
For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.

Store the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.
2. Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Other Classification Options**

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

32-1945
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitcnb assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), fitcnb assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Order the classes during training.
• Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.

• Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{ 'a', 'b', 'c' }`. To train the model using observations from classes 'a' and 'c' only, specify `ClassNames`, { 'a', 'c' }.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

• Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.

• Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i!=j`, and `Cost(i,j)=0` if `i=j`.

Example: 'Cost', struct('ClassNames', {'b', 'g'}, 'ClassificationCosts', [0 0.5; 1 0])

Data Types: single | double | struct

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

• If you supply `X` and `Y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
• The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.

• By default, PredictorNames is {'x1','x2',...}.

• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcnb uses only the predictor variables in PredictorNames and the response variable in training.

• PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.

• By default, PredictorNames contains the names of all predictor variables.

• It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>1/(1 + e(^{-2x}))</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>log(x / (1-x))</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>1/(1 + e(^{-x}))</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for x &lt; 0&lt;br&gt;0 for x = 0&lt;br&gt;1 for x &gt; 0</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>2x - 1</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>2/(1 + e(^{-x})) - 1</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.
The software normalizes **Weights** to sum up to the value of the prior probability in the respective class.

By default, **Weights** is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.  

**Data Types:** double | single | char | string

### Hyperparameter Optimization

**OptimizeHyperparameters — Parameters to optimize**  
'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.  
- 'auto' — Use {'DistributionNames','Width'}.  
- 'all' — Optimize all eligible parameters.  
- String array or cell array of eligible parameter names.  
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcnb` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** `OptimizeHyperparameters` values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcnb` are:

- **DistributionNames** — `fitcnb` searches among 'normal' and 'kernel'.  
- **Width** — `fitcnb` searches among real values, by default log-scaled in the range `[MinPredictorDiff/4,max(MaxPredictorRange,MinPredictorDiff)]`.  
- **Kernel** — `fitcnb` searches among 'normal', 'box', 'epanechnikov', and 'triangle'.

32-1951
Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcnb',meas,species);
params(2).Range = [1e-2,1e2];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Naive Bayes Classifier” on page 32-1933.

Example: 'auto'

**HyperparameterOptimizationOptions — Options for optimization**

*structure*

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| Optimizer            | • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt.  
                      | • 'gridsearch' — Use grid search with NumGridDivisions values per dimension.  
                      | • 'randomsearch' — Search at random among MaxObjectiveEvaluations points.  
                      | 'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command sortrows(Mdl.HyperparameterOptimizationResults). | 'bayesopt'               |
| AcquisitionFunctionName | • 'expected-improvement-per-second-plus'  
                      | • 'expected-improvement'  
                      | • 'expected-improvement-plus'  
                      | • 'expected-improvement-per-second'  
                      | • 'lower-confidence-bound'  
                      | • 'probability-of-improvement'  
<pre><code>                  | For details, see the bayesopt AcquisitionFunctionName name-value pair argument, or “Acquisition Function Types” on page 10-4. | 'expected-improvement-per-second-plus' |
</code></pre>
<p>| MaxObjectiveEvaluations | Maximum number of objective function evaluations. | 30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch' |</p>
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxTime</td>
<td>Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.</td>
<td>Inf</td>
</tr>
<tr>
<td>NumGridDivisions</td>
<td>For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.</td>
<td>10</td>
</tr>
<tr>
<td>ShowPlots</td>
<td>Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.</td>
<td>true</td>
</tr>
<tr>
<td>SaveIntermediateResults</td>
<td>Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.</td>
<td>false</td>
</tr>
<tr>
<td>Verbose</td>
<td>Display to the command line.</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>• 0 — No iterative display</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 1 — Iterative display</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 2 — Iterative display with extra information</td>
<td></td>
</tr>
</tbody>
</table>

For details, see the `bayesopt Verbose` name-value pair argument.
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>

</thead>
<tbody>
<tr>
<td>UseParallel</td>
<td>Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-9.</td>
<td>false</td>
</tr>
<tr>
<td>Repartition</td>
<td>Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. True usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations.</td>
<td>false</td>
</tr>
</tbody>
</table>

Use no more than one of the following three field names.

| CVPartition     | A cvpartition object, as created by cvpartition.                       | 'Kfold',5 if you do not specify any cross-validation field |
| Holdout         | A scalar in the range (0,1) representing the holdout fraction.         |         |
| Kfold           | An integer greater than 1.                                             |         |

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

**Mdl — Trained naive Bayes classification model**

ClassificationNaiveBayes model object | ClassificationPartitionedModel

Trained naive Bayes classification model, returned as a ClassificationNaiveBayes model object or a ClassificationPartitionedModel cross-validated model object.
If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationNaiveBayes model object.

To reference properties of Mdl, use dot notation. For example, to access the estimated distribution parameters, enter Mdl.DistributionParameters.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor \( j \) is the nonnegative number of occurrences of token \( j \) in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

1. Estimates the densities of the predictors within each class.
2. Models posterior probabilities according to Bayes rule. That is, for all \( k = 1,\ldots,K, \)

\[
\hat{P}(Y = k | X_1,\ldots,X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P(X_j | Y = k)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P(X_j | Y = k)},
\]

where:
• Y is the random variable corresponding to the class index of an observation.
• X₁,...,Xₚ are the random predictors of an observation.
• \( \pi(Y = k) \) is the prior probability that a class index is \( k \).

3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

\[
\hat{P}(Y = k | X_1,...,X_p) \propto \pi(Y = k)P_{mn}(X_1,...,X_p | Y = k), \quad \text{where} \quad P_{mn}(X_1,...,X_p | Y = k) \quad \text{is the probability mass function of a multinomial distribution.}
\]

**Tips**

For classifying count-based data, such as the bag-of-tokens model on page 32-1956, use the multinomial distribution (e.g., set 'DistributionNames','mn').

**Algorithms**

• If you specify 'DistributionNames','mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1956. The software stores the probability that token \( j \) appears in class \( k \) in the property DistributionParameters\{k,j\}. Using additive smoothing [2], the estimated probability is

\[
P(\text{token } j \mid \text{class } k) = \frac{1 + c_{jk}}{P + c_k},
\]

where:

\[
c_{jk} = n_k \sum_{i: y_i \in \text{class } k} x_{ij}w_i; \quad \text{which is the weighted number of occurrences of token } j \text{ in class } k.
\]

\[
\sum_{i: y_i \in \text{class } k} w_i
\]
• $n_k$ is the number of observations in class $k$.

• $w_i$ is the weight for observation $i$. The software normalizes weights within a class such that they sum to the prior probability for that class.

\[ c_k = \sum_{i=1}^{P} c_{j|k}; \] which is the total weighted number of occurrences of all tokens in class $k$.

• If you specify 'DistributionNames', 'mvmn' when training Mdl using fitcnb, then:

1. For each predictor, the software collects a list of the unique levels, stores the sorted list in CategoricalLevels, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.

2. For predictor $j$ in class $k$, the software counts instances of each categorical level using the list stored in CategoricalLevels{$j$}.

3. The software stores the probability that predictor $j$, in class $k$, has level $L$ in the property DistributionParameters{$k, j$}, for all levels in CategoricalLevels{$j$}. Using additive smoothing [2], the estimated probability is

\[ P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k}, \]

where:

•

\[ m_{j|k}(L) = \sum_{i: y_i \in \text{class } k} I(x_{ij} = L)w_i \]

which is the weighted number of observations for which predictor $j$ equals $L$ in class $k$.

• $n_k$ is the number of observations in class $k$.

• $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
• \( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.
• \( m_j \) is the number of distinct levels in predictor \( j \).
• \( m_k \) is the weighted number of observations in class \( k \).

References

Extended Capabilities

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

• Supported syntaxes are:
  • \( \text{Mdl} = \text{fitcnb}(\text{Tbl},Y) \)
  • \( \text{Mdl} = \text{fitcnb}(X,Y) \)
  • \( \text{Mdl} = \text{fitcnb}([],[],\text{Name},\text{Value}) \)
• Options related to kernel densities, cross-validation, and hyperparameter optimization are not supported. The supported name-value pair arguments are:
  • 'DistributionNames' — 'kernel' value is not supported.
  • 'CategoricalPredictors'
  • 'Cost'
  • 'PredictorNames'
  • 'Prior'
• 'ResponseName'
• 'ScoreTransform'
• 'Weights' — Value must be a tall array.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

**Topics**

“Naive Bayes Classification” on page 21-2
“Grouping Variables” on page 2-57

**Introduced in R2014b**
fitcsvm

Train binary support vector machine (SVM) classifier

fitcsvm trains or cross-validates a support vector machine (SVM) model for two-class (binary) classification on a low-dimensional or moderate-dimensional predictor data set. fitcsvm supports mapping the predictor data using kernel functions, and supports sequential minimal optimization (SMO), iterative single data algorithm (ISDA), or \( L_1 \) soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM model for binary classification on a high-dimensional data set, that is, a data set that includes many predictor variables, use fitclinear instead.

For multiclass learning with combined binary SVM models, use error-correcting output codes (ECOC). For more details, see fitcecoc.

To train an SVM regression model, see fitrsvm for low-dimensional and moderate-dimensional predictor data sets, or fitrlinear for high-dimensional data sets.

**Syntax**

```matlab
Mdl = fitcsvm(Tbl,ResponseVarName)
Mdl = fitcsvm(Tbl,formula)
Mdl = fitcsvm(Tbl,Y)
Mdl = fitcsvm(X,Y)
Mdl = fitcsvm(___,'Name',Value)
```

**Description**

```matlab
Mdl = fitcsvm(Tbl,ResponseVarName) returns a support vector machine (SVM) classifier on page 32-2002 Mdl trained using the sample data contained in the table Tbl. ResponseVarName is the name of the variable in Tbl that contains the class labels for one-class or two-class classification.
```
Mdl = fitcsvm(Tbl,formula) returns an SVM classifier trained using the sample data contained in the table Tbl. formula is an explanatory model of the response and a subset of the predictor variables in Tbl used to fit Mdl.

Mdl = fitcsvm(Tbl,Y) returns an SVM classifier trained using the predictor variables in the table Tbl and the class labels in vector Y.

Mdl = fitcsvm(X,Y) returns an SVM classifier trained using the predictors in the matrix X and the class labels in vector Y for one-class or two-class classification.

Mdl = fitcsvm(___,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the type of cross-validation, the cost for misclassification, and the type of score transformation function.

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);

Train an SVM classifier using the processed data set.

SVMMModel = fitcsvm(X,y)

SVMMModel =
    ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 100
    Alpha: [24x1 double]
    Bias: -14.4149
    KernelParameters: [1x1 struct]
BoxConstraints: [100x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [100x1 logical]
Solver: 'SMO'

Properties, Methods

**SVMModel** is a trained `ClassificationSVM` classifier. Display the properties of SVMModel. For example, to determine the class order, use dot notation.

```matlab
classOrder = SVMModel.ClassNames
```

```
classOrder = 2x1 cell array
    {'versicolor'}
    {'virginica' }
```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```matlab
sv = SVMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
```
The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

**Train and Cross-Validate SVM Classifier**

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```
Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. Standardize the predictors.

```matlab
SVMMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',... 'KernelScale','auto');
```

`SVMMModel` is a trained `ClassificationSVM` classifier.

Cross-validate the SVM classifier. By default, the software uses 10-fold cross-validation.

```matlab
CVSVMModel = crossval(SVMModel); 
```

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```matlab
classLoss = kfoldLoss(CVSVMModel)
classLoss = 0.0484
```

The generalization rate is approximately 5%.

---

**Detect Outliers Using SVM and One-Class Learning**

Modify Fisher's iris data set by assigning all the irises to the same class. Detect outliers in the modified data set, and confirm the expected proportion of the observations that are outliers.

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```matlab
load fisheriris
X = meas(:,1:2);
y = ones(size(X,1),1);
```

Train an SVM classifier using the modified data set. Assume that 5% of the observations are outliers. Standardize the predictors.

```matlab
rng(1);
SVMMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,... 'OutlierFraction',0.05);
```
SVMModel is a trained ClassificationSVM classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```matlab
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));

figure
plot(X(:,1),X(:,2),'k. ')
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{\bf Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```
The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```matlab
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate = 0.0467
```
Find Multiple Class Boundaries Using Binary SVM

Create a scatter plot of the *fisheriris* data set. Treat coordinates of a grid within the plot as new observations from the distribution of the data set, and find class boundaries by assigning the coordinates to one of the three classes in the data set.

Load Fisher's iris data set. Use the petal lengths and widths as the predictors.

```matlab
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```matlab
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
lims = [h.XLim h.YLim]; % Extract the x and y axis limits
title('{\bf Scatter Diagram of Iris Measurements}');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location','Northwest');
```
The data contains three classes, one of which is linearly separable from the others.

For each class:

1. Create a logical vector (indx) indicating whether an observation is a member of the class.
2. Train an SVM classifier using the predictor data and indx.
3. Store the classifier in a cell of a cell array.

Define the class order:

```matlab
SVMMModels = cell(3,1);
classes = unique(Y);
```
rng(1); % For reproducibility

for j = 1:numel(classes)
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames', [false true], 'Standardize', true,...
        'KernelFunction','rbf','BoxConstraint',1);
end

SVMModels is a 3-by-1 cell array, with each cell containing a ClassificationSVM classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes)
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end

Each row of Scores contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

[~,maxScore] = max(Scores,[],2);

Color in the regions of the plot based on the class to which the corresponding new observation belongs.

figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...
    [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);
hold on
h(4:6) = gscatter(X(:,1),X(:,2),Y);

xlabel('Petal Length (cm)');
Optimize SVM Classifier

Optimize hyperparameters automatically using `fitcsvm`.

Load the `ionosphere` data set.
load ionosphere

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

rng default
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))

Properties, Methods
Input Arguments

`Tbl` — Sample data
    table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using `ResponseVarName`.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using `formula`.

If Tbl does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name
    name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response and subset of predictor variables
    character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of 'Y~X1+X2+X3'. In this form, Y represents
the response variable, and $X_1$, $X_2$, and $X_3$ represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: fitcsvm(X,Y,'KFold',10,'Cost',[0 2;1 0],'ScoreTransform','sign') performs 10-fold cross-validation, applies double the penalty to false positives compared to false negatives, and transforms scores using the sign function.

SVM Options

BoxConstraint — Box constraint
1 (default) | positive scalar

Box constraint on page 32-2000, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see “Algorithms” on page 32-2005.

Example: 'BoxConstraint',100

Data Types: double | single

KernelFunction — Kernel function
'linear' (default)| 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the elements of the Gram matrix on page 32-2000, specified as the comma-separated pair consisting of 'KernelFunction' and a kernel function name. Suppose \( G(x_j, x_k) \) is element \((j,k)\) of the Gram matrix, where \( x_j \) and \( x_k \) are \( p\)-dimensional vectors representing observations \( j \) and \( k \) in \( X \). This table describes supported kernel function names and their functional forms.
<table>
<thead>
<tr>
<th>Kernel Function Name</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'gaussian' or 'rbf'</td>
<td>Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning</td>
<td>( G(x_j, x_k) = \exp \left( -|x_j - x_k|^2 \right) )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear kernel, default for two-class learning</td>
<td>( G(x_j, x_k) = x_j^T x_k )</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>Polynomial kernel. Use 'PolynomialOrder', ( q ) to specify a polynomial kernel of order ( q ).</td>
<td>( G(x_j, x_k) = (1 + x_j^T x_k)^q )</td>
</tr>
</tbody>
</table>

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. The value `kernel` must have this form.

```matlab
function G = kernel(U,V)

where:
- \( U \) is an \( m \)-by-\( p \) matrix. Columns correspond to predictor variables, and rows correspond to observations.
- \( V \) is an \( n \)-by-\( p \) matrix. Columns correspond to predictor variables, and rows correspond to observations.
- \( G \) is an \( m \)-by-\( n \) Gram matrix on page 32-2000 of the rows of \( U \) and \( V \).

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char  | string

**KernelScale — Kernel scale parameter**

1 (default) | 'auto'  | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix \( X \) by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.
• If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using rng before training.

• If you specify KernelScale and your own kernel function, for example, 'KernelFunction','kernel', then the software throws an error. You must apply scaling within kernel.

Example: 'KernelScale','auto'
Data Types: double | single | char | string

**PolynomialOrder — Polynomial kernel function order**
3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software throws an error.

Example: 'PolynomialOrder',2
Data Types: double | single

**KernelOffset — Kernel offset parameter**
nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:
• 0 if the solver is SMO (that is, you set 'Solver','SMO')
• 0.1 if the solver is ISDA (that is, you set 'Solver','ISDA')

Example: 'KernelOffset',0
Data Types: double | single

**Standardize — Flag to standardize predictor data**
false (default) | true
Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:

- The software centers and scales each predictor variable (X or Tbl) by the corresponding weighted column mean and standard deviation. For details on weighted standardizing, see “Algorithms” on page 32-2005. MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictors, but stores the unstandardized predictors as a matrix or table in the classifier property X.

Example: 'Standardize',true
Data Types: logical

Solver — Optimization routine
'SISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ISDA'</td>
<td>Iterative Single Data Algorithm (see [30])</td>
</tr>
<tr>
<td>'L1QP'</td>
<td>Uses quadprog to implement L1 soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).</td>
</tr>
<tr>
<td>'SMO'</td>
<td>Sequential Minimal Optimization (see [17])</td>
</tr>
</tbody>
</table>

The default value is 'ISDA' for two-class learning or if you set 'OutlierFraction' to a positive value, and 'SMO' otherwise.

Example: 'Solver','ISDA'

Alpha — Initial estimates of alpha coefficients
numeric vector of nonnegative values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector of nonnegative values. The length of Alpha must be equal to the number of rows in X.
• Each element of 'Alpha' corresponds to an observation in X.
• 'Alpha' cannot contain any NaNs.
• If you specify 'Alpha' and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and 'Alpha' that correspond to the missing values. That is, enter:

\[
\text{idx} = \neg \text{isundefined(categorical(Y))}; \\
Y = Y(idx,:); \\
X = X(idx,:); \\
alpha = alpha(idx);
\]

Then pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The default values are:
• 0.5*ones(size(X,1),1) for one-class learning
• zeros(size(X,1),1) for two-class learning

Example: 'Alpha',0.1*ones(size(X,1),1)

Data Types: double

**CacheSize — Cache size**

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n-by-n Gram matrix on page 32-2000.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of memory for training the model.

Example: 'CacheSize','maximal'

Data Types: double | single | char | string

**ClipAlphas — Flag to clip alpha coefficients**

true (default) | false
Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation $j$ is $\alpha_j$ and the box constraint of observation $j$ is $C_j$, $j = 1,\ldots,n$, where $n$ is the training sample size.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>At each iteration, if $\alpha_j$ is near 0 or near $C_j$, then MATLAB sets $\alpha_j$ to 0 or to $C_j$, respectively.</td>
</tr>
<tr>
<td>false</td>
<td>MATLAB does not change the alpha coefficients during optimization.</td>
</tr>
</tbody>
</table>

MATLAB stores the final values of $\alpha$ in the Alpha property of the trained SVM model object.

ClipAlphas can affect SMO and ISDA convergence.

Example: 'ClipAlphas',false

Data Types: logical

**Nu — $\nu$ parameter for one-class learning**

0.5 (default) | positive scalar

$\nu$ parameter for “One-Class Learning” on page 32-2001, specified as the comma-separated pair consisting of 'Nu' and a positive scalar. Nu must be greater than 0 and at most 1.

Set Nu to control the tradeoff between ensuring that most training examples are in the positive class and minimizing the weights in the score function.

Example: 'Nu',0.25

Data Types: double | single

**NumPrint — Number of iterations between optimization diagnostic message output**

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.
If you specify 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint',500

Data Types: double | single

OutlierFraction — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1).

Suppose that you set 'OutlierFraction',outlierfraction, where outlierfraction is a value greater than 0.

• For two-class learning, the software implements robust learning. In other words, the software attempts to remove 100*outlierfraction% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

• For one-class learning, the software finds an appropriate bias term such that outlierfraction of the observations in the training set have negative scores.

Example: 'OutlierFraction',0.01

Data Types: double | single

RemoveDuplicates — Flag to replace duplicate observations with single observations

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If RemoveDuplicates is true, then fitcsvm replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see Weights).

Tip If your data set contains many duplicate observations, then specifying 'RemoveDuplicates',true can decrease convergence time considerably.
Data Types: logical

Verbose — Verbosity level
0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of Verbose controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to Mdl.ConvergenceInfo.History.

This table summarizes the available verbosity level options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display or save convergence information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages and saves convergence criteria every numprint iterations, where numprint is the value of the name-value pair argument 'NumPrint'.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays diagnostic messages and saves convergence criteria at every iteration.</td>
</tr>
</tbody>
</table>

Example: 'Verbose',1

Data Types: double | single

Other Classification Options

CategoricalPredictors — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td><strong>Value</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code>. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code>.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (`Tbl`), `fitcsvm` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcsvm` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `{'CategoricalPredictors','all'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**ClassNames — Names of classes to use for training**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `ClassNames`,{'a','c'}. 
The default value for **ClassNames** is the set of all distinct class names in \( Y \).

Example: `ClassNames`,{
'\( b \)', '\( g \)'}

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**Cost — Misclassification cost**

Square matrix | structure array

Misclassification cost specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify the square matrix \( \text{Cost} \) and the true class of an observation is \( i \), then \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \). That is, rows correspond to the true classes and columns correspond to predicted classes. To specify the class order for the corresponding rows and columns of \( \text{Cost} \), also specify the **ClassNames** name-value pair argument.

- If you specify the structure \( S \), then it must have two fields:
  - \( S.\text{ClassNames} \), which contains the class names as a variable of the same data type as \( Y \)
  - \( S.\text{ClassificationCosts} \), which contains the cost matrix with rows and columns ordered as in \( S.\text{ClassNames} \)

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Consequently, the cost matrix resets to the default. For more details on the relationships and algorithmic behavior of **BoxConstraint**, **Cost**, **Prior**, **Standardize**, and **Weights**, see “Algorithms” on page 32-2005.

The default values are:

- \( \text{Cost} = 0 \) for one-class learning
- \( \text{Cost}(i,j) = 1 \) if \( i \neq j \) and \( \text{Cost}(i,j) = 0 \) if \( i = j \) for two-class learning

Example: 'Cost',[0,1;2,0]

Data Types: `double` | `single` | `struct`

**PredictorNames — Predictor variable names**

String array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character
vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcsvm uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
</tbody>
</table>
### Value | Description
--- | ---
numeric vector | Each element in the vector is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements to sum to 1.

structure | A structure `S` with two fields:
- `S.ClassNames` contains the class names as a variable of the same type as `Y`.
- `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements of the vector to sum to 1.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2005.

Example: `struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...
Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'            | -1 for \( x < 0 \) 
                    0 for \( x = 0 \) 
                    1 for \( x > 0 \) |
| 'symmetric'       | \( 2x - 1 \)                                        |
| 'symmetricismax'  | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit'  | \( \frac{2}{1 + e^{-x}} - 1 \)                       |

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or the name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a
character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response variable when training the model.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

The software normalizes Weights to sum up to the value of the prior probability in the respective class. For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see “Algorithms” on page 32-2005.

Data Types: double | single | char | string

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier
'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the CVPartition, Holdout, KFold, or Leaveout name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'Crossval','on'

CVPartition — Cross-validation partition
[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The
partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1. Randomly partition the data into k sets.
2. For each set, reserve the set as validation data, and train the model using the other k - 1 sets.
3. Store the k compact, trained models in the cells of a k-by-1 cell vector in the `Trained` property of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the $n$ observations (where $n$ is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
2. Store the $n$ compact, trained models in the cells of an $n$-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Convergence Control Options**

**DeltaGradientTolerance — Tolerance for gradient difference**

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

If DeltaGradientTolerance is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- $1 \times 10^{-3}$ if the solver is SMO (for example, you set 'Solver','SMO')
- 0 if the solver is ISDA (for example, you set 'Solver','ISDA')
Example: 'DeltaGradientTolerance',1e-2
Data Types: double | single

**GapTolerance — Feasibility gap tolerance**

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If GapTolerance is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: 'GapTolerance',1e-2
Data Types: double | single

**IterationLimit — Maximal number of numerical optimization iterations**

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. Mdl.ConvergenceInfo contains convergence information.

Example: 'IterationLimit',1e8
Data Types: double | single

**KKTTolerance — Karush-Kuhn-Tucker complementarity conditions violation tolerance**

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2001 violation tolerance, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar.

If KKTTolerance is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- 0 if the solver is SMO (for example, you set 'Solver','SMO')
• 1e-3 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'KKT Tolerance', 1e-2
Data Types: double | single

**ShrinkagePeriod — Number of iterations between reductions of active set**

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod', 0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod', 1000
Data Types: double | single

**Hyperparameter Optimization Options**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

• 'none' — Do not optimize.
• 'auto' — Use {'BoxConstraint', 'KernelScale'}.
• 'all' — Optimize all eligible parameters.
• String array or cell array of eligible parameter names.
• Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitcsvm by varying the parameters. For information about cross-validation loss see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair argument.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.
The eligible parameters for \texttt{fitcsvm} are:

- **BoxConstraint** — \texttt{fitcsvm} searches among positive values, by default log-scaled in the range $[1e^{-3}, 1e3]$.
- **KernelScale** — \texttt{fitcsvm} searches among positive values, by default log-scaled in the range $[1e^{-3}, 1e3]$.
- **KernelFunction** — \texttt{fitcsvm} searches among 'gaussian', 'linear', and 'polynomial'.
- **PolynomialOrder** — \texttt{fitcsvm} searches among integers in the range $[2, 4]$.
- **Standardize** — \texttt{fitcsvm} searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of \texttt{optimizableVariable} objects that have nondefault values. For example:

```matlab
load fisheriris
params = hyperparameters('fitcsvm', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass \texttt{params} as the value of \texttt{OptimizeHyperparameters}.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log$(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the \texttt{Verbose} field of the \texttt{'HyperparameterOptimizationOptions'} name-value pair argument. To control the plots, set the \texttt{ShowPlots} field of the \texttt{'HyperparameterOptimizationOptions'} name-value pair argument.

For an example, see “Optimize SVM Classifier” on page 32-1971.

**Example: 'auto'

**HyperparameterOptimizationOptions** — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of \texttt{'HyperparameterOptimizationOptions'} and a structure. This argument modifies the effect of the \texttt{OptimizeHyperparameters} name-value pair argument. All fields in the structure are optional.

Data Types: struct

### Output Arguments

**Md1 — Trained SVM classification model**

ClassificationSVM model object | ClassificationPartitionedModel cross-validated model object

Trained SVM classification model, returned as a ClassificationSVM model object or ClassificationPartitionedModel cross-validated model object.
If you set any of the name-value pair arguments KFold, Holdout, Leaveout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated classifier. Otherwise, Mdl is a ClassificationSVM classifier.

To reference properties of Mdl, use dot notation. For example, enter Mdl.Alpha in the Command Window to display the trained Lagrange multipliers.

Limitations

- fitcsvm trains SVM classifiers for one-class or two-class learning applications. To train SVM classifiers using data with more than two classes, use fitcecoc.
- fitcsvm supports low-dimensional and moderate-dimensional data sets. For high-dimensional data sets, use fitclinear instead.

Definitions

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors \{x_1,..,x_n; x_j \in \mathbb{R}^p\} is an n-by-n matrix with element (j,k) defined as \(G(x_j,x_k) = \langle \phi(x_j), \phi(x_k) \rangle\), an inner product of the transformed predictors using the kernel function \(\phi\).

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data X. The dual formalization replaces the inner product of the observations in X with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.
Karush-Kuhn-Tucker (KKT) Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

\[
\begin{align*}
\alpha_j \left[ y_j f(x_j) - 1 + \xi_j \right] &= 0 \\
\xi_j (C - \alpha_j) &= 0 
\end{align*}
\]

for all \( j = 1,\ldots,n \), where \( f(x_j) = \phi(x_j)^T \beta + b \), \( \phi \) is a kernel function (see Gram matrix on page 32-2000), and \( \xi_j \) is a slack variable. If the classes are perfectly separable, then \( \xi_j = 0 \) for all \( j = 1,\ldots,n \).

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-2002. The objective is to minimize the dual expression

\[
0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)
\]

with respect to \( \alpha_1,\ldots,\alpha_n \), subject to

\[
\sum \alpha_j = n\nu
\]

and \( 0 \leq \alpha_j \leq 1 \) for all \( j = 1,\ldots,n \). The value of \( G(x_j,x_k) \) is in element \((j,k)\) of the Gram matrix on page 32-2000.

A small value of \( \nu \) leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of \( \nu \) leads to more support vectors and, therefore, a curvy, flexible
decision boundary. The optimal value of $\nu$ should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see [5].

**Support Vector**

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \ldots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

**Support Vector Machines for Binary Classification**

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- $x$ is an observation (corresponding to a row of $X$).
- The vector $\beta$ contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `Mdl.Beta`). For separable data, the optimal margin length is $2 / \|\beta\|$.  
- $b$ is the bias term (corresponding to `Mdl.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point $z$ to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate.
For separable classes, the objective is to minimize $\|\beta\|$ with respect to the $\beta$ and $b$ subject to $y_j f(x_j) \geq 1$, for all $j = 1,...,n$. This is the primal formalization for separable classes.

For inseparable classes, the algorithm uses slack variables ($\xi_j$) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the $\beta$, $b$, and $\xi_j$ subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1,...,n$, and for a positive scalar box constraint on page 32-2000 $C$. This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces $n$ coefficients $\alpha_1,...,\alpha_n$ (corresponding to `Mdl.Alpha`). The dual formalizations for linear SVM are as follows:

For separable classes, minimize

$$0.5\sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k x_j^\prime x_k - \sum_{j=1}^{n} \alpha_j$$

with respect to $\alpha_1,...,\alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1,...,n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2001.

For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1,...,n$.

The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^{n} \hat{\alpha}_j y_j x^\prime x_j + \hat{b}.$$ 

$\hat{b}$ is the estimate of the bias and $\hat{\alpha}_j$ is the $j$th estimate of the vector $\hat{\alpha}$, $j = 1,...,n$. Written this way, the score function is free of the estimate of $\beta$ as a result of the primal formalization.
The SVM algorithm classifies a new observation \( z \) using \( \text{sign}(\hat{f}(z)) \).

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

\[
0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^{n} \alpha_j
\]

with respect to \( \alpha_1, \ldots, \alpha_n \), subject to \( \sum \alpha_j y_j = 0 \), \( 0 \leq \alpha_j \leq C \) for all \( j = 1, \ldots, n \), and the KKT complementarity conditions. \( G(x_k, x_j) \) are elements of the Gram matrix on page 32-2000.

The resulting score function is

\[
\hat{f}(x) = \sum_{j=1}^{n} \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.
\]

For more details, see Understanding Support Vector Machines on page 18-183, [1], and [3].

**Tips**

- Unless your data set is large, always try to standardize the predictors (see Standardize). Standardization makes predictors insensitive to the scales on which they are measured.

- It is a good practice to cross-validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.

- For one-class learning:
  - The default setting for the name-value pair argument Alpha can lead to long training times. To speed up training, set Alpha to a vector mostly composed of 0s.
  - Set the name-value pair argument Nu to a value closer to 0 to yield fewer support vectors and, therefore, a smoother but crude decision boundary.
• Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set BoxConstraint to a large value. This action increases the training time.

• For optimal training time, set CacheSize as high as the memory limit your computer allows.

• If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active set using the name-value pair argument 'ShrinkagePeriod'. It is a good practice to specify 'ShrinkagePeriod',1000.

• Duplicate observations that are far from the decision boundary do not affect convergence. However, just a few duplicate observations that occur near the decision boundary can slow down convergence considerably. To speed up convergence, specify 'RemoveDuplicates',true if:

  • Your data set contains many duplicate observations.
  • You suspect that a few duplicate observations fall near the decision boundary.

To maintain the original data set during training, fitcsvm must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify true for data sets containing few duplicates, then fitcsvm consumes close to double the memory of the original data.

• After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

• For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-2002 and “Understanding Support Vector Machines” on page 18-183.

• NaN, <undefined>, empty character vector (''), empty string ('"'), and <missing> values indicate missing values. fitcsvm removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), fitcsvm ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal BoxConstraint.
• `fitcsvm` removes observations that have zero weight or prior probability.
• For two-class learning, if you specify the cost matrix \( C \) (see `Cost`), then the software updates the class prior probabilities \( p \) (see `Prior`) to \( p_c \) by incorporating the penalties described in \( C \).

Specifically, `fitcsvm` completes these steps:

1. Compute \( p^*_c = p'C \).
2. Normalize \( p^*_c \) so that the updated prior probabilities sum to 1.

\[
p_c = \frac{1}{K} \sum_{j=1}^{K} p^*_{c,j}.
\]

\( K \) is the number of classes.
3. Reset the cost matrix to the default

\[
C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.
\]
4. Remove observations from the training data corresponding to classes with zero prior probability.

• For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation \( j \) in class \( k \) is

\[
w^*_j = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k}.
\]

\( w_j \) is the normalized weight for observation \( j \); \( p_{c,k} \) is the updated prior probability of class \( k \) (see previous bullet).

• For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation \( j \) is
\[ C_j = nC_0w_j^*. \]

\( n \) is the training sample size, \( C_0 \) is the initial box constraint (see the 'BoxConstraint' name-value pair argument), and \( w_j^* \) is the total weight of observation \( j \) (see previous bullet).

- If you set 'Standardize', true and the 'Cost', 'Prior', or 'Weights' name-value pair argument, then fitcsvm standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, fitcsvm standardizes predictor \( j \) (\( x_j \)) using

\[ x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}. \]

\[ \mu_j^* = \frac{1}{\sum_j w_j^*} \sum_k w_k^* x_{jk}. \]

\( x_{jk} \) is observation \( k \) (row) of predictor \( j \) (column).

\[ (\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* (x_{jk} - \mu_j^*)^2. \]

\[ v_1 = \sum_j w_j^*. \]

\[ v_2 = \sum (w_j^*)^2. \]

- Assume that \( p \) is the proportion of outliers that you expect in the training data, and that you set 'OutlierFraction', \( p \).

- For one-class learning, the software trains the bias term such that 100\( p \)% of the observations in the training data have negative scores.

- The software implements robust learning for two-class learning. In other words, the software attempts to remove 100\( p \)% of the observations when the optimization
algorithm converges. The removed observations correspond to gradients that are large in magnitude.

- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.

- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.

- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.

- The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are \( m \) support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an \( n \)-by-5 matrix.

- The `X` property stores the training data as originally input and does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.

- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.

  - For a variable with \( k \) ordered levels, the software creates \( k - 1 \) dummy variables. The \( j \)th dummy variable is -1 for levels up to \( j \), and +1 for levels \( j + 1 \) through \( k \).

  - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores \( k - 1 \) additional predictor names for the dummy variables, including the names of levels 2, 3, ..., \( k \).

- All solvers implement \( L1 \) soft-margin minimization.

- For one-class learning, the software estimates the Lagrange multipliers, \( \alpha_1, ..., \alpha_n \), such that
\[ \sum_{j=1}^{n} \alpha_j = nv. \]

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.
To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
- The 'KernelFunction' option must not specify a custom kernel.
- The 'Solver' option can be set to only 'SMO'.
- The 'OutlierFraction' option is not supported.
- The 'Alpha' option must specify a feasible starting point.
- The 'OptimizeHyperparameters' option is not supported.
- One-class classification is not supported. The labels must contain two different classes.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced in R2014a**
fitctree

Fit binary classification decision tree for multiclass classification

Syntax

tree = fitctree(Tbl,ResponseVarName)
tree = fitctree(Tbl,formula)
tree = fitctree(Tbl,Y)
tree = fitctree(X,Y)
tree = fitctree(___,Name,Value)

Description

tree = fitctree(Tbl,ResponseVarName) returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table Tbl and output (response or labels) contained in ResponseVarName. The returned binary tree splits branching nodes based on the values of a column of Tbl.

tree = fitctree(Tbl,formula) returns a fitted binary classification decision tree based on the input variables contained in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit tree.

tree = fitctree(Tbl,Y) returns a fitted binary classification decision tree based on the input variables contained in the table Tbl and output in vector Y.

tree = fitctree(X,Y) returns a fitted binary classification decision tree based on the input variables contained in matrix X and output Y. The returned binary tree splits branching nodes based on the values of a column of X.

tree = fitctree(___,Name,Value) fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.
Examples

Grow a Classification Tree

Grow a classification tree using the ionosphere data set.

```matlab
load ionosphere
tc = fitctree(X,Y)
```

```matlab
tc =
    ClassificationTree
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
        ScoreTransform: 'none'
        NumObservations: 351
```

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the ionosphere data set.

```matlab
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.
Train a classification tree using the default values for tree depth control. Cross-validate the model using 10-fold cross-validation.

```matlab
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```matlab
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```
view(MdlDefault.Trained{1},'Mode','graph')

The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model using 10-fold cross-validation.

Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
Compare the cross-validation classification errors of the models.

classErrorDefault = kfoldLoss(MdlDefault)
classErrorDefault = 0.1140

classError7 = kfoldLoss(Mdl7)
classError7 = 0.1254

Mdl7 is much less complex and performs only slightly worse than MdlDefault.
**Optimize Classification Tree**

This example shows how to optimize hyperparameters automatically using `fitctree`. The example uses Fisher's iris data.

Load Fisher's iris data.

```matlab
load fisheriris
```

Optimize the cross-validation loss of the classifier, using the data in `meas` to predict the response in `species`.

```matlab
X = meas;
Y = species;
Mdl = fitctree(X,Y,'OptimizeHyperparameters','auto')
```

Properties, Methods

Unbiased Predictor Importance Estimates

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, martial status, race, sex, capital gain and loss, and number of working hours per week.

load census1994
X = adultdata(:,{'age','workClass','education_num','marital_status','race','...' sex','capital_gain','capital_loss','hours_per_week','salary'});

Display the number of categories represented in the categorical variables using summary.

- Median: 40
- Max: 99

salary: 32561x1 categorical

Values:
Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```matlab
Mdl = fitctree(X,'salary','PredictorSelection','curvature',... 'Surrogate','on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```matlab
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```
In this case, `capital_gain` is the most important predictor, followed by `education_num`.

**Optimize Classification Tree on Tall Array**

This example shows how to optimize hyperparameters of a classification tree automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.
Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat 'NA' values as missing data so that datastore replaces them with NaN values. Create a tall table that contains the data in the datastore.

```matlab
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',... 'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table
```

```
M×7 tall table
    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    Distance    DepDelay
    _____    __________    _________    _______    ________    ________    ________
    10          21            3          642          8         308          12
    10          26            1         1021          8         296           1
    10          23            5         2055         21         480          20
    10          23            5         1332         13         296          12
    10          22            4          629          4         373          -1
    10          28            3         1446         59         308          63
    10           8            4          928          3         447          -2
    10          10            6          859         11         954          -1
    :          :             :           :          :           :           :
    :          :             :           :          :           :           :
```

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment.

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

```matlab
Y = tt.DepDelay > 10 % Class labels
```

```
M×1 tall logical array

1
0
```
Create a tall array for the predictor data.

\[ X = tt\{:,1:end-1\} \quad \% \text{Predictor data} \]

\[ X = \]

\[
\begin{array}{cccccc}
10 & 21 & 3 & 642 & 8 & 308 \\
10 & 26 & 1 & 1021 & 8 & 296 \\
10 & 23 & 5 & 2055 & 21 & 480 \\
10 & 23 & 5 & 1332 & 13 & 296 \\
10 & 22 & 4 & 629 & 4 & 373 \\
10 & 28 & 3 & 1446 & 59 & 308 \\
10 & 8 & 4 & 928 & 3 & 447 \\
10 & 10 & 6 & 859 & 11 & 954 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\end{array}
\]

Remove rows in \( X \) and \( Y \) that contain missing data.

\[ R = rmmissing([X \ Y]); \quad \% \text{Data with missing entries removed} \]

\[ X = R(:,1:end-1); \]

\[ Y = R(:,end); \]

Standardize the predictor variables.

\[ Z = zscore(X); \]

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'MinLeafSize' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'MinLeafSize'.) For reproducibility, set the random seed for tall arrays and use the 'expected-improvement-plus' acquisition function.

\[ \text{rng('default') } \% \text{For reproducibility} \]

\[ [Mdl,FitInfo,HyperparameterOptimizationResults] = fitctree(Z,Y,...] \]
'OptimizeHyperparameters', 'auto', ...
'HyperparameterOptimizationOptions', struct('Holdout', 0.3, ...
'AcquisitionFunctionName', 'expected-improvement-plus'))

Input Arguments

Tbl — Sample data
    table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to
one observation, and each column corresponds to one predictor variable. Optionally, Tbl
can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

**ResponseVarName — Response variable name**

`name of variable in Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

**formula — Explanatory model of response and subset of predictor variables**

`character vector | string scalar`

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`. 
Data Types: char | string

Y — Class labels
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

When fitting the tree, fitctree considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. fitctree does not use observations with missing values for Y in the fit.

For numeric Y, consider fitting a regression tree using fitrtree instead.

Data Types: single | double | categorical | logical | char | string | cell

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

fitctree considers NaN values in X as missing values. fitctree does not use observations with all missing values for X in the fit. fitctree uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.
Example: 'CrossVal','on','MinLeafSize',40 specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

Model Parameters

AlgorithmForCategorical — Algorithm for best categorical predictor split

Value for best categorical predictor split: 'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with C categories for data and K ≥ 3 classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Exact'</td>
<td>Consider all $2^{C-1} - 1$ combinations.</td>
</tr>
<tr>
<td>'PullLeft'</td>
<td>Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.</td>
</tr>
<tr>
<td>'PCA'</td>
<td>Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all C - 1 splits.</td>
</tr>
<tr>
<td>'OVAbyClass'</td>
<td>Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.</td>
</tr>
</tbody>
</table>
**fitctree** automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, **fitctree** always performs the exact search. To specify a particular algorithm, use the 'AlgorithmForCategorical' name-value pair argument.

Example: 'AlgorithmForCategorical','PCA'

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), **fitctree** assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), **fitctree** assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell
ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, also specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same data type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.
Data Types: single | double | struct

MaxDepth — Maximum tree depth
positive integer

Maximum tree depth, specified as a positive integer. Specify a value for this parameter to return a tree with fewer levels that requires fewer passes through the tall array to compute. Generally the algorithm of fitctree takes one pass through the data and an additional pass for each tree level. There is no maximum tree depth by default.

**Note** This option only applies when using fitctree on tall arrays. See Extended Capabilities on page 32-2092 for more information.

MaxNumCategories — Maximum category levels
10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. fitctree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxNumCategories levels in the split node. Otherwise, fitctree finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: 'MaxNumCategories',8

MergeLeaves — Leaf merge flag
'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If MergeLeaves is 'on', then fitctree:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, fitctree does not merge leaves.
Example: 'MergeLeaves','off'

**MinParentSize — Minimum number of branch node observations**

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize,2*MinLeafSize).

Example: 'MinParentSize',8

Data Types: single | double

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2','...'}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitctree uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.
Example: 'PredictorNames',
{ 'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth' }
Data Types: string | cell

**PredictorSelection — Algorithm used to select the best split predictor**
'
'allsplit'
's'(default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-
separated pair consisting of 'PredictorSelection' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allsplit'</td>
<td>Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].</td>
</tr>
<tr>
<td>'curvature'</td>
<td>Curvature test on page 32-2083 — Selects the split predictor that minimizes the ( p )-value of chi-square tests of independence between each predictor and the response [4]. Training speed is similar to standard CART.</td>
</tr>
</tbody>
</table>
| 'interaction-
  curvature'         | Interaction test on page 32-2085 — Chooses the split predictor that minimizes the \( p \)-value of chi-square tests of independence between each predictor and the response, and that minimizes the \( p \)-value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART. |

For 'curvature' and 'interaction-curvature', if all tests yield \( p \)-values greater than 0.05, then fitctree stops splitting nodes.

**Tip**

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see predictorImportance.
• Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].

• Prediction speed is unaffected by the value of 'PredictorSelection'.

For details on how fitctree selects split predictors, see “Node Splitting Rules” on page 32-2087.

Example: 'PredictorSelection', 'curvature'

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

• A character vector or string scalar:
  • 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, fitctree uses the weights to compute the class probabilities.
  • 'uniform' sets all class probabilities equal.

• A vector (one scalar value for each class). To specify the class order for the corresponding elements of Prior, also specify the ClassNames name-value pair argument.

• A structure S with two fields:
  • S.ClassNames containing the class names as a variable of the same type as Y
  • S.ClassProbs containing a vector of corresponding probabilities

If you set values for both weights and prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Data Types: char | string | single | double | struct
**Prune — Flag to estimate optimal sequence of pruned subtrees**

'off' (default) | 'on'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If Prune is 'on', then fitctree grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, fitctree grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained ClassificationTree model, pass it to prune.

Example: 'Prune','off'

**PruneCriterion — Pruning criterion**

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'error' or 'impurity'.

Example: 'PruneCriterion','impurity'

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar representing the name of the response variable.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName','IrisType'

Data Types: char | string

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1-x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>(-1 ) for ( x &lt; 0 ) \n( 0 ) for ( x = 0 ) \n( 1 ) for ( x &gt; 0 )</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>( 2x - 1 )</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to (-1)</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{-x}} - 1 )</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Surrogate — Surrogate decision splits flag**

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits on page 32-2087 flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', fitctree finds at most 10 surrogate splits at each branch node.
- When set to 'all', fitctree finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, fitctree finds at most the specified number of surrogate splits at each branch node.
Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 32-2087.

Example: 'Surrogate','on'

Data Types: single | double | char | string

**Weights — Observation weights**

`ones(size(x,1),1)` (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The software weights the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors when training the model.

**fitctree** normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double | char | string

**Cross-Validation**

**CrossVal — Flag to grow cross-validated decision tree**

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If 'on', **fitctree** grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: 'CrossVal','on'
**CVPartition — Partition for cross-validated tree**
cvpartition object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout — Fraction of data for holdout validation**
\[ 0 \text{ (default)} | \text{scalar value in the range } [0,1] \]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range \([0,1]\). Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

**KFold — Number of folds**
\[ 10 \text{ (default)} | \text{positive integer value greater than 1} \]

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', \(k\), then the software:

1. Randomly partitions the data into \(k\) sets
2. For each set, reserves the set as validation data, and trains the model using the other \(k-1\) sets
3. Stores the \(k\) compact, trained models in the cells of a \(k\)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold', 8

Data Types: single | double
Leaveout — Leave-one-out cross-validation flag
'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Specify 'on' to use leave-one-out cross-validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

Hyperparameter Optimization

MaxNumSplits — Maximal number of decision splits
size(X,1) - 1 (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. fitctree splits MaxNumSplits or fewer branch nodes. For more details on splitting behavior, see Algorithms on page 32-2087.

Example: 'MaxNumSplits',5

Data Types: single | double

MinLeafSize — Minimum number of leaf node observations
1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize,2*MinLeafSize).

Example: 'MinLeafSize',3

Data Types: single | double

NumVariablesToSample — Number of predictors to select at random for each split
'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. You can also specify 'all' to use all available predictors.
Example: 'NumVariablesToSample',3
Data Types: char | string | single | double

**SplitCriterion — Split criterion**

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion','deviance'

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitctree by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitctree are:
• **MaxNumSplits** — `fitctree` searches among integers, by default log-scaled in the range \([1, \max(2, \text{NumObservations}-1)]\).

• **MinLeafSize** — `fitctree` searches among integers, by default log-scaled in the range \([1, \max(2, \text{floor(NumObservations/2)})]\).

• **SplitCriterion** — For two classes, `fitctree` searches among 'gdi' and 'deviance'. For three or more classes, `fitctree` also searches among 'twoing'.

• **NumVariablesToSample** — `fitctree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitctree` simply uses the full number of predictors. However, `fitcensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitctree',meas,species);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \(\log(1 + \text{cross-validation loss})\) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Classification Tree” on page 32-2016.

Example: 'auto'

**HyperparameterOptimizationOptions** — Options for optimization

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>
<thead>

Example:

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

**tree — Classification tree**
classification tree object

Classification tree, returned as a classification tree object.

Using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a
partitioned tree for prediction, so this kind of tree does not have a predict method. Instead, use kfoldpredict to predict responses for observations not used for training.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

Definitions

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable \( x \) and \( y \) is conducted using this process.

1. If \( x \) is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2. For each level in the partitioned predictor \( j = 1...J \) and class in the response \( k = 1,...,K \), compute the weighted proportion of observations in class \( k \)

\[
\hat{p}_{jk} = \frac{1}{n} \sum_{i=1}^{n} I(y_i = k)w_i.
\]

\( w_i \) is the weight of observation \( i \), \( \sum w_i = 1 \), \( I \) is the indicator function, and \( n \) is the sample size. If all observations have the same weight, then \( \hat{p}_{jk} = \frac{n_{jk}}{n} \), where \( n_{jk} \) is the number of observations in level \( j \) of the predictor that are in class \( k \).

3. Compute the test statistic

\[
t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \left( \frac{\hat{p}_{jk} - \hat{p}_{j+k} + \hat{p}_{j+k}}{\hat{p}_{j+k} + \hat{p}_{j+k}} \right)^2
\]
\[ \hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}, \] that is, the marginal probability of observing the predictor at level \( j \).

\[ \hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}, \] that is the marginal probability of observing class \( k \). If \( n \) is large enough, then \( t \) is distributed as a \( \chi^2 \) with \((K - 1)(J - 1)\) degrees of freedom.

4 If the \( p \)-value for the test is less than 0.05, then reject the null hypothesis that there is no association between \( x \) and \( y \).

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant \( p \)-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

**Note** If levels of a predictor are pure for a particular class, then \texttt{fitctree} merges those levels. Therefore, in step 3 of the algorithm, \( J \) can be less than the actual number of levels in the predictor. For example, if \( x \) has 4 levels, and all observations in bins 1 and 2 belong to class 1, then those levels are pure for class 1. Consequently, \texttt{fitctree} merges the observations in bins 1 and 2, and \( J \) reduces to 3.

For more details on how the curvature test applies to growing classification trees, see “Node Splitting Rules” on page 32-2087 and [4].

**Impurity and Node Error**

\texttt{ClassificationTree} splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the \texttt{SplitCriterion} name-value pair argument:

- Gini's Diversity Index (\texttt{gdi}) — The Gini index of a node is
where the sum is over the classes $i$ at the node, and $p(i)$ is the observed fraction of classes with class $i$ that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$1 - \sum_i p^2(i),$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class $i$ in the left child node after a split, and $R(i)$ denote the fraction of members of class $i$ in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If $j$ is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

**Interaction Test**

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables $x_1$ and $x_2$ with respect to $y$ is conducted using this process.
1 If \( x_1 \) or \( x_2 \) is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2 Create the nominal variable \( z \) with \( J = J_1J_2 \) levels that assigns an index to observation \( i \) according to which levels of \( x_1 \) and \( x_2 \) it belongs. Remove any levels of \( z \) that do not correspond to any observations.

3 Conduct a curvature test on page 32-2083 between \( z \) and \( y \).

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-2083, “Node Splitting Rules” on page 32-2087 and [3].

**Predictive Measure of Association**

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2087 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose \( x_j \) and \( x_k \) are predictor variables \( j \) and \( k \), respectively, and \( j \neq k \). At node \( t \), the predictive measure of association between the optimal split \( x_j < u \) and a surrogate split \( x_k < v \) is

\[
\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j}L_{k} - P_{R_j}R_{k})}{\min(P_L, P_R)}.
\]

- \( P_L \) is the proportion of observations in node \( t \), such that \( x_j < u \). The subscript \( L \) stands for the left child of node \( t \).
- \( P_R \) is the proportion of observations in node \( t \), such that \( x_j \geq u \). The subscript \( R \) stands for the right child of node \( t \).
- \( P_{L_j}L_{k} \) is the proportion of observations at node \( t \), such that \( x_j < u \) and \( x_k < v \).
$P_{R_j R_k}$ is the proportion of observations at node $t$, such that $x_j \geq u$ and $x_k \geq v$.

• Observations with missing values for $x_j$ or $x_k$ do not contribute to the proportion calculations.

$\lambda_{jk}$ is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

**Surrogate Decision Splits**

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2562.

**Tip**

• By default, Prune is 'on'. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to prune.

• After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see "Introduction to Code Generation" on page 31-2.

**Algorithms**

**Node Splitting Rules**

`fitctree` uses these processes to determine how to split node $t$.

• For standard CART (that is, if `PredictorSelection` is 'allpairs') and for all predictors $x_i, i = 1, \ldots, p$: 
1. `fitctree` computes the weighted impurity of node $t$, $i_t$. For supported impurity measures, see `SplitCriterion`.

2. `fitctree` estimates the probability that an observation is in node $t$ using

$$ P(T) = \sum_{j \in T} w_j. $$

$w_j$ is the weight of observation $j$, and $T$ is the set of all observation indices in node $t$. If you do not specify `Prior` or `Weights`, then $w_j = 1/n$, where $n$ is the sample size.

3. `fitctree` sorts $x_i$ in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitctree` stores any indices corresponding to missing values in the set $T_U$, which is the unsplit set.

4. `fitctree` determines the best way to split node $t$ using $x_i$ by maximizing the impurity gain ($\Delta I$) over all splitting candidates. That is, for all splitting candidates in $x_i$:

a. `fitctree` splits the observations in node $t$ into left and right child nodes ($t_L$ and $t_R$, respectively).

b. `fitctree` computes $\Delta I$. Suppose that for a particular splitting candidate, $t_L$ and $t_R$ contain observation indices in the sets $T_L$ and $T_R$, respectively.

   - If $x_i$ does not contain any missing values, then the impurity gain for the current splitting candidate is

   $$ \Delta I = P(T)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}. $$

   - If $x_i$ contains missing values then, assuming that the observations are missing at random, the impurity gain is

   $$ \Delta I_U = P(T - T_U)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}. $$

   $T - T_U$ is the set of all observation indices in node $t$ that are not missing.

   - If you use surrogate decision splits on page 32-2087, then:

   i. `fitctree` computes the predictive measures of association on page 32-2086 between the decision split $x_j < u$ and all possible decision splits $x_k < v$, $j \neq k$. 

   32-2088
ii \texttt{fitctree} sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.

iii \texttt{fitctree} decides the child node assignments for observations with a missing value for $x_i$ using the surrogate split. If the surrogate predictor also contains a missing value, then \texttt{fitctree} uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for \texttt{fitctree} to split two different observations at node $t$ using two different surrogate splits. For example, suppose the predictors $x_1$ and $x_2$ are the best and second best surrogates, respectively, for the predictor $x_i$, $i \notin \{1,2\}$, at node $t$. If observation $m$ of predictor $x_i$ is missing (i.e., $x_{mi}$ is missing), but $x_{m1}$ is not missing, then $x_1$ is the surrogate predictor for observation $x_{mi}$. If observations $x_{(m+1)2}$ and $x(m+1)1$ are missing, but $x_{(m+1)2}$ is not missing, then $x_2$ is the surrogate predictor for observation $m+1$.

iv \texttt{fitctree} uses the appropriate impurity gain formula. That is, if \texttt{fitctree} fails to assign all missing observations in node $t$ to children nodes using surrogate splits, then the impurity gain is $\Delta I_U$. Otherwise, \texttt{fitctree} uses $\Delta I$ for the impurity gain.

c \texttt{fitctree} chooses the candidate that yields the largest impurity gain.

\texttt{fitctree} splits the predictor variable at the cut point that maximizes the impurity gain.

- For the curvature test (that is, if \texttt{PredictorSelection} is 'curvature'):

1 \texttt{fitctree} conducts curvature tests on page 32-2083 between each predictor and the response for observations in node $t$.

- If all $p$-values are at least 0.05, then \texttt{fitctree} does not split node $t$.
- If there is a minimal $p$-value, then \texttt{fitctree} chooses the corresponding predictor to split node $t$.
- If more than one $p$-value is zero due to underflow, then \texttt{fitctree} applies standard CART to the corresponding predictors to choose the split predictor.

2 If \texttt{fitctree} chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

- For the interaction test (that is, if \texttt{PredictorSelection} is 'interaction-curvature'):
For observations in node $t$, `fitctree` conducts curvature tests on page 32-2083 between each predictor and the response and interaction tests on page 32-2085 between each pair of predictors and the response.

- If all $p$-values are at least 0.05, then `fitctree` does not split node $t$.
- If there is a minimal $p$-value and it is the result of a curvature test, then `fitctree` chooses the corresponding predictor to split node $t$.
- If there is a minimal $p$-value and it is the result of an interaction test, then `fitctree` chooses the split predictor using standard CART on the corresponding pair of predictors.
- If more than one $p$-value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.

If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

**Tree Depth Control**

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'error' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.
- To accommodate `MaxNumSplits`, `fitctree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitctree` follows this procedure:

  1. Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
  2. Sort the branch nodes by their impurity gains.
  3. Unsplit the number of least successful branches.
  4. Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
  - There are `MaxNumSplits` branch nodes.
• A proposed split causes the number of observations in at least one branch node to be fewer than MinParentSize.
• A proposed split causes the number of observations in at least one leaf node to be fewer than MinLeafSize.
• The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see PruneCriterion), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
• For values 'curvature' or 'interaction-curvature' of PredictorSelection, all tests yield p-values greater than 0.05.

MaxNumSplits and MinLeafSize do not affect splitting at their default values. Therefore, if you set 'MaxNumSplits', splitting might stop due to the value of MinParentSize, before MaxNumSplits splits occur.

**Parallelization**

**References**

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- Supported syntaxes for tall arrays return the additional output arguments FitInfo and HyperparameterOptimizationResults. The supported syntaxes are:
  - \([\text{tree}, \text{FitInfo}, \text{HyperparameterOptimizationResults}] = \text{fitctree}(\text{Tbl}, Y)\)
  - \([\text{tree}, \text{FitInfo}, \text{HyperparameterOptimizationResults}] = \text{fitctree}(X, Y)\)
  - \([\text{tree}, \text{FitInfo}, \text{HyperparameterOptimizationResults}] = \text{fitctree}(..., \text{Name}, \text{Value})\)
- The FitInfo output argument is an empty structure array currently reserved for possible future use.
- The HyperparameterOptimizationResults output argument is a BayesianOptimization object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

- 'HyperparameterOptimizationResults' is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty at the time you create the model. The values in 'HyperparameterOptimizationResults' depend on the value you specify for the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model.
  - If you specify 'bayesopt' (default), then HyperparameterOptimizationResults is an object of class BayesianOptimization.
  - If you specify 'gridsearch' or 'randomsearch', then HyperparameterOptimizationResults is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).
- Supported name-value pair arguments, and any differences, are:
• 'AlgorithmForCategorical'
• 'CategoricalPredictors'
• 'ClassNames'
• 'Cost'
• 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitctree(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
• 'MaxNumCategories'
• 'MaxNumSplits'— for tall optimization, fitctree searches among integers, by default log-scaled in the range $[1, \max(2, \min(10000, \text{NumObservations}-1))]$.
• 'MergeLeaves'
• 'MinLeafSize'
• 'MinParentSize'
• 'NumVariablesToSample'
• 'OptimizeHyperparameters'
• 'PredictorNames'
• 'Prior'
• 'ResponseName'
• 'ScoreTransform'
• 'SplitCriterion'
• 'Weights'
• There is an additional name-value pair argument specific to tall arrays:

  • 'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this parameter to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally the algorithm of fitctree takes one pass through the data and an additional pass for each tree level. There is no maximum tree depth by default.

For more information, see “Tall Arrays” (MATLAB).
Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

“Splitting Categorical Predictors” on page 19-31

Introduced in R2014a
fitglm

Create generalized linear regression model

Syntax

mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm(___,modelspec)
mdl = fitglm(___,Name,Value)

Description

mdl = fitglm(tbl) returns a generalized linear model fit to variables in the table or dataset array tbl. By default, fitglm takes the last variable as the response variable.

mdl = fitglm(X,y) returns a generalized linear model of the responses y, fit to the data matrix X.

mdl = fitglm(___modelspec) returns a generalized linear model of the type you specify in modelspec.

mdl = fitglm(___Name,Value) returns a generalized linear model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

Examples

Fit a Logistic Regression Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.
Load the hospital dataset array.

```matlab
load hospital
dsa = hospital;
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```matlab
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```matlab
mdl = fitglm(dsa,modelspec,'Distribution','binomial')
```

```matlab
mdl =
Generalized linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
    Distribution = Binomial

Estimated Coefficients:
                          Estimate    SE         tStat     pValue
    __________             _________    ________    _______
    (Intercept)            -6.0492      19.749     -0.3063    0.75938
    Sex_Male               -2.2859      12.424    -0.18399    0.85402
    Age                    0.11691      0.50977     0.22934    0.81861
    Weight                 0.031109     0.15208     0.20455    0.83792
    Sex_Male:Age           0.020734      0.20681     0.10025    0.92014
    Sex_Male:Weight        0.012160      0.053168    0.22871     0.8191
    Age:Weight             -0.00071959   0.0038964    -0.18468    0.85348
```

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large $P$-value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.
GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```matlab
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6])*[.4;.2;.3] + 1);
y = poissrnd(mu);

Fit a generalized linear model using the Poisson distribution.

mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl = 
Generalized linear regression model: 
    log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
    Distribution = Poisson

Estimated Coefficients:
            Estimate    SE         tStat    pValue
    ____________________    ________    ________    __________
    (Intercept)      0.88723    0.070969      12.502    7.3149e-36
    x1               0.44413    0.052337      8.4858    2.1416e-17
    x2             0.0083388    0.056527     0.14752       0.88272
    x3               0.21518    0.063416      3.3932    0.00069087
    x4             -0.058386    0.065503    -0.89135       0.37274
    x5             -0.060824    0.073441     -0.8282       0.40756
    x6               0.34267    0.06146     0.70225       0.48252
    x7               0.04316    0.06146     0.70225       0.48252

100 observations, 92 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22
```

The p-values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables x1, x3, and |x6| are statistically significant.
### Input Arguments

**tbl — Input data**  
`table | dataset array`

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-57).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

**X — Predictor variables**  
`matrix`

Predictor variables, specified as an `n`-by-`p` matrix, where `n` is the number of observations and `p` is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

**y — Response variable**  
`vector`

Response variable, specified as an `n`-by-1 vector, where `n` is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

**modelspec — Model specification**  
`character vector or string scalar specifying the model | t-by-(p+1) terms matrix |  
character vector or string scalar of the form 'Y ~ terms'`

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:
- Character vector or string scalar specifying the type of model.

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear terms for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept, linear terms, and squared terms.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept, linear terms, interactions, and squared terms.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.</td>
</tr>
</tbody>
</table>

- $t$-by-$(p+1)$ matrix, namely “Terms Matrix” on page 32-2106, specifying terms to include in model, where $t$ is the number of terms and $p$ is the number of predictor variables, and plus one is for the response variable.

- Character vector or string scalar representing a “Formula” on page 32-2109 in the form

  `'Y ~ terms'`,

  where the terms are in “Wilkinson Notation” on page 32-2110.

Example: 'quadratic'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
Example: 'Distribution','normal','link','probit','Exclude',[23,59] specifies that the distribution of the response is normal, and instructs \texttt{fitglm} to use the probit link function and exclude the 23rd and 59th observations from the fit.

**BinomialSize — Number of trials for binomial distribution**

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter \( n \) for the fitted binomial distribution. \texttt{BinomialSize} applies only when the \texttt{Distribution} parameter is 'binomial'.

If \texttt{BinomialSize} is a scalar value, that means all observations have the same number of trials.

As an alternative to \texttt{BinomialSize}, you can specify the response as a two-column vector with counts in column 1 and \texttt{BinomialSize} in column 2.

Data Types: single | double

**CategoricalVars — Categorical variable list**

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array \( \texttt{tbl} \), or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array \( \texttt{tbl} \), then, by default, \texttt{fitglm} treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix \( \texttt{X} \), then the default value of 'CategoricalVars' is an empty matrix \([\text{}]\). That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars',[2,3]

Example: 'CategoricalVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell
**DispersionFlag — Indicator to compute dispersion parameter**
false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<table>
<thead>
<tr>
<th>true</th>
<th>Estimate a dispersion parameter when computing standard errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>Default. Use the theoretical value when computing standard errors</td>
</tr>
</tbody>
</table>

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag',true

**Distribution — Distribution of the response variable**
'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

| 'normal'       | Normal distribution                           |
| 'binomial'     | Binomial distribution                         |
| 'poisson'      | Poisson distribution                          |
| 'gamma'        | Gamma distribution                            |
| 'inverse gaussian' | Inverse Gaussian distribution              |

Example: 'Distribution','gamma'

**Exclude — Observations to exclude**
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Intercept — Indicator for constant term**

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

**Link — Link function**

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

<table>
<thead>
<tr>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>( f(\mu) = \mu )</td>
<td>( \mu = Xb )</td>
</tr>
<tr>
<td>'log'</td>
<td>( f(\mu) = \log(\mu) )</td>
<td>( \mu = \exp(Xb) )</td>
</tr>
<tr>
<td>'logit'</td>
<td>( f(\mu) = \log(\mu/(1-\mu)) )</td>
<td>( \mu = \exp(Xb) / (1 + \exp(Xb)) )</td>
</tr>
<tr>
<td>'probit'</td>
<td>( f(\mu) = \Phi^{-1}(\mu) )</td>
<td>( \mu = \Phi(Xb) )</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>( f(\mu) = \log(-\log(1 - \mu)) )</td>
<td>( \mu = 1 - \exp(-\exp(Xb)) )</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>( f(\mu) = 1/\mu )</td>
<td>( \mu = 1/(Xb) )</td>
</tr>
<tr>
<td>p (a number)</td>
<td>( f(\mu) = \mu^p )</td>
<td>( \mu = Xb^{1/p} )</td>
</tr>
</tbody>
</table>
The link function defines the relationship \( f(\mu) = X*b \) between the mean response \( \mu \) and the linear combination of predictors \( X*b \).

For more information on the canonical link functions, see Definitions.

Example: 'Link','probit'

Data Types: char | string | single | double | struct

**Offset — Offset variable**

[ ] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

\[
\mu \sim \text{Offset} + (\text{terms involving real predictors})
\]

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor \( A \). By using the log link function and by specifying \( \log(A) \) as an offset, you can force the model to satisfy this theoretical constraint.
Data Types: single | double | char | string

**PredictorVars — Predictor variables**
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**
last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 1 0 0])
Data Types: single | double | logical | char | string
**VarNames — Names of variables**

```{'x1', 'x2', ..., 'xn', 'y'} (default) | string array | cell array of character vectors```

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: string | cell

**Weights — Observation weights**

```ones(n,1) (default) | n-by-1 vector of nonnegative scalar values```

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

**Output Arguments**

**mdl — Generalized linear model**

```GeneralizedLinearModel object```

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.
Definitions

Terms Matrix

A terms matrix is a $t$-by-$(p + 1)$ matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and plus one is for the response variable. The value of $T(i,j)$ is the exponent of variable $j$ in term $i$. Suppose there are three predictor variables $A$, $B$, and $C$:

\[
\begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 \\
2 & 0 & 0 & 0 \\
0 & 1 & 2 & 0
\end{bmatrix}
\]

% Constant term or intercept
% $B$; equivalently, $A^0 * B^1 * C^0$
% $A*C$
% $A^2$
% $B*(C^2)$

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this using a table.

Load the sample data and define a table.

```matlab
load hospital
dsa = table(hospital.Sex, hospital.BloodPressure(:,1), ...
hospital.Age, hospital.Smoker, 'VariableNames', ...
{'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of 0s for the response variable.

\[
T = [0 \ 0 \ 0 \ 0; 1 \ 0 \ 0 \ 0; 0 \ 0 \ 1 \ 0; 0 \ 0 \ 0 \ 1]
\]

Redefine the table.
dsa = table(hospital.BloodPressure(:,1),hospital.Sex, ... hospital.Age,hospital.Smoker,'VariableNames', ... {'BloodPressure','Sex','Age','Smoker'});

Now, the response variable is the first term in the table. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

\[
T = \begin{bmatrix} 0 & 0 & 0 & 0; 1 & 0 & 0; 0 & 1 & 0; 0 & 0 & 1 \end{bmatrix}
\]

• If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

load carsmall
X = [Acceleration,Weight];

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

\[
T = \begin{bmatrix} 0 & 0 & 0; 1 & 0 & 0; 1 & 0; 0 & 0 \end{bmatrix}
\]

Fit a linear model.

mdl = fitlm(X,MPG,T)

mdl =
Linear regression model:
\[ y \sim 1 + x_1 \times x_2 + x_2^2 \]

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>48.906</td>
<td>12.589</td>
<td>3.8847</td>
<td>0.00019665</td>
</tr>
<tr>
<td>x1</td>
<td>0.54418</td>
<td>0.57125</td>
<td>0.95261</td>
<td>0.34337</td>
</tr>

<td>x2</td>
<td>-0.012781</td>
<td>0.0060312</td>
<td>-2.1192</td>
<td>0.036857</td>
</tr>
<tr>
<td>x1:x2</td>
<td>-0.00010892</td>
<td>0.00017925</td>
<td>-0.6076</td>
<td>0.545</td>
</tr>
<tr>
<td>x2^2</td>
<td>9.7518e-07</td>
<td>7.5389e-07</td>
<td>1.2935</td>
<td>0.19917</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 4.1
R-squared: 0.751, Adjusted R-Squared 0.739
F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

\[ T = [0 \ 0 \ 0;1 \ 0 \ 0;0 \ 1 \ 0;1 \ 1 \ 0]; \]
\[ mdl = \text{stepwiselm}(X, 
\text{MPG},[0 \ 0 \ 0],'\text{upper}',T) \]

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

\[ mdl = \]

Linear regression model:
\[ y \sim 1 + x_2 \]

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>49.238</td>
<td>1.6411</td>
<td>30.002</td>
<td>2.7015e-49</td>
</tr>
<tr>
<td>x2</td>
<td>-0.0086119</td>
<td>0.0005348</td>
<td>-16.103</td>
<td>1.6434e-28</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of \text{fitlm} in the previous step.
**Formula**

A formula for model specification is a character vector or string scalar of the form \( Y \sim \text{terms} \)

where

- \( Y \) is the response name.
- \( \text{terms} \) contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - * defines an interaction and all lower-order terms
  - ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
  - () groups terms

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

\[ Y \sim A + B + C \] means a three-variable linear model with intercept.
\[ Y \sim A + B + C - 1 \] is a three-variable linear model without intercept.
\[ Y \sim A + B + C + B^2 \] is a three-variable model with intercept and a \( B^2 \) term.
\[ Y \sim A + B^2 + C \] is the same as the previous example because \( B^2 \) includes a \( B \) term.
\[ Y \sim A + B + C + A:B \] includes an \( A*B \) term.
\[ Y \sim A*B + C \] is the same as the previous example because \( A*B = A + B + A:B \).
\[ Y \sim A*B*C - A:B:C \] has all interactions among \( A, B, \) and \( C \), except the three-way interaction.
\[ Y \sim A*(B + C + D) \] has all linear terms, plus products of \( A \) with each of the other variables.
Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>

<td>( f(\mu) = 1/\mu^2 )</td>
<td>( \mu = (Xb)^{-1/2} )</td>
</tr>
</tbody>
</table>
Tips

• The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
• For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
• After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Alternative Functionality

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

References

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• If any input argument to `fitglm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights', 'Exclude', 'Offset', and 'BinomialSize' name-value pairs.
• The default number of iterations is 5. You can change the number of iterations using
the 'Options' name-value pair to pass in an options structure. Create an options
structure using statset to specify a different value for MaxIter.

• For tall data, fitglm returns a CompactGeneralizedLinearModel object that
contains most of the same properties as a GeneralizedLinearModel object. The
main difference is that the compact object is sensitive to memory requirements. The
compact object does not include properties that include the data, or that include an
array of the same size as the data. The compact object does not contain these
GeneralizedLinearModel properties:

  • Diagnostics
  • Fitted
  • Offset
  • ObservationInfo
  • ObservationNames
  • Residuals
  • Steps
  • Variables

You can compute the residuals directly from the compact object returned by

GLM = fitglm(X,Y) using

\[
RES = Y - \text{predict(GLM,X)};
S = \sqrt{\text{GLM.SSE/GLM.DFE)}};
\text{histogram(RES,linspace(-3*S,3*S,51))}
\]

For more information, see “Tall Arrays” (MATLAB).

“Generalized Linear Models” on page 12-12

**Introduced in R2013b**
fitglme

Fit generalized linear mixed-effects model

Syntax

```matlab
glme = fitglme(tbl,formula)
glme = fitglme(tbl,formula,Name,Value)
```

Description

glme = fitglme(tbl,formula) returns a generalized linear mixed-effects model, glme. The model is specified by formula and fitted to the predictor variables in the table or dataset array, tbl.

glme = fitglme(tbl,formula,Name,Value) returns a generalized linear mixed-effects model using additional options specified by one or more Name,Value pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

**Fit a Generalized Linear Mixed-Effects Model**

Load the sample data.

```matlab
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In
each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[
defects_{ij} \sim \text{Poisson}(\mu_{ij}).
\]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i,
\]

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- \(\mu_{ij}\) is the mean number of defects corresponding to factory i (where \(i = 1, 2, ..., 20\)) during batch j (where \(j = 1, 2, ..., 5\)).
• `newprocess_{ij}`, `time_dev_{ij}`, and `temp_dev_{ij}` are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, `newprocess_{ij}` indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• `supplier_C_{ij}` and `supplier_B_{ij}` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma^2_b)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)',
               'Distribution','Poisson','Link','log','FitMethod','Laplace',
               'DummyVarCoding','effects');
```

Display the model.

```matlab
disp(glme)
```

Generalized linear mixed-effects model fit by ML

Model information:
- Number of observations: 100
- Fixed effects coefficients: 6
- Random effects coefficients: 20
- Covariance parameters: 1
- Distribution: Poisson
- Link: Log
- FitMethod: Laplace

Formula:
- `defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)`

Model fit statistics:
- AIC: 416.35
- BIC: 434.58
- LogLikelihood: -201.17
- Deviance: 402.35

Random effects covariance parameters:
Group: factory (20 Levels)
Name1                Name2                Type         Estimate
'(Intercept)'        '(Intercept)'        'std'        0.31381

Group: Error
Name                      Estimate
'sqrt(Dispersion)'        1

The Model information table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

Formula indicates the model specification using Wilkinson’s notation.

The Model fit statistics table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The Fixed effects coefficients table indicates that fitglme returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the t-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and p-value that correspond to the t-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.
Random effects covariance parameters displays a table for each grouping variable (here, only factory), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, std indicates that fitglme returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by fitglme does not provide confidence intervals for the random-effects parameters. To compute and display these values, use covarianceParameters.

### Input Arguments

**tbl** — Input data  
`table | dataset array`

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

**formula** — Formula for model specification  
character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 32-2131.

Example: `'y ~ treatment + (1|block)'`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

'`Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVa'
Coding', 'effects' specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

**BinomialSize — Number of trials for binomial distribution**

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. BinomialSize applies only when the Distribution parameter is 'binomial'.

If BinomialSize is a scalar value, that means all observations have the same number of trials.

Data Types: single | double

**CheckHessian — Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

If you specify 'FitMethod' as 'MPL' or 'REMPL', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CheckHessian', true

**CovarianceMethod — Method to compute covariance of estimated parameters**

'conditional' (default) | 'JointHessian'

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of 'CovarianceMethod' and either 'conditional' or 'JointHessian'. If you specify 'conditional', then fitglme computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify 'JointHessian', then fitglme computes the joint covariance of fixed effects and
covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify 'FitMethod' as 'MPL' or 'REMPL', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CovarianceMethod','JointHessian'

**CovariancePattern — Pattern of covariance matrix**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FullCholesky'</td>
<td>Full covariance matrix using the Cholesky parameterization. fitglme estimates all elements of the covariance matrix.</td>
</tr>
</tbody>
</table>

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and 'FullCholesky', 'Isotropic', 'Full', 'Diagonal', 'CompSymm', a square symmetric logical matrix, a string array, or a cell array containing character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'Isotropic' | Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like  
\[
\begin{pmatrix}
\sigma^2_b & 0 & 0 \\
0 & \sigma^2_b & 0 \\
0 & 0 & \sigma^2_b \\
\end{pmatrix}
\]
where \(\sigma^2_1\) is the common variance of the random-effects terms. |
| 'Full'     | Full covariance matrix, using the log-Cholesky parameterization. \texttt{fitlme} estimates all elements of the covariance matrix.             |
| 'Diagonal' | Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.                             |
\[
\begin{pmatrix}
\sigma^2_{b1} & 0 & 0 \\
0 & \sigma^2_{b2} & 0 \\
0 & 0 & \sigma^2_{b3} \\
\end{pmatrix}
\]
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'CompSymm'</td>
<td>Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like $\begin{pmatrix} \sigma^2_{b_1} &amp; \sigma_{b_1,b_2} &amp; \sigma_{b_1,b_2} \ \sigma_{b_1,b_2} &amp; \sigma^2_{b_1} &amp; \sigma_{b_1,b_2} \ \sigma_{b_1,b_2} &amp; \sigma_{b_1,b_2} &amp; \sigma^2_{b_1} \end{pmatrix}$, where $\sigma^2_{b_1}$ is the common variance of the random-effects terms and $\sigma_{b_1,b_2}$ is the common covariance between any two random-effects term.</td>
</tr>
<tr>
<td>PAT</td>
<td>Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if PAT(a,b) = false, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.</td>
</tr>
</tbody>
</table>

For scalar random-effects terms, the default is 'Isotropic'. Otherwise, the default is 'FullCholesky'.

Example: 'CovariancePattern', 'Diagonal'
Example: 'CovariancePattern', {'Full', 'Diagonal'}

Data Types: char | string | logical | cell

**DispersionFlag — Indicator to compute dispersion parameter**

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Estimate a dispersion parameter when computing standard errors</td>
</tr>
<tr>
<td>false</td>
<td>Use the theoretical value of 1.0 when computing standard errors</td>
</tr>
</tbody>
</table>

'DispersionFlag' only applies if 'FitMethod' is 'MPL' or 'REML'.

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag',true

**Distribution — Distribution of the response variable**

'Normal' (default) | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Normal'</td>
<td>Normal distribution</td>
</tr>
<tr>
<td>'Binomial'</td>
<td>Binomial distribution</td>
</tr>
<tr>
<td>'Poisson'</td>
<td>Poisson distribution</td>
</tr>
<tr>
<td>'Gamma'</td>
<td>Gamma distribution</td>
</tr>
<tr>
<td>'InverseGaussian'</td>
<td>Inverse Gaussian distribution</td>
</tr>
</tbody>
</table>

Example: 'Distribution','Binomial'

**DummyVarCoding — Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

**EBMethod — Method used to approximate empirical Bayes estimates of random effects**

'Auto' (default) | 'LineSearchNewton' | 'TrustRegion2D' | 'fsolve'

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of 'EBMethod' and one of the following.

- 'Auto'
- 'LineSearchNewton'
- 'TrustRegion2D'
- 'fsolve'

'Auto' is similar to 'LineSearchNewton' but uses a different convergence criterion and does not display iterative progress. 'Auto' and 'LineSearchNewton' may fail for non-canonical link functions. For non-canonical link functions, 'TrustRegion2D' or 'fsolve' are recommended. You must have Optimization Toolbox to use 'fsolve'.

Example: 'EBMethod','LineSearchNewton'

**EBOptions — Options for empirical Bayes optimization structure**

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of 'EBOptions' and a structure containing the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'TolFun'</td>
<td>Relative tolerance on the gradient norm. Default is 1e-6.</td>
</tr>
<tr>
<td>'TolX'</td>
<td>Absolute tolerance on the step size. Default is 1e-8.</td>
</tr>
<tr>
<td>'MaxIter'</td>
<td>Maximum number of iterations. Default is 100.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'Display'</td>
<td>'off', 'iter', or 'final'. Default is 'off'.</td>
</tr>
</tbody>
</table>

If `EBMethod` is 'Auto' and `FitMethod` is 'Laplace', `TolFun` is the relative tolerance on the linear predictor of the model, and the 'Display' option does not apply.

If 'EBMethod' is 'fsolve', then 'EBOptions' must be specified as an object created by `optimoptions('fsolve')`.

Data Types: struct

**Exclude — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13, 67]

Data Types: single | double | logical

**FitMethod — Method for estimating model parameters**

'MPL' (default) | 'REML' | 'Laplace' | 'ApproximateLaplace'

Method for estimating model parameters, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REML' — Restricted maximum pseudo likelihood
- 'Laplace' — Maximum likelihood using Laplace approximation
- 'ApproximateLaplace' — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: 'FitMethod', 'REML'

**InitPLIterations — Initial number of pseudo likelihood iterations**

10 (default) | integer value in the range [1, ∞)
Initial number of pseudo likelihood iterations used to initialize parameters for ApproximateLaplace and Laplace fit methods, specified as the comma-separated pair consisting of 'InitPLIterations' and an integer value greater than or equal to 1.

Data Types: single | double

**Link — Link function**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>( g(mu) = mu )</td>
</tr>
<tr>
<td></td>
<td>This is the default for the normal distribution.</td>
</tr>
<tr>
<td>'log'</td>
<td>( g(mu) = \log(mu) )</td>
</tr>
<tr>
<td></td>
<td>This is the default for the Poisson distribution.</td>
</tr>
<tr>
<td>'logit'</td>
<td>( g(mu) = \log(mu/(1-mu)) )</td>
</tr>
<tr>
<td></td>
<td>This is the default for the binomial distribution.</td>
</tr>
<tr>
<td>'loglog'</td>
<td>( g(mu) = \log(-\log(mu)) )</td>
</tr>
<tr>
<td>'probit'</td>
<td>( g(mu) = \text{norminv}(mu) )</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>( g(mu) = \log(-\log(1-mu)) )</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>( g(mu) = mu.^(1) )</td>
</tr>
<tr>
<td>Scalar value P</td>
<td>( g(mu) = mu.^(P) )</td>
</tr>
</tbody>
</table>
A structure containing four fields whose values are function handles with the following names:

- S.Link — Link function
- S.Derivative — Derivative
- S.SecondDerivative — Second derivative
- S.Inverse — Inverse of link

Specification of S.SecondDerivative can be omitted if FitMethod is MPL or REMPL, or if S is the canonical link for the specified distribution.

The default link function used by fitglme is the canonical link that depends on the distribution of the response.

<table>
<thead>
<tr>
<th>Response Distribution</th>
<th>Canonical Link Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Normal'</td>
<td>'identity'</td>
</tr>
<tr>
<td>'Binomial'</td>
<td>'logit'</td>
</tr>
<tr>
<td>'Poisson'</td>
<td>'log'</td>
</tr>
<tr>
<td>'Gamma'</td>
<td>-1</td>
</tr>
<tr>
<td>'InverseGaussian'</td>
<td>-2</td>
</tr>
</tbody>
</table>

Example: 'Link', 'log'

Data Types: char | string | single | double | struct

**MuStart — Starting value for conditional mean**

scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of 'MuStart' and a scalar value. Valid values are as follows.
Response Distribution | Valid Values
--- | ---
'Normal' | (-Inf, Inf)
'Binomial' | (0, 1)
'Poisson' | (0, Inf)
'Gamma' | (0, Inf)
'InverseGaussian' | (0, Inf)

Data Types: single | double

**Offset — Offset**

zeros(n, 1) (default) | n-by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an n-by-1 vector of scalar values, where n is the length of the response vector. You can also specify the variable name of an n-by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.

Data Types: single | double

**Optimizer — Optimization algorithm**

'quasinewton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'quasinewton'</td>
<td>Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using statset('fitglme'). If you do not specify the options, then fitglme uses the default options of statset('fitglme').</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'fminsearch'</td>
<td>Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using optimset('fminsearch'). If you do not specify the options, then fitglme uses the default options of optimset('fminsearch').</td>
</tr>
<tr>
<td>'fminunc'</td>
<td>Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using optimoptions('fminunc'). If you do not specify the options, then fitglme uses the default options of optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.</td>
</tr>
</tbody>
</table>

Example: 'Optimizer','fminsearch'

**OptimizerOptions — Options for optimization algorithm**
structure returned by statset | structure returned by optimset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by statset('fitglme'), a structure created by optimset('fminsearch'), or an object returned by optimoptions('fminunc').

- If 'Optimizer' is 'fminsearch', then use optimset('fminsearch') to change the options of the algorithm. If 'Optimizer' is 'fminsearch' and you do not supply 'OptimizerOptions', then the defaults used in fitglme are the default options created by optimset('fminsearch').
- If 'Optimizer' is 'fminunc', then use optimoptions('fminunc') to change the options of the optimization algorithm. See optimoptions for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the defaults used in fitglme are the default options created by optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

32 Functions — Alphabetic List
• If 'Optimizer' is 'quasinewton', then use `statset('fitglme')` to change the optimization parameters. If 'Optimizer' is 'quasinewton' and you do not change the optimization parameters using `statset`, then `fitglme` uses the default options created by `statset('fitglme')`.

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('fitglme')`.

**TolFun — Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**PLIterations — Maximum number of pseudo likelihood iterations**

100 (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of 'PLIterations' and a positive integer value. PL is used for fitting the model if 'FitMethod' is 'MPL' or 'REMPL'. For other 'FitMethod' values, PL iterations are used to initialize parameters for subsequent optimization.

Example: 'PLIterations', 200

Data Types: `single` | `double`

**PLTolerance — Relative tolerance factor for pseudo likelihood iterations**

1e-08 (default) | positive scalar value
Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of 'PLTolerance' and a positive scalar value.

Example: 'PLTolerance',1e-06

Data Types: single | double

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**UseSequentialFitting — Initial fitting type**

false (default) | true

, specified as the comma-separated pair consisting of 'UseSequentialFitting' and either false or true. If 'UseSequentialFitting' is false, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If 'UseSequentialFitting' is true, the initial values from pseudo likelihood iterations are refined using 'ApproximateLaplace' for 'Laplace' fitting.

Example: 'UseSequentialFitting',true

**Verbose — Indicator to display optimization process on screen**

0 (default) | 1 | 2

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. If 'Verbose' is specified as 1 or 2, then fitglme displays the progress of the iterative model-fitting process. Specifying 'Verbose' as 2 displays iterative optimization information from the individual pseudo likelihood iterations. Specifying 'Verbose' as 1 omits this display.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',1

32-2130
Weights — Observation weights
vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: single | double

Output Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table tbl contains the following:

- A response variable, y
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random_1|g_1) + ... + (random_R|g_R)', the term fixed corresponds to a specification of the fixed-effects design matrix X,
random_i is a specification of the random-effects design matrix \( Z_i \) corresponding to grouping variable \( g_i \), and similarly random_R is a specification of the random-effects design matrix \( Z_R \) corresponding to grouping variable \( g_R \). You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>( X^k ), where ( k ) is a positive integer</td>
<td>( X, X^2, \ldots, X^k )</td>
</tr>
<tr>
<td>( X_1 + X_2 )</td>
<td>( X_1, X_2 )</td>
</tr>
<tr>
<td>( X_1\times X_2 )</td>
<td>( X_1, X_2, X_1\times X_2 ) (elementwise multiplication of ( X_1 ) and ( X_2 ))</td>
</tr>
<tr>
<td>( X_1: X_2 )</td>
<td>( X_1\times X_2 ) only</td>
</tr>
<tr>
<td>- ( X_2 )</td>
<td>Do not include ( X_2 )</td>
</tr>
<tr>
<td>( X_1\times X_2 + X_3 )</td>
<td>( X_1, X_2, X_3, X_1\times X_2 )</td>
</tr>
<tr>
<td>( X_1 + X_2 + X_3 + X_1\times X_2 )</td>
<td>( X_1, X_2, X_3, X_1\times X_2 )</td>
</tr>
<tr>
<td>( X_1\times X_2\times X_3 - X_1\times X_2 : X_3 )</td>
<td>( X_1, X_2, X_3, X_1\times X_2, X_1\times X_3, X_2\times X_3 )</td>
</tr>
<tr>
<td>( X_1\times(X_2 + X_3) )</td>
<td>( X_1, X_2, X_3, X_1\times X_2, X_1\times X_3 )</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using \(-1\). Here are some examples for generalized linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ ( X_1 + X_2 )'</td>
<td>Fixed effects for the intercept, ( X_1 ) and ( X_2 ). This is equivalent to 'y ~ 1 + ( X_1 + X_2 )' .</td>
</tr>
<tr>
<td>'y ~ -1 + ( X_1 + X_2 )'</td>
<td>No intercept and fixed effects for ( X_1 ) and ( X_2 ). The implicit intercept term is suppressed by including (-1) .</td>
</tr>
<tr>
<td>Formula</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>`'y ~ 1 + (1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (X1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>`'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>

Introduced in R2014b
fitgmdist

Fit Gaussian mixture model to data

Syntax

GMMModel = fitgmdist(X,k)
GMMModel = fitgmdist(X,k,Name,Value)

Description

GMMModel = fitgmdist(X,k) returns a Gaussian mixture distribution model (GMMModel) with k components fitted to data (X).

GMMModel = fitgmdist(X,k,Name,Value) returns a Gaussian mixture distribution model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify a regularization value or the covariance type.

Examples

Cluster Data Using a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions.

mu1 = [1 2];
Sigma1 = [2 0; 0 0.5];
mu2 = [-3 -5];
Sigma2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

Fit a Gaussian mixture model. Specify that there are two components.

GMMModel = fitgmdist(X,2);
Plot the data over the fitted Gaussian mixture model contours.

```matlab
figure
y = [zeros(1000,1);ones(1000,1)];
h = gscatter(X(:,1),X(:,2),y);
hold on
ezcontour(@(x1,x2)pdf(GMModel,[x1 x2]),get(gca,{'XLim','YLim'}))
title({'\bf Scatter Plot and Fitted Gaussian Mixture Contours'})
legend(h,'Model 0','Model1')
hold off
```
**Regularize Gaussian Mixture Model Estimation**

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

\[
\begin{align*}
\mu_1 &= [1 \ 2]; \\
\Sigma_1 &= [1 \ 0; \ 0 \ 1]; \\
\mu_2 &= [3 \ 4]; \\
\Sigma_2 &= [0.5 \ 0; \ 0 \ 0.5]; \\
\text{rng}(3); & \quad \% \text{For reproducibility} \\
X_1 &= \text{mvnrnd}(\mu_1, \Sigma_1, 100); \text{mvnrnd}(\mu_2, \Sigma_2, 100)]; \\
X &= [X_1, X_1(:,1)+X_1(:,2)];
\end{align*}
\]

The columns of \(X\) are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use `try / catch` statements to help manage error messages.

\[
\text{rng}(1); \quad \% \text{Reset seed for common start values} \\
\text{try} \\
\quad \text{GMMModel} = \text{fitgmdist}(X,2) \\
\text{catch \ exception} \\
\quad \text{disp('There was an error fitting the Gaussian mixture model')} \\
\quad \text{error} = \text{exception.message} \\
\text{end}
\]

There was an error fitting the Gaussian mixture model

\[
\text{error} = '\text{Ill-conditioned covariance created at iteration 2}.'
\]

The covariance estimates are ill-conditioned. Consequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

\[
\text{rng}(3); \quad \% \text{Reset seed for common start values} \\
\text{GMMModel} = \text{fitgmdist}(X,2,'\text{RegularizationValue}',0.1)
\]

\[
\text{GMMModel} =
\]

Gaussian mixture distribution with 2 components in 3 dimensions
Component 1:
Mixing proportion: 0.536725
In this case, the algorithm converges to a solution due to regularization.

Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris
classes = unique(species)
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

```
[~,score] = pca(meas,'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMMModels = cell(3,1); % Preallocation
options = statset('MaxIter',1000);
```
rng(1); % For reproducibility

for j = 1:3
    GMMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('
 GM Mean for %i Component(s)
',j)
    Mu = GMMModels{j}.mu
end

GM Mean for 1 Component(s)

Mu = 1×2
10^{-14} ×

-0.2743   -0.0870

GM Mean for 2 Component(s)

Mu = 2×2
1.3212   -0.0954
-2.6424    0.1909

GM Mean for 3 Component(s)

Mu = 3×2
0.4856   -0.1287
1.4484   -0.0904
-2.6424    0.1909

GMMModels is a cell array containing three, fitted gmdistribution models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use gscatter to distinguish between the true number of components.

figure
for j = 1:3
    subplot(2,2,j)
    h1 = gscatter(score(:,1),score(:,2),species);
    h = gca;
end
hold on
ezcontour(@(x1,x2)pdf(GMModels{j},[x1 x2]),...
    [h.XLim h.YLim],100)
title(sprintf('GM Model - %i Component(s)',j));
xlabel('1st principal component');
ylabel('2nd principal component');
if(j ~= 3)
    legend off;
end
end
hold off
g = legend(h1);
g.Position = [0.7 0.25 0.1 0.1];
The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

**Determine the Best Gaussian Mixture Fit Using AIC**

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```plaintext
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

```plaintext
plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```
Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a **statset** structure as the value of the **Options** name-value pair argument.
options = statset('Display','final');
GMMModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);

11 iterations, log-likelihood = -4787.38

GMMModel is a fitted gmdistribution model.

Examine the AIC over varying numbers of components.

AIC = zeros(1,4);
GMMModels = cell(1,4);
options = statset('MaxIter',500);
for k = 1:4
    GMMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k) = GMMModels{k}.AIC;
end

[minAIC,numComponents] = min(AIC);
numComponents = 2

BestModel = GMMModels{numComponents}

BestModel =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.501719
Mean: 1.9824 4.0013

Component 2:
Mixing proportion: 0.498281
Mean: 0.9880 1.0511

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.
Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using fitgmdist.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```matlab
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify \( k = 3 \) components.

```matlab
rng(10); % For reproducibility
GMModel1 = fitgmdist(X,3);
```

By default, the software:

1. Implements the “k-means++ Algorithm for Initialization” on page 32-2152 to choose \( k = 3 \) initial cluster centers.
2. Sets the initial covariance matrices as diagonal, where element \((j, j)\) is the variance of \( X(:,j) \).
3. Treats the initial mixing proportions as uniform.

Fit a Gaussian mixture model by connecting each observation to its label.

```matlab
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;
GMModel2 = fitgmdist(X,3,'Start',y);
```

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

```matlab
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);
GMModel3 = fitgmdist(X,3,'Start',S);
```
Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```matlab
figure
subplot(2,2,1)
   h = gscatter(X(:,1),X(:,2),species,[],'o',4);
   haxis = gca;
   xlim = haxis.XLim;
   ylim = haxis.YLim;
   d = (max([xlim ylim])-min([xlim ylim]))/1000;
   hold on
   contour(X1Grid,X2Grid,reshape(pdf(GMModel1,[X1Grid(:) X2Grid(:)]),
          size(X1Grid,1),size(X1Grid,2)),20)
   uistack(h,'top')
   title('{\bf Random Initial Values}');
   xlabel('Sepal length');
   ylabel('Sepal width');
   legend off;
   hold off
subplot(2,2,2)
   h = gscatter(X(:,1),X(:,2),species,[],'o',4);
   hold on
   contour(X1Grid,X2Grid,reshape(pdf(GMModel2,[X1Grid(:) X2Grid(:)]),
          size(X1Grid,1),size(X1Grid,2)),20)
   uistack(h,'top')
   title('{\bf Initial Values from Labels}');
   xlabel('Sepal length');
   ylabel('Sepal width');
   legend off
   hold off
subplot(2,2,3)
   h = gscatter(X(:,1),X(:,2),species,[],'o',4);
   hold on
   contour(X1Grid,X2Grid,reshape(pdf(GMModel3,[X1Grid(:) X2Grid(:)]),
          size(X1Grid,1),size(X1Grid,2)),20)
   uistack(h,'top')
   title('{\bf Initial Values from the Structure}');
   xlabel('Sepal length');
   ylabel('Sepal width');
   legend('Location',[0.7,0.25,0.1,0.1]);
   hold off
```
According to the contours, GMModel2 seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```matlab
table(GMModel1.mu,GMModel2.mu,GMModel3.mu,'VariableNames',{'Model1','Model2','Model3'})
```

```
ans=3×3 table
     Model1      Model2      Model3
    ______      ______      ______
     5.2115      4.2857      1.4604
    1.4610      1.3339      0.2429
     0.2442      1.4629      4.7509
```

32-2145
GMMmodel2 seems to distinguish between the iris species the best.

**Input Arguments**

- **X — Data**
  
  numeric matrix

  Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

  The rows of X correspond to observations, and the columns of X correspond to variables. The number of observations must be larger than each of the following: the number of variables and the number of components.

  NaNs indicate missing values. The software removes rows of X containing at least one NaN before fitting, which decreases the effective sample size.

  Data Types: `single` | `double`

- **k — Number of components**
  
  positive integer

  Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify k = 3, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (X).

  Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'RegularizationValue',0.1,'CovarianceType','diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.
CovarianceType — Type of covariance matrix

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of 'CovarianceType' and either 'diagonal' or 'full'.

If you set 'diagonal', then the software fits diagonal covariance matrices. In this case, the software estimates k*d covariance parameters, where d is the number of columns in X (i.e., d = size(X,2)).

Otherwise, the software fits full covariance matrices. In this case, the software estimates k*d*(d+1)/2 covariance parameters.

Example: 'CovarianceType','diagonal'

Options — Iterative EM algorithm optimization options

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of 'Options' and a statset options structure.

This table describes the available name-value pair arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Display'</td>
<td>'final': Display the final output.</td>
</tr>
<tr>
<td></td>
<td>'iter': Display iterative output to the Command Window for some functions; otherwise display the final output.</td>
</tr>
<tr>
<td></td>
<td>'off': Do not display optimization information.</td>
</tr>
<tr>
<td>'MaxIter'</td>
<td>Positive integer indicating the maximum number of iterations allowed. The default is 100</td>
</tr>
<tr>
<td>'TolFun'</td>
<td>Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is 1e-6.</td>
</tr>
</tbody>
</table>

Example: 'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)
**ProbabilityTolerance — Tolerance for posterior probabilities**

1e-8 (default) | nonnegative scalar value in range [0,1e-6]

Tolerance for posterior probabilities, specified as the comma-separated pair consisting of `ProbabilityTolerance` and a nonnegative scalar value in the range [0,1e-6].

In each iteration, after the estimation of posterior probabilities, `fitgmdist` sets any posterior probability that is not larger than the tolerance value to zero. Using a nonzero tolerance might speed up `fitgmdist`.

Example: 'ProbabilityTolerance',0.0000025

Data Types: `single` | `double`

**RegularizationValue — Regularization parameter value**

0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of 'RegularizationValue' and a nonnegative scalar.

Set `RegularizationValue` to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: 'RegularizationValue',0.01

Data Types: `single` | `double`

**Replicates — Number of times to repeat EM algorithm**

1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of 'Replicates' and a positive integer.

If `Replicates` is greater than 1, then:

- The name-value pair argument `Start` must be `plus` (the default) or `randSample`.
- `GMModel` is the fit with the largest loglikelihood.

Example: 'Replicates',10

Data Types: `single` | `double`

**SharedCovariance — Flag indicating whether all covariance matrices are identical**

`logical false` (default) | `logical true`
Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCovariance' and either logical value false or true.

If SharedCovariance is true, then all k covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of k.

**Start — Initial value setting method**

'plus' (default) | 'randSample' | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', 'plus', a vector of integers, or a structure array.

The value of Start determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

<table>
<thead>
<tr>
<th>Value</th>

<td>- A ( 1 )-by-( d ) vector. ( \text{diag}(\Sigma) ) is the initial covariance matrix for all components.</td>
</tr>
<tr>
<td></td>
<td>- ( S\text{ComponentProportion} ): A ( 1 )-by-( k ) vector of scalars specifying the initial mixing proportions of each component. The default is uniform.</td>
</tr>
</tbody>
</table>

Example: 'Start', ones(n,1)

Data Types: single | double | char | string | struct

### Output Arguments

**GMMModel** — Fitted Gaussian mixture model
gmdistribution model

Fitted Gaussian mixture model, returned as a gmdistribution model.

Access properties of GMMModel using dot notation. For example, display the AIC by entering GMMModel.AIC.

### Tips

fitgmdist might:
• Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

• The number of dimensions of your data is relatively high and there are not enough observations.
• Some of the predictors (variables) of your data are highly correlated.
• Some or all the features are discrete.
• You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

• Preprocess your data to remove correlated features.
• Set 'SharedCovariance' to true to use an equal covariance matrix for every component.
• Set 'CovarianceType' to 'diagonal'.
• Use 'RegularizationValue' to add a very small positive number to the diagonal of every covariance matrix.
• Try another set of initial values.
• Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

fitgmdist fits GMMs to data using the iterative Expectation-Maximization (EM) algorithm. Using initial values for component means, covariance matrices, and mixing proportions, the EM algorithm proceeds using these steps.

1 For each observation, the algorithm computes posterior probabilities of component memberships. You can think of the result as an n-by-k matrix, where element $(i,j)$
contains the posterior probability that observation \( i \) is from component \( j \). This is the E-step of the EM algorithm.

2 Using the component-membership posterior probabilities as weights, the algorithm estimates the component means, covariance matrices, and mixing proportions by applying maximum likelihood. This is the M-step of the EM algorithm.

The algorithm iterates over these steps until convergence. The likelihood surface is complex, and the algorithm might converge to a local optimum. Also, the resulting local optimum might depend on the initial conditions. \texttt{fitgmdist} has several options for choosing initial conditions, including random component assignments for the observations and the \( k \)-means ++ algorithm.

**\( k \)-means++ Algorithm for Initialization**

The \( k \)-means++ algorithm uses an heuristic to find centroid seeds for \( k \)-means clustering. \texttt{fitgmdist} can apply the same principle to initialize the EM algorithm by using the \( k \)-means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The \( k \)-means++ algorithm assumes the number of clusters is \( k \) and chooses the initial parameter values as follows.

1 Select the component mixture probability to be the uniform probability \( p_i = \frac{1}{k} \), where \( i = 1, \ldots, k \).

2 Select the covariance matrices to be diagonal and identical, where

\[
\sigma_i = \text{diag}(a_1, a_2, \ldots, a_k) \quad \text{and} \quad a_j = \text{var}(X_j).
\]

3 Select the first initial component center \( \mu_1 \) uniformly from all data points in \( X \).

4 To choose center \( j \):
   
   a Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.

   b For \( m = 1, \ldots, n \) and \( p = 1, \ldots, j - 1 \), select centroid \( j \) at random from \( X \) with probability
where \( d(x_m, \mu_p) \) is the distance between observation \( m \) and \( \mu_p \), and \( M_p \) is the set of all observations closest to centroid \( \mu_p \) and \( x_m \) belongs to \( M_p \).

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5 Repeat step 4 until \( k \) centroids are chosen.

Introduced in R2014a
fitlm

Create linear regression model

fitlm creates a LinearModel object. Once you create the object, you can see it in the workspace. You can see all the properties on page 32-3593 the object contains by clicking on it. You can create plots and do further diagnostic analysis by using methods such as plot, plotResiduals, and plotDiagnostics. For a full list of methods for LinearModel, see methods on page 32-3604.

Syntax

mdl = fitlm(tbl)
mdl = fitlm(tbl,modelspec)
mdl = fitlm(X,y)
mdl = fitlm(X,y,modelspec)
mdl = fitlm(___,Name,Value)

Description

mdl = fitlm(tbl) returns a linear model fit to variables in the table or dataset array tbl. By default, fitlm takes the last variable as the response variable.

mdl = fitlm(tbl,modelspec) returns a linear model of the type you specify in modelspec fit to variables in the table or dataset array tbl.

mdl = fitlm(X,y) returns a linear model of the responses y, fit to the data matrix X.

mdl = fitlm(X,y,modelspec) returns a linear model of the type you specify in modelspec for the responses y, fit to the data matrix X.

mdl = fitlm(___,Name,Value) returns a linear model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify which variables are categorical, perform robust regression, or use observation weights.
Examples

Fit Linear Regression Using Data in Table

Load the sample data.

```matlab
load carsmall
```

Store the variables in a table.

```matlab
tbl = table(Weight,Acceleration,MPG,'VariableNames',{'Weight','Acceleration','MPG'});
```

Display the first five rows of the table.

```matlab
tbl(1:5,:)
```

```
ans=5×3 table
    Weight    Acceleration    MPG
         ___    ____________    ___
        3504           12        18
        3693         11.5        15
        3436           11        18
        3433           12        16
        3449         10.5        17
```

Fit a linear regression model for miles per gallon (MPG).

```matlab
lm = fitlm(tbl,'MPG~Weight+Acceleration')
```

```
  Linear regression model:
  MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743, Adjusted R-Squared 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27

This syntax uses Wilkinson notation to specify the \textit{modelspec}.

The model 'MPG~Weight+Acceleration' in this example is equivalent to fitting the model using 'linear' as \textit{modelspec}. For example,

\begin{verbatim}
lm2 = fitlm(tbl,'linear');
\end{verbatim}

When you use a character vector as \textit{modelspec} and do not specify the response variable, \texttt{fitlm} by default accepts the last variable in tbl as the response variable and the other variables as the predictor variables.

\section*{Fit Linear Regression Using Specified Model Formula}

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

\texttt{load carsmall}

Store the variables in a table.

\texttt{tbl = table(Weight,Acceleration,Model_Year,MPG,'VariableNames',{'Weight','Acceleration','Model_Year','MPG'})}

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

\begin{verbatim}
lm = fitlm(tbl,'MPG~Weight+Acceleration')
\end{verbatim}

\begin{verbatim}
lm =

Linear regression model:
    MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:
    Estimate       SE       tStat       pValue
    ________________    ______    _______    __________
     (Intercept)    32.688     0.52417    62.402    6.905e-29
    Weight        0.0094088   0.00031292  30.214     3.1635e-27
    Acceleration -0.068914    0.0012909 -53.188    1.8923e-53
\end{verbatim}
The $p$-value of 0.18493 indicates that **Acceleration** does not have a significant impact on **MPG**.

Remove **Acceleration** from the model, and try improving the model by adding the predictor variable **Model_Year**. First define **Model_Year** as a categorical variable.

```matlab
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl,'MPG~Weight+Model_Year')
```

```matlab
lm =

Linear regression model:
  MPG ~ 1 + Weight + Model_Year

Estimated Coefficients:
                      Estimate       SE         tStat       pValue
  ____________________    __________    _______    __________
  (Intercept)            40.11        1.5418     26.016    1.2024e-43
  Weight                 -0.0066475 0.00042802    -15.531    3.3639e-27
  Model_Year_76          1.9291       0.74761     2.5804      0.011488
  Model_Year_82          7.9093       0.84975     9.3078    7.8681e-15

Number of observations: 94, Error degrees of freedom: 90
Root Mean Squared Error: 2.92
R-squared: 0.873,  Adjusted R-Squared 0.868
F-statistic vs. constant model: 206, p-value = 3.83e-40
```

Specifying `modelspec` using Wilkinson notation enables you to update the model without having to change the design matrix. `fitlm` uses only the variables that are specified in
the formula. It also creates the necessary two dummy indicator variables for the categorical variable Model_Year.

**Linear Regression with Categorical Predictor**

Fit a model of a table that contains a categorical predictor.

Load the carsmall data.

```matlab
load carsmall
```

Construct a table containing continuous predictor variable Weight, categorical predictor variable Year, and response variable MPG.

```matlab
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
```

Create a fitted model of MPG as a function of Year, Weight, and Weight^2. You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight^2. The fitlm function includes Weight automatically.

```matlab
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =  
Linear regression model: 
    MPG ~ 1 + Weight + Year + Weight^2 

Estimated Coefficients:  
                      Estimate     SE         tStat     pValue
    ________    _______    _______    __________
    (Intercept)        54.206        4.7117     11.505    2.6648e-19
    Weight          -0.016404     0.0031249    -5.2493    1.0283e-06
    Year_76            2.0887       0.71491     2.9215     0.0044137
    Year_82            8.1864       0.81531    10.041    2.6364e-16
    Weight^2       1.5573e-06    4.9454e-07      3.149     0.0022303

Number of observations: 94, Error degrees of freedom: 89 
Root Mean Squared Error: 2.78  
R-squared: 0.885,  Adjusted R-Squared 0.88  
F-statistic vs. constant model: 172, p-value = 5.52e-41
```
fitlm creates two dummy (indicator) variables for the categorical variate, Year. The dummy variable Year_76 takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable Year_82 takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

\[ \text{MPG} = 54.206 - 0.016404 \text{Weight} + 2.0887 \text{Year}_76 + 8.1864 \text{Year}_82 + 1.5573 \times 10^{-06} \text{Weight}^2. \]

**Specify Response and Predictor Variables for Linear Model**

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```matlab
load hospital
```

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.

```matlab
mdl = fitlm(hospital,'interactions','ResponseVar','Weight',... 'PredictorVars',{'Sex','Age','Smoker'},... 'CategoricalVar',{'Sex','Smoker'})
```

```matlab
mdl =
Linear regression model:
  Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>118.7</td>
<td>7.0718</td>
<td>16.785</td>
<td>6.821e-30</td>
</tr>
<tr>
<td>Sex_Male</td>
<td>68.336</td>
<td>9.7153</td>
<td>7.0339</td>
<td>3.3386e-10</td>
</tr>

<tr>
<td>Age:Smoker_1</td>
<td>-0.07288</td>
<td>0.26275</td>
<td>-0.27737</td>
<td>0.78211</td>
</tr>
</tbody>
</table>
```
Number of observations: 100, Error degrees of freedom: 93
Root Mean Squared Error: 8.75
R-squared: 0.898, Adjusted R-Squared 0.892
F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

**Fit a Robust Linear Regression Model**

Fit a linear regression model using a robust fitting method.

Load the sample data.

```matlab
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```matlab
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```matlab
mdl = Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
      Estimate     SE         tStat     pValue
    ________    _______    ________    ________
(Intercept)     60.09     75.818     0.79256      0.4509
     x1         1.5753    0.80585      1.9548    0.086346
     x2         0.5322    0.78315     0.67957     0.51596
     x3        -0.12052     0.7672    -0.15709     0.87906
     x4         0.13346     0.8166     0.16343     0.87424
```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

**Input Arguments**

**tbl — Input data**

`table | dataset array`

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-57). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

**X — Predictor variables**

`matrix`

Predictor variables, specified as an `n`-by-`p` matrix, where `n` is the number of observations and `p` is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

**y — Response variable**

`vector`

Response variable, specified as an `n`-by-1 vector, where `n` is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. 

32-2161
Data Types: single | double | logical

**modelspec — Model specification**

'linear' (default) | character vector or string scalar naming the model | \( t \)-by-(\( p + 1 \)) terms matrix | character vector or string scalar of the form '\( Y \sim \) terms'

Model specification, specified as one of the following.

- A character vector or string scalar naming the model.

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear terms for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept, linear terms, and squared terms.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept, linear terms, interactions, and squared terms.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree ( i ) in the first predictor, degree ( j ) in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.</td>
</tr>
</tbody>
</table>

- \( t \)-by-(\( p + 1 \)) matrix, namely terms matrix on page 32-2168, specifying terms to include in the model, where \( t \) is the number of terms and \( p \) is the number of predictor variables, and plus 1 is for the response variable.

- A character vector or string scalar representing a formula on page 32-2171 in the form

  '\( Y \sim \) terms',

  where the terms are in Wilkinson Notation on page 32-2172.

Example: 'quadratic'
Example: 'y ~ X1 + X2^2 + X1:X2'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Intercept',false,'PredictorVars',[1,3],'ResponseVar',5,'RobustOpts','logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

**CategoricalVars — Categorical variable list**

`string array | cell array of character vectors | logical or numeric index vector`

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitlm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

**Exclude — Observations to exclude**

`logical or numeric index vector`
Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Intercept — Indicator for constant term**

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])
Data Types: `single` | `double` | `logical` | `string` | `cell`

**ResponseVar — Response variable**

- last column in `tbl` (default) | character vector or string scalar containing variable name |
- logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

- Example: 'ResponseVar','yield'
- Example: 'ResponseVar',[4]
- Example: 'ResponseVar',logical([0 0 1 0 0])

Data Types: `single` | `double` | `logical` | `char` | `string`

**RobustOpts — Indicator of robust fitting type**

- 'off' (default) | 'on' | character vector | string scalar | structure with character vector, string scalar, or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.

- Character vector or string scalar — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.

- Structure with the character vector or string scalar `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.
### Weight Functions

<table>
<thead>
<tr>
<th>Weight Function</th>
<th>Equation</th>
<th>Default Tuning Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>'andrews'</td>
<td>( w = (\text{abs}(r)&lt;\pi) \times \sin(r) / r )</td>
<td>1.339</td>
</tr>
<tr>
<td>'bisquare'</td>
<td>( w = (\text{abs}(r)&lt;1) \times (1 - r.^2).^2 )</td>
<td>4.685</td>
</tr>
<tr>
<td>'cauchy'</td>
<td>( w = 1 / (1 + r.^2) )</td>
<td>2.385</td>
</tr>
<tr>
<td>'fair'</td>
<td>( w = 1 / (1 + \text{abs}(r)) )</td>
<td>1.400</td>
</tr>
<tr>
<td>'huber'</td>
<td>( w = 1 / \max(1, \text{abs}(r)) )</td>
<td>1.345</td>
</tr>
<tr>
<td>'logistic'</td>
<td>( w = \tanh(r) / r )</td>
<td>1.205</td>
</tr>
<tr>
<td>'ols'</td>
<td>Ordinary least squares (no weighting function)</td>
<td>None</td>
</tr>
<tr>
<td>'talwar'</td>
<td>( w = 1 \times (\text{abs}(r)&lt;1) )</td>
<td>2.795</td>
</tr>
<tr>
<td>'welsch'</td>
<td>( w = \exp(-(r.^2)) )</td>
<td>2.985</td>
</tr>
</tbody>
</table>

The value \( r \) in the weight functions is

\[
r = \frac{\text{resid}}{(\text{tune} \times s \times \sqrt{1-h})},
\]

where \( \text{resid} \) is the vector of residuals from the previous iteration, \( h \) is the vector of leverage values from a least-squares fit, and \( s \) is an estimate of the standard deviation of the error term given by

\[
s = \frac{\text{MAD}}{0.6745}.
\]

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are \( p \) columns in \( X \), the smallest \( p \) absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle RobustWgtFun and optional scalar Tune fields — You can specify a custom weight function. `fitlm` uses the RobustWgtFun weight function and Tune tuning constant from the structure. Specify RobustWgtFun as a
function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: 'RobustOpts','andrews'

**VarNames — Names of variables**

`{'x1','x2',..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: string | cell

**Weights — Observation weights**

`ones(n,1)` (default) | n-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

**Output Arguments**

mdl — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.
If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For more information on the properties and methods of the linear model object, mdl, see the LinearModel class page.

**Definitions**

**Terms Matrix**

A terms matrix is a $t$-by-($p + 1$) matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable $j$ in term $i$. Suppose there are three predictor variables $A$, $B$, and $C$:

\[
\begin{align*}
[0 & 0 & 0 & 0] & \text{ % Constant term or intercept} \\
[0 & 1 & 0 & 0] & \text{ % B; equivalently, A^0 * B^1 * C^0} \\
[1 & 0 & 1 & 0] & \text{ % A*C} \\
[2 & 0 & 0 & 0] & \text{ % A^2} \\
[0 & 1 & 2 & 0] & \text{ % B*(C^2)}
\end{align*}
\]

The $0$ at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then $0$ must represent the response variable depending on the position of the response variable. The following example illustrates this using a table.

Load the sample data and define a table.

```matlab
load hospital
dsa = table(hospital.Sex,hospital.BloodPressure(:,1), ...
hospital.Age,hospital.Smoker,'VariableNames', ...
{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of $0$s for the response variable.

\[
T = [0 \ 0 \ 0 \ 0;1 \ 0 \ 0 ;0 \ 0 \ 1 ;0 \ 0 \ 0 \ 1]
\]
Redefine the table.

dsa = table(hospital.BloodPressure(:,1),hospital.Sex, ... hospital.Age,hospital.Smoker,'VariableNames', ... {'BloodPressure','Sex','Age','Smoker'});

Now, the response variable is the first term in the table. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

\[
T = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

load carsmall
X = [Acceleration,Weight];

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

\[
T = \begin{bmatrix}
0 & 0 & 0; 0 & 1 & 0; 0 & 0 & 1 \\
0 & 0 & 0; 1 & 0 & 0; 1 & 1 & 0; 0 & 2 & 0 \\
\end{bmatrix}
\]
Fit a linear model.

mdl = fitlm(X,MPG,T)

mdl =

Linear regression model:
  y ~ 1 + x1*x2 + x2^2

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

**Formula**

A formula for model specification is a character vector or string scalar of the form `'Y ~ terms'` where

- `Y` is the response name.
- `terms` contains
  - Variable names
  - `+` means include the next variable
  - `-` means do not include the next variable
  - `:` defines an interaction, a product of terms
  - `*` defines an interaction **and all lower-order terms**
  - `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower order terms as well
  - `()` groups terms

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include `-1` in the formula.

For example,

- `'Y ~ A + B + C'` means a three-variable linear model with intercept.
- `'Y ~ A + B + C - 1'` is a three-variable linear model without intercept.
- `'Y ~ A + B + C + B^2'` is a three-variable model with intercept and a `B^2` term.
'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.
'Y ~ A + B + C + A:B' includes an A*B term.
'Y ~ A*B + C' is the same as the previous example because A*B = A + B + A:B.
'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.
'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>-B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Tips

- To access the model properties of the LinearModel object mdl, you can use dot notation. For example, mdl.Residuals returns a table of the raw, Pearson, Studentized, and standardized residual values for the model.
After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to \texttt{fitlm} is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights' and 'Exclude' name-value pairs.
- The 'RobustOpts' name-value pair is not supported with tall arrays.
- For tall data, \texttt{fitlm} returns a CompactLinearModel object that contains most of the same properties as a LinearModel object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these LinearModel properties:
  - Diagnostics
  - Fitted
  - ObservationInfo
  - ObservationNames
  - Residuals
  - Steps
  - Variables

You can compute the residuals directly from the compact object returned by \texttt{LM} = \texttt{fitlm}(	exttt{X},	exttt{Y}) using

\begin{verbatim}
RES = Y - predict(LM,X);
S = LM.RMSE;
histogram(RES,linspace(-3*S,3*S,51))
\end{verbatim}
• If the CompactLinearModel object is missing lower order terms that include categorical factors:
  • The plotEffects and plotInteraction methods are not supported.
  • The anova method with the 'components' option is not supported.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2013b
**fitlme**

Fit linear mixed-effects model

**Syntax**

```plaintext
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

**Description**

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

**Examples**

**Fit Linear Mixed-Effects Model**

Load the sample data.

```plaintext
load imports-85
```

Store the variables in a table.

```plaintext
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{'Horsepower','CityMPG','EngineType'});
```

Display the first five rows of the table.

```plaintext
tbl(1:5,:)
```
Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```matlab
lme = fitlme(tbl,'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, CityMPG is the response variable, horsepower is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to 1 + Horsepower, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a –1 to eliminate the intercept from the second random-effect term.

Display the model.

```matlab
lme
```

```
lme = 
Linear mixed-effects model fit by ML

Model information: 
  Number of observations             203

<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Res Std'</td>
<td>3.226</td>
<td>2.9078</td>
<td>3.5789</td>
</tr>
</tbody>
</table>

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```matlab
lme2 = fitlme(tbl,'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower|EngineType).
Display the model.

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

**Fit Random Intercept LME Model**

Load the sample data.
```matlab
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...                     'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of `flu2`.
```matlab
flu2(1:6,:)  
```

```
ans =
      Date    WtdILI   Region    FluRate
   10/9/2005   1.182    NE       0.97
   10/9/2005   1.182  MidAtl    1.025
   10/9/2005   1.182  ENCcentral 1.232
   10/9/2005   1.182  WNCentral 1.286
   10/9/2005   1.182     SAtl    1.082
   10/9/2005   1.182  ESCentral 1.457
```
Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, WtdILI, and a random intercept that varies by Date. The model corresponds to

\[ y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + e_{im}, \quad i = 1, 2, ..., 468, \quad m = 1, 2, ..., 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( e_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma_b^2), \]

and the error term has the distribution,

\[ e_{im} \sim N(0, \sigma^2). \]

\[
\text{lme} = \text{fitlme(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')}
\]

\[
\text{lme} =
\text{Linear mixed-effects model fit by ML}
\]

Model information:
- Number of observations: 468
- Fixed effects coefficients: 2
- Random effects coefficients: 52
- Covariance parameters: 2

Formula:
- FluRate ~ 1 + WtdILI + (1 | Date)

Model fit statistics:
- AIC: 286.24
- BIC: 302.83
- LogLikelihood: -139.12
- Deviance: 278.24

Fixed effects coefficients (95% CIs):

<td>3.0502e-76</td>
</tr>
</tbody>
</table>

Lower       Upper
Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of $\sigma_b$ is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\hat{y}_{28} = \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005}$$
$$= 0.1639 + 0.7236 \times (1.343) + 0.3318$$
$$= 1.46749,$$

where $\hat{b}$ is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```matlab
beta = fixedEffects(lme);
[-~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat = 1.4674
```
You can display the fitted value using the `fitted` method.

```matlab
F = fitted(lme);
F(28)
```

```matlab
ans = 1.4674
```

**LME Model for Randomized Block Design**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a fixed effects design matrix to describe the effect of shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

\[
\text{Shift}_\text{Evening} = \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

\[
\text{Shift}_\text{Morning} = \begin{cases} 
1, & \text{if Morning} \\
0, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

The model corresponds to
Morning Shift: \[ QCD_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + e_{im}, \]
Evening Shift: \[ QCD_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + e_{im}, \]
Night Shift: \[ QCD_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + e_{im}, \]

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, \ldots, 15 \), and \( m = 1, 2, \ldots, 5 \). The random effects and the observation error have the following distributions:

\[ b_{0m} \sim N(0, \sigma^2_b) \]

and

\[ e_{im} \sim N(0, \sigma^2). \]

\[ \text{lme} = \text{fitlme}(\text{shift},'QCD_{im} \sim \text{Shift} + (1|\text{Operator})',\ldots \]
\[ '\text{FitMethod}','\text{REML}','\text{DummyVarCoding}','\text{effects}') \]

\[ \text{lme} = \]
Linear mixed-effects model fit by REML

Model information:

   'Res Std'        0.85462     0.52357    1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[ B = \text{randomEffects}(lme) \]

\[ B = 5 \times 1 \]

\[
\begin{align*}
0.5775 \\
1.1757 \\
-2.1715 \\
2.3655 \\
-1.9472 \\
\end{align*}
\]

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

\[
\hat{y}_{\text{Evening,Operator3}} = \hat{\beta}_0 + \hat{\beta}_{1\text{Shift_Evening}} + \hat{b}_{03}
\]

\[
= 3.6525 - 0.53293 - 2.1715
\]

\[= 0.94807.\]

You can also display this value as follows.

\[ F = \text{fitted}(lme); \]
\[ F(\text{shift.Shift=='Evening' & shift.Operator=='3'}) \]
ans = 0.9481

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

\[ \hat{y}_{\text{Morning,Operator3}} = \hat{\beta}_0 + \hat{\beta}_2 \text{Shift}_\text{Morning} + \hat{b}_{03} \]
\[ = 3.6525 - 0.91973 - 2.1715 \]
\[ = 0.56127. \]

You can also display this value as follows.

\[ F(\text{shift.Shift}=='\text{Morning}' \& \text{shift.Operator}=='3') \]
\[ ans = 0.5613 \]

The operator tends to make a smaller magnitude of error during the morning shift.

**LME Model for Split-Plot Experiment**

Load the sample data.

\[ \text{load(fullfile(matlabroot,'examples','stats','fertilizer.mat'))} \]

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called ds, and define Tomato, Soil, and Fertilizer as categorical variables.

\[ \text{ds = fertilizer;} \]
\[ \text{ds.Tomato = nominal(ds.Tomato);} \]
\[ \text{ds.Soil = nominal(ds.Soil);} \]
\[ \text{ds.Fertilizer = nominal(ds.Fertilizer);} \]

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.
This model corresponds to

\[
y_{imjk} = \beta_0 + \sum_{m=2}^{4} \beta_{im} I[F]_{im} + \sum_{j=2}^{5} \beta_{2j} I[T]_{ij} + \sum_{j=2}^{5} \sum_{m=2}^{4} \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S \times T)_{jk} + \epsilon_{imjk},
\]

where \( i = 1, 2, ..., 60 \), index \( m \) corresponds to the fertilizer types, \( j \) corresponds to the tomato types, and \( k = 1, 2, 3 \) corresponds to the blocks (soil). \( S_k \) represents the \( k \)th soil type, and \( (S \times T)_{jk} \) represents the \( j \)th tomato type nested in the \( k \)th soil type. \( I[F]_{im} \) is the dummy variable representing level \( m \) of the fertilizer. Similarly, \( I[T]_{ij} \) is the dummy variable representing level \( j \) of the tomato type.

The random effects and observation error have these prior distributions: \( b_{0k} \sim N(0, \sigma_S^2) \), \( b_{0jk} \sim N(0, \sigma_{S \times T}^2) \), and \( \epsilon_{imjk} \sim N(0, \sigma^2) \).

\[
lme = \text{fitlme}(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')

Random effects covariance parameters (95% CIs):
Group: Soil (3 Levels)
The \( P \)-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the anova method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms (\( \sigma^2_s \)), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term Tomato:Fertilizer and the random-effects term (1 | Soil).

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

**Longitudinal Study with a Covariate**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[.]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 I[W]_i + \beta_2 \text{Week}_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i$$

$$+ \beta_6 (\text{Week}_i \times I[PB]_i) + \beta_7 (\text{Week}_i \times I[PC]_i) + \beta_8 (\text{Week}_i \times I[PD]_i)$$

$$+ b_{0m} + b_{1m} \text{Week}_{im} + \epsilon_{im}.$$ 

where $i = 1, 2, ..., 120$, and $m = 1, 2, ..., 20$. $\beta_j$ are the fixed-effects coefficients, $j = 0, 1, ..., 8$, and $b_{0m}$ and $b_{1m}$ are random effects. $I[W]$ stands for initial weight and $I[.\cdot]$ is a
dummy variable representing a type of program. For example, $I_{[PB]}_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2)
\]

\[
b_{1m} \sim N(0, \sigma_1^2)
\]

\[
\varepsilon_{im} \sim N(0, \sigma^2).
\]

\[
lme = \text{fitlme}(\text{tbl}, 'y \sim \text{InitialWeight} + \text{Program*Week} + (\text{Week}|\text{Subject})')
\]

\[

</tbody>
</table>

32-2191
The $p$-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

### Input Arguments

tbl — Input data

table | dataset array
Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using formula.

Data Types: table

### formula — Formula for model specification

character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'  

Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. The formula is case sensitive. For a full description, see “Formula” on page 32-2199.

Example: 'y ~ treatment + (1|block)'

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:  
'CovariancePattern','Diagonal','Optimizer','fminunc','OptimizerOptions',opt specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and fitlme uses the fminunc optimization algorithm with the custom optimization parameters defined in variable opt.

### CovariancePattern — Pattern of covariance matrix

'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length R, where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the rth random-effects term. The options for each element follow.
| 'FullCholesky'          | Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix. |
| 'Full'                 | Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix. |
| 'Diagonal'             | Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.  
\[
\begin{pmatrix}
\sigma_{b1}^2 & 0 & 0 \\
0 & \sigma_{b2}^2 & 0 \\
0 & 0 & \sigma_{b3}^2 \\
\end{pmatrix}
\]
| 'Isotropic'            | Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like  
\[
\begin{pmatrix}
\sigma_b^2 & 0 & 0 \\
0 & \sigma_b^2 & 0 \\
0 & 0 & \sigma_b^2 \\
\end{pmatrix}
\]
where \(\sigma_b^2\) is the common variance of the random-effects terms.
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_{b1} & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma^2_{b1} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma^2_{b1}
\end{pmatrix}
\]

where \( \sigma^2_{b1} \) is the common variance of the random-effects terms and \( \sigma_{b1,b2} \) is the common covariance between any two random-effects term.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \( \text{PAT}(a,b) = \text{false} \), then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern','{Full','Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod','REML'
Weights — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude
use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.
'quasinewton' Default. Uses a trust region based quasi-
Newton optimizer. Change the options of
the algorithm using
statset('LinearMixedModel'). If you
don’t specify the options, then
LinearMixedModel uses the default
options of
statset('LinearMixedModel').

'fminunc' You must have Optimization Toolbox to
specify this option. Change the options of
the algorithm using
optimoptions('fminunc'). If you don’t
specify the options, then
LinearMixedModel uses the default
options of optimoptions('fminunc')
with 'Algorithm' set to 'quasi-
newton'.

Example: 'Optimizer','fminunc'

OptimizerOptions — Options for optimization algorithm
structure returned by statset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by
statset('LinearMixedModel') or an object returned by
optimoptions('fminunc').

- If 'Optimizer' is 'fminunc', then use optimoptions('fminunc') to change the
  options of the optimization algorithm. See optimoptions for the options 'fminunc'
  uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions',
  then the default for LinearMixedModel is the default options created by
  optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use statset('LinearMixedModel') to
  change the optimization parameters. If you don’t change the optimization parameters,
  then LinearMixedModel uses the default options created by
  statset('LinearMixedModel'):

The 'quasinewton' optimizer uses the following fields in the structure created by
statset('LinearMixedModel').
**TolFun — Relative tolerance on gradient of objective function**
1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**
1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**
10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**
'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**
'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**
false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true
CheckHessian — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table tbl contains the following:

- A response variable, y
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random_1|g_1) + ... + (random_R|g_R)', the term fixed corresponds to a specification of the fixed-effects design matrix X,
random\textsubscript{1} is a specification of the random-effects design matrix \(Z_1\) corresponding to grouping variable \(g_1\), and similarly random\textsubscript{R} is a specification of the random-effects design matrix \(Z_R\) corresponding to grouping variable \(g_R\). You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>(X^k), where (k) is a positive integer</td>
<td>(X, X^2, ..., X^k)</td>
</tr>
<tr>
<td>(X_1 + X_2)</td>
<td>(X_1, X_2)</td>
</tr>
<tr>
<td>(X_1 \times X_2)</td>
<td>(X_1, X_2, X_1 \times X_2) (elementwise multiplication of (X_1) and (X_2))</td>
</tr>
<tr>
<td>(X_1 : X_2)</td>
<td>(X_1 \times X_2) only</td>
</tr>
<tr>
<td>(- X_2)</td>
<td>Do not include (X_2)</td>
</tr>
<tr>
<td>(X_1 \times X_2 + X_3)</td>
<td>(X_1, X_2, X_3, X_1 \times X_2)</td>
</tr>
<tr>
<td>(X_1 + X_2 + X_3 + X_1 : X_2)</td>

</tr>
<tr>
<td>(X_1 \times X_2 \times X_3 - X_1 : X_2 : X_3)</td>
<td>(X_1, X_2, X_3, X_1 \times X_2, X_1 \times X_3, X_2 \times X_3)</td>
</tr>
<tr>
<td>(X_1 \times (X_2 + X_3))</td>
<td>(X_1, X_2, X_3, X_1 \times X_2, X_1 \times X_3)</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y \sim X_1 + X_2'</td>

**Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[
b \sim N\left(0, \sigma^2 D(\theta)\right),
\]

where \(D\) is a \(q\)-by-\(q\) symmetric and positive semidefinite matrix, parameterized by a variance component vector \(\theta\), \(q\) is the number of variables in the random-effects term, and \(\sigma^2\) is the observation error variance. Since the covariance matrix of the random effects, \(D\), is symmetric, it has \(q(q+1)/2\) free parameters. Suppose \(L\) is the lower triangular Cholesky factor of \(D(\theta)\) such that

\[
D(\theta) = L(\theta) L(\theta)^T,
\]

then the \(q^*(q+1)/2\)-by-1 unconstrained parameter vector \(\theta\) is formed from elements in the lower triangular part of \(L\).

For example, if
\[ L = \begin{bmatrix}
  L_{11} & 0 & 0 \\
  L_{21} & L_{22} & 0 \\
  L_{31} & L_{32} & L_{33}
\end{bmatrix}, \]

then

\[ \theta = \begin{bmatrix}
  L_{11} \\
  L_{21} \\
  L_{31} \\
  L_{22} \\
  L_{32} \\
  L_{33}
\end{bmatrix}. \]

**Log-Cholesky Parameterization**

When the diagonal elements of \( L \) in Cholesky parameterization are constrained to be positive, then the solution for \( L \) is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of \( L \) are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing \( L_{ii} \geq 0 \),

\[ \theta = \begin{bmatrix}
  \log(L_{11}) \\
  L_{21} \\
  L_{31} \\
  \log(L_{22}) \\
  L_{32} \\
  \log(L_{33})
\end{bmatrix}. \]

**Alternatives**

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

LinearMixedModel | fitlmematrix

Introduced in R2013b
**fitlmematrix**

Fit linear mixed-effects model

**Syntax**

```matlab
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix(___,'Name',Value)
```

**Description**

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `fitlmematrix(X,y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(___,'Name',Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name`, `Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.
Examples

No Grouping Variable Specified

Load the sample data.

load carsmall

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)

lme =

Longitudinal Study with a Covariate

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\
+ \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\
+ b_{0m} + b_{1m} \text{Week}_{im} + \epsilon_{im},
\]

where \( i = 1, 2, ..., 120 \) and \( m = 1, 2, ..., 20 \). \( \beta_j \) are the fixed-effects coefficients, \( j = 0, 1, ..., 8 \), and \( b_{0m} \) and \( b_{1m} \) are random effects. \( IW \) stands for initial weight and \( I[\cdot] \) is a dummy variable representing a type of program. For example, \( I[\text{PB}]_i \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2) \\
b_{1m} \sim N(0, \sigma_1^2)
\]
\[ \epsilon_{im} \sim N(0, \sigma^2). \]

```matlab
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...
    D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

Since the model has an intercept, you only need the dummy variables for programs B, C,
and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping
variables.

```matlab
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...%
{[Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD'],...
'ReferenceGroup','Subject')
```
Examine the fixed effects coefficients table. The row labeled 'InitWeight' has a \( p \)-value of 0.0228, and the row labeled 'Week' has a \( p \)-value of 0.0115. These \( p \)-values indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.
Random Intercept Model

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, FluRate, and a nominal variable, Region, the nationwide estimate WtdILI, that shows which region each estimate is from, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
             'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

\[
y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + e_{im}, \quad i = 1, 2, ..., 468, \quad m = 1, 2, ..., 52,
\]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( e_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[
b_{0m} \sim N(0, \sigma_b^2),
\]

and the error term has the distribution,

\[
e_{im} \sim N(0, \sigma^2).
\]

y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
Fit the linear mixed-effects model.

\[
lme = \text{fitlmematrix}(X,y,Z,G,'FixedEffectPredictors',\{'\text{Intercept}','\text{NationalRate}'\},...\text{\}'RandomEffectPredictors',\{\{'\text{Intercept}'\}\},'RandomEffectGroups',\{'\text{Date}'\})
\]

\[
lme =
\]
Linear mixed-effects model fit by ML

Model information:

  0.66028 & 0.78691 \\
  \end{array}
  \]

- Group: Error
  \[
  \begin{array}{llll}
  \text{Name} & \text{Estimate} & \text{Lower} & \text{Upper} \\
  '\text{Res Std}' & 0.30201 & 0.28217 & 0.32324 \\
  \end{array}
  \]

32-2211
The confidence limits of the standard deviation of the random-effects term $\sigma_b$, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using the `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\hat{y}_{28} = \hat{\beta}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{b}_{10/30/2005}$$

$$= 0.1639 + 0.7236 \times (1.343) + 0.3318$$

$$= 1.46749,$$

where $\hat{b}$ is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```matlab
beta = fixedEffects(lme);
 [~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

```matlab
y_hat = 1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```matlab
F = fitted(lme);
F(28)
```

```matlab
ans = 1.4674
```

**Randomized Block Design**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','shift.mat'))
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and
night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, $X_1$ and $X_2$, where

$$\text{Shift}_\text{Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift}_\text{Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\begin{align*}
\text{Morning Shift:} & \quad \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + e_{im}, \\
\text{Evening Shift:} & \quad \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift}_\text{Evening}_i + b_{0m} + e_{im}, \\
\text{Night Shift:} & \quad \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift}_\text{Evening}_i - \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + e_{im},
\end{align*}$$

where $i$ represents the observations, and $m$ represents the operators, $i = 1, 2, \ldots, 15$, and $m = 1, 2, \ldots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$e_{im} \sim N(0, \sigma^2).$$

```python
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
```
```matlab
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',....
    {'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
    'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')

32-2214
Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[
B = \text{randomEffects}(lme)
\]

\[
B = \begin{bmatrix}
0.5775 \\
1.1757 \\
-2.1715 \\
2.3655 \\
-1.9472
\end{bmatrix}
\]

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

\[
\hat{y}_{\text{Evening,Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\
= 3.6525 - 0.53293 - 2.1715 \\
= 0.94807.
\]

You can also display this value as follows.

\[
F = \text{fitted}(lme);
F(\text{shift.Shift=='Evening' & shift.Operator=='3'})
\]

\[
\text{ans} = 0.9481
\]

**Correlated and Uncorrelated Random-Effects Terms**

Load the sample data.
load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

\[
MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \epsilon_{im}, \quad m = 1, 2, 3,
\]

with the random-effects terms having the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2), \quad b_{1m} \sim N(0, \sigma_1^2),
\]

where \( m \) represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

\[
X = [\text{ones}(406,1) \text{ Acceleration} \text{ Horsepower}];
\]
\[
Z = \{\text{ones}(406,1), \text{Acceleration}\};
\]
\[
G = \{\text{Model Year}, \text{Model Year}\};
\]
\[
\text{Model Year} = \text{nominal}(\text{Model Year});
\]

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

\[
lme = \text{fitlmematrix}(X, \text{MPG}, Z, G, 'FixedEffectPredictors', ....
\{\text{'Intercept'}, \text{'Acceleration'}, \text{'Horsepower'}\}, 'RandomEffectPredictors', ....
\{\{\text{'Intercept'}\}, \{\text{'Acceleration'}\}\}, 'RandomEffectGroups', \{\text{'Model Year'}, \text{'Model Year'}\})
\]

\[
lme =

</table>

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.
Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

\[ b_m = (b_{0m}, b_{1m}) \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right), \]

where \( m \) represents the model year.

First, prepare the random-effects design matrix and grouping variable.

\[
Z = \begin{bmatrix} \text{ones}(406,1) & \text{Acceleration} \end{bmatrix};
\]

\[
G = \text{Model\_Year};
\]

\[
lme = \text{fitlmematrix}(X, \text{MPG}, Z, G, 'FixedEffectPredictors', ...,
\{\text{'Intercept'}, \text{'Acceleration'}, \text{'Horsepower'}\},
\text{'RandomEffectPredictors', ...,
\{\{\text{'Intercept'}, \text{'Acceleration'}\}\},
\text{'RandomEffectGroups', \{'\text{Model\_Year}'\}}
\]

\[
lme = \quad \text{Linear mixed-effects model fit by ML}
\]

**Model information:**
- Number of observations: 392
- Fixed effects coefficients: 3
- Random effects coefficients: 26
- Covariance parameters: 4

**Formula:**
Linear Mixed Formula with 4 predictors.

**Model fit statistics:**
- AIC: 2193.5
- BIC: 2221.3
- LogLikelihood: -1089.7
- Deviance: 2179.5

**Fixed effects coefficients (95% CIs):**

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the compare method.

### Specify the Covariance Pattern

Load the sample data.

```matlab
code
load(fullfile(matlabroot,'examples','stats','weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```matlab
code
Subject = nominal(Subject);
Program = nominal(Program);
```
Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

\[
D = \text{dummyvar}(\text{Program});
X = \begin{bmatrix} \text{ones}(120,1) & \text{InitialWeight} & D(:,2:4) & \text{Week}\end{bmatrix};
Z = \begin{bmatrix} \text{ones}(120,1) & \text{Week}\end{bmatrix};
G = \text{Subject};
\]

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 I[\text{IW}_i] + \beta_2 I[\text{Week}_i] + \beta_3 I[\text{PB}_i] + \beta_4 I[\text{PC}_i] + \beta_5 I[\text{PD}_i] + b_{0m} + b_{1m} I[\text{Week2}_i] + b_{2m} I[\text{Week4}_i] + b_{3m} I[\text{Week6}_i] + b_{4m} I[\text{Week8}_i] + b_{5m} I[\text{Week10}_i] + b_{6m} I[\text{Week12}_i] + \epsilon_{im},
\]

where \(i = 1, 2, \ldots, 120,\) and \(m = 1, 2, \ldots, 20.\)

\(\beta_j\) are the fixed-effects coefficients, \(j = 0, 1, \ldots, 8,\) and \(b_{0m}\) and \(b_{1m}\) are random effects. \(I[\cdot]\) stands for initial weight and \(I[\cdot]\) is a dummy variable representing a type of program. For example, \(I[\text{PB}_i]\) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2)
\]
\[
b_{1m} \sim N(0, \sigma_1^2)
\]
\[
\epsilon_{im} \sim N(0, \sigma^2).
\]

Fit the model using \texttt{fitlmematrix} with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

\[
lme = \text{fitlmematrix}(X,y,Z,G,'\text{FixedEffectPredictors}',\ldots
\{\text{\'Intercept\}',\text{\'InitWeight\}',\text{\'PrgB\}',\text{\'PrgC\}',\text{\'PrgD\}',\text{\'Week\}'},\ldots
\text{\'RandomEffectPredictors\}',\{\{	ext{\'Intercept\}',\text{\'Week\}'\},\ldots
\text{\'RandomEffectGroups\}',\{\text{\'Subject\}'},\text{\'CovariancePattern\}',\text{\'Isotropic\}'
\]
\]
\[
lme = \text{Linear mixed-effects model fit by ML}
\]
Model information:
   Number of observations             120
   Fixed effects coefficients           6
   Random effects coefficients         40
   Covariance parameters                2

Input Arguments

X — Fixed-effects design matrix
n-by-p matrix

Fixed-effects design matrix, specified as an n-by-p matrix, where n is the number of observations, and p is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

Data Types: single | double

y — Response values
n-by-1 vector

Response values, specified as an n-by-1 vector, where n is the number of observations.

Data Types: single | double

Z — Random-effects design
n-by-q matrix | cell array of R n-by-q(r) matrices, r = 1, 2, ..., R

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an n-by-q matrix, where n is the number of observations and q is the number of variables in the random-effects term.
- If there are R random-effects terms, then Z must be a cell array of length R. Each cell of Z contains an n-by-q(r) design matrix Z{r}, r = 1, 2, ..., R, corresponding to each random-effects term. Here, q(r) is the number of random effects term in the rth random effects design matrix, Z{r}.

Data Types: single | double | cell

G — Grouping variable or variables
n-by-1 vector | cell array of R n-by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.
• If there is one random-effects term, then G must be an n-by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

• If there are multiple random-effects terms, then G must be a cell array of length R. Each cell of G contains a grouping variable G{r}, r = 1, 2, ..., R, with M(r) levels.

G{r} can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: categorical | logical | single | double | char | string | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example:
'CovariancePattern','Diagonal','DummyVarCoding','full','Optimizer','fminunc' specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the fminunc optimization algorithm.

**FixedEffectPredictors** — Names of columns in fixed-effects design matrix

`{'x1','x2',...,'xP'}` (default) | string array or cell array of length p

Names of columns in the fixed-effects design matrix X, specified as the comma-separated pair consisting of 'FixedEffectPredictors' and a string array or cell array of length p.

For example, if you have a constant term and two predictors, say TimeSpent and Gender, where Female is the reference level for Gender, as the fixed effects, then you can specify the names of your fixed effects in the following way. Gender_Male represents the dummy variable you must create for category Male. You can choose different names for these variables.

Example: 'FixedEffectPredictors',
`{'Intercept','TimeSpent','Gender_Male'}`,
Data Types: string | cell

**RandomEffectPredictors** — Names of columns in random-effects design matrix or cell array

string array or cell array of length q | cell array of length R with elements of length q(r), r = 1, 2, ..., R

Names of columns in the random-effects design matrix or cell array Z, specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A string array or cell array of length q when Z is an n-by-q design matrix. In this case, the default is {'z1', 'z2', ..., 'zQ'}.
- A cell array of length R, when Z is a cell array of length R with each element Z{r} of length q(r), r = 1, 2, ..., R. In this case, the default is {'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}.

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors', {'Intercept','Acceleration'}

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable g1, and the second for the intercept, grouped by the variable g2, then you specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors',{{'Intercept','Acceleration'},
{'Intercept'}}

Data Types: string | cell

**ResponseVarName** — Name of response variable

'y' (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a character vector or string scalar.

For example, if your response variable name is score, then you can specify it as follows.

Example: 'ResponseVarName','score'

Data Types: char | string
**RandomEffectGroups — Names of random effects grouping variables**

'g' or {'g1','g2',...,'gR'} (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if \( G \) is a vector, then the value of 'RandomEffectGroups' is the name for the grouping variable \( G \). The default is 'g'.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if \( G \) is a cell array of length \( R \), then the value of 'RandomEffectGroups' is a string array or cell array of length \( R \), where each element is the name for the grouping variable \( G[r] \). The default is {'g1','g2',...,'gR'}.

For example, if you have two random-effects terms, \( z_1 \) and \( z_2 \), grouped by the grouping variables \( \text{sex} \) and \( \text{subject} \), then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups',{'}sex','subject'}

Data Types: char | string | cell

**CovariancePattern — Pattern of covariance matrix**

'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.
| 'FullCholesky' | Default. Full covariance matrix using the Cholesky parameterization. fitlme estimates all elements of the covariance matrix. |
| 'Full'         | Full covariance matrix, using the log-Cholesky parameterization. fitlme estimates all elements of the covariance matrix. |
| 'Diagonal'     | Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0. |
|                | $\begin{pmatrix}
\sigma^2_{b1} & 0 & 0 \\
0 & \sigma^2_{b2} & 0 \\
0 & 0 & \sigma^2_{b3}
\end{pmatrix}$ |
| 'Isotropic'    | Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like |
|                | $\begin{pmatrix}
\sigma^2_{b} & 0 & 0 \\
0 & \sigma^2_{b} & 0 \\
0 & 0 & \sigma^2_{b}
\end{pmatrix}$ |
|                | where $\sigma^2_{b}$ is the common variance of the random-effects terms. |
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_{b_1} & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\
\sigma_{b_1,b_2} & \sigma^2_{b_2} & \sigma_{b_1,b_2} \\
\sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma^2_{b_2}
\end{pmatrix}
\]

where $\sigma^2_{b_1}$ is the common variance of the random-effects terms and $\sigma_{b_1,b_2}$ is the common covariance between any two random-effects terms.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if PAT(a,b) = false, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern',{"Full","Diagonal"}

Data Types: char | string | logical | cell

**FitMethod — Method for estimating parameters**

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod','REML'
Weights — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length $n$, where $n$ is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude
use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.
'quasinewton'

Default. Uses a trust region based quasi-
Newton optimizer. Change the options of
the algorithm using
\texttt{statset('LinearMixedModel')}. If you
don't specify the options, then
\texttt{LinearMixedModel} uses the default
options of
\texttt{statset('LinearMixedModel')}.

'fminunc'

You must have Optimization Toolbox to
specify this option. Change the options of
the algorithm using
\texttt{optimoptions('fminunc')}. If you don't
specify the options, then
\texttt{LinearMixedModel} uses the default
options of \texttt{optimoptions('fminunc')}
with 'Algorithm' set to 'quasi-
newton'.

Example: 'Optimizer','fminunc'

\textbf{OptimizerOptions — Options for optimization algorithm}

\texttt{structure returned by \texttt{statset} \mid \texttt{object returned by \texttt{optimoptions}}}

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by
\texttt{statset('LinearMixedModel')} or an object returned by
\texttt{optimoptions('fminunc')}.

- If 'Optimizer' is 'fminunc', then use \texttt{optimoptions('fminunc')} to change the
  options of the optimization algorithm. See \texttt{optimoptions} for the options 'fminunc'
  uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions',
  then the default for \texttt{LinearMixedModel} is the default options created by
  \texttt{optimoptions('fminunc')} with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use \texttt{statset('LinearMixedModel')} to
  change the optimization parameters. If you don't change the optimization parameters,
  then \texttt{LinearMixedModel} uses the default options created by
  \texttt{statset('LinearMixedModel')}.

The 'quasinewton' optimizer uses the following fields in the structure created by
\texttt{statset('LinearMixedModel')}.
**TolFun — Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true
CheckHessian — Indicator to check positive definiteness of Hessian
false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[ b \sim N(0, \sigma^2 D(\theta)) \]

where \( D \) is a \( q \)-by-\( q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the observation error variance. Since the covariance matrix of the random effects, \( D \), is symmetric, it has \( q(q+1)/2 \) free parameters. Suppose \( L \) is the lower triangular Cholesky factor of \( D(\theta) \) such that

\[ D(\theta) = L(\theta)L(\theta)^T, \]
then the $q^*(q+1)/2$-by-1 unconstrained parameter vector $\theta$ is formed from elements in the lower triangular part of $L$.

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\
L_{21} & L_{22} & 0 \\
L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\
L_{21} \\
L_{31} \\
L_{22} \\
L_{32} \\
L_{33} \end{bmatrix}.$$

**Log-Cholesky Parameterization**

When the diagonal elements of $L$ in Cholesky parameterization are constrained to be positive, then the solution for $L$ is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of $L$ are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33}) \end{bmatrix}.$$
Alternative Functionality

You can also fit a linear mixed-effects model using \texttt{fitlme(tbl,formula)}, where \texttt{tbl} is a table or dataset array containing the response \(y\), the predictor variables \(X\), and the grouping variables, and \texttt{formula} is of the form 
\[ y \sim \text{fixed} + (\text{random}_1|g_1) + \ldots + (\text{random}_R|g_R). \]

See Also

\texttt{LinearMixedModel} | \texttt{compare} | \texttt{fitlme}

Introduced in R2013b
**fitrgp**

Fit a Gaussian process regression (GPR) model

**Syntax**

```matlab
fitrgp(tbl,ResponseVarName)
gprMdl = fitrgp(tbl,formula)
gprMdl = fitrgp(tbl,y)
gprMdl = fitrgp(tbl,formula)
gprMdl = fitrgp(tbl,y)
gprMdl = fitrgp(X,y)
gprMdl = fitrgp(___,'Name',Value)
```

**Description**

- `gprMdl = fitrgp(tbl,ResponseVarName)`: returns a Gaussian process regression (GPR) model trained using the sample data in `tbl`, where `ResponseVarName` is the name of the response variable in `tbl`.

- `gprMdl = fitrgp(tbl,formula)`: returns a Gaussian process regression (GPR) model, trained using the sample data in `tbl`, for the predictor variables and response variables identified by `formula`.

- `gprMdl = fitrgp(tbl,y)`: returns a GPR model for the predictors in table `tbl` and continuous response vector `y`.

- `gprMdl = fitrgp(X,y)`: returns a GPR model for predictors `X` and continuous response vector `y`.

- `gprMdl = fitrgp(___,'Name',Value)` returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.
gprMdl is a RegressionGP object. For methods and properties of this class, see RegressionGP class page.

If you train a cross-validated model, then gprMdl is a RegressionPartitionedModel object. For further analysis on the cross-validated object, use the methods of RegressionPartitionedModel class. For the methods of this class, see the RegressionPartitionedModel class page.

**Examples**

**Train GPR Model Using Data in Table**

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name ‘abalone.data’.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data','Filetype','text',...  
    'ReadVariableNames',false);

tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height',...  
    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};

ans =
    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRings
    ___    ______    ________    ______    _______    _______    _______    ________    ____________
    'M'    0.455     0.365       0.095      0.514     0.2245      0.101      0.15       15
    'M'     0.35     0.265        0.09     0.2255     0.0995     0.0485      0.07        7
    'F'     0.53      0.42       0.135      0.677     0.2565     0.1415      0.21        9
    'M'     0.44     0.365       0.125      0.516     0.2155      0.114     0.155       10
    'I'     0.33     0.255        0.08      0.205     0.0895     0.0395     0.055        7
    'I'    0.425       0.3       0.095     0.3515      0.141     0.0775      0.12        8
    'F'     0.53     0.415        0.15     0.7775      0.237     0.1415      0.33       20
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.
Fit a GPR model using the subset of regressors method for parameter estimation and fully independent conditional method for prediction. Standardize the predictors.

gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',... 'FitMethod','sr','PredictMethod','fic','Standardize',1)

grMdl =

RegressionGP
    PredictorNames: {1x8 cell}

    ActiveSetHistory: [1x1 struct]
    BCDInformation: []

Predict the responses using the trained model.

ypred = resubPredict(gprMdl);

Plot the true response and the predicted responses.

figure();
plot(tbl.NoShellRings,'r.');
hold on
plot(ypred,'b');
xlabel('x');
ylabel('y');
legend({'data','predictions'},'Location','Best');
Compute the regression loss on the training data (resubstitution loss) for the trained model.

L = resubLoss(gprMdl)

L =

4.0064

**Train GPR Model and Plot Predictions**

Generate sample data.

rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);

Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

```
gprMdl = fitrgp(x,y,'Basis','linear',...'
    'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of x (resubstitution predictions) using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```
plot(x,y,'b.');
hold on;
plot(x,ypred,'r','LineWidth',1.5);
xlabel('x');
ylabel('y');
legend('Data','GPR predictions');
hold off
```
Impact of Specifying Initial Kernel Parameter Values

Load the sample data.

load(fullfile(matlabroot,'examples','stats','gprdata2.mat'))

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
Now, fit a second model, where you specify the initial values for the kernel parameters.

```matlab
sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',...
    'KernelParameters',kparams0,'Sigma',sigma0);
```

Compute the resubstitution predictions from both models.

```matlab
ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);
```

Plot the response predictions from both models and the responses in training data.

```matlab
figure();
plot(x,y,'r.');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters',...
    'kparams0 = [3.5,6.2], sigma0 = 0.2','Location','Best'});
title('Impact of initial kernel parameter values');
hold off
```
The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

**Use Separate Length Scales for Predictors**

Load the sample data.
There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

\[ k(x_i, x_j|\theta) = \sigma_f^2 \exp \left[ -\frac{1}{2} \sum_{m=1}^{d} \frac{(x_{im} - x_{jm})^2}{\sigma_m^2} \right]. \]

where \( \sigma_m \) represents the length scale for predictor \( m, \) \( m = 1, 2, \ldots, d \) and \( \sigma_f \) is the signal standard deviation. The unconstrained parametrization \( \theta \) is

\[ \theta_m = \log \sigma_m, \quad \text{for } m = 1, 2, \ldots, d \\
\theta_{d+1} = \log \sigma_f. \]

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

\[
\begin{align*}
\text{sigma0} &= \text{std(ytrain)}; \\
\text{sigmaF0} &= \text{sigma0}; \\
d &= \text{size(Xtrain,2)}; \\
\text{sigmaM0} &= 10 \times \text{ones}(d,1);
\end{align*}
\]

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

\[
\text{gprMdl} = \text{fitrgp(Xtrain,ytrain,'Basis','constant','FitMethod','exact',...}
\text{'PredictMethod','exact','KernelFunction','ardsquaredexponential',...}
\text{'KernelParameters',[sigmaM0;sigmaF0],}'Sigma',\text{sigma0,'Standardize',1});
\]

Compute the regression loss on the test data.

\[
\begin{align*}
L &= \text{loss(gprMdl,Xtest,ytest)} \\
L &= 0.6919
\end{align*}
\]

Access the kernel information.

\[
\text{gprMdl.KernelInformation}
\]
ans = struct with fields:  
    Name: 'ARDSquaredExponential'  
    KernelParameters: [7x1 double]  
    KernelParameterNames: {7x1 cell}  

Display the kernel parameter names.

gprMdl.KernelInformation.KernelParameterNames

ans = 7x1 cell array  
    {'LengthScale1'}  
    {'LengthScale2'}  
    {'LengthScale3'}  
    {'LengthScale4'}  
    {'LengthScale5'}  
    {'LengthScale6'}  
    {'SigmaF'      }  

Display the kernel parameters.

sigmaM = gprMdl.KernelInformation.KernelParameters(1:end-1,1)

sigmaM = 6x1
10^4 *
    0.0004  
    0.0007  
    0.0004  
    4.1730  
    0.1018  
    0.0056

sigmaF = gprMdl.KernelInformation.KernelParameters(end)

sigmaF = 28.1718

sigma  = gprMdl.Sigma

sigma = 0.8162

Plot the log of learned length scales.

figure()  
plot((1:d)',log(sigmaM),'ro-');
The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```matlab
X = [Xtrain(:,1:3) Xtrain(:,6)];
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(X,2);
sigmaM0 = 10*ones(d,1);
```
gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',... 'PredictMethod','exact','KernelFunction','ard squared exponential',... 'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);

Compute the regression error on the test data.

xtest = [Xtest(:,1:3) Xtest(:,6)];
L = loss(gprMdl,xtest,ytest)

L = 0.6928

The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

ypred = predict(gprMdl,xtest);

Plot the original response along with the fitted values.

figure;
plot(ytest,'r');
hold on;
plot(ypred,'b');
legend('True response','GPR predicted values','Location','Best');
hold off
Optimize GPR Regression

This example shows how to optimize hyperparameters automatically using `fitrgp`. The example uses the `gprdata2` data that ships with your software.

Load the data.

```matlab
load(fullfile(matlabroot,'examples','stats','gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.
Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```matlab
gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng default

gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',
                 'OptimizeHyperparameters','auto',
                 'HyperparameterOptimizationOptions',
                 struct('AcquisitionFunctionName','expected-improvement-plus'));
```

n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as
\[ k(x_i, x_j | \theta) = \sigma_f^2 \exp \left( -\frac{1}{2} \frac{(x_i - x_j)^T(x_i - x_j)}{\sigma_l^2} \right), \]

where \( \sigma_f \) is the signal standard deviation, \( \sigma_l \) is the length scale. Both \( \sigma_f \) and \( \sigma_l \) must be greater than zero. This condition can be enforced by the unconstrained parametrization, \( \sigma_l = \exp(\theta(1)) \) and \( \sigma_f = \exp(\theta(2)) \), for some unconstrained parametrization vector \( \theta \).

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

\[
kfcn = @(XN,XM,theta) \left( \exp(\theta(2))^2 \right) \exp\left( -(\text{pdist2}(XN,XM).^2)/(2*\exp(\theta(1))^2) \right);
\]

Here \( \text{pdist2}(XN,XM).^2 \) computes the distance matrix.

Fit a GPR model using the custom kernel function, \( kfcn \). Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, \( \theta \)).

\[
\theta0 = [1.5,0.2];
gprMdl = \text{fitrgp}(x,y,'KernelFunction',kfcn,'KernelParameters',\theta0);
\]

\text{fitrgp} uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

\[
L = \text{resubLoss}(gprMdl)
\]

\[
L = 0.0391
\]

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

\[
\sigmaL0 = \exp(1.5);
\sigmaF0 = \exp(0.2);
gprMdl2 = \text{fitrgp}(x,y,'KernelFunction','squaredexponential','KernelParameters',[\sigmaL0 \sigmaF0]);
\]

Compute the resubstitution loss for this model.

\[
L2 = \text{resubLoss}(gprMdl2)
\]

\[
L2 = 0.0391
\]
The two loss values are the same as expected.

**Specify Initial Step Size for LBFGS Optimization**

Train a GPR model on generated data with many predictors. Specify the initial step size for the LBFGS optimizer.

Set the seed and type of the random number generator for reproducibility of the results.

```matlab
rng(0,'twister'); % For reproducibility
```

Generate sample data with 300 observations and 3000 predictors, where the response variable depends on the 4th, 7th, and 13th predictors.

```matlab
N = 300;
P = 3000;
X = rand(N,P);
y = cos(X(:,7)) + sin(X(:,4).*X(:,13)) + 0.1*randn(N,1);
```

Set initial values for the kernel parameters.

```matlab
sigmaL0 = sqrt(P)*ones(P,1); % Length scale for predictors
sigmaF0 = 1; % Signal standard deviation
```

Set initial noise standard deviation to 1.

```matlab
sigmaN0 = 1;
```

Specify `1e-2` as the termination tolerance for the relative gradient norm.

```matlab
opts = statset('fitrgp');
opts.TolFun = 1e-2;
```

Fit a GPR model using the initial kernel parameter values, initial noise standard deviation, and an automatic relevance determination (ARD) squared exponential kernel function.

Specify the initial step size as 1 for determining the initial Hessian approximation for an LBFGS optimizer.

```matlab
gpr = fitrgp(X,y,'KernelFunction','ardsquaredexponential','Verbose',1, ... 'Optimizer','lbfgs','OptimizerOptions',opts, ... 'KernelParameters',[sigmaL0;sigmaF0],'Sigma',sigmaN0,'InitialStepSize',1);
```
Parameter estimation: FitMethod = Exact, Optimizer = lbfgs

Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

</tbody>
</table>
Because the GPR model uses an ARD kernel with many predictors, using an LBFGS approximation to the Hessian is more memory efficient than storing the full Hessian matrix. Also, using the initial step size to determine the initial Hessian approximation may help speed up optimization.

Find the predictor weights by taking the exponential of the negative learned length scales. Normalize the weights.

\[
\text{sigmaL} = \text{gpr.KernelInformation.KernelParameters}(1:\text{end-1}); \quad \% \text{Learned length scales}
\]

\[
\text{weights} = \exp(-\text{sigmaL}); \quad \% \text{Predictor weights}
\]

\[
\text{weights} = \text{weights} / \text{sum} (\text{weights}); \quad \% \text{Normalized predictor weights}
\]

Plot the normalized predictor weights.

\[
\text{figure;}
\text{semilogx} (\text{weights},'ro');
\text{xlabel('Predictor index')};
\text{ylabel('Predictor weight')};
\]
The trained GPR model assigns the largest weights to the 4th, 7th, and 13th predictors. The irrelevant predictors have weights close to zero.

**Input Arguments**

**tbl — Sample data**

*table*

Sample data used to train the model, specified as a *table*. Each row of *tbl* corresponds to one observation, and each column corresponds to one variable. *tbl* contains the predictor variables, and optionally it can also contain one column for the response.
variable. Multi-column variables and cell arrays other than cell arrays of character
vectors are not allowed.

- If \(tbl\) contains the response variable, and you want to use all the remaining variables
  as predictors, then specify the response variable using \(\text{ResponseVarName}\).
- If \(tbl\) contains the response variable, and you want to use only a subset of the
  predictors in training the model, then specify the response variable and the predictor
  variables using \(\text{formula}\).
- If \(tbl\) does not contain the response variable, then specify a response variable using
  \(y\). The length of the response variable and the number of rows in \(tbl\) must be equal.

For more information on the table data type, please see \(\text{table}\).

If your predictor data contains categorical variables, then the software uses full dummy
coding for these variables. The software creates one dummy variable for each level of the
categorical variable.

Data Types: \(\text{table}\)

\(\text{ResponseVarName} \rightarrow \text{Response variable name}\)

name of a variable in \(tbl\)

Response variable name, specified as the name of a variable in \(tbl\). You must specify
\(\text{ResponseVarName}\) as a character vector or string scalar. For example, if the response
variable \(y\) is stored in \(tbl\) (as \(tbl.y\)), then specify it as \(\text{''y''}\). Otherwise, the software
treats all the columns of \(tbl\), including \(y\), as predictors when training the model.

Data Types: \(\text{char} | \text{string}\)

\(\text{formula} \rightarrow \text{Response and predictor variables to use in model training}\)

character vector or string scalar in the form of \(\text{''y~x1+x2+x3''}\)

Response and predictor variables to use in model training, specified as a character vector
or string scalar in the form of \(\text{''y~x1+x2+x3''}\). In this form, \(y\) represents the response
variable; \(x1, x2, x3\) represent the predictor variables to use in training the model.

Use a formula if you want to specify a subset of variables in \(tbl\) as predictors to use
when training the model. If you specify a formula, then any variables that do not appear
in \(\text{formula}\) are not used to train the model.

The formula does not indicate the form of the \(\text{BasisFunction}\).
Example: 'PetalLength~PetalWidth+Species' identifies the variable PetalLength as the response variable, and PetalWidth and Species as the predictor variables.

Data Types: char | string

**X — Predictor data for the GPR model**

n-by-d matrix

Predictor data for the GPR model, specified as an n-by-d matrix. n is the number of observations (rows), and d is the number of predictors (columns).

The length of y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the `PredictorNames` name-value pair argument.

Data Types: double

**y — Response data for the GPR model**

n-by-1 vector

Response data for the GPR model, specified as an n-by-1 vector. You can omit y if you provide the tbl training data that also includes y. In that case, use `ResponseVarName` to identify the response variable or use `formula` to identify the response and predictor variables.

Data Types: double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example:

'FitMethod','sr','BasisFunction','linear','ActiveSetMethod','sgma','
PredictMethod', 'fic' trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

**Fitting**

**FitMethod** — Method to estimate parameters of the GPR model

'done' | 'exact' | 'sd' | 'sr' | 'fic'

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

<table>
<thead>
<tr>
<th>Fit Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>No estimation, use the initial parameter values as the known parameter values.</td>
</tr>
<tr>
<td>'exact'</td>
<td>Exact Gaussian process regression. Default if ( n \leq 2000 ), where ( n ) is the number of observations.</td>
</tr>
<tr>
<td>'sd'</td>
<td>Subset of data points approximation. Default if ( n &gt; 2000 ), where ( n ) is the number of observations.</td>
</tr>
<tr>
<td>'sr'</td>
<td>Subset of regressors approximation.</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully independent conditional approximation.</td>
</tr>
</tbody>
</table>

Example: 'FitMethod', 'fic'

**BasisFunction** — Explicit basis in the GPR model

'constant' (default) | 'none' | 'linear' | 'pureQuadratic' | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of 'BasisFunction' and one of the following. If \( n \) is the number of observations, the basis function adds the term \( H\beta \) to the model, where \( H \) is the basis matrix and \( \beta \) is a \( p \)-by-1 vector of basis coefficients.

<table>
<thead>
<tr>
<th>Explicit Basis</th>
<th>Basis Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>Empty matrix.</td>
</tr>
<tr>
<td>Explicit Basis</td>
<td>Basis Matrix</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'constant'</td>
<td>$H = 1$</td>
</tr>
<tr>
<td></td>
<td>(n-by-1 vector of 1s, where n is the number of observations)</td>
</tr>
<tr>
<td>'linear'</td>
<td>$H = [1, X]$</td>
</tr>
<tr>
<td>'pureQuadratic'</td>
<td>$H = [1, X, X_2]$,</td>
</tr>
<tr>
<td></td>
<td>where $X_2 = \begin{bmatrix} x_{11}^2 &amp; x_{12}^2 &amp; \cdots &amp; x_{1d}^2 \ x_{21}^2 &amp; x_{22}^2 &amp; \cdots &amp; x_{2d}^2 \ \vdots &amp; \vdots &amp; \ddots &amp; \vdots \ x_{n1}^2 &amp; x_{n2}^2 &amp; \cdots &amp; x_{nd}^2 \end{bmatrix}$.</td>
</tr>
</tbody>
</table>

**Function handle**

Function handle, `hfcn`, that `fitrgp` calls as:

$$H = hfcn(X),$$

where $X$ is an $n$-by-$d$ matrix of predictors and $H$ is an $n$-by-$p$ matrix of basis functions.

Example: 'BasisFunction','pureQuadratic'

Data Types: char | string | function_handle

**Beta — Initial value of the coefficients**

$p$-by-1 vector

Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of 'Beta' and $p$-by-1 vector, where $p$ is the number of columns in the basis matrix $H$.

The basis matrix depends on the choice of the explicit basis function as follows (also see `BasisFunction`).

32-2263
fitrgp uses the coefficient initial values as the known coefficient values, only when FitMethod is 'none'.

Data Types: double

**Sigma — Initial value for the noise standard deviation of the Gaussian process model**

std(y)/sqrt(2) (default) | positive scalar value

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of 'Sigma' and a positive scalar value.

Example: 'Sigma',2

Data Types: double

**ConstantSigma — Constant value of Sigma for the noise standard deviation of the Gaussian process model**

false (default) | true

Constant value of Sigma for the noise standard deviation of the Gaussian process model, specified as a logical scalar. When ConstantSigma is true, fitrgp does not optimize the value of Sigma, but instead takes the initial value as the value throughout its computations.

Example: 'ConstantSigma',true

Data Types: logical

**SigmaLowerBound — Lower bound on the noise standard deviation**

1e-2*std(y) (default) | positive scalar value

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of 'SigmaLowerBound' and a positive scalar value.

Example: 'SigmaLowerBound',0.02

Data Types: double

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of these values:
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>array of character vectors</td>
<td></td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (tbl), fitrgp assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), fitrgp assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

**Standardize — Indicator to standardize data**

0 (false) (default) | logical value

Indicator to standardize data, specified as the comma-separated pair consisting of 'Standardize' and a logical value.

If you set 'Standardize',1, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: 'Standardize',1
Example: 'Standardize',true

Data Types: logical
Regularization — Regularization standard deviation
1e-2*std(y) (default) | positive scalar value

Regularization standard deviation for sparse methods subset of regressors ('sr') and fully independent conditional ('fic'), specified as the comma-separated pair consisting of 'Regularization' and a positive scalar value.

Example: 'Regularization',0.2
Data Types: double

ComputationMethod — Method for computing log likelihood and gradient
'qr' (default) | 'v'

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors ('sr') and fully independent conditional ('fic') approximation methods, specified as the comma-separated pair consisting of 'ComputationMethod' and one of the following.

- 'qr' — Use QR factorization based approach, this option provides better accuracy.
- 'v' — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: 'ComputationMethod','v'

Kernel (Covariance) Function

KernelFunction — Form of the covariance function
'squaredexponential' (default) | 'exponential' | 'matern32' | 'matern52' | 'rationalquadratic' | 'ardsquaredexponential' | 'ardexponential' | 'ardmatern32' | 'ardmatern52' | 'ardrationalquadratic' | function handle

Form of the covariance function, specified as the comma-separated pair consisting of 'KernelFunction' and one of the following.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exponential'</td>
<td>Exponential kernel.</td>
</tr>
<tr>
<td>'squaredexponential'</td>
<td>Squared exponential kernel.</td>
</tr>
<tr>
<td>'matern32'</td>
<td>Matern kernel with parameter 3/2.</td>
</tr>

</tbody>
</table>

Function handle

A function handle that can be called like this:

\[
\text{Kmn} = kfcn(Xm,Xn,theta)
\]

where \(Xm\) is an \(m\)-by-\(d\) matrix, \(Xn\) is an \(n\)-by-\(d\) matrix and \(\text{Kmn}\) is an \(m\)-by-\(n\) matrix of kernel products such that \(\text{Kmn}(i,j)\) is the kernel product between \(Xm(i,:)\) and \(Xn(j,:)\). \(\text{theta}\) is the \(r\)-by-1 unconstrained parameter vector for \(kfcn\).

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-7.

Example: 'KernelFunction','matern32'

Data Types: char | string | function_handle

**KernelParameters — Initial values for the kernel parameters**

vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of 'KernelParameters' and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the KernelFunction name-value pair argument.
<table>
<thead>
<tr>
<th>'KernelFunction'</th>

</tr>
</tbody>
</table>

Function handle $r$-by-1 vector as the initial value of the unconstrained parameter vector $\phi$ for the custom kernel function $kfcn$. When KernelFunction is a function handle, you must supply initial values for the kernel parameters.

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-7.

Example: 'KernelParameters',theta

Data Types: double

**DistanceMethod — Method for computing inter-point distances**

'fast' (default) | 'accurate'

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of 'DistanceMethod' and either 'fast' or 'accurate'. fitrgp computes $(x - y)^2$ as $x^2 + y^2 - 2 * x * y$ when you choose the fast option and as $(x - y)^2$ when you choose the accurate option.

Example: 'DistanceMethod','accurate'
Active Set Selection

**ActiveSet — Observations in the active set**

[] (default) | \( m \)-by-1 vector of integers ranging from 1 to \( n \) (\( m \leq n \)) | logical vector of length \( n \)

Observations in the active set, specified as the comma-separated pair consisting of 'ActiveSet' and an \( m \)-by-1 vector of integers ranging from 1 to \( n \) (\( m \leq n \)) or a logical vector of length \( n \) with at least one true element. \( n \) is the total number of observations in the training data.

fitrgp uses the observations indicated by ActiveSet to train the GPR model. The active set cannot have duplicate elements.

If you supply ActiveSet, then:
- fitrgp does not use ActiveSetSize and ActiveSetMethod.
- You cannot perform cross-validation on this model.

Data Types: double | logical

**ActiveSetSize — Size of the active set for sparse methods**

an integer \( m \) (\( 1 \leq m \leq n \))

Size of the active set for sparse methods ('sd', 'sr', 'fic'), specified as the comma-separated pair consisting of 'ActiveSetSize' and an integer \( m \), \( 1 \leq m \leq n \), where \( n \) is the number of observations.

Default is min(1000,\( n \)) when FitMethod is 'sr' or 'fic', and min(2000,\( n \)), otherwise.

Example: 'ActiveSetSize',100

Data Types: double

**ActiveSetMethod — Active set selection method**

'random' (default) | 'sgma' | 'entropy' | 'likelihood'

Active set selection method, specified as the comma-separated pair consisting of 'ActiveSetMethod' and one of the following.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'random'</td>
<td>Random selection</td>
</tr>
</tbody>
</table>
All active set selection methods (except 'random') require the storage of an $n$-by-$m$ matrix, where $m$ is the size of the active set and $n$ is the number of observations.

Example: 'ActiveSetMethod','entropy'

**RandomSearchSetSize — Random search set size**  
59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of 'RandomSearchSetSize' and an integer value.

Example: 'RandomSearchSetSize',30  
Data Types: double

**ToleranceActiveSet — Relative tolerance for terminating active set selection**  
1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of 'ToleranceActiveSet' and a positive scalar value.

Example: 'ToleranceActiveSet',0.0002  
Data Types: double

**NumActiveSetRepeats — Number of repetitions**  
3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation on page 32-2284 when ActiveSetMethod is not 'random', specified as the comma-separated pair consisting of 'NumActiveSetRepeats' and an integer value.

Example: 'NumActiveSetRepeats',5  
Data Types: double
Prediction

**PredictMethod — Method used to make predictions**

'exact' | 'bcd' | 'sd' | 'sr' | 'fic'

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of 'PredictMethod' and one of the following.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exact'</td>
<td>Exact Gaussian process regression method. Default, if ( n \leq 10000 ).</td>
</tr>
<tr>
<td>'bcd'</td>
<td>Block Coordinate Descent. Default, if ( n &gt; 10000 ).</td>
</tr>
<tr>
<td>'sd'</td>
<td>Subset of Datapoints approximation.</td>
</tr>
<tr>
<td>'sr'</td>
<td>Subset of Regressors approximation.</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully Independent Conditional approximation.</td>
</tr>
</tbody>
</table>

Example: 'PredictMethod','bcd'

**BlockSizeBCD — Block size**

minimum of 1000 or \( n \) (default) | integer in the range from 1 to \( n \)

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to \( n \), where \( n \) is the number of observations.

Example: 'BlockSizeBCD',1500

Data Types: double

**NumGreedyBCD — Number of greedy selections**

minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.

Example: 'NumGreedyBCD',150
Data Types: double

**ToleranceBCD — Relative tolerance on gradient norm**

1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.

Example: 'ToleranceBCD', 0.002

Data Types: double

**StepToleranceBCD — Absolute tolerance on step size**

1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.

Example: 'StepToleranceBCD', 0.002

Data Types: double

**IterationLimitBCD — Maximum number of BCD iterations**

1000000 (default) | integer value

Maximum number of block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'IterationLimitBCD' and an integer value.

Example: 'IterationLimitBCD', 10000

Data Types: double

**Optimization**

**Optimizer — Optimizer to use for parameter estimation**

'quasinewton' (default) | 'lbfgs' | 'fminsearch' | 'fminunc' | 'fmincon'

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of 'Optimizer' and one of the values in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'quasinewton'</td>
<td>Dense, symmetric rank-1-based, quasi-Newton approximation to the Hessian</td>
</tr>
<tr>
<td>'lbfgs'</td>
<td>LBFGS-based quasi-Newton approximation to the Hessian</td>
</tr>
<tr>
<td>'fminsearch'</td>
<td>Unconstrained nonlinear optimization using the simplex search method of Lagarias et al. [5]</td>
</tr>
<tr>
<td>'fminunc'</td>
<td>Unconstrained nonlinear optimization (requires an Optimization Toolbox license)</td>
</tr>
<tr>
<td>'fmincon'</td>
<td>Constrained nonlinear optimization (requires an Optimization Toolbox license)</td>
</tr>
</tbody>
</table>

For more information on the optimizers, see Algorithms on page 32-2286.

Example: 'Optimizer','fmincon'

**OptimizerOptions — Options for the optimizer**

*structure | object*

Options for the optimizer you choose using the `Optimizer` name-value pair argument, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure or object created by `optimset`, `statset('fitrgp')`, or `optimoptions`.

<table>
<thead>
<tr>
<th>Optimizer</th>
<th>Create Optimizer Options Using</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fminsearch'</td>
<td><code>optimset</code> (structure)</td>
</tr>
<tr>
<td>'quasinewton' or 'lbfgs'</td>
<td><code>statset('fitrgp')</code> (structure)</td>
</tr>
<tr>
<td>'fminunc' or 'fmincon'</td>
<td><code>optimoptions</code> (object)</td>
</tr>
</tbody>
</table>

The default options depend on the type of optimizer.

Example: 'OptimizerOptions',opt

**InitialStepSize — Initial step size**

*[] (default) | real positive scalar | 'auto'*

Initial step size, specified as the comma-separated pair consisting of `'InitialStepSize'` and a real positive scalar or 'auto'.

32-2274
'InitialStepSize' is the approximate maximum absolute value of the first optimization step when the optimizer is 'quasinewton' or 'lbfgs'. The initial step size can determine the initial Hessian approximation during optimization.

By default, fitrgp does not use the initial step size to determine the initial Hessian approximation. To use the initial step size, set a value for the 'InitialStepSize' name-value pair argument, or specify 'InitialStepSize','auto' to have fitrgp determine a value automatically. For more information on 'auto', see Algorithms on page 32-2286.

Example: 'InitialStepSize','auto'

**Cross-Validation**

**CrossVal — Indicator for cross-validation**

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of 'CrossVal' and either 'off' or 'on'. If it is 'on', then fitrgp returns a GPR model cross-validated with 10 folds.

You can use one of the KFold, Holdout, Leaveout or CVPartition name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the crossval method for your model.

Example: 'CrossVal','on'

**CVPartition — Random partition for a stratified k-fold cross-validation**

cvpagination object

Random partition for a stratified k-fold cross-validation, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object.

Example: 'CVPartition',cvp uses the random partition defined by cvp.

If you specify CVPartition, then you cannot specify Holdout, KFold, or Leaveout.

**Holdout — Fraction of data to use for testing**

scalar value in the range from 0 to 1
Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p, then the software:
1. Randomly reserves around $p \times 100\%$ of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in cvgprMdl.Trained.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify Holdout, then you cannot specify CVPartition, KFold, or Leaveout.

Data Types: double

**KFold — Number of folds**

10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. KFold must be greater than 1. If you specify 'KFold', k then the software:
1. Randomly partitions the data into $k$ sets.
2. For each set, reserves the set as test data, and trains the model using the other $k - 1$ sets.
3. Stores the $k$ compact, trained models in the cells of a $k$-by-1 cell array in cvgprMdl.Trained.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify KFold, then you cannot specify CVPartition, Holdout, or Leaveout.

Data Types: double

**Leaveout — Indicator for leave-one-out cross-validation**

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and either 'off' or 'on'.

If you specify 'Leaveout', 'on', then, for each of the $n$ observations, the software:
1. Reserves the observation as test data, and trains the model using the other $n - 1$ observations.
2. Stores the compact, trained model in a cell in the $n$-by-1 cell array cvgprMdl.Trained.
Example: 'Leaveout','on'

If you specify Leaveout, then you cannot specify CVPartition, Holdout, or KFold.

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Sigma'}.
- 'all' — Optimize all eligible parameters, equivalent to {'BasisFunction','KernelFunction','KernelScale','Sigma','Standardize'}.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrgp by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3215. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrgp are:

- **BasisFunction** — fitrgp searches among 'constant', 'none', 'linear', and 'pureQuadratic'.
- **KernelFunction** — fitrgp searches among 'ardexponential', 'ardmatern32', 'ardmatern52', 'ardrationalquadratic', 'ardsquaredexponential', 'exponential', 'matern32', 'matern52', 'rationalquadratic', and 'squaredexponential'.
- **KernelScale** — `fitrgp` uses the `KernelParameters` argument to specify the value of the kernel scale parameter, which is held constant during fitting. In this case, all input dimensions are constrained to have the same `KernelScale` value. `fitrgp` searches among real value in the range 
\[1e-3 \times \text{MaxPredictorRange}, \text{MaxPredictorRange}\], where

\[
\text{MaxPredictorRange} = \max(\max(X) - \min(X)).
\]

`KernelScale` cannot be optimized for any of the ARD kernels.

- **Sigma** — `fitrgp` searches among real value in the range 
\[1e-4, \max(1e-3, 10 \times \text{ResponseStd})\], where

\[
\text{ResponseStd} = \text{std}(y).
\]

Internally, `fitrgp` sets the `ConstantSigma` name-value pair to `true` so the value of `Sigma` is constant during the fitting.

- **Standardize** — `fitrgp` searches among `true` and `false`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitrgp', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \(\log(1 + \text{cross-validation loss})\) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `HyperparameterOptimizationOptions` name-value pair argument. To control the plots, set the `ShowPlots` field of the `HyperparameterOptimizationOptions` name-value pair argument.

For an example, see “Optimize GPR Regression” on page 32-2246.

Example: `'auto'`
Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Data Types: struct
Other

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in `PredictorNames` must correspond to the column order of X. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{’x1’,’x2’,…}`.
- If you supply tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitrgp` uses the predictor variables in `PredictorNames` and the response only in training.
  - `PredictorNames` must be a subset of `tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.

Example: 'PredictorNames',{’PedalLength’,’PedalWidth’}

Data Types: string | cell

**ResponseName — Response variable name**

‘Y’ (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.
Example: 'ResponseName','response'
Data Types: char | string

Verbose — Verbosity level
0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and one of the following.

- 0 — *fitrgp* suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of 'Display' in OptimizerOptions.
- 1 — *fitrgp* displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: 'Verbose',1

CacheSize — Cache size in megabytes
1000 MB (default) | positive scalar

Cache size in megabytes (MB), specified as the comma-separated pair consisting of 'CacheSize' and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. *fitrgp* uses CacheSize to:

- Decide whether interpoint distances should be cached when estimating parameters.
- Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: 'CacheSize',2000
Data Types: double

Output Arguments

gprMdl — Gaussian process regression model
RegressionGP object | RegressionPartitionedModel object

Gaussian process regression model, returned as a RegressionGP or a RegressionPartitionedModel object.
• If you cross-validate, that is, if you use one of the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pairs, then gprMdl is a RegressionPartitionedModel object. You cannot use a RegressionPartitionedModel object to make predictions using predict. For more information on the methods and properties of this object, see RegressionPartitionedModel.

• If you do not cross-validate, then gprMdl is a RegressionGP object. You can use this object for predictions using the predict method. For more information on the methods and properties of this object, see RegressionGP.

Definitions

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to 'sd', 'sr', or 'fic'), if you do not provide the active set, fitrgp selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector \( \eta_0 = [\beta_0, \sigma_0, \theta_0] \) to select an active set \( A_1 \). It maximizes the GPR marginal log likelihood or its approximation using \( \eta_0 \) as the initial values and \( A_1 \) to compute the new parameter estimates \( \eta_1 \). Next, it computes the new log likelihood value \( L_1 \).

In the second iteration, the software selects the active set \( A_2 \) using the parameter values in \( \eta_1 \). Then, using \( \eta_1 \) as the initial values and \( A_2 \), it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values \( \eta_2 \). Then using \( \eta_2 \) and \( A_2 \), computes the new log likelihood value \( L_2 \).

The following table summarizes the iterations and what is computed at each iteration.

<table>
<thead>
<tr>
<th>Iteration Number</th>
<th>Active Set</th>

</table>

32-2284
The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the NumActiveSetRepeats name-value pair argument.

**Tips**

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.

- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of character vectors.

- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors.

- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.

- The `X` property stores the training data as originally input. It does not include the dummy variables.

- The default approach to initializing the Hessian approximation in `fitrgp` can be slow when you have a GPR model with many kernel parameters, such as when using an ARD kernel with many predictors. In this case, consider specifying `'auto'` or a value for the initial step size.

You can set `'Verbose', 1` for display of iterative diagnostic messages, and begin training a GPR model using an LBFGS or quasi-Newton optimizer with the default `fitrgp` optimization. If the iterative diagnostic messages are not displayed after a few seconds, it is possible that initialization of the Hessian approximation is taking too long. In this case, consider restarting training and using the initial step size to speed up optimization.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.
Algorithms

- Fitting a GPR model involves estimating the following model parameters from the data:
  
  - Covariance function \( k(x_i, x_j | \theta) \) parameterized in terms of kernel parameters in vector \( \theta \) (see “Kernel (Covariance) Function Options” on page 6-7)
  
  - Noise variance, \( \sigma^2 \)
  
  - Coefficient vector of fixed basis functions, \( \beta \)

The value of the 'KernelParameters' name-value pair argument is a vector that consists of initial values for the signal standard deviation \( \sigma_f \) and the characteristic length scales \( \sigma_l \). The \texttt{fitrgp} function uses these values to determine the kernel parameters. Similarly, the 'Sigma' name-value pair argument contains the initial value for the noise standard deviation \( \sigma \).

- During optimization, \texttt{fitrgp} creates a vector of unconstrained initial parameter values \( \eta_0 \) by using the initial values for the noise standard deviation and the kernel parameters.

- \texttt{fitrgp} analytically determines the explicit basis coefficients \( \beta \), specified by the 'Beta' name-value pair argument, from estimated values of \( \theta \) and \( \sigma^2 \). Therefore, \( \beta \) does not appear in the \( \eta_0 \) vector when \texttt{fitrgp} initializes numerical optimization.

\textbf{Note} If you specify no estimation of parameters for the GPR model, \texttt{fitrgp} uses the value of the 'Beta' name-value pair argument and other initial parameter values as the known GPR parameter values (see \texttt{Beta}). In all other cases, the value of the 'Beta' argument is optimized analytically from the objective function.

- The quasi-Newton optimizer uses a trust-region method with a dense, symmetric rank-1-based (SR1), quasi-Newton approximation to the Hessian, while the LBFGS optimizer uses a standard line-search method with a limited-memory Broyden-
Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton approximation to the Hessian. See Nocedal and Wright [6].

- If you set the 'InitialStepSize' name-value pair argument to 'auto', fitrgp determines the initial step size, $\|s_0\|_\infty$, by using $\|s_0\|_\infty = 0.5\|\eta_0\|_\infty + 0.1$.

$s_0$ is the initial step vector, and $\eta_0$ is the vector of unconstrained initial parameter values.

- During optimization, fitrgp uses the initial step size, $\|s_0\|_\infty$, as follows:
  
  If you use 'Optimizer','quasinewton' with the initial step size, then the initial Hessian approximation is $\frac{\|g_0\|_\infty I}{\|s_0\|_\infty}$.

  If you use 'Optimizer','lbfgs' with the initial step size, then the initial inverse-Hessian approximation is $\frac{\|s_0\|_\infty I}{\|g_0\|_\infty}$.

$g_0$ is the initial gradient vector, and $I$ is the identity matrix.

Introduced in R2015b
**fitrlinear**

Fit linear regression model to high-dimensional data

*fitrlinear* efficiently trains linear regression models with high-dimensional, full or sparse predictor data. Available linear regression models include regularized support vector machines (SVM) and least-squares regression methods. *fitrlinear* minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

A high-dimensional data set includes many predictor variables. Although such a data set can consume a significant fraction of memory, it must fit in the MATLAB Workspace. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 32-2328.

**Syntax**

```matlab
Mdl = fitrlinear(X,Y)
Mdl = fitrlinear(X,Y,Name,Value)
[ Mdl,FitInfo] = fitrlinear(___) 
[ Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(___) 
```

**Description**

*Mdl = fitrlinear(X,Y)* returns a trained regression model object that contains the results of fitting a support vector machine regression model to the predictors *X* and response *Y*.

*Mdl = fitrlinear(X,Y,Name,Value)* returns a trained linear regression model with additional options specified by one or more Name,Value pair arguments. For example, you can specify implement least-squares regression, specify to cross-validate, or specify the type of regularization. It is good practice to cross-validate using the Kfold Name,Value pair argument. The cross-validation results determine how well the model generalizes.

*[Mdl,FitInfo] = fitrlinear(__)* also returns optimization details using any of the previous syntaxes. You cannot request FitInfo for cross-validated models.
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(__)
also returns hyperparameter optimization details when you pass an
OptimizeHyperparameters name-value pair.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e.\]

- \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Train a linear regression model. By default, fitrlinear uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

[Mdl,FitInfo] = fitrlinear(X,Y)

Mdl = 
RegressionLinear
    ResponseName: 'Y'

    DeltaGradientTolerance: 0.1000
    TerminationCode: 0
    TerminationStatus: {'Iteration limit exceeded.'}
    Alpha: [10000x1 double]
    History: []
    FitTime: 0.1190
    Solver: {'dual'}

Mdl is a RegressionLinear model. You can pass Mdl and the training or new data to loss to inspect the in-sample mean-squared error. Or, you can pass Mdl and new predictor data to predict to predict responses for new observations.

FitInfo is a structure array containing, among other things, the termination status (TerminationStatus) and how long the solver took to fit the model to the data (FitTime). It is good practice to use FitInfo to determine whether optimization-termination measurements are satisfactory. In this case, fitrlinear reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.
Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \( 10^{-5} \) through \( 10^{-1} \).

```matlab
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```matlab
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,... 'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```matlab
numCLModels = numel(CVMdl.Trained)
```

```matlab
numCLModels = 5
```

\( CVMdl \) is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, \( CVMdl \) contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```matlab
Mdl1 = CVMdl.Trained{1}
```

```matlab
Mdl1 =
    RegressionLinear
```
Mdl1 is a RegressionLinear model object. fitrlinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

\[
\text{mse} = \text{kfoldLoss}(\text{CVMdl});
\]

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

\[
\text{Mdl} = \text{fitrlinear}(X,Y,\text{ObservationsIn},'columns',\text{Lambda},...\text{Learner},'leastsquares',\text{Solver},'sparsa',\text{Regularization},'lasso');
\]

\[
\text{numNZCoeff} = \text{sum}(\text{Mdl}.\text{Beta}==0);
\]

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

\[
\text{figure}
\]

\[
[\text{h,hl1,hl2}] = \text{plotyy}(\text{log10(Lambda)},\text{log10(mse)},...\text{log10(Lambda)},\text{log10(numNZCoeff)});
\]

\[
\text{hl1.Marker} = 'o';
\]

\[
\text{hl2.Marker} = 'o';
\]

\[
\text{ylabel(h(1),'log}_{10}\text{ MSE')}
\]

\[
\text{ylabel(h(2),'log}_{10}\text{ nonzero-coefficient frequency')}
\]

\[
\text{xlabel('log}_{10}\text{ Lambda')}
\]

\[
\text{hold off}
\]
Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, \( \text{Lambda}(10) \)).

\[
\text{idxFinal} = 10;
\]

Extract the model with corresponding to the minimal MSE.

\[
\text{MdlFinal} = \text{selectModels}(\text{Mdl}, \text{idxFinal})
\]

\[
\text{MdlFinal} = \text{RegressionLinear}
\]
\[
\begin{align*}
\text{ResponseName: 'Y'} \\
\text{ResponseTransform: 'none'} \\
\text{Beta: [1000x1 double]}
\end{align*}
\]
Bias: -0.0050
Lambda: 0.0037
Learner: 'leastsquares'

Properties, Methods

idxNZCoeff = find(MdlFinal.Beta~=0)
idxNZCoeff = 2×1
    100
    200

EstCoeff = Mdl.Beta(idxNZCoeff)
EstCoeff = 2×1
    1.0051
    1.9965

MdlFinal is a RegressionLinear model with one regularization strength. The nonzero coefficients EstCoeff are close to the coefficients that simulated the data.

Optimize a Linear Regression

This example shows how to optimize hyperparameters automatically using fitrlinear. The example uses artificial (simulated) data for the model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Find hyperparameters that minimize five-fold cross validation loss by using automatic hyperparameter optimization.

For reproducibility, use the 'expected-improvement-plus' acquisition function.

hyperopts = struct('AcquisitionFunctionName','expected-improvement-plus');
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(X,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',hyperopts)

This optimization technique is simpler than that shown in “Find Good Lasso Penalty Using Cross-Validation” on page 32-2291, but does not allow you to trade off model complexity and cross-validation loss.

**Input Arguments**

**X — Predictor data**

full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix.

The length of Y and the number of observations in X must be equal.
**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in optimization-execution time.

Data Types: single | double

**Y — Response data**
numeric vector

Response data, specified as an n-dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: single | double

**Note** `fitrlinear` removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y or ValidationData{2})
- At least one NaN value in a predictor observation (row in X or ValidationData{1})
- NaN value or 0 weight (Weights or ValidationData{3})

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.
Example: `Mdl = fitrlinear(X,Y,'Learner','leastsquares','CrossVal','on','Regularization','lasso')` specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

**Linear Regression Options**

**Epsilon — Half the width of epsilon-insensitive band**

iqr(Y)/1.349 (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value. 'Epsilon' applies to SVM learners only.

The default Epsilon value is `iqr(Y)/1.349`, which is an estimate of standard deviation using the interquartile range of the response variable Y. If `iqr(Y)` is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon',0.3

Data Types: single | double

**Lambda — Regularization term strength**

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', Lambda = 1/n.
  - If you specify a cross-validation, name-value pair argument (e.g., CrossVal), then n is the number of in-fold observations.
  - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in Lambda in ascending order.
  - If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-1916 for the next optimization iteration. Otherwise, the software uses warm starts.
  - If Regularization is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in Lambda.
Returns coefficient estimates for all optimization iterations.

Example: 'Lambda',10.^(-(10:-2:2))

Data Types: char | string | double | single

**Learner — Linear regression model type**

'svm' (default) | 'leastsquares'

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In this table, \( f(x) = x\beta + b \).

- \( \beta \) is a vector of \( p \) coefficients.
- \( x \) is an observation from \( p \) predictor variables.
- \( b \) is the scalar bias.

<table>
<thead>

<td>Epsilon-insensitive: ( \ell[y, f(x)] = \max[0,</td>
</tr>
</tbody>
</table>

Example: 'Learner','leastsquares'

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.
Regularization — Complexity penalty type
'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

<tr>
<td>'lasso'</td>
<td>Lasso (L1) penalty: $\lambda \sum_{j=1}^{p}</td>
</tr>
<tr>
<td>'ridge'</td>
<td>Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$</td>
</tr>
</tbody>
</table>

To specify the regularization term strength, which is $\lambda$ in the expressions, use Lambda.

The software excludes the bias term ($\beta_0$) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

**Tip**
- For predictor variable selection, specify 'lasso'.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization','lasso'

Solver — Objective function minimization technique
'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sgd'</td>
<td>Stochastic gradient descent (SGD) [5][3]</td>
<td></td>
</tr>
<tr>
<td>'asgd'</td>
<td>Average stochastic gradient descent (ASGD) [8]</td>
<td></td>
</tr>
<tr>
<td>'dual'</td>
<td>Dual SGD for SVM [2][7]</td>
<td>Regularization must be 'ridge' and Learner must be 'svm'.</td>
</tr>
<tr>
<td>'bfgs'</td>
<td>Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]</td>
<td>Inefficient if X is very high-dimensional.</td>
</tr>
<tr>
<td>'lbfgs'</td>
<td>Limited-memory BFGS (LBFGS) [4]</td>
<td>Regularization must be 'ridge'.</td>
</tr>
<tr>
<td>'sparsa'</td>
<td>Sparse Reconstruction by Separable Approximation (SpaRSA) [6]</td>
<td>Regularization must be 'lasso'.</td>
</tr>
</tbody>
</table>

If you specify:

- A ridge penalty (see Regularization) and size(X,1) <= 100 (100 or fewer predictor variables), then the default solver is 'bfgs'.
- An SVM regression model (see Learner), a ridge penalty, and size(X,1) > 100 (more than 100 predictor variables), then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each Lambda.

For more details on which solver to choose, see “Tips” on page 32-2329.

Example: 'Solver', {'sgd','lbfgs'}

**Beta — Initial linear coefficient estimates**
zeros(p,1) (default) | numeric vector | numeric matrix
Initial linear coefficient estimates ($\beta$), specified as the comma-separated pair consisting of 'Beta' and a $p$-dimensional numeric vector or a $p$-by-$L$ numeric matrix. $p$ is the number of predictor variables in $X$ and $L$ is the number of regularization-strength values (for more details, see Lambda).

- If you specify a $p$-dimensional vector, then the software optimizes the objective function $L$ times using this process.
  
  1 The software optimizes using $\text{Beta}$ as the initial value and the minimum value of $\text{Lambda}$ as the regularization strength.
  
  2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-1916, and the next smallest value in $\text{Lambda}$ as the regularization strength.
  
  3 The software implements step 2 until it exhausts all values in $\text{Lambda}$.

- If you specify a $p$-by-$L$ matrix, then the software optimizes the objective function $L$ times. At iteration $j$, the software uses $\text{Beta}(:,j)$ as the initial value and, after it sorts $\text{Lambda}$ in ascending order, uses $\text{Lambda}(j)$ as the regularization strength.

If you set 'Solver','dual', then the software ignores $\text{Beta}$.

Data Types: single | double

**Bias — Initial intercept estimate**

numeric scalar | numeric vector

Initial intercept estimate ($b$), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an $L$-dimensional numeric vector. $L$ is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function $L$ times using this process.
  
  1 The software optimizes using $\text{Bias}$ as the initial value and the minimum value of $\text{Lambda}$ as the regularization strength.
  
  2 The uses the resulting estimate as a warm start on page 32-2328 to the next optimization iteration, and uses the next smallest value in $\text{Lambda}$ as the regularization strength.
  
  3 The software implements step 2 until it exhausts all values in $\text{Lambda}$.

- If you specify an $L$-dimensional vector, then the software optimizes the objective function $L$ times. At iteration $j$, the software uses $\text{Bias}(j)$ as the initial value and,
after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.

• By default:
  • If Learner is 'leastsquares', then Bias is the weighted average of Y for training or, for cross-validation, in-fold responses.
  • If Learner is 'svm', then Bias is the weighted median of Y for all training or, for cross-validation, in-fold observations that are greater than Epsilon.

Data Types: single | double

**FitBias — Linear model intercept inclusion flag**

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The software includes the bias term b in the linear model, and then estimates it.</td>
</tr>
<tr>
<td>false</td>
<td>The software sets b = 0 during estimation.</td>
</tr>
</tbody>
</table>

Example: 'FitBias',false

Data Types: logical

**PostFitBias — Flag to fit linear model intercept after optimization**

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>The software estimates the bias term b and the coefficients β during optimization.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| true  | To estimate $b$, the software:  
1. Estimates $\beta$ and $b$ using the model.  
2. Computes residuals.  
3. Refits $b$. For least squares, $b$ is the weighted average of the residuals. For SVM regression, $b$ is the weighted median between all residuals with magnitude greater than Epsilon. |

If you specify `true`, then `FitBias` must be `true`.

Example: `'PostFitBias',true`

Data Types: `logical`

**Verbose — Verbosity level**

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitrlinear` displays at the command line.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>fitrlinear</code> does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td><code>fitrlinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
<tr>
<td>Any other positive integer</td>
<td><code>fitrlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
</tbody>
</table>

Example: `'Verbose',1`

Data Types: `double` | `single`
**SGD and ASGD Solver Options**

**BatchSize — Mini-batch size**
positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is \( \text{max}([10, \text{ceil}(\sqrt{ff})]) \), where \( ff = \text{numel}(X)/\text{nnz}(X) \) (the fullness factor of X).

Example: 'BatchSize',100

Data Types: single | double

**LearnRate — Learning rate**
positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate \( \gamma_0 \). The software determines the learning rate for iteration \( t \), \( \gamma_t \), using

\[
\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0^c)^c}.
\]

- \( \lambda \) is the value of Lambda.
- If Solver is 'sgd', then \( c = 1 \).
- If Solver is 'asgd', then \( c \) is:
  - 2/3 if Learner is 'leastsquares'
  - 3/4 if Learner is 'svm' [8]
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is \( 1/\sqrt{1+\text{max}((\text{sum}(X.^2,\text{obsDim})))} \), where obsDim is 1 if the observations compose the columns of X, and 2 otherwise.
Example: 'LearnRate', 0.01
Data Types: single | double

**OptimizeLearnRate — Flag to decrease learning rate**
true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, overstepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:

1. For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true
Data Types: logical

**TruncationPeriod — Number of mini-batches between lasso truncation runs**
10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient $j$ using

$$
\hat{\beta}_j^* = \begin{cases} 
\hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t, \\
0 & \text{if } |\hat{\beta}_j| \leq u_t, \\
\hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t.
\end{cases}
$$

For SGD, $\hat{\beta}_j$ is the estimate of coefficient $j$ after processing $k$ mini-batches. $u_t = k \gamma_t \lambda$. $\gamma_t$ is the learning rate at iteration $t$. $\lambda$ is the value of Lambda.
• For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient $j$ after processing $k$ mini-batches, $u_t = k\lambda$.

If Regularization is 'ridge', then the software ignores TruncationPeriod.
Example: 'TruncationPeriod',100
Data Types: single | double

Other Regression Options

Weights — Observation weights
ones($n,1$)/$n$ (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. fitrlinear weighs the observations in $X$ with the corresponding value in Weights. The size of Weights must equal $n$, the number of observations in $X$.

fitrlinear normalizes Weights to sum to 1.
Data Types: double | single

ResponseName — Response variable name
'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.
• If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
• If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

ResponseTransform — Response transformation
'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none',
which means @\( y \) \textit{y}, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using \texttt{myfunction = @(y)exp(y)}. Then, you can specify the response transformation as 'ResponseTransform', myfunction.

Data Types: char | string | function_handle

Cross-Validation Options

\textbf{CrossVal — Cross-validation flag}

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, or KFold. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: 'Crossval','on'

\textbf{CVPartition — Cross-validation partition}

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

\textbf{Holdout — Fraction of data for holdout validation}

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', \( p \), then the software:
Randomly reserves $p\times100\%$ of the data as validation data, and trains the model using the rest of the data.

Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', $k$, then the software:

1. Randomly partitions the data into $k$ sets
2. For each set, reserves the set as validation data, and trains the model using the other $k-1$ sets
3. Stores the $k$ compact, trained models in the cells of a $k$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold', 8

Data Types: single | double

**SGD and ASGD Convergence Controls**

**BatchLimit — Maximal number of batches**

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
• The software passes through the data PassLimit times.
• If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is ceil(1e6/BatchSize). BatchSize is the value of the 'BatchSize' name-value pair argument.
• If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
• If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100
Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term
1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let \( B_t = [\beta_t \ b_t] \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \| B_t - B_{t-1} \|_2 < \text{BetaTolerance} \), then optimization terminates.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6
Data Types: single | double

NumCheckConvergence — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see BatchSize.
The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence',100

Data Types: single | double

**PassLimit — Maximal number of passes**

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

`fitrlinear` processes all observations when it completes one pass through the data.

When `fitrlinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify 'BatchLimit' and `PassLimit`, then `fitrlinear` chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 32-2331.

Example: 'PassLimit',5

Data Types: single | double

**ValidationData — Validation data for optimization convergence detection**

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2331. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an $m$-by-$p$ or $p$-by-$m$ full or sparse matrix of predictor data that has the same orientation as $X$. The predictor variables in the training data $X$ and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of $m$ responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, ValidationData(3) can contain an m-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**GradientTolerance — Absolute gradient tolerance**

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar. GradientTolerance applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Let \( \nabla L_t \) be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration \( t \). If \( \| \nabla L_t \|_\infty = \max |\nabla L_t| < \text{GradientTolerance} \), then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when fitrlinear satisfies either stopping criterion.

If fitrlinear converges for the last solver specified in Solver, then optimization terminates. Otherwise, fitrlinear uses the next solver specified in Solver.

Example: 'GradientTolerance',eps

Data Types: single | double

**IterationLimit — Maximal number of optimization iterations**

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',1e7

Data Types: single | double
**Dual SGD Optimization Convergence Controls**

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let \( B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix} \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \frac{\|B_t - B_{t-1}\|_2}{B_t} < \text{BetaTolerance} \), then optimization terminates.

If you also specify DeltaGradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

**DeltaGradientTolerance — Gradient-difference tolerance**

0.1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2001 violations, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar. DeltaGradientTolerance applies to the 'dual' value of Solver only.

- If the magnitude of the KKT violators is less than DeltaGradientTolerance, then fitrlinear terminates optimization.
- If fitrlinear converges for the last solver specified in Solver, then optimization terminates. Otherwise, fitrlinear uses the next solver specified in Solver.

Example: 'DeltaGapTolerance',1e-2

Data Types: double | single
**NumCheckConvergence — Number of passes through entire data set to process before next convergence check**
5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence',100
Data Types: single | double

**PassLimit — Maximal number of passes**
10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data PassLimit times, it terminates optimization.

Example: 'PassLimit',5
Data Types: single | double

**ValidationData — Validation data for optimization convergence detection**

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2331. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an m-by-p or p-by-m full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData(2) must contain an array of m responses with length corresponding to the number of observations in ValidationData{1}. 
• Optionally, ValidationData(3) can contain an \( m \)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**BFGS, LBFGS, and SpaRSA Convergence Controls**

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let \( B_t = [\beta_t' \ b_t] \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \frac{\|B_t - B_{t-1}\|_2}{B_t} < \text{BetaTolerance} \), then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

**GradientTolerance — Absolute gradient tolerance**

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.
Let $\nabla L_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration $t$. If $\|\nabla L_t\|_\infty = \max |\nabla L_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'GradientTolerance',1e-5
Data Types: single | double

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize',10
Data Types: single | double

**IterationLimit — Maximal number of optimization iterations**

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500
Data Types: single | double

**ValidationData — Validation data for optimization convergence detection**

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.
During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2331. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an \( m \)-by-\( p \) or \( p \)-by-\( m \) full or sparse matrix of predictor data that has the same orientation as \( X \). The predictor variables in the training data \( X \) and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData(2) must contain an array of \( m \) responses with length corresponding to the number of observations in ValidationData{1}.
- Optionally, ValidationData(3) can contain an \( m \)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use {'Lambda','Learner'}.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.
The optimization attempts to minimize the cross-validation loss (error) for \texttt{fitrlinear} by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the \texttt{HyperparameterOptimizationOptions} name-value pair.

\textbf{Note} 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for \texttt{fitrlinear} are:

- \texttt{Lambda} — \texttt{fitrlinear} searches among positive values, by default log-scaled in the range $[1e^{-5}/\text{NumObservations},1e^{5}/\text{NumObservations}]$.
- \texttt{Learner} — \texttt{fitrlinear} searches among 'svm' and 'leastsquares'.
- \texttt{Regularization} — \texttt{fitrlinear} searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of \texttt{optimizableVariable} objects that have nondefault values. For example,

```matlab
load carsmall
params = hyperparameters('fitrlinear',[Horsepower,Weight],MPG);
params(1).Range = [1e-3,2e4];
```

Pass \texttt{params} as the value of \texttt{OptimizeHyperparameters}.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the \texttt{Verbose} field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the \texttt{ShowPlots} field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize a Linear Regression” on page 32-2295.

Example: 'OptimizeHyperparameters','auto'

\textbf{HyperparameterOptimizationOptions — Options for optimization}

\texttt{structure}

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies
the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>

Example:

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct
Output Arguments

**Mdl — Trained linear regression model**

*RegressionLinear* model object | *RegressionPartitionedLinear* cross-validated model object

Trained linear regression model, returned as a *RegressionLinear* model object or *RegressionPartitionedLinear* cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a *RegressionPartitionedLinear* cross-validated model object. Otherwise, `Mdl` is a *RegressionLinear* model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

**Note** Unlike other regression models, and for economical memory usage, *RegressionLinear* and *RegressionPartitionedLinear* model objects do not store the training data or optimization details (for example, convergence history).

**FitInfo — Optimization details**

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TerminationStatus</td>
<td>• Reason for optimization termination</td>
</tr>
<tr>
<td></td>
<td>• Corresponds to a value in <code>TerminationCode</code></td>
</tr>
<tr>
<td>FitTime</td>
<td>Elapsed, wall-clock time in seconds</td>
</tr>
</tbody>
</table>
### Field Description

**History**

A structure array of optimization information for each iteration. The field **Solver** stores solver types using integer coding.

<table>
<thead>
<tr>
<th>Integer</th>
<th>Solver</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SGD</td>
</tr>
<tr>
<td>2</td>
<td>ASGD</td>
</tr>
<tr>
<td>3</td>
<td>Dual SGD for SVM</td>
</tr>
<tr>
<td>4</td>
<td>LBFGS</td>
</tr>
<tr>
<td>5</td>
<td>BFGS</td>
</tr>
<tr>
<td>6</td>
<td>SpaRSA</td>
</tr>
</tbody>
</table>

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

### HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of `'OptimizeHyperparameters'` is not `'none'`. The output value depends on the `Optimizer` field value of the `'HyperparameterOptimizationOptions'` name-value pair argument:

<table>
<thead>
<tr>
<th>Value of Optimizer Field</th>
<th>Value of HyperparameterOptimizationResults</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bayesopt' (default)</td>
<td>Object of class <code>BayesianOptimization</code></td>
</tr>
<tr>
<td>'gridsearch' or 'randomsearch'</td>
<td>Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)</td>
</tr>
</tbody>
</table>
Note If Learner is 'leastsquares', then the loss term in the objective function is half of the MSE. loss returns the MSE by default. Therefore, if you use loss to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by loss and optimization results in FitInfo or returned to the command line by setting a positive verbosity level using Verbose.

Definitions

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

<table>
<thead>
<tr>

<td>• Solves dual problem using SMO, ISDA, or L1 minimization via quadratic programming using quadprog.</td>
</tr>
</tbody>
</table>
Model to Fit | Function | Notable Algorithmic Differences
---|---|---
Linear regression | • Least-squares without regularization: fitlm
• Regularized least-squares using a lasso penalty: lasso
• Ridge regression: ridge or lasso | • lasso implements cyclic coordinate descent.

Logistic regression | • Logistic regression without regularization: fitglm.
• Regularized logistic regression using a lasso penalty: lassoglm | • fitglm implements iteratively reweighted least squares.
• lassoglm implements cyclic coordinate descent.

**Tips**

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify 'ObservationsIn','columns'. As a result, you can experience a significant reduction in optimization-execution time.

- For better optimization accuracy if X is high-dimensional and Regularization is 'ridge', set any of these combinations for Solver:
  - 'sgd'
  - 'asgd'
  - 'dual' if Learner is 'svm'
  - {'sgd','lbfgs'}
  - {'asgd','lbfgs'}
  - {'dual','lbfgs'} if Learner is 'svm'

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if X is moderate- through low-dimensional and Regularization is 'ridge', set Solver to 'bfgs'.

32-2329
• If Regularization is 'lasso', set any of these combinations for Solver:
  • 'sgd'
  • 'asgd'
  • 'sparsa'
  • {'sgd','sparsa'}
  • {'asgd','sparsa'}

• When choosing between SGD and ASGD, consider that:
  • SGD takes less time per iteration, but requires more iterations to converge.
  • ASGD requires fewer iterations to converge, but takes more time per iteration.

• If X has few observations, but many predictor variables, then:
  • Specify 'PostFitBias',true.
  • For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.

• For SGD and ASGD solvers, BatchSize affects the rate of convergence.
  • If BatchSize is too small, then fitrlinear achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  • If BatchSize is too large, then fitrlinear achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.

• Large learning rates (see LearnRate) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.

• When using lasso penalties, experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.

• For efficiency, fitrlinear does not standardize predictor data. To standardize X, enter

\[ X = \text{bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2))}; \]

The code requires that you orient the predictors and observations as the rows and columns of X, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.
• After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

• If you specify ValidationData, then, during objective-function optimization:
  
  • fitrlinear estimates the validation loss of ValidationData periodically using the current model, and tracks the minimal estimate.
  
  • When fitrlinear estimates a validation loss, it compares the estimate to the minimal estimate.
  
  • When subsequent, validation loss estimates exceed the minimal estimate five times, fitrlinear terminates optimization.
  
• If you specify ValidationData and to implement a cross-validation routine (CrossVal, CVPartition, Holdout, or KFold), then:
  
  1 fitrlinear randomly partitions X and Y according to the cross-validation routine that you choose.
  
  2 fitrlinear trains the model using the training-data partition. During objective-function optimization, fitrlinear uses ValidationData as another possible way to terminate optimization (for details, see the previous bullet).
  
  3 Once fitrlinear satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
    
    a If you implement k-fold cross-validation, and fitrlinear has not exhausted all training-set folds, then fitrlinear returns to Step 2 to train using the next training-set fold.
    
    b Otherwise, fitrlinear terminates training, and then returns the cross-validated model.
  
  4 You can determine the quality of the cross-validated model. For example:
    
    • To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to kfoldLoss.
    
    • To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to kfoldPredict.
References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:
• Some name-value pair arguments have different defaults and values compared to the in-memory fitrlinear function. Supported name-value pair arguments, and any differences, are:
  • 'Epsilon'
  • 'ObservationsIn' — Supports only 'rows'.
  • 'Lambda' — Can be 'auto' (default) or a scalar.
  • 'Learner'
  • 'Regularization' — Supports only 'ridge'.
  • 'Solver' — Supports only 'lbfgs'.
  • 'Verbose' — Default value is 1
  • 'Beta'
  • 'Bias'
  • 'FitBias' — Supports only true.
  • 'Weights' — Value must be a tall array.
  • 'HessianHistorySize'
  • 'BetaTolerance' — Default value is relaxed to 1e-3.
  • 'GradientTolerance' — Default value is relaxed to 1e-3.
  • 'IterationLimit' — Default value is relaxed to 20.
  • 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
  • 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitrlinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
• For tall arrays fitrlinear implements LBFGS by distributing the calculation of the loss and the gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for Beta and Bias are not given, fitrlinear first refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).
Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-9.

Introduced in R2016a
**fitrm**

Fit repeated measures model

**Syntax**

```matlab
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

**Description**

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

**Examples**

**Fit a Repeated Measures Model**

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```matlab
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),... 'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4],'VariableNames',{'Measurements'});
```
Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```matlab
rm =
    RepeatedMeasuresModel with properties:
    Between Subjects:
        BetweenDesign: [150x5 table]
        ResponseNames: {'meas1'  'meas2'  'meas3'  'meas4'}
        BetweenFactorNames: {'species'}
        BetweenModel: '1 + species'
    Within Subjects:
        WithinDesign: [4x1 table]
        WithinFactorNames: {'Measurements'}
        WithinModel: 'separatemeans'
    Estimates:
        Coefficients: [3x4 table]
        Covariance: [4x4 table]
```

Display the coefficients.

```matlab
rm.Coefficients
ans=3×4 table
```

```
<table>

<td>0.092667</td>
<td>-0.28733</td>
<td>0.502</td>
<td>0.12667</td>
</tr>
</tbody>
</table>
```

`fitrm` uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

```matlab
species_setosa = \(\begin{cases} 1 & \text{if setosa} \\ 0 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases}\)

species_versicolor = \(\begin{cases} 0 & \text{if setosa} \\ 1 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases}\)
Display the covariance matrix.

```matlab
rm.Covariance
```

```

</table>
```

**Specify the Within-Subject Hypothesis**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','longitudinalData.mat'));
```

The matrix $Y$ contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of $Y$ corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```matlab
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to conduct repeated measures analysis.

```matlab
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```matlab
Time = [0 2 4 6 8];
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```matlab
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts');
```
Fit a Model with Covariates

Load the sample data.

load repeatedmeas

The table `between` includes the eight repeated measurements, `y1` through `y8`, as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where age, IQ, and group, gender are the predictor variables, and the model includes the interaction effect of group and gender. Also define the within-subject factors.

```matlab
rm = fitrm(between,'y1-y8 ~ Group*Gender+Age+IQ','WithinDesign',within)
```

```matlab
rm =
    RepeatedMeasuresModel with properties:

    Between Subjects:
        BetweenDesign: [30x12 table]
        ResponseNames: {'y1'  'y2'  'y3'  'y4'  'y5'  'y6'  'y7'  'y8'}
        BetweenFactorNames: {'Age'  'IQ'  'Group'  'Gender'}

    Within Subjects:
        WithinDesign: [5x1 table]
        WithinFactorNames: {'Time'}
        WithinModel: 'orthogonalcontrasts'

    Estimates:
        Coefficients: [2x5 table]
        Covariance: [5x5 table]
```
BetweenModel: '1 + Age + IQ + Group*Gender'

Within Subjects:
  WithinDesign: [8x2 table]
  WithinFactorNames: {'w1' 'w2'}
  WithinModel: 'separatemeans'

Estimates:
  Coefficients: [8x8 table]
  Covariance: [8x8 table]

Display the coefficients.

```
rm.Coefficients
ans=8x8 table

Group_B:Gender_Female   -0.48486   -2.9202    1.1222     0.69715    -0.065945
```

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

**Input Arguments**

- **t — Input data**
  - table

  Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

  Data Types: table
modelspec — Formula for model specification
character vector or string scalar of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector or string scalar of the form 'y1-yk ~ terms'. The responses and terms are specified using Wilkinson notation on page 32-2342. fitrm treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or cell arrays of character vectors.

For example, if you have four repeated measures as responses and the factors x1, x2, and x3 as the predictor variables, then you can define a repeated measures model as follows.

Example: 'y1-y4 ~ x1 + x2 * x3'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,..., NameN, ValueN.

Example: 'WithinDesign','W','WithinModel','w1+w2' specifies the matrix w as the design matrix for within-subject factors, and the model for within-subject factors w1 and w2 is 'w1+w2'.

WithinDesign — Design for within-subject factors
numeric vector of length r (default) | r-by-k numeric matrix | r-by-k table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and one of the following:

- Numeric vector of length r, where r is the number of repeated measures. In this case, fitrm treats the values in the vector as continuous, and these are typically time values.
- r-by-k numeric matrix of the values of the k within-subject factors, w1, w2, ..., wk. In this case, fitrm treats all k variables as continuous.
- r-by-k table that contains the values of the k within-subject factors. In this case, fitrm treats all numeric variables as continuous, and all categorical variables as categorical.
For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: `'WithinDesign',weeks`

Data Types: `single` | `double` | `table`

**WithinModel — Model specifying within-subject hypothesis test**

'`separatemeans`' (default) | `'orthogonalcontrasts`' | character vector or string

scalar that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — This is valid only when the within-subject model has a single numeric factor `T`. Responses are the average, the slope of centered `T`, and, in general, all orthogonal contrasts for a polynomial up to `T^(p - 1)`, where `p` is the number of rows in the within-subject model.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the terms in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel','w1+w2+w2*w3'`

Data Types: `char` | `string`

**Output Arguments**

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`. 
Definitions

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y1,Y2,Y3</td>
<td>Specific list of variables</td>
</tr>
<tr>
<td>Y1-Y5</td>
<td>All table variables from Y1 through Y5</td>
</tr>
</tbody>
</table>

The following rules specify terms in `modelspec`.

<table>
<thead>
<tr>
<th>Wilkinson notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>X^k, where k is a positive integer</td>
<td>X, X^2, ..., X^k</td>
</tr>
<tr>
<td>X1 + X2</td>
<td>X1, X2</td>
</tr>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1*X2</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1*X2 only</td>
</tr>
<tr>
<td>-X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Introduced in R2014a
fitdist

Fit probability distribution object to data

Syntax

pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)

Description

pd = fitdist(x,distname) creates a probability distribution object by fitting the distribution specified by distname to the data in column vector x.

pd = fitdist(x,distname,Name,Value) creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar) creates probability distribution objects by fitting the distribution specified by distname to the data in x based on the grouping variable groupvar. It returns a cell array of fitted probability distribution objects, pdca, a cell array of group labels, gn, and a cell array of grouping variable levels, gl.

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value) returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples
Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```matlab
pd = fitdist(x,'Normal')
```

```matlab
dpd =
   NormalDistribution

   Normal distribution
   mu = 154 [148.728, 159.272]
   sigma = 26.5714 [23.3299, 30.8674]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Plot the pdf of the distribution.

```matlab
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y,'LineWidth',2)
```
Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```matlab
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```
pd = 
    KernelDistribution

    Kernel = epanechnikov
    Bandwidth = 14.3792
    Support = unbounded

Plot the pdf of the distribution.

x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y)
Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```matlab
code:
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```matlab
code:
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca = 1x2 cell array
{1x1 prob.NormalDistribution}    {1x1 prob.NormalDistribution}

 gn = 2x1 cell array
{ 'Female'  }
{ 'Male'   }

gl = 2x1 cell array
{ 'Female'  }
{ 'Male'   }
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two group labels. The cell array `gl` contains two group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```matlab
code:
female = pdca{1}  % Distribution for females
female =
    NormalDistribution
    Normal distribution
    mu = 130.472   [128.183, 132.76]
    sigma = 8.30339   [6.96947, 10.2736]

male = pdca{2}  % Distribution for males
```

```matlab
```
male = 
    NormalDistribution

    Normal distribution
    mu = 180.532 [177.833, 183.231]
    sigma = 9.19322 [7.63933, 11.5466]

Compute the pdf of each distribution.

x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);

Plot the pdfs for a visual comparison of weight distribution by gender.

figure
plot(x_values,femalepdf,'LineWidth',2)
hold on
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gca,'Location','NorthEast')
hold off
Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```matlab
gender = hospital.Sex;
[pdca, gn, gl] = fitdist(x, 'Kernel', 'By', gender, 'Kernel', 'triangle');
```
View each distribution in the cell array pdca to see the kernel distributions for each gender.

```matlab
female = pdca{1}  % Distribution for females
female = 
    KernelDistribution
        Kernel = triangle
        Bandwidth = 4.25894
        Support = unbounded

male = pdca{2}   % Distribution for males
male = 
    KernelDistribution
        Kernel = triangle
        Bandwidth = 5.08961
        Support = unbounded
```

Compute the pdf of each distribution.

```matlab
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);

Plot the pdfs for a visual comparison of weight distribution by gender.

```matlab
figure
plot(x_values,femalepdf,'LineWidth',2)
hold on
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast')
hold off
```
Input Arguments

x — Input data
column vector

Input data, specified as a column vector. fitdist ignores NaN values in x. Additionally, any NaN values in the censoring vector or frequency vector causes fitdist to ignore the corresponding values in x.

Data Types: double
distname — Distribution name
class | description
--- | ---
character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by distname determines the type of the returned probability distribution object.

**groupvar — Grouping variable**

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if Gender is a cell array of character vectors with values 'Male' and 'Female', you can use Gender as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variables. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if Smoker is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array {Gender,Smoker} divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: {Gender,Smoker}

Data Types: categorical | logical | single | double | char | string | cell
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

**Censoring — Logical flag for censored data**

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of **'Censoring'** and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding element is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

This argument is valid only if `distname` is 'BirnbaumSaunders', 'Burr', 'Exponential', 'ExtremeValue', 'Gamma', 'InverseGaussian', 'Kernel', 'Logistic', 'Loglogistic', 'Lognormal', 'Nakagami', 'Normal', 'Rician', 'tLocationScale', or 'Weibull'.

Data Types: logical

**Frequency — Observation frequency**

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of **'Frequency'** and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.
Data Types: `single` | `double`

**Options — Control parameters**
structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using `statset`.

Data Types: `struct`

**NTrials — Number of trials**
positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify `distname` as 'Binomial' to use this option.

Data Types: `single` | `double`

**Theta — Threshold parameter**
0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of 'Theta' and a scalar value. You must specify `distname` as 'GeneralizedPareto' to use this option.

Data Types: `single` | `double`

**mu — Location parameter**
0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of 'mu' and a scalar value. You must specify `distname` as 'HalfNormal' to use this option.

Data Types: `single` | `double`

**Kernel — Kernel smoother type**
'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following:

- 'normal'
• 'box'
• 'triangle'
• 'epanechnikov'

You must specify distname as 'Kernel' to use this option.

**Support — Kernel density support**

| 'unbounded' (default) | 'positive' | two-element vector |

Kernel density support, specified as the comma-separated pair consisting of 'Support' and 'unbounded', 'positive', or a two-element vector.

- 'unbounded'  
  Density can extend over the whole real line.
- 'positive' 
  Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify distname as 'Kernel' to use this option.

Data Types: single | double | char | string

**Width — Bandwidth of kernel smoothing window**

| scalar value |

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by fitdist is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify distname as 'Kernel' to use this option.

Data Types: single | double

**Output Arguments**

**pd — Probability distribution**

| probability distribution object |

Probability distribution, returned as a probability distribution object. The distribution specified by distname determines the class type of the returned probability distribution object.
pdca — Probability distribution objects
  cell array

Probability distribution objects of the type specified by distname, returned as a cell array.

gn — Group labels
  cell array of character vectors

Group labels, returned as a cell array of character vectors.

gl — Grouping variable levels
  cell array of character vectors

Grouping variable levels, returned as a cell array of character vectors containing one column for each grouping variable.

Algorithms

The fitdist function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

• For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
• For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

Alternative Functionality

App

The Distribution Fitter app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using distributionFitter, or click Distribution Fitter on the Apps tab.

Introduced in R2009a
fitensemble

Fit ensemble of learners for classification and regression

fitensemble can boost or bag decision tree learners or discriminant analysis classifiers. The function can also train random subspace ensembles of KNN or discriminant analysis classifiers.

For simpler interfaces that fit classification and regression ensembles, instead use fitcensemble and fitrensemble, respectively. Also, fitcensemble and fitrensemble provide options for Bayesian optimization.

Syntax

Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)
Mdl = fitensemble(X,Y,Method,NLearn,Learners)
Mdl = fitensemble(___,Name,Value)

Description

Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners) returns a trained ensemble model object that contains the results of fitting an ensemble of NLearn classification or regression learners (Learners) to all variables in the table Tbl. ResponseVarName is the name of the response variable in Tbl. Method is the ensemble-aggregation method.

Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners) fits the model specified by formula.

Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners) treats all variables in Tbl as predictor variables. Y is the response variable that is not in Tbl.

Mdl = fitensemble(X,Y,Method,NLearn,Learners) trains an ensemble using the predictor data in X and response data in Y.
Mdl = fitensemble(___,Name,Value) trains an ensemble using additional options specified by one or more Name,Value pair arguments and any of the previous syntaxes. For example, you can specify the class order, to implement 10-fold cross-validation, or the learning rate.

**Examples**

**Estimate the Resubstitution Loss of a Boosting Ensemble**

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the ionosphere data set.

```matlab
load ionosphere;
```

Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```matlab
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

ClassTreeEns is a trained ClassificationEnsemble ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```matlab
rsLoss = resubLoss(ClassTreeEns,'Mode','Cumulative');
```

rsLoss is a 100-by-1 vector, where element k contains the resubstitution loss after the first k learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```matlab
plot(rsLoss);
xlabel('Number of Learning Cycles');
ylabel('Resubstitution Loss');
```
In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

1. Randomly partitioning the data into training and cross-validation sets. Do this by specifying 'holdout', holdoutProportion when you train the ensemble using fitensemble.
2. Passing the trained ensemble to kfoldLoss, which estimates the generalization error.
Train Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors. Then, train an ensemble using fewer predictors and compare its in-sample predictive accuracy against the first ensemble.

Load the carsmall data set. Store the training data in a table.

```matlab
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```matlab
t = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```matlab
Mdl1 = fitensemble(Tbl,'MPG','LSBoost',100,t);
Mdl1
```

Mdl1 is a trained RegressionEnsemble regression ensemble. Because MPG is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```matlab
Mdl1 = fitensemble(Tbl,MPG,'LSBoost',100,t);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```matlab
predMPG = predict(Mdl1,[4 200 150 3000])
predMPG = 22.8462
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Train a new ensemble using all predictors in Tbl except Displacement.

```matlab
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula,'LSBoost',100,t);
```

Compare the resubstitution MSEs between Mdl1 and Mdl2.
mse1 = resubLoss(Mdl1)
mse1 = 6.4721
mse2 = resubLoss(Mdl2)
mse2 = 7.8599

The in-sample MSE for the ensemble that trains on all predictors is lower.

**Estimate the Generalization Error of a Boosting Ensemble**

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```matlab
load ionosphere;
```

Train a decision tree ensemble using AdaBoostM1, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```matlab
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```matlab
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
genError` is a 100-by-1 vector, where element k contains the generalization error after the first k learning cycles.

Plot the generalization error over the number of learning cycles.

```matlab
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```
The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

**Find the Optimal Number of Splits and Trees for an Ensemble**

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.
• When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```matlab
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:

• 1 for `MaxNumSplits`. This option grows stumps.
• 5 for `MinLeafSize`
• 10 for `MinParentSize`

To search for the optimal number of splits:

1. Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most \( n - 1 \) splits, where \( n \) is the training sample size. Also, decrease the learning rate for each ensemble from 1 to 0.1.
2. Cross validate the ensembles.
3. Estimate the cross-validated mean-squared error (MSE) for each ensemble.
4. Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep regression tree and a stump. Specify to use surrogate splits because the data contains missing values. These serve as benchmarks.

```matlab
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',
                    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence \( \{2^0, 2^1, \ldots, 2^m\} \), where \( m \) is such that \( 2^m \) is no greater than \( n - 1 \), where \( n \) is the training sample size. For each variant, adjust the learning rate to each value in the set \( \{0.1, 0.25, 0.5, 1\} \).

```matlab
n = size(X,1);
m = floor(log2(n - 1));
```
lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;

Compute the cross-validated MSE for each ensemble.

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-.b','LineWidth',2);
    plot(h.XLim,[errorStump errorStump],'-.r','LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'-k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend({cellstr(num2str(lr,'Learning Rate = %0.2f'))};

fitensemble
Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```matlab
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
fprintf('
Min. MSE = %0.5f',minErr)
Min. MSE = 18.42979
```
fprintf('
Optimal Parameter Values:
Num. Trees = %d', idxNumTrees);

Optimal Parameter Values:
Num. Trees = 1

fprintf('
MaxNumSplits = %d
Learning Rate = %0.2f\n', ...
    maxNumSplits(idxMNS), lr(idxLR))

MaxNumSplits = 4
Learning Rate = 1.00

For a different approach to optimizing this ensemble, see “Optimize a Boosted Regression Ensemble” on page 10-78.

**Input Arguments**

**Tbl** — Sample data
table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using `formula`.
- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

**Note** To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

**ResponseVarName** — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.  

Data Types: `char`
You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `string`

**formula — Explanatory model of response and subset of predictor variables**

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

**X — Predictor data**

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`
**Y — Response data**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each entry in Y is the response to or label for the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

- For classification, Y can be any of the supported data types. You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.
- For regression, Y must be a numeric column vector.

Data Types: categorical | char | string | logical | single | double | cell

**Method — Ensemble-aggregation method**
'AdaBoostM1' | 'LogitBoost' | 'GentleBoost' | 'RUSBoost' | 'Subspace' | 'Bag' | 'AdaBoostM2' | 'LSBoost' | ...

Ensemble-aggregation method, specified as one of the method names in this list.

- For classification with two classes:
  - 'AdaBoostM1'
  - 'LogitBoost'
  - 'GentleBoost'
  - 'RobustBoost' (requires Optimization Toolbox)
  - 'LPBoost' (requires Optimization Toolbox)
  - 'TotalBoost' (requires Optimization Toolbox)
  - 'RUSBoost'
  - 'Subspace'
  - 'Bag'
- For classification with three or more classes:
  - 'AdaBoostM2'
  - 'LPBoost' (requires Optimization Toolbox)
• 'TotalBoost' (requires Optimization Toolbox)
• 'RUSBoost'
• 'Subspace'
• 'Bag'

  For regression:
  • 'LSBoost'
  • 'Bag'

Because you can specify 'Bag' for classification and regression problems, specify the problem type using the Type name-value pair argument.

**NLearn — Number of ensemble learning cycles**

positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

  • If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NLearn*numel(Learners) learners.
  • If you specify 'AllPredictorCombinations', then set Method to 'Subspace' and specify one learner only in Learners. With these settings, the software trains learners for all possible combinations of predictors taken NPredToSample at a time. Consequently, the software trains nchoosek(size(X,2),NPredToSample) leaners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-2386.

Data Types: single | double | char | string

**Learners — Weak learners to use in ensemble**

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.
<table>
<thead>
<tr>
<th>Weak Learner</th>
<th>Weak-Learner Name</th>
<th>Template Object Creation Function</th>
<th>Method Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discriminant analysis</td>
<td>'Discriminant'</td>
<td>templateDiscriminant</td>
<td>Recommended for 'Subspace'</td>
</tr>
<tr>
<td>k nearest neighbors</td>
<td>'KNN'</td>
<td>templateKNN</td>
<td>For 'Subspace' only</td>
</tr>
<tr>
<td>Decision tree</td>
<td>'Tree'</td>
<td>templateTree</td>
<td>All methods except 'Subspace'</td>
</tr>
</tbody>
</table>

For more details, see NLear and “Tips” on page 32-2386.

Example: For an ensemble composed of two types of classification trees, supply \{t1 t2\}, where t1 and t2 are classification tree templates.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: 'CrossVal','on','LearnRate',0.05 specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

**General Ensemble Options**

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
</tbody>
</table>
### Value

<table>
<thead>
<tr>
<th><strong>Value</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code>. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code>.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

Specification of `CategoricalPredictors` is appropriate if:

- 'Learners' is 'tree'.
- 'Learners' is 'knn' when all predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitensemble` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitensemble` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

### NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or 'off'.

To track the number of weak learners or folds that `fitensemble` trained so far, specify a positive integer. That is, if you specify the positive integer `m`:

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitensemble` displays a message to the command line every time it completes training `m` weak learners.
- And a cross-validation option, then `fitensemble` displays a message to the command line every time it finishes training `m` folds.
If you specify 'off', then fitensemble does not display a message when it completes training weak learners.

**Tip** When training an ensemble of many weak learners on a large data set, specify a positive integer for NPrint.

Example: 'NPrint', 5

Data Types: single | double | char | string

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitensemble uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**Type — Supervised learning type**

'classification' | 'regression'

Supervised learning type, specified as the comma-separated pair consisting of 'Type' and 'classification' or 'regression'.

- If Method is 'bag', then the supervised learning type is ambiguous. Therefore, specify Type when bagging.
- Otherwise, the value of Method determines the supervised learning type.

Example: 'Type','classification'

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval or crossval.

Example: 'Crossval','on'
CVPartition — Cross-validation partition

CVPartition = [] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

Holdout — Fraction of data for holdout validation

Holdout = scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

KFold = 10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1 Randomly partition the data into k sets.
For each set, reserve the set as validation data, and train the model using the other $k-1$ sets.

Store the $k$ compact, trained models in the cells of a $k$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the $n$ observations (where $n$ is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other $n-1$ observations.
2. Store the $n$ compact, trained models in the cells of an $n$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

**Other Classification or Regression Options**

**ClassNames — Names of classes to use for training**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.
Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes 'a' and 'c' only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Misclassification cost**

Square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

**Note** `fitensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 1 2; 1 0 2; 2 2 0]`
Prior — Prior probabilities
'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure array</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>- S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>- S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

fitensemble normalizes the prior probabilities in Prior to sum to 1.

Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)

Data Types: char | string | double | single | struct

Weights — Observation weights
numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the
observations in each row of \( X \) or \( Tbl \) with the corresponding value in \( Weights \). The size of \( Weights \) must equal the number of rows of \( X \) or \( Tbl \).

If you specify the input data as a table \( Tbl \), then \( Weights \) can be the name of a variable in \( Tbl \) that contains a numeric vector. In this case, you must specify \( Weights \) as a character vector or string scalar. For example, if the weights vector \( W \) is stored as \( Tbl.W \), then specify it as \('W'\). Otherwise, the software treats all columns of \( Tbl \), including \( W \), as predictors or the response when training the model.

The software normalizes \( Weights \) to sum up to the value of the prior probability in the respective class.

By default, \( Weights \) is \( \text{ones}(n,1) \), where \( n \) is the number of observations in \( X \) or \( Tbl \).

Data Types: \text{double} \mid \text{single} \mid \text{char} \mid \text{string}

**Sampling Options for Boosting Methods and Bagging**

\( FResample \) — Fraction of training set to resample

1 (default) \mid \text{positive scalar in (0,1]}

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of \( FResample \) and a positive scalar in \((0,1]\).

To use \('FResample'\), specify \('bag'\) for \( Method \) or set \( Resample \) to \('on'\).

Example: \('FResample',0.75\)

Data Types: \text{single} \mid \text{double}

\( Replace \) — Flag indicating to sample with replacement

\('on' \) (default) \mid \('off'\)

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of \( Replace \) and \('off' \) or \('on'\).

- For \('on'\), the software samples the training observations with replacement.
- For \('off'\), the software samples the training observations without replacement. If you set \( Resample \) to \('on'\), then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set \( Method \) to \('bag' \) or set \( Resample \) to \('on'\), \( Replace \) has no effect.
Example: 'Replace','off'

**Resample — Flag indicating to resample**

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is any boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off' specifies to reweight observations at every learning iteration. This setting is the default.

- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

**AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**RUSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].
To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**RatioToSmallest — Sampling proportion with respect to lowest-represented class**

Positive numeric scalar | Numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are \( K \) classes in the training data and the lowest-represented class has \( m \) observations in the training data.

- If you specify the positive numeric scalar \( s \), then fitensemble samples \( s \times m \) observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2388.
- If you specify the numeric vector \([s_1, s_2, \ldots, s_K]\), then fitensemble samples \( s_i \times m \) observations from class \( i, i = 1, \ldots, K \). The elements of RatioToSmallest correspond to the order of the class names specified using ClassNames (see “Tips” on page 32-2386).

The default value is \( \text{ones}(K,1) \), which specifies to sample \( m \) observations from each class.

Example: 'RatioToSmallest',[2,1]

Data Types: single | double

**LPBoost and TotalBoost Method Options**

**MarginPrecision — Margin precision to control convergence speed**

0.1 (default) | Numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of 'MarginPrecision' and a numeric scalar in the interval [0,1]. MarginPrecision affects the number of boosting iterations required for convergence.
**Tip** To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: 'MarginPrecision',0.5

Data Types: `single` | `double`

**RobustBoost Method Options**

**RobustErrorGoal — Target classification error**

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of 'RobustErrorGoal' and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

**Tip** For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: 'RobustErrorGoal',0.05

Data Types: `single` | `double`

**RobustMarginSigma — Classification margin distribution spread**

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on RobustBoost, for example, [19].

Example: 'RobustMarginSigma',0.5

Data Types: `single` | `double`

**RobustMaxMargin — Maximal classification margin**

0 (default) | nonnegative numeric scalar
Maximal classification margin in the training data, specified as the comma-separated pair consisting of 'RobustMaxMargin' and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below RobustMaxMargin.

Example: 'RobustMaxMargin',1

Data Types: single | double

### Random Subspace Method Options

**NPredToSample — Number of predictors to sample**

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of 'NPredToSample' and a positive integer in the interval 1,...,p, where p is the number of predictor variables (size(X,2) or size(Tbl, 2)).

Data Types: single | double

### Output Arguments

**Md1 — Trained ensemble model**

ClassificationBaggedEnsemble model object | ClassificationEnsemble model object | ClassificationPartitionedEnsemble cross-validated model object | RegressionBaggedEnsemble model object | RegressionEnsemble model object | RegressionPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

<table>
<thead>
<tr>
<th>Model Object</th>
<th>Type Setting</th>
<th>Specify Any Cross-Validation Options?</th>
<th>Method Setting</th>
<th>Resample Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classification BaggedEnsemble</td>
<td>'classification'</td>
<td>No</td>
<td>'Bag'</td>
<td>'on'</td>
</tr>
<tr>
<td>Classification Ensemble</td>
<td>'classification'</td>
<td>No</td>
<td>Any ensemble-aggregation method for classification</td>
<td>'off'</td>
</tr>
</tbody>
</table>

32-2385
The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

**Tips**

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.

</table>
In classification problems (that is, Type is 'classification'):

- If the ensemble-aggregation method (Method) is 'bag' and:
  
  - The misclassification cost (Cost) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
  
  - The class prior probabilities (Prior) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using Cost or a less skewed prior probability vector using Prior.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the ClassNames name-value pair argument.

  - To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for ClassNames. For example, suppose the response variable (Y) is a cell array of labels. This code specifies the class order in the variable classNames.

    \[
    \begin{align*}
    Ycat &= \text{categorical}(Y) \\
    \text{classNames} &= \text{categories}(Ycat)
    \end{align*}
    \]

    categorical assigns <undefined> to unclassified observations and categories excludes <undefined> from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

  - To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to ClassNames. Following from the previous example, this code specifies the class order from lowest- to most-represented in classNamesLH.
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
[~,idx] = sort(freq);
classNamesLH = classNames(idx);

Algorithms

• For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-50.

• If you specify Method to be a boosting algorithm and Learners to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using templateTree.

• fitensemble generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

• For the RUSBoost ensemble-aggregation method (Method), the name-value pair argument RatioToSmallest specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: A and B. A have 100 observations and B have 10 observations. and that the lowest-represented class has m observations in the training data.

  • If you set 'RatioToSmallest',2, then $s \times m = 2 \times 10 = 20$. Consequently, fitensemble trains every learner using 20 observations from class A and 20 observations from class B. If you set 'RatioToSmallest',[2 2], then you obtain the same result.

  • If you set 'RatioToSmallest',[2,1], then $s_1 \times m = 2 \times 10 = 20$ and $s_2 \times m = 1 \times 10 = 10$. Consequently, fitensemble trains every learner using 20 observations from class A and 10 observations from class B.
For ensembles of decision trees, and for dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Introduced in R2011a
fitnlm

Fit nonlinear regression model

Syntax

mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm(___,modelfun,beta0,Name,Value)

Description

mdl = fitnlm(tbl,modelfun,beta0) fits the model specified by modelfun to variables in the table or dataset array tbl, and returns the nonlinear model mdl.

fitnlm estimates model coefficients using an iterative procedure starting from the initial values in beta0.

mdl = fitnlm(X,y,modelfun,beta0) fits a nonlinear regression model using the column vector y as a response variable and the columns of the matrix X as predictor variables.

mdl = fitnlm(___,modelfun,beta0,Name,Value) fits a nonlinear regression model with additional options specified by one or more Name,Value pair arguments.

Examples

Nonlinear Model from Table

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
   b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)

mdl = 
Nonlinear regression model:
    MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:
    Estimate    SE         tStat    pValue
    ______   _____    ________    ________
    b1     -49.383   119.97     -0.41164     0.68083
    b2     376.43    567.05     0.66384     0.50719
    b3    -0.78193   0.47168    -1.6578    0.098177
    b4     422.37   776.02     0.54428     0.58656
    b5    -0.24127   0.48325    -0.49926     0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

**Nonlinear Model from Matrix Data**

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
   b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)

mdl = 
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5

Adjust Fitting Options in Nonlinear Model

Create a nonlinear model for auto mileage based on the carbig data. Strive for more accuracy by lowering the TolFun option, and observe the iterations by setting the Display option.

Load the data and create a nonlinear model.

```plaintext
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) +...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Specify Nonlinear Regression Using Model Name Syntax

Specify a nonlinear regression model for estimation using a function handle or model syntax.

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```matlab
mdl = fitnlm(X,y,@hougen,beta0)
```

```matlab
mdl = 
Nonlinear regression model: 
y ~ hougen(b,X)
```

```matlab
Estimated Coefficients:
    Estimate       SE       tStat     pValue
    ______    ________    ______    _______
    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075157    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923
```

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use an expression to specify the Hougen-Watson model for the rate data.

```matlab
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

```matlab
mdl2 = 
Nonlinear regression model: 
y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```
Estimated Coefficients:

<table>

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

**Estimate Nonlinear Regression Using Robust Fitting Options**

Generate sample data from the nonlinear regression model

\[ y = b_1 + b_2 \exp(-b_3 x) + \varepsilon, \]

where \( b_1, b_2, \text{ and } b_3 \) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```matlab
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```matlab
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```matlab
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use an expression to specify the model.
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = fitnlm(x,y,modelstr,b0,'Options',opts)

mdl =
Nonlinear regression model (robust fit):
y ~ b1 + b2*exp(-b3*x)

Estimated Coefficients:

<table>
<thead>
<tr>

Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35

**Fit Nonlinear Regression Model Using Weights Function Handle**

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```matlab
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```matlab
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```
mdl =
Nonlinear regression model:
y ~ hougen(b,X)

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Fit the Hougen-Watson model to the rate data using the combined error variance model.
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')

mdl =
Nonlinear regression model:
y ~ hougen(b,X)

Estimated Coefficients:

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Input Arguments

tbl — Input data
table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model specification. If you do not specify a model, you can set a different column as the response variable by using the ResponseVar name-value pair argument. You can select a subset of the columns as predictors by using the PredictorVars name-value pair argument.

Data Types: table

X — Predictor variables
matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

Data Types: single | double

y — Response variable
vector
Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X.

Data Types: single | double

**modelfun — Functional form of the model**

function handle | character vector or string scalar of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - `b` is a coefficient vector with the same number of elements as `beta0`.
  - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

  \[ modelfun(b,x) \]
  Returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- Character vector or string scalar of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)', where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

Data Types: function_handle | char | string

**beta0 — Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. 32-2402
Example: 'ErrorModel','combined','Exclude',2,'Options',opt specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure opt to control the iterative fitting procedure.

**CoefficientNames — Names of the model coefficients**

{'b1','b2',...,bk} (default) | string array | cell array of character vectors

Names of the model coefficients, specified as a string array or cell array of character vectors.

Data Types: string | cell

**ErrorModel — Form of the error variance model**

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b

<table>
<thead>
<tr>
<th>ErrorModel</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>( y = f + ae )</td>
</tr>
<tr>
<td>'proportional'</td>
<td>( y = f + bfe )</td>
</tr>
<tr>
<td>'combined'</td>
<td>( y = f + (a + b</td>
</tr>
</tbody>
</table>

The only allowed error model when using Weights is 'constant'.

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

Example: 'ErrorModel','proportional'

**ErrorParameters — Initial estimates of the error model parameters**

numeric array

Initial estimates of the error model parameters for the chosen ErrorModel, specified as a numeric array.
### Error Model

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>(a)</td>
<td>1</td>
</tr>
<tr>
<td>'proportional'</td>
<td>(b)</td>
<td>1</td>
</tr>
<tr>
<td>'combined'</td>
<td>(a, b)</td>
<td>[1,1]</td>
</tr>
</tbody>
</table>

You can only use the 'constant' error model when using Weights.

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for \(a\) and the starting value 2 for \(b\) as follows.

Example: 'ErrorParameters',[1,2]

Data Types: single | double

**Exclude — Observations to exclude**

Logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Options — Options for controlling the iterative fitting procedure**

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by statset. The relevant fields are the nonempty fields in the structure returned by the call statset('fitnlm').
<table>
<thead>
<tr>
<th><strong>Option</strong></th>
<th><strong>Meaning</strong></th>
<th><strong>Default</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>DerivStep</td>
<td>Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.</td>
<td>eps^(1/3)</td>
</tr>
<tr>

<td>Character vector or string scalar indicating to check for invalid values, such as NaN or Inf, from the model function.</td>
<td>'on'</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of iterations allowed. Positive integer.</td>
<td>200</td>
</tr>
<tr>
<td>RobustWgtFun</td>
<td>Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-2408</td>
<td>[]</td>
</tr>
<tr>
<td>Tune</td>
<td>Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.</td>
<td>See “Robust Options” on page 32-2408 for the default, which depends on RobustWgtFun.</td>
</tr>
<tr>
<td>TolFun</td>
<td>Termination tolerance for the objective function value. Positive scalar.</td>
<td>1e-8</td>
</tr>
<tr>
<td>TolX</td>
<td>Termination tolerance for the parameters. Positive scalar.</td>
<td>1e-8</td>
</tr>
</tbody>
</table>

Data Types: struct
**PredictorVars — Predictor variables**
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**
last column of tbl (default) | variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable.

If you specify a model, it specifies the response variable. Otherwise, when fitting a table or dataset array, 'ResponseVar' indicates which variable fitnlm should use as the response.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 1 0 0])
Data Types: single | double | logical | char | string

**VarNames — Names of variables**
{'x1','x2',..., 'xn', 'y'} (default) | string array | cell array of character vectors
Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: string | cell

Weights — Observation weights
ones(n,1) (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in tbl or y.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W, NonLinearModel estimates the error variance at observation i by MSE*(1/W(i)), where MSE is the mean squared error.

Data Types: single | double | function_handle

Output Arguments

mdl — Nonlinear model
NonLinearModel object

Nonlinear model representing a least-squares fit of the response to the data, returned as a NonLinearModel object.

If the Options structure contains a nonempty RobustWgtFun field, the model is not a least-squares fit, but uses the RobustWgtFun robust fitting function.
For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

**Introduced in R2013b**
**LinearMixedModel.fitmatrix**

**Class:** LinearMixedModel

Fit linear mixed-effects model using design matrices

**Note** LinearMixedModel.fitmatrix will be removed in a future release. Use fitlmematrix instead.

**Syntax**

```matlab
lme = LinearMixedModel.fitmatrix(X,y,Z,[])
lme = LinearMixedModel.fitmatrix(X,y,Z,G)
lme = LinearMixedModel.fitmatrix(___,Name,Value)
```

**Description**

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using `’CovariancePattern’` name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(___,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.
For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

### Input Arguments

**X — Fixed-effects design matrix**

*n-by-\( p \)* matrix

Fixed-effects design matrix, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations, and \( p \) is the number of fixed-effects predictor variables. Each row of \( X \) corresponds to one observation, and each column of \( X \) corresponds to one variable.

Data Types: `single` | `double`

**y — Response values**

*n*-by-1 vector

Response values, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations.

Data Types: `single` | `double`

**Z — Random-effects design**

\( n \)-by-\( q \) matrix | cell array of \( R \) \( n \)-by-\( q(r) \) matrices, \( r = 1, 2, \ldots, R \)

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then \( Z \) must be an \( n \)-by-\( q \) matrix, where \( n \) is the number of observations and \( q \) is the number of variables in the random-effects term.
- If there are \( R \) random-effects terms, then \( Z \) must be a cell array of length \( R \). Each cell of \( Z \) contains an \( n \)-by-\( q(r) \) design matrix \( Z\{r\}, \ r = 1, 2, \ldots, R \), corresponding to each random-effects term. Here, \( q(r) \) is the number of random effects term in the \( r \)th random effects design matrix, \( Z\{r\} \).

Data Types: `single` | `double` | `cell`

**G — Grouping variable or variables**

\( n \)-by-1 vector | cell array of \( R \) \( n \)-by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.
• If there is one random-effects term, then \( G \) must be an \( n \)-by-1 vector corresponding to a single grouping variable with \( M \) levels or groups.

\( G \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

• If there are multiple random-effects terms, then \( G \) must be a cell array of length \( R \). Each cell of \( G \) contains a grouping variable \( G\{r\}, r = 1, 2, \ldots, R \), with \( M(r) \) levels.

\( G\{r\} \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: categorical | logical | single | double | char | string | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name, Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, ... , NameN, ValueN**.

**FixedEffectPredictors — Names of columns in fixed-effects design matrix**

`{'x1','x2',...,'xP'}` (default) | string array or cell array of length \( p \)

Names of columns in the fixed-effects design matrix \( X \), specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a string array or cell array of length \( p \).

For example, if you have a constant term and two predictors, say TimeSpent and Gender, where Female is the reference level for Gender, as the fixed effects, then you can specify the names of your fixed effects in the following way. Gender_Male represents the dummy variable you must create for category Male. You can choose different names for these variables.

Example: `'FixedEffectPredictors'`,

`{'Intercept','TimeSpent','Gender_Male'}`,

Data Types: string | cell

**RandomEffectPredictors — Names of columns in random-effects design matrix or cell array**

string array or cell array of length \( q \) | cell array of length \( R \) with elements of length \( q(r), r = 1, 2, \ldots, R \)
Names of columns in the random-effects design matrix or cell array $Z$, specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A string array or cell array of length $q$ when $Z$ is an $n$-by-$q$ design matrix. In this case, the default is {'$z1$','$z2$',...,'$zQ$'}.
- A cell array of length $R$, when $Z$ is a cell array of length $R$ with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, ..., R$. In this case, the default is {'$z11$','$z12$',...,'$z1Q(1)$'},...,'$zr1$','$zr2$',...,'$zrQ(r)$'}.

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors',{"Intercept','Acceleration'}

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable $g_1$, and the second for the intercept, grouped by the variable $g_2$, then you specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors',{{'Intercept','Acceleration'},
{"Intercept'}}

Data Types: string | cell

**ResponseVarName — Name of response variable**

'y' (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a character vector or string scalar.

For example, if your response variable name is score, then you can specify it as follows.

Example: 'ResponseVarName','score'

Data Types: char | string

**RandomEffectGroups — Names of random effects grouping variables**

'g' or {'$g1$','$g2$',...,'$gR$'} (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:
• Character vector or string scalar — If there is only one random-effects term, that is, if \( G \) is a vector, then the value of \('RandomEffectGroups'\) is the name for the grouping variable \( G \). The default is \('g'\).

• String array or cell array of character vectors — If there are multiple random-effects terms, that is, if \( G \) is a cell array of length \( R \), then the value of \('RandomEffectGroups'\) is a string array or cell array of length \( R \), where each element is the name for the grouping variable \( G\{r\} \). The default is \{'g1','g2',...,'gR'\}.

For example, if you have two random-effects terms, \( z1 \) and \( z2 \), grouped by the grouping variables \( \text{sex} \) and \( \text{subject} \), then you can specify the names of your grouping variables as follows.

Example: \('RandomEffectGroups',{\'sex','subject\}')

Data Types: char | string | cell

\textbf{CovariancePattern — Pattern of covariance matrix}

\texttt{'FullCholesky'} (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of \('CovariancePattern'\) and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of \('CovariancePattern'\) must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.

\texttt{'FullCholesky'}

Default. Full covariance matrix using the Cholesky parameterization. \texttt{fitlme} estimates all elements of the covariance matrix.

\texttt{'Full'}

Full covariance matrix, using the log-Cholesky parameterization. \texttt{fitlme} estimates all elements of the covariance matrix.
'Diagonal' Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

\[
\begin{pmatrix}
\sigma^2_{b1} & 0 & 0 \\
0 & \sigma^2_{b2} & 0 \\
0 & 0 & \sigma^2_{b3}
\end{pmatrix}
\]

'Isotropic' Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_b & 0 & 0 \\
0 & \sigma^2_b & 0 \\
0 & 0 & \sigma^2_b
\end{pmatrix}
\]

where \(\sigma^2_b\) is the common variance of the random-effects terms.
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_{b_1} & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\
\sigma_{b_1,b_2} & \sigma^2_{b_2} & \sigma_{b_1,b_2} \\
\sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma^2_{b_2}
\end{pmatrix}
\]

where \(\sigma^2_{b_1}\) is the common variance of the random-effects terms and \(\sigma_{b_1,b_2}\) is the common covariance between any two random-effects terms.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \(\text{PAT}(a,b) = \text{false}\), then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern',{'Full','Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML' Default. Maximum likelihood estimation
'REML' Restricted maximum likelihood estimation

Example: 'FitMethod','REML'
Weights — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude
use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.
'quasinewton'  
Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using 
statset('LinearMixedModel'). If you don’t specify the options, then 
LinearMixedModel uses the default options of 
statset('LinearMixedModel').

'fminunc'  
You must have Optimization Toolbox to specify this option. Change the options of the algorithm using 
optimoptions('fminunc'). If you don’t specify the options, then 
LinearMixedModel uses the default options of optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

**OptimizerOptions — Options for optimization algorithm**
structure returned by statset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by
statset('LinearMixedModel') or an object returned by
optimoptions('fminunc').

- If 'Optimizer' is 'fminunc', then use optimoptions('fminunc') to change the options of the optimization algorithm. See optimoptions for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for LinearMixedModel is the default options created by
  optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use statset('LinearMixedModel') to change the optimization parameters. If you don’t change the optimization parameters, then LinearMixedModel uses the default options created by
  statset('LinearMixedModel'):

  The 'quasinewton' optimizer uses the following fields in the structure created by
  statset('LinearMixedModel').
**TolFun** — Relative tolerance on gradient of objective function
1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX** — Absolute tolerance on step size
1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter** — Maximum number of iterations allowed
10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display** — Level of display
'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod** — Method to start iterative optimization
'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod', 'random'

**Verbose** — Indicator to display optimization process on screen
false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true
CheckHessian — Indicator to check positive definiteness of Hessian
false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Examples

No Grouping Variable Specified

Load the sample data.

load carsmall

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)

lme = Linear mixed-effects model fit by ML

Model information:
Number of observations               94
Fixed effects coefficients           2
Random effects coefficients          3
Covariance parameters                2

Formula:
  y ~ x1 + x2 + (z11 | g1)

Model fit statistics:
  AIC       BIC       LogLikelihood    Deviance
  486.09    496.26    -239.04          478.09

Fixed effects coefficients (95% CIs):
  Name        Estimate      SE           tStat      DF    pValue
  'x1'            43.575       2.3038     18.915    92    1.8371e-33
  'x2'        -0.0067097    0.0004242    -15.817    92    5.5373e-28

  Lower         Upper
  39        48.151
  -0.0075522    -0.0058672

   Name             Estimate    Lower     Upper
   'Res Std'        2.8997      2.5075    3.3532

Longitudinal Study with Covariate

Load the sample data.

load(fullfile(matlabroot,'examples','stats','weight.mat'));

weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define Subject and Program as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the
interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

\[ y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i + \beta_6(Week_i \times I[PB]_i) + \beta_7(Week_i \times I[PC]_i) + \beta_8(Week_i \times I[PD]_i) + b_{0m} + b_{1m} Week_{im} + \epsilon_{im}, \]

where \( i = 1, 2, \ldots, 120 \), and \( m = 1, 2, \ldots, 20 \). \( \beta_j \) are the fixed-effects coefficients, \( j = 0, 1, \ldots, 8 \), and \( b_{0m} \) and \( b_{1m} \) are random effects. \( IW \) stands for initial weight and \( I[\cdot] \) is a dummy variable representing a type of program. For example, \( I[PB]_i \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[ b_{0m} \sim N(0, \sigma_0^2) \]
\[ b_{1m} \sim N(0, \sigma_1^2) \]
\[ \epsilon_{im} \sim N(0, \sigma^2). \]

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program);  % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...
    D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using LinearMixedModel.fitmatrix with the defined design matrices and grouping variables.

lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...'
    'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
    'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{{'Subject'}})
lme =
Linear mixed-effects model fit by ML

  Lower         Upper
  0.14798       1.1741
  0.00045067    0.0059252
  0.10044      0.32113
  -0.29319      0.22666
  -0.14706       0.3734
  0.039536      0.30686
  -0.15026      0.2278
  -0.15849      0.21957
  -0.15592      0.22214

Random effects covariance parameters (95% CIs):
  Group: Subject (20 Levels)
Name1         Name2         Type     Estimate     Lower
  'Intercept'    'Intercept'   'std'     0.18407     0.12281
The $P$-values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

**Random-Intercept Model**

Load the sample data.

```matlab
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',... 'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```
Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

\[ y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, ..., 468, \quad m = 1, 2, ..., 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma_b^2), \]

and the error term has the distribution,

\[ \epsilon_{im} \sim N(0, \sigma^2). \]

\[ y = \text{flu2.FluRate}; \]
\[ X = [\text{ones}(468,1) \text{flu2.WtdILI}]; \]
\[ Z = [\text{ones}(468,1)]; \]
\[ G = \text{flu2.Date}; \]

Fit the linear mixed-effects model.

\[ \text{lme} = \text{LinearMixedModel.fitmatrix}(X,y,Z,G,'FixedEffectPredictors',\{'\text{Intercept}','\text{NationalRate}'\},'
\text{RandomEffectPredictors}',\{\{'\text{Intercept}'\}\},'
\text{RandomEffectGroups}',\{'\text{Date}'\}) \]

\[ \text{lme} = \]
Linear mixed-effects model fit by ML

Model information:
- Number of observations: 468
- Fixed effects coefficients: 2
- Random effects coefficients: 52
- Covariance parameters: 2

The confidence limits of the standard deviation of the random-effects term $\sigma_b$ do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using compare method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\hat{y}_{28} = \hat{b}_0 + \hat{\beta}_1 WtdILL_28 + \hat{b}_{10/30/2005}$$

$$= 0.1639 + 0.7236 \times (1.343) + 0.3318$$

$$= 1.46749,$$

where $\hat{b}$ is the BLUP of the random effects for the intercept. You can compute this value in the following way.
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat = 1.4674

You can simply display the fitted value using the fitted(lme) method.

F = fitted(lme);
F(28)

ans = 1.4674

Randomized-Block Design

Load the sample data.

load(fullfile(matlabroot,'examples','stats','shift.mat'));

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

\[
\text{Shift}_\text{Morning} = \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

\[
\text{Shift}_\text{Evening} = \begin{cases} 
1, & \text{if Morning} \\
0, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]
The model corresponds to

\[
\begin{align*}
\text{Morning Shift:} & \quad QCD_{im}^\text{Morning} = \beta_0 + \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + \epsilon_{im}, \\
\text{Evening Shift:} & \quad QCD_{im}^\text{Evening} = \beta_0 + \beta_1 \text{Shift}_\text{Evening}_i + b_{0m} + \epsilon_{im}, \\
\text{Night Shift:} & \quad QCD_{im}^\text{Night} = \beta_0 - \beta_1 \text{Shift}_\text{Evening}_i - \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + \epsilon_{im},
\end{align*}
\]

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, \ldots, 15 \), and \( m = 1, 2, \ldots, 5 \). The random effects and the observation error have the following distributions:

\[
b_{0m} \sim N(0, \sigma_b^2)
\]

and

\[
\epsilon_{im} \sim N(0, \sigma^2).
\]

\[
S = \text{shift.Shift};
X1 = (S == 'Morning') - (S == 'Night');
X2 = (S == 'Evening') - (S == 'Night');
X = [ones(15,1), X1, X2];
y = \text{shift.QCDDev};
Z = ones(15,1);
G = \text{shift.Operator};

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[ B = \text{randomEffects(lme)} \]

\[ B = 5 \times 1 \]

\[ \begin{pmatrix} 0.5775 \\ 1.1757 \\ -2.1715 \\ 2.3655 \\ -1.9472 \end{pmatrix} \]
The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

\[
\widehat{y}_{\text{Evening,Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift}_{\text{Evening}} + \hat{b}_{03}
\]

\[
= 3.6525 - 0.53293 - 2.1715
\]

\[
= 0.94807.
\]

You can also display this value in the following way.

```matlab
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
ans = 0.9481
```

### Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```matlab
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

\[
\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_i + e_{im}, \quad m = 1, 2, 3,
\]

with the random-effects terms having the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2),
\]

\[
b_{1m} \sim N(0, \sigma_1^2),
\]

where \( m \) represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```matlab
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
```
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);

Now, fit the model using LinearMixedModel.fitmatrix with the defined design
matrices and grouping variables.

lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',....
{"Intercept","Acceleration","Horsepower"},'RandomEffectPredictors',....
{"Intercept"},{"Acceleration"},'RandomEffectGroups',{"Model_Year","Model_Year"})

lme =

  Upper

32-2432
The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

\[ b_m = (b_{0m}, b_{1m}) \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right), \]

where \( m \) represents the model year.

First prepare the random-effects design matrix and grouping variable.

\[
Z = \begin{bmatrix} \text{ones}(406,1) & \text{Acceleration} \end{bmatrix};
\]

\[
G = \text{Model\_Year};
\]

\[

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the compare method.
Specify the Covariance Pattern

Load the sample data.

load(fullfile(matlabroot,'examples','stats','weight.mat'));

weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define Subject and Program as categorical variables.

Subject = nominal(Subject);
Program = nominal(Program);

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;

This model corresponds to

\[ y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \epsilon_{im}, \]

where \( i = 1, 2, \ldots, 120 \), and \( m = 1, 2, \ldots, 20 \).

\( \beta_j \) are the fixed-effects coefficients, \( j = 0, 1, \ldots, 8 \), and \( b_{0m} \) and \( b_{1m} \) are random effects. \( IW \) stands for initial weight and \( I[.] \) is a dummy variable representing a type of program. For example, \( I[PB] \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[ b_{0m} \sim N(0, \sigma_0^2) \]
\[ b_{1m} \sim N(0, \sigma_1^2) \]
\[ \varepsilon_{im} \sim N(0, \sigma^2). \]

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```matlab
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{ 'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups', {'Subject'}, 'CovariancePattern', 'Isotropic')
```

```

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[ b \sim N\left(0, \sigma^2 D(\theta)\right), \]

where \( D \) is a \( q \)-by-\( q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the observation error variance. Since the covariance matrix of the random effects, \( D \), is symmetric, it has \( q(q+1)/2 \) free parameters. Suppose \( L \) is the lower triangular Cholesky factor of \( D(\theta) \) such that

\[ D(\theta) = L(\theta)L(\theta)^T, \]

then the \( q^*(q+1)/2 \)-by-1 unconstrained parameter vector \( \theta \) is formed from elements in the lower triangular part of \( L \).

For example, if
\[
L = \begin{bmatrix}
L_{11} & 0 & 0 \\
L_{21} & L_{22} & 0 \\
L_{31} & L_{32} & L_{33}
\end{bmatrix},
\]

then

\[
\theta = \begin{bmatrix}
L_{11} \\
L_{21} \\
L_{31} \\
L_{22} \\
L_{32} \\
L_{33}
\end{bmatrix}.
\]

**Log-Cholesky Parameterization**

When the diagonal elements of \( L \) in Cholesky parameterization are constrained to be positive, then the solution for \( L \) is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of \( L \) are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing \( L_{ii} \geq 0 \),

\[
\theta = \begin{bmatrix}
\log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33})
\end{bmatrix}.
\]

**Tips**

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using fitlmematrix.
Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl,formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random_1|g_1) + ... + (random_R|g_R)'`.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G).

See Also

LinearMixedModel | fitlme
**fitPosterior**

Fit posterior probabilities for support vector machine (SVM) classifier

**Syntax**

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

**Description**

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 32-2451.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or the holdout sample proportion.

**Examples**

**Estimate In-Sample Posterior Probabilities of SVM Classifiers**

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```
SVMModel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function.

```matlab
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```matlab
ScoreSVMModel =
    ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
    NumObservations: 351
    Alpha: [90×1 double]
    Bias: -0.1343
    KernelParameters: [1×1 struct]
    Mu: [1×34 double]
    Sigma: [1×34 double]
    BoxConstraints: [351×1 double]
    ConvergenceInfo: [1×1 struct]
    IsSupportVector: [351×1 logical]
    Solver: 'SMO'
```

Because the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```matlab
[label, scores] = resubPredict(SVMModel);
[~, postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10), label(1:10), scores(1:10,2), postProbs(1:10,2), 'VariableNames',...
    {'TrueLabel', 'PredictedLabel', 'Score', 'PosteriorProbability'})
```

```matlab
table=10×4 table
    TrueLabel    PredictedLabel     Score     PosteriorProbability
          {'g'  }            {'g'  }      1.4861           0.82215
          {'b'  }            {'b'  }     -1.0004           0.30436
```

32-2441
Plot Posterior Probability Contours for Multiple Classes

Train a multiclass SVM classifier through the process of one-versus-all (OVA) classification, and then plot probability contours for each class. To implement OVA directly, see fitcecoc.

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data.

```matlab
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```matlab
figure
gscatter(X(:,1),X(:,2),Y);
title('{\bf Scatter Diagram of Iris Measurements}');
xlabel('Petal length');
ylabel('Petal width');
legend('Location','Northwest');
axis tight
```
Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. Define the class order.

```matlab
classNames = {'setosa'; 'virginica'; 'versicolor'};
umClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMMModel{j} = fitcsvm(X,inds{j},'ClassNames', [false true],...
fitcsvm uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```matlab
for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```matlab
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];

posterior = cell(3,1);
for j = 1:numClasses
    [~,posterior{j}] = predict(SVMModel{j},xGrid);
end
```

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```matlab
figure
h = zeros(numClasses + 1,1); % Preallocation for graphics handles
for j = 1:numClasses
    subplot(2,2,j)
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));
    hold on
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);
    title(sprintf('Posteriors for %s Class',classNames{j}));
    xlabel('Petal length');
    ylabel('Petal width');
    legend off
    axis tight
    hold off
end
h(numClasses + 1) = colorbar('Location','EastOutside',...
Fit Optimal Posterior Probability Function Using Holdout Cross-Validation

Estimate the score-to-posterior-probability transformation function after training an SVM classifier. Use cross-validation during the estimation to reduce bias, and compare the run times for 10-fold cross-validation and holdout cross-validation.

Load the ionosphere data set.
load ionosphere

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

SVMMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);

SVMMModel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function. Compare the run times from using 10-fold cross-validation (the default) and a 10% holdout test sample.

rng(1); % For reproducibility
tic;   % Start the stopwatch
SVMMModel_10FCV = fitPosterior(SVMMModel);
toc    % Stop the stopwatch and display the run time

Elapsed time is 1.617765 seconds.

tic;
SVMMModel_HO = fitPosterior(SVMMModel,'Holdout',0.10);
toc

Elapsed time is 0.367623 seconds.

Although both run times are short because the data set is relatively small, SVMMModel_HO fits the score transformation function much faster than SVMMModel_10FCV. You can specify holdout cross-validation (instead of the default 10-fold cross validation) to reduce run time for larger data sets.

Input Arguments

SVMMModel — Full, trained SVM classifier
ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: fitPosterior(SVMModel,'KFold',5) uses five folds in a cross-validated model.

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

The crossval name-value pair argument of fitcsvm splits the data into subsets using cvpartition.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.
You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'Leaveout', 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

## Output Arguments

**ScoreSVMModel — Trained SVM classifier**

*ClassificationSVM classifier*

Trained SVM classifier, returned as a *ClassificationSVM* classifier. The trained classifier contains the estimated score-to-posterior-probability transformation function.

To estimate posterior probabilities for the training set observations, pass `ScoreSVMModel` to `resubPredict`.

To estimate posterior probabilities for new observations, pass the new observations and `ScoreSVMModel` to `predict`.

**ScoreTransform — Optimal score-to-posterior-probability transformation function parameters**

*structure array*

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.
• If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then `ScoreTransform` also has these fields:
  - **Slope**: The value of $A$ in the sigmoid function on page 32-2461
  - **Intercept**: The value of $B$ in the sigmoid function

• If the value of the `Type` field of `ScoreTransform` is `step`, then `ScoreTransform` also has these fields:
  - **PositiveClassProbability**: The value of $\pi$ in the step function on page 32-2461. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval $(\text{LowerBound}, \text{UpperBound})$.
  - **LowerBound**: The value $\max_{n} s_{n}$ in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class $\text{PositiveClassProbability}$. Any observation with a score less than $\text{LowerBound}$ has the posterior probability of being in the positive class equal to 0.
  - **UpperBound**: The value $\min_{n} s_{n}$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class $\text{PositiveClassProbability}$. Any observation with a score greater than $\text{UpperBound}$ has the posterior probability of being in the positive class equal to 1.

• If the value of the `Type` field of `ScoreTransform` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

  This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

---

**Definitions**

**Sigmoid Function**

The sigmoid function that maps score $s_{j}$ corresponding to observation $j$ to the positive class posterior probability is
\[
P(s_j) = \frac{1}{1 + \exp(As_j + B)}.
\]

If the value of the Type field of ScoreTransform is sigmoid, then parameters \(A\) and \(B\) correspond to the fields Scale and Intercept of ScoreTransform, respectively.

**Step Function**

The step function that maps score \(s_j\) corresponding to observation \(j\) to the positive class posterior probability is

\[
P(s_j) = \begin{cases} 
0; & s < \max_{y_k=-1} s_k \\
\pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\
1; & s_j > \min_{y_k=+1} s_k 
\end{cases}
\]

where:

- \(s_j\) is the score of observation \(j\).
- +1 and -1 denote the positive and negative classes, respectively.
- \(\pi\) is the prior probability that an observation is in the positive class.

If the value of the Type field of ScoreTransform is step, then the quantities \(\max_{y_k=-1} s_k\) and \(\min_{y_k=+1} s_k\) correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.
If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

- This process describes one way to predict positive class posterior probabilities.

1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.

2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as, `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

   If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMModel` and by conducting 10-fold cross-validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2461.
• If the classes are perfectly separable, then the transformation function is the step function on page 32-2461.
• In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2581. The fitPosterior function is not appropriate for one-class learning.
• The software stores the optimal score-to-posterior-probability transformation function in ScoreSVMModel.ScoreTransform.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to fitPosterior or fitSVMPosterior and its ScoreTransform property is not none, then the software:

• Displays a warning
• Resets the original transformation function to 'none' before estimating the new one

**Alternative Functionality**

You can also fit the posterior probability function by using fitSVMPosterior. This function is similar to fitPosterior, except it is more broad because it accepts a wider range of SVM classifier types.

*Introduced in R2014a*

**fitPosterior**

**Package:** classreg.learning.classif

Fit posterior probabilities for compact support vector machine (SVM) classifier

**Syntax**

ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior(__)

**Description**

ScoreSVMModel = fitPosterior(SVMModel,TBL,Y) returns a trained support vector machine (SVM) classifier ScoreSVMModel containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms“ on page 32-2463. If you train SVMModel using a table, then you must use a table as input for fitPosterior.

ScoreSVMModel = fitPosterior(SVMModel,X,Y) returns a trained SVM classifier ScoreSVMModel containing the optimal score-to-posterior-probability transformation function for two-class learning. If you train SVMModel using a matrix, then you must use a matrix as input for fitPosterior.

[ScoreSVMModel,ScoreTransform] = fitPosterior(__) additionally returns the optimal score-to-posterior-probability transformation function parameters (ScoreTransform) for any of the input argument combinations in the previous syntaxes.

**Examples**

**Estimate Posterior Probabilities for Data with Inseparable Classes**

Load the ionosphere data set. Reserve 20 random observations of the data, and consider this set new data.
load ionosphere
n = size(X,1);
 rng(1); % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data

The classes of this data set are inseparable.

Train an SVM classifier using the training data. Standardize the data and specify that 'g' is the positive class.

SVMMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
                      'Standardize',true);

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as g. For efficiency, make a compact version of SVMMModel, and pass it and the new data to fitPosterior.

CompactSVMMModel = compact(SVMMModel);
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...
                  X(~indx,:),Y(~indx));

ScoreTransform = ScoreCSVMMModel.ScoreTransform

ScoreTransform = @(S)sigmoid(S,-1.098922e+00,4.519963e-01)

ScoreParameters

ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -1.0989
    Intercept: 0.4520

ScoreTransform is the optimal score transformation function. ScoreParameters is a structure array with three fields: the score transformation function name (Type), the sigmoid slope (Slope), and the sigmoid intercept estimates (Intercept).

Alternatively, you can pass SVMMModel and the new data to fitSVMPosterior, but this process is not as efficient.
Estimate the posterior probabilities that the observations in the new data are in class g.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=20×3 table
    TrueLabel    PredictedLabel    PosteriorProbability
    ___________    ______________    ____________________
    'g'           'g'                 0.78437
    'b'           'b'                 0.024588
    'g'           'g'                 0.82399
    'b'           'b'                 0.0061637
    'b'           'b'                 3.6118e-06
    'b'           'b'                 0.15688
    'b'           'g'                 0.9622
    'b'           'b'                 6.1348e-09
    'b'           'b'                 0.0019646
    'g'           'g'                 0.7251
    'g'           'g'                 0.70263
    'b'           'b'                 0.075298
    'g'           'g'                 0.90691
    'g'           'g'                 0.82849
    'b'           'b'                 0.051193
    'g'           'g'                 0.95331
    ⋮
```

**Estimate Posterior Probabilities for Data with Separable Classes**

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1);  % For reproducibility
indx1 = 1:numel(species);
```
indx2 = indx1(classKeep);
indx = ~ismember(indx2, randsample(indx2, 10));  % Indices for the training data

gscatter(X(indx,1), X(indx,2), Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa', 'Versicolor')

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. Standardize the data and specify that versicolor is the positive class.
SVMModel = fitcsvm(X(indx,:),Y(indx),...
    'ClassNames',{'setosa','versicolor'},'Standardize',true);

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as versicolor. For efficiency, make a compact version SVMModel, and pass it and the new data to fitPosterior.

CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

ScoreTransform = ScoreCSVMModel.ScoreTransform

ScoreTransform =
    @(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)'

fitPosterior displays a warning whenever the classes are separable, and stores the step function in ScoreCSVMModel.ScoreTransform.

Display the score function type and its estimated values.

ScoreParameters

ScoreParameters = struct with fields:
    Type:  'step'
    LowerBound: -1.3385
    UpperBound:  2.0125
    PositiveClassProbability: 0.5333

ScoreParameters is a structure array with four fields:

• Score transformation function type (Type)
• Score corresponding to the negative class boundary (LowerBound)
• Score corresponding to the positive class boundary (UpperBound)
• Positive class probability (PositiveClassProbability)
Alternatively, you can pass SVMModel and the new data to fitSVMPosterior, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are versicolor irisises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=10×3 table
    TrueLabel      PredictedLabel    PosteriorProbability
    ______________    ______________    ____________________
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'setosa'         'setosa'                  0
    'versicolor'     'versicolor'              1
    'versicolor'     'versicolor'              1
```

Because the classes are separable, the step function transforms the positive-class score to:

- 0 if the score is less than ScoreParameters.LowerBound
- 1 if the score is greater than ScoreParameters.UpperBound
- ScoreParameters.PositiveClassProbability if the score is in the interval
  
```
[ScoreParameters.LowerBound,ScoreParameters.LowerBound]
```

### Input Arguments

**SVMModel — Trained, compact SVM classifier**

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM` model returned by `compact`. 
**TBL — Sample data**

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. TBL must contain all of the predictors used to train SVMModel. Optionally, TBL can contain an additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMModel, then you do not need to specify Y. If TBL does not include the response variable, then the length of Y must be equal to the number of rows in TBL.

If the sample data used to train SVMModel is a table, then you must specify the input data for fitPosterior as a table.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software fits the transformation function parameter estimates using standardized data.

Data Types: table

**X — Predictor data**

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows in X must be equal.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software fits the transformation function parameter estimates using standardized data.

Data Types: double | single

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.
If \( Y \) is a character array, then each element must correspond to one class label.

The length of \( Y \) and the number of rows in \( X \) must be equal.

Data Types: \texttt{categorical} | \texttt{char} | \texttt{string} | \texttt{logical} | \texttt{single} | \texttt{double} | \texttt{cell}

### Output Arguments

#### ScoreSVMModel — Trained, compact SVM classifier

\texttt{CompactClassificationSVM} classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a \texttt{CompactClassificationSVM} classifier.

To estimate posterior probabilities for new observations, pass \texttt{ScoreSVMModel} and the new observations to \texttt{predict}.

#### ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

\texttt{structure array}

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the Type field of \texttt{ScoreTransform} is sigmoid, then \texttt{ScoreTransform} also has these fields:
  - \texttt{Slope}: The value of \( A \) in the sigmoid function on page 32-2461
  - \texttt{Intercept}: The value of \( B \) in the sigmoid function
- If the value of the Type field of \texttt{ScoreTransform} is step, then \texttt{ScoreTransform} also has these fields:
  - \texttt{PositiveClassProbability}: The value of \( \pi \) in the step function on page 32-2461. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval \((\text{LowerBound},\text{UpperBound})\).
  - \texttt{LowerBound}: The value \( \max \left\{ s_n \right\} \) in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class.
PositiveClassProbability. Any observation with a score less than LowerBound has the posterior probability of being in the positive class equal to 0.

- UpperBound: The value $\min_{n} s_n$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class PositiveClassProbability. Any observation with a score greater than UpperBound has the posterior probability of being in the positive class equal to 1.

- If the value of the Type field of ScoreTransform is constant, then ScoreTransform.PredictedClass contains the name of the class prediction.

This result is the same as SVMModel.ClassNames. The posterior probability of an observation being in ScoreTransform.PredictedClass is always 1.

**Definitions**

**Sigmoid Function**

The sigmoid function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$  

If the value of the Type field of ScoreTransform is sigmoid, then parameters $A$ and $B$ correspond to the fields Scale and Intercept of ScoreTransform, respectively.

**Step Function**

The step function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is
\[
P(s_j) = \begin{cases} 
0; & s < \max_{y_k = -1} s_k \\
\pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\
1; & s_j > \min_{y_k = +1} s_k 
\end{cases}
\]

where:

• \( s_j \) is the score of observation \( j \).
• +1 and -1 denote the positive and negative classes, respectively.
• \( \pi \) is the prior probability that an observation is in the positive class.

If the value of the Type field of ScoreTransform is step, then the quantities \( \max_{y_k = -1} s_k \) and \( \min_{y_k = +1} s_k \) correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

• This process describes one way to predict positive class posterior probabilities.

1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`. 

32-2462
2 Pass the trained SVM classifier \texttt{SVMModel} to \texttt{fitSVMPosterior} or \texttt{fitPosterior}. The result, such as, \texttt{ScoreSVMModel}, is the same trained SVM classifier as \texttt{SVMModel}, except the software sets \texttt{ScoreSVMModel.ScoreTransformation} to the optimal score transformation function.

3 Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (\texttt{ScoreSVMModel}) to \texttt{predict}. The second column in the second output argument of \texttt{predict} stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

If you skip step 2, then \texttt{predict} returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

\section*{Algorithms}

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier \texttt{SVMModel} and by conducting 10-fold cross-validation using the stored predictor data (\texttt{SVMModel}.\texttt{X}) and the class labels (\texttt{SVMModel}.\texttt{Y}), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (\texttt{SVMModel}.\texttt{Classnames}(2)).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2461.
- If the classes are perfectly separable, then the transformation function is the step function on page 32-2461.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2581. The \texttt{fitPosterior} function is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in \texttt{ScoreSVMModel.ScoreTransform}.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to \texttt{fitPosterior} or \texttt{fitSVMPosterior} and its \texttt{ScoreTransform} property is not \texttt{none}, then the software:
• Displays a warning
• Resets the original transformation function to 'none' before estimating the new one

**Alternative Functionality**

You can also fit the optimal score-to-posterior-probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

**Introduced in R2014a**
**fitrensemble**

Fit ensemble of learners for regression

**Syntax**

Mdl = fitrensemble(Tbl,ResponseVarName)
Mdl = fitrensemble(Tbl,formula)
Mdl = fitrensemble(Tbl,Y)
Mdl = fitrensemble(X,Y)
Mdl = fitrensemble(___,'Name',Value)

**Description**

Mdl = fitrensemble(Tbl,ResponseVarName) returns the trained regression ensemble model object (Mdl) that contains the results of boosting 100 regression trees using LSBoost and the predictor and response data in the table Tbl. ResponseVarName is the name of the response variable in Tbl.

Mdl = fitrensemble(Tbl,formula) applies formula to fit the model to the predictor and response data in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl. For example, 'Y~X1+X2+X3' fits the response variable Tbl.Y as a function of the predictor variables Tbl.X1, Tbl.X2, and Tbl.X3.

Mdl = fitrensemble(Tbl,Y) treats all variables in the table Tbl as predictor variables. Y is the vector of responses that is not in Tbl.

Mdl = fitrensemble(X,Y) uses the predictor data in the matrix X and response data in the vector Y.

Mdl = fitrensemble(__,Name,Value) uses additional options specified by one or more Name,Value pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble-aggregation method, or to implement 10-fold cross-validation.
Examples

Train Regression Ensemble

Create a regression ensemble that predicts the fuel economy of a car given the number of cylinders, volume displaced by the cylinders, horsepower, and weight. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the carsmall data set. Store the variables to be used in training in a table.

load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);

Train a regression ensemble.

Mdl1 = fitrensemble(Tbl,'MPG');

Mdl1 is a RegressionEnsemble model. Some notable characteristics of Mdl1 are:

• The ensemble-aggregation algorithm is 'LSBoost'.
• Because the ensemble-aggregation method is a boosting algorithm, regression trees that allow a maximum of 10 splits compose the ensemble.
• One hundred trees compose the ensemble.

Because MPG is a variable in the MATLAB® Workspace, you can obtain the same result by entering

Mdl1 = fitrensemble(Tbl,MPG);

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

pMPG = predict(Mdl1,[4 200 150 3000])

pMPG = 25.6467

Train a new ensemble using all predictors in Tbl except Displacement.

formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitrensemble(Tbl,formula);
Compare the resubstitution MSEs between Mdl1 and Mdl2.

```matlab
mse1 = resubLoss(Mdl1)
mse1 = 0.3096
mse2 = resubLoss(Mdl2)
mse2 = 0.5861
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

**Estimate Generalization Error of Boosting Ensemble**

Estimate the generalization error of an ensemble of boosted regression trees.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```matlab
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

Cross-validate an ensemble of regression trees using 10-fold cross-validation. Using a decision tree template, specify that each tree should be a split once only.

```matlab
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitrensemble(X,MPG,'Learners',t,'CrossVal','on');
```

Mdl is a `RegressionPartitionedEnsemble` model.

Plot the cumulative, 10-fold cross-validated, mean-squared error (MSE). Display the estimated generalization error of the ensemble.

```matlab
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold cross-validated MSE');
xlabel('Learning cycle');
```
estGenError = kflc(end)
estGenError = 25.5184

kfoldLoss returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves an MSE of around 23.5 after accumulating about 30 weak learners.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-
validation. However, it is good practice to tune hyperparameters such as the maximum number of decision splits per tree and the number of learning cycles.

**Optimize Regression Ensemble**

This example shows how to optimize hyperparameters automatically using `fitrensemble`. The example uses the `carsmall` data.

Load the data.

```
load carsmall
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng(1)
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto',
                   'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods
The optimization searched over the methods for regression (Bag and LSBoost), over NumLearningCycles, over the LearnRate for LSBoost, and over the tree learner MinLeafSize. The output is the ensemble regression with the minimum estimated cross-validation loss.

Create Predictive Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree-complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.
Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```matlab
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most \( n - 1 \) splits. \( n \) is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.

2. Estimate the cross-validated mean-squared error (MSE) for each ensemble.

3. For tree-complexity level \( j, j = 1\ldots J \), compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.

4. Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```matlab
rng(1); % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off',... 'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on',... 'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence \( \{2^0, 2^1, \ldots, 2^m\} \). \( m \) is such that \( 2^m \) is no greater than \( n - 1 \).
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set \( \{0.1, 0.25, 0.5, 1\} \):

```matlab
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
umeLR = numel(learnRate);
maxNumSplits = 2.^((0:m));
```
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);
for k = 1:numLR;
    for j = 1:numMNS;
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees,...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end;
end;

Estimate the cumulative, cross-validated MSE of each ensemble.

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-b','LineWidth',2);
    plot(h.XLim,[errorStump errorStump],'-r','LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'-k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;

hL = legend([cellstr(num2str(learnRate,'Learning Rate = %0.2f'));...
    'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;
Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```matlab
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('Min. MSE = %0.5f',minErr)
fprintf('Optimal Parameter Values:
Num. Trees = %d',idxNumTrees);
fprintf('
MaxNumSplits = %d
Learning Rate = %0.2f
',maxNumSplits(idxMNS),learnRate(idxLR))
```
Min. MSE = 17.01148
Optimal Parameter Values:
Num. Trees = 38
MaxNumSplits = 4
Learning Rate = 0.10

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');
MdlFinal = fitrensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees,...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))

MdlFinal =
classreg.learning.regr.RegressionEnsemble
    PredictorNames: {1×4 cell}
    ResponseName: 'MPG'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94

    Method: 'LSBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of learning cycles.'
    FitInfo: [38×1 double]
    FitInfoDescription: {2×1 cell}
    Regularization: []

MdlFinal is a RegressionEnsemble. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, pass the predictor data and MdlFinal to predict.

Input Arguments

Tbl — Sample data
table
Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using ResponseVarName.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using formula.
- If Tbl does not contain the response variable, then specify the response data using Y. The length of response variable and the number of rows of Tbl must be equal.

**Note** To save memory and execution time, supply X and Y instead of Tbl.

Data Types: table

**ResponseVarName — Response variable name**

name of response variable in Tbl

Response variable name, specified as the name of the response variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if Tbl.Y is the response variable, then specify ResponseVarName as 'Y'. Otherwise, fitrensemble treats all columns of Tbl as predictor variables.

Data Types: char | string

**formula — Explanatory model of response and subset of predictor variables**

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in Tbl (Tbl.Properties.VariableNames).

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char | string
X — **Predictor data**  
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — **Response**  
numeric vector

Response, specified as a numeric vector. Each element in Y is the response to the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal.

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.  

**Note** You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'NumLearningCycles', 500,'Method','Bag','Learners',templateTree(),'CrossVal','on'` cross-validates an ensemble of 500 bagged regression trees using 10-fold cross-validation.
General Ensemble Options

**Method — Ensemble-aggregation method**

'LSBoost' (default) | 'Bag'

Ensemble-aggregation method, specified as the comma separated pair consisting of 'Method' and 'Bag' or 'LSBoost'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Bag'</td>
<td>Bootstrap aggregating or bagging (for example, random forest)</td>
</tr>
<tr>
<td>'LSBoost'</td>
<td>Least-squares boosting or LSBoost</td>
</tr>
</tbody>
</table>

Example: 'Method','Bag'

**NumLearningCycles — Number of ensemble learning cycles**

100 (default) | positive integer

Number of ensemble learning cycles, specified as a positive integer. At every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles*numel(Learners) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-2493.

Example: 'NumLearningCycles',500

Data Types: single | double

**Learners — Weak learners to use in ensemble**

'tree' (default) | regression tree template object | cell vector of regression tree template objects

Weak learners to use in the ensemble, specified as 'tree', a regression tree template object, or a cell vector of regression tree template objects.

- 'tree' specifies to train an ensemble of regression trees using default regression tree options.
  - For bagging, fitrensemble grows deep trees by default. For a complete list of defaults, see templateTree.
For LSBoost, `fitrensemble` grows shallow trees by default. That is, 'Learners' is `templateTree('MaxNumSplits',10)`.

- A regression tree template object specifies how to grow all trees in the ensemble. You can create a regression tree template using `templateTree`.
- A cell vector of \( m \) regression tree templates specifies to grow \( m \) regression trees per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of regression trees, supply \( \{t1 \ t2\} \), where \( t1 \) and \( t2 \) are regression tree templates returned by `templateTree`.

`fitrensemble` sets the maximum number of splits for regression tree weak learners to 10 when both of these conditions occur:

- You do not set a value for the 'MaxNumSplits' property of the weak learners.
- You use a boosting algorithm as the ensemble-aggregation method for `fitrensemble`.

For example, if you specify 'Learners', `templateTree()` and 'Method', 'LSBoost', then `fitrensemble` sets the maximum number of splits of the tree weak learners to 10.

Otherwise, `fitrensemble` defers to the regression tree template object to choose any required default values for the 'Learners' name-value pair argument.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 32-2493.

Example: 'Learners', `templateTree('MaxNumSplits',5)`

**NPrint — Printout frequency**

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of weak learners or folds that `fitrensemble` trained so far, specify a positive integer. That is, if you specify the positive integer \( m \):

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitrensemble` displays a message to the command line every time it completes training \( m \) weak learners.
- And a cross-validation option, then `fitrensemble` displays a message to the command line every time it finishes training \( m \) folds.
If you specify 'off', then fitrensemble does not display a message when it completes training weak learners.

**Tip** When training an ensemble of many weak learners on a large data set, specify a positive integer for NPrint.

Example: 'NPrint',5

Data Types: single | double | char | string

### CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitrensemble assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), fitrensemble assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.
Example: 'CategoricalPredictors','all'
Data Types: single | double | logical | char | string | cell

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitrensemble uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

**ResponseName — Response variable name**
'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.
• If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
• If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

ResponseTransform — Response transformation

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform',myfunction.

Data Types: char | string | function_handle

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval or crossval.

Example: 'Crossval','on'

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object
Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | 0.1

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps.

1 Randomly partition the data into k sets.
2 For each set, reserve the set as validation data, and train the model using the other k - 1 sets.
3 Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \( n-1 \) observations.
2. Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Other Regression Options**

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of \( X \) or \( Tbl \) with the corresponding value in Weights. The size of Weights must equal the number of rows of \( X \) or \( Tbl \).

If you specify the input data as a table \( Tbl \), then Weights can be the name of a variable in \( Tbl \) that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector \( W \) is stored as \( Tbl.W \), then specify it as 'W'. Otherwise, the software treats all columns of \( Tbl \), including \( W \), as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.
By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

**Sampling Options**

**FResample — Fraction of training set to resample**

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample',0.75`

Data Types: `single` | `double`

**Replace — Flag indicating to sample with replacement**

'off' (default) | 'on'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set `Resample` to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to 'bag' or set `Resample` to 'on', `Replace` has no effect.

Example: `'Replace','off'`

**Resample — Flag indicating to resample**

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is any boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
• 'Resample','off' specifies to reweight observations at every learning iteration. This setting is the default.
• If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

**LSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

• 'none' — Do not optimize.
• 'auto' — Use {'Method','NumLearningCycles','LearnRate'} along with the default parameters for the specified Learners:
  • Learners = 'tree' (default) — {'MinLeafSize'}

**Note** For hyperparameter optimization, Learners must be a single argument, not a string array or cell array.

• 'all' — Optimize all eligible parameters.
• String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitrensemble` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrensemble` are:

- **Method** — Eligible methods are 'Bag' or 'LSBoost'.
- **NumLearningCycles** — `fitrensemble` searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — `fitrensemble` searches among positive reals, by default log-scaled with range [1e-3,1].
- **MinLeafSize** — `fitrensemble` searches among integers log-scaled in the range [1,max(2,floor(NumObservations/2))].
- **MaxNumSplits** — `fitrensemble` searches among integers log-scaled in the range [1,max(2,NumObservations-1)].
- **NumVariablesToSample** — `fitrensemble` searches among integers in the range [1,max(2,NumPredictors)].

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load carsmall
params = hyperparameters('fitrensemble',[Horsepower,Weight],MPG,'Tree');
params(4).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the
plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Regression Ensemble” on page 32-2469.

Example: `'auto'`

**HyperparameterOptimizationOptions — Options for optimization**
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| `Optimizer`   | • `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`.  
• `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension.  
• `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points.  
'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)` | `'bayesopt'` |
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

**Output Arguments**

Mdl — Trained regression ensemble model
RegressionBaggedEnsemble model object | RegressionEnsemble model object | RegressionPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

<table>
<thead>
<tr>
<th>Model Object</th>
<th>Specify Any Cross-Validation Options?</th>
<th>Method Setting</th>
<th>Resample Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegressionBaggedEnsemble</td>
<td>No</td>
<td>'Bag'</td>
<td>'on'</td>
</tr>
</tbody>
</table>
The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

### Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume`.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

### Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-50.
• If you specify 'Method','LSBoost', then the software grows shallow decision trees by default. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using templateTree.

• For dual-core systems and above, fitrensemble parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Topics
“Supervised Learning Workflow and Algorithms” on page 18-2
“Framework for Ensemble Learning” on page 18-40

Introduced in R2016b
Fit a support vector machine regression model

`fitrsvm` trains or cross-validates a support vector machine (SVM) regression model on a low-through moderate-dimensional predictor data set. `fitrsvm` supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or $L_1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM regression model on a high-dimensional data set, that is, data sets that include many predictor variables, use `fitrlinear` instead.

To train an SVM model for binary classification, see `fitcsvm` for low-through moderate-dimensional predictor data sets, or `fitclinear` for high-dimensional data sets.

### Syntax

```plaintext
Mdl = fitrsvm(Tbl,ResponseVarName)
Mdl = fitrsvm(Tbl,formula)
Mdl = fitrsvm(Tbl,Y)
Mdl = fitrsvm(X,Y)
Mdl = fitrsvm(___,Name,Value)
```

### Description

`Mdl = fitrsvm(Tbl,ResponseVarName)` returns a full, trained support vector machine (SVM) regression model `Mdl` trained using the predictors values in the table `Tbl` and the response values in `Tbl.ResponseVarName`.

`Mdl = fitrsvm(Tbl,formula)` returns a full SVM regression model trained using the predictors values in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrsvm(Tbl,Y)` returns a full, trained SVM regression model trained using the predictors values in the table `Tbl` and the response values in the vector `Y`. 
Mdl = fitrsvm(X,Y) returns a full, trained SVM regression model trained using the predictors values in the matrix X and the response values in the vector Y.

Mdl = fitrsvm(___,Name,Value) returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

**Examples**

**Train Linear Support Vector Machine Regression Model**

Train a support vector machine (SVM) regression model using sample data stored in matrices.

Load the carsmall data set.

```matlab
load carsmall
rng 'default'  % For reproducibility
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```matlab
X = [Horsepower,Weight];
Y = MPG;
```

Train a default SVM regression model.

```matlab
Mdl = fitrsvm(X,Y)
```

```
Mdl = RegressionSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Alpha: [76x1 double]
    Bias: 43.1920
    KernelParameters: [1x1 struct]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
```
IsSupportVector: [93x1 logical]
Solver: 'SMO'

Properties, Methods

Mdl is a trained RegressionSVM model.

Check the model for convergence.
Mdl.ConvergenceInfo.Converged
ans = logical
0

0 indicates that the model did not converge.

Retrain the model using standardized data.
MdlStd = fitrsvm(X,Y,'Standardize',true)
MdlStd =
    RegressionSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Alpha: [77x1 double]
    Bias: 22.9131
    KernelParameters: [1x1 struct]
    Mu: [109.3441 2.9625e+03]
    Sigma: [45.3545 805.9668]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [93x1 logical]
    Solver: 'SMO'

Properties, Methods

Check the model for convergence.
MdlStd.ConvergenceInfo.Converged
ans = logical
  1

1 indicates that the model did converge.

Compute the resubstitution (in-sample) mean-squared error for the new model.

\[ l_{\text{Std}} = \text{resubLoss}(Mdl_{\text{Std}}) \]

\[ l_{\text{Std}} = 17.0256 \]

---

**Train Support Vector Machine Regression Model**

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name 'abalone.csv'.

```
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...
            'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for Sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings (stored in Rings) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default  % For reproducibility
Mdl = fitrsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...
              'Standardize',true)
```

\[ Mdl = \]
The Command Window shows that Mdl is a trained RegressionSVM model and displays a property list.

Display the properties of Mdl using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```matlab
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```matlab
conv =
   logical
      1

iter =
   2759
```

The returned results indicate that the model converged after 2759 iterations.
Cross-Validate SVM Regression Model

Load the carsmall data set.

```matlab
load carsmall
rng 'default' % For reproducibility
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```matlab
X = [Horsepower Weight];
Y = MPG;
```

Cross-validate two SVM regression models using 5-fold cross-validation. For both models, specify to standardize the predictors. For one of the models, specify to train using the default linear kernel, and the Gaussian kernel for the other model.

```matlab
MdlLin = fitrsvm(X,Y,'Standardize',true,'KFold',5)
```

```matlab
MdlLin =
    classreg.learning.partition.RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    NumObservations: 94
    KFold: 5
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'
```

Properties, Methods

```matlab
MdlGau = fitrsvm(X,Y,'Standardize',true,'KFold',5,'KernelFunction','gaussian')
```

```matlab
MdlGau =
    classreg.learning.partition.RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    NumObservations: 94
    KFold: 5
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'
```
Properties, Methods

MdlLin.Trained
ans = 5x1 cell array
   {1x1 classreg.learning.regr.CompactRegressionSVM}
   {1x1 classreg.learning.regr.CompactRegressionSVM}
   {1x1 classreg.learning.regr.CompactRegressionSVM}
   {1x1 classreg.learning.regr.CompactRegressionSVM}
   {1x1 classreg.learning.regr.CompactRegressionSVM}

MdlLin and MdlGau are RegressionPartitionedSVM cross-validated models. The Trained property of each model is a 5-by-1 cell array of CompactRegressionSVM models. The models in the cell store the results of training on 4 folds of observations, and leaving one fold of observations out.

Compare the generalization error of the models. In this case, the generalization error is the out-of-sample mean-squared error.

mseLin = kfoldLoss(MdlLin)

mseLin = 17.4417

mseGau = kfoldLoss(MdlGau)

mseGau = 16.7333

The SVM regression model using the Gaussian kernel performs better than the one using the linear kernel.

Create a model suitable for making predictions by passing the entire data set to fitrsvm, and specify all name-value pair arguments that yielded the better-performing model. However, do not specify any cross-validation options.

MdlGau = fitrsvm(X,Y,'Standardize',true,'KernelFunction','gaussian');

To predict the MPG of a set of cars, pass Mdl and a table containing the horsepower and weight measurements of the cars to predict.
Optimize SVM Regression

This example shows how to optimize hyperparameters automatically using \texttt{fitrsvm}. The example uses the \texttt{carsmall} data.

Load the \texttt{carsmall} data set.

\begin{verbatim}
load carsmall
\end{verbatim}

Specify \texttt{Horsepower} and \texttt{Weight} as the predictor variables (X) and \texttt{MPG} as the response variable (Y).

\begin{verbatim}
X = [Horsepower Weight];
Y = MPG;
\end{verbatim}

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the \texttt{'expected-improvement-plus'} acquisition function.

\begin{verbatim}
rng default
Md1 = fitrsvm(X,Y,'OptimizeHyperparameters','auto',...
  'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','...
  'expected-improvement-plus'))
\end{verbatim}

    IsSupportVector: [93×1 logical]
    Solver: 'SMO'

Properties, Methods
The optimization searched over BoxConstraint, KernelScale, and Epsilon. The output is the regression with the minimum estimated cross-validation loss.

**Input Arguments**

**Tbl** — Predictor data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl
can contain one additional column for the response variable. Multi-column variables and

cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl

as predictors, then specify the response variable using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining

variables in Tbl as predictors, then specify a formula using formula.

If Tbl does not contain the response variable, then specify a response variable using Y.
The length of response variable and the number of rows of Tbl must be equal.

If a row of Tbl or an element of Y contains at least one NaN, then fitrsvm removes those

rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in Tbl, use the

PredictorNames name-value pair argument.

Data Types: table

ResponseVarName — Response variable name

name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl. The response

variable must be a numeric vector.

You must specify ResponseVarName as a character vector or string scalar. For example,

if Tbl stores the response variable Y as Tbl.Y, then specify it as 'Y'. Otherwise, the

software treats all columns of Tbl, including Y, as predictors when training the model.

Data Types: char | string

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a

classifier in the form of 'Y~X1+X2+X3'. In this form, Y represents

the response variable, and X1, X2, and X3 represent the predictor variables. The variables

must be variable names in Tbl (Tbl.Properties.VariableNames).

To specify a subset of variables in Tbl as predictors for training the model, use a formula.
If you specify a formula, then the software does not use any variables in Tbl that do not
appear in formula.
Data Types: char | string

**Y — Response data**
numeric vector

Response data, specified as an n-by-1 numeric vector. The length of Y and the number of rows of Tbl or X must be equal.

If a row of Tbl or X, or an element of Y, contains at least one NaN, then fitrsvm removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the ResponseName name-value pair argument.

Data Types: single | double

**X — Predictor data**
numeric matrix

Predictor data to which the SVM regression model is fit, specified as an n-by-p numeric matrix. n is the number of observations and p is the number of predictor variables.

The length of Y and the number of rows of X must be equal.

If a row of X or an element of Y contains at least one NaN, then fitrsvm removes those rows and elements from both arguments.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-
validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example:
'KernelFunction','gaussian','Standardize',true,'CrossVal','on' trains a 10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

**Support Vector Machine Options**

**BoxConstraint — Box constraint**

positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar value.

The absolute value of the Alpha coefficients cannot exceed the value of BoxConstraint.

The default BoxConstraint value for the 'gaussian' or 'rbf' kernel function is \( \text{iqr}(Y)/1.349 \), where \( \text{iqr}(Y) \) is the interquartile range of response variable \( Y \). For all other kernels, the default BoxConstraint value is 1.

Example: BoxConstraint,10

Data Types: single | double

**KernelFunction — Kernel function**

'linear' (default) | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the Gram matrix on page 32-2000, specified as the comma-separated pair consisting of 'KernelFunction' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'gaussian' or 'rbf'</td>
<td>Gaussian or Radial Basis Function (RBF) kernel</td>
<td>( G(x_j,x_k) = \exp\left(-|x_j-x_k|^2\right) )</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear kernel</td>
<td>( G(x_j,x_k) = x_j'x_k )</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
<td>Formula</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>Polynomial kernel. Use 'PolynomialOrder', p to specify a polynomial kernel of order p.</td>
<td>$G(x_j,x_k) = (1 + x_j'x_k)^q$</td>
</tr>
</tbody>
</table>

You can set your own kernel function, for example, kernel, by setting 'KernelFunction', 'kernel'. kernel must have the following form:

```matlab
function G = kernel(U,V)
```

where:

- U is an $m$-by-$p$ matrix.
- V is an $n$-by-$p$ matrix.
- G is an $m$-by-$n$ Gram matrix of the rows of U and V.

And kernel.m must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char | string

**KernelScale — Kernel scale parameter**

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of KernelScale. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using rng before training.
- If you specify KernelScale and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within kernel.
Example: 'KernelScale','auto'
Data Types: double | single | char | string

**PolynomialOrder — Polynomial kernel function order**
3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software throws an error.

Example: 'PolynomialOrder',2
Data Types: double | single

**KernelOffset — Kernel offset parameter**
nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver','SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver','ISDA')

Example: 'KernelOffset',0
Data Types: double | single

**Epsilon — Half the width of epsilon-insensitive band**
iqr(Y)/13.49 (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value.

The default Epsilon value is iqr(Y)/13.49, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y. If iqr(Y) is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon',0.3
Data Types: single | double

**Standardize** — Flag to standardize predictor data  
false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:

- The software centers and scales each column of the predictor data ($X$) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 32-2005). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the model using the standardized predictor matrix, but stores the unstandardized data in the model property $X$.

Example: 'Standardize',true

Data Types: logical

**Solver** — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ISDA'</td>
<td>Iterative Single Data Algorithm (see [30])</td>
</tr>
<tr>
<td>'L1QP'</td>
<td>Uses quadprog to implement $L1$ soft-margin minimization by quadratic</td>
</tr>
<tr>
<td></td>
<td>programming. This option requires an Optimization Toolbox license. For more</td>
</tr>
<tr>
<td></td>
<td>details, see “Quadratic Programming Definition” (Optimization Toolbox).</td>
</tr>
<tr>
<td>'SMO'</td>
<td>Sequential Minimal Optimization (see [17])</td>
</tr>
</tbody>
</table>

The defaults are:

- 'ISDA' if you set 'OutlierFraction' to a positive value
• 'SMO' otherwise

Example: 'Solver','ISDA'

**Alpha — Initial estimates of alpha coefficients**

numeric vector

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector. The length of Alpha must be equal to the number of rows of X.

- Each element of Alpha corresponds to an observation in X.
- Alpha cannot contain any NaNs.
- If you specify Alpha and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and Alpha that correspond to the missing values. That is, enter:

```matlab
idx = ~isnan(Y);  
Y = Y(idx);  
X = X(idx,:);  
alpha = alpha(idx);
```

Then, pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The default is `zeros(size(Y,1))`.

Example: 'Alpha', 0.1*ones(size(X,1),1)

Data Types: `single` | `double`

**CacheSize — Cache size**

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n-by-n Gram matrix on page 32-2000.
If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: 'CacheSize','maximal'

Data Types: double | single | char | string

**ClipAlphas — Flag to clip alpha coefficients**

true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation \( j \) is \( \alpha_j \) and the box constraint of observation \( j \) is \( C_j, j = 1,...,n \), where \( n \) is the training sample size.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>At each iteration, if ( \alpha_j ) is near 0 or near ( C_j ), then MATLAB sets ( \alpha_j ) to 0 or to ( C_j ), respectively.</td>
</tr>
<tr>
<td>false</td>
<td>MATLAB does not change the alpha coefficients during optimization.</td>
</tr>
</tbody>
</table>

MATLAB stores the final values of \( \alpha \) in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: 'ClipAlphas',false

Data Types: logical

**NumPrint — Number of iterations between optimization diagnostic message output**

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: 'NumPrint',500
**OutlierFraction** — Expected proportion of outliers in training data  
0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1). `fitrsvm` removes observations with large gradients, ensuring that `fitrsvm` removes the fraction of observations specified by `OutlierFraction` by the time convergence is reached. This name-value pair is only valid when 'Solver' is 'ISDA'.

Example: 'OutlierFraction',0.1

Data Types: single | double

**RemoveDuplicates** — Flag to replace duplicate observations with single observations  
false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If `RemoveDuplicates` is true, then `fitrsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

**Tip** If your data set contains many duplicate observations, then specifying 'RemoveDuplicates',true can decrease convergence time considerably.

Data Types: logical

**Verbose** — Verbosity level  
0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display or save convergence information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays diagnostic messages and saves convergence criteria at every iteration.</td>
</tr>
</tbody>
</table>

Example: 'Verbose', 1

Data Types: double | single

**Other Regression Options**

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitrsvm assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of
character vectors. If the predictor data is a matrix (X), fitrsvm assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

PredictorNames — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitrsvm uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

ResponseName — Response variable name
'Y' (default) | character vector | string scalar

fitrsvm
Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**ResponseTransform — Response transformation**

'default' | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'default' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform',myfunction.

Data Types: char | string | function_handle

**Weights — Observation weights**

one(size(X,1),1) (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of numeric values. The size of Weights must equal the number of rows in X. fitrsvm normalizes the values of Weights to sum to 1.

Data Types: single | double

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.
To override this cross-validation setting, use one of these name-value pair arguments: \texttt{CVPartition}, \texttt{Holdout}, \texttt{KFold}, or \texttt{Leaveout}. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, you can cross-validate the model later using the \texttt{crossval} method.

Example: \texttt{'CrossVal','on'}

\textbf{CVPartition — Cross-validation partition}

\[[\text{default}] | \texttt{cvpartition} \text{ partition object}\]

Cross-validation partition, specified as the comma-separated pair consisting of \texttt{CVPartition} and a \texttt{cvpartition} partition object as created by \texttt{cvpartition}. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: \texttt{CVPartition}, \texttt{Holdout}, \texttt{KFold}, or \texttt{Leaveout}.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using \texttt{cvp = cvpartition(500,'KFold',5)}. Then, you can specify the cross-validated model by using \texttt{'CVPartition',cvp}.

\textbf{Holdout — Fraction of data for holdout validation}

\texttt{scalar value in the range (0,1)}

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of \texttt{Holdout} and a scalar value in the range (0,1). If you specify \texttt{Holdout}, \texttt{p}, then the software completes these steps:

1. Randomly select and reserve \texttt{p*100\%} of the data as validation data, and train the model using the rest of the data.

2. Store the compact, trained model in the \texttt{Trained} property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: \texttt{CVPartition}, \texttt{Holdout}, \texttt{KFold}, or \texttt{Leaveout}.

Example: \texttt{'Holdout',0.1}

Data Types: \texttt{double} | \texttt{single}

\textbf{KFold — Number of folds}

\texttt{10 (default) | positive integer value greater than 1}
Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps.

1. Randomly partition the data into k sets.
2. For each set, reserve the set as validation data, and train the model using the other \( k - 1 \) sets.
3. Store the k compact, trained models in the cells of a \( k \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the \( n \) observations (where \( n \) is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other \( n - 1 \) observations.
2. Store the \( n \) compact, trained models in the cells of an \( n \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Convergence Controls**

**DeltaGradientTolerance — Tolerance for gradient difference**

0 (default) | nonnegative scalar
Tolerance for gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

Example: 'DeltaGradientTolerance',1e-4
Data Types: single | double

**GapTolerance — Feasibility gap tolerance**

1e-3 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If GapTolerance is 0, then fitrsvm does not use this parameter to check convergence.

Example: 'GapTolerance',1e-4
Data Types: single | double

**IterationLimit — Maximal number of numerical optimization iterations**

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. Mdl.ConvergenceInfo contains convergence information.

Example: 'IterationLimit',1e8
Data Types: double | single

**KKTTolerance — Tolerance for KKT violation**

0 | nonnegative scalar value

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar value.

This name-value pair applies only if 'Solver' is 'SMO' or 'ISDA'.

If KKTTolerance is 0, then fitrsvm does not use this parameter to check convergence.

Example: 'KKTTolerance',1e-4
Data Types: single | double
**ShrinkagePeriod** — Number of iterations between reductions of active set

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000

Data Types: double | single

**Hyperparameter Optimization**

**OptimizeHyperparameters** — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'BoxConstraint','KernelScale','Epsilon'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrsvm by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrsvm are:

- **BoxConstraint** — fitrsvm searches among positive values, by default log-scaled in the range [1e-3,1e3].
• **KernelScale** — `fitrsvm` searches among positive values, by default log-scaled in the range $[1e^{-3}, 1e3]$.

• **Epsilon** — `fitrsvm` searches among positive values, by default log-scaled in the range $[1e^{-3}, 1e2] \times \text{iqr}(Y)/1.349$.

• **KernelFunction** — `fitrsvm` searches among 'gaussian', 'linear', and 'polynomial'.

• **PolynomialOrder** — `fitrsvm` searches among integers in the range $[2, 4]$.

• **Standardize** — `fitrsvm` searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
classf
classify = load carsmall
classif = hyperparameters('fitrsvm',[Horsepower,Weight],MPG);
classif(1).Range = [1e-4,1e6];
classif(2).Range = [1e-3,1e3];
classif(3).Range = [1e-2,1e2];
classif(4).Range = [2,4];
classif(5).Range = [true,false];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize SVM Regression” on page 32-2502.

Example: 'OptimizeHyperparameters','auto'

**HyperparameterOptimizationOptions — Options for optimization**

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.
<table>

Data Types: struct

Output Arguments

**Mdl — Trained SVM regression model**

RegressionSVM model | RegressionPartitionedSVM cross-validated model

Trained SVM regression model, returned as a RegressionSVM model or RegressionPartitionedSVM cross-validated model.
If you set any of the name-value pair arguments KFold, Holdout, Leaveout, CrossVal, or CVPartition, then Mdl is a RegressionPartitionedSVM cross-validated model. Otherwise, Mdl is a RegressionSVM model.

Limitations

fitrsvm supports low- through moderate-dimensional data sets. For high-dimensional data set, use fitrlinear instead.

Tips

- Unless your data set is large, always try to standardize the predictors (see Standardize). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM model generalizes.
- Sparsity in support vectors is a desirable property of an SVM model. To decrease the number of support vectors, set the BoxConstraint name-value pair argument to a large value. This action also increases the training time.
- For optimal training time, set CacheSize as high as the memory limit on your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active-set using the name-value pair argument 'ShrinkagePeriod'. It is good practice to use 'ShrinkagePeriod',1000.
- Duplicate observations that are far from the regression line do not affect convergence. However, just a few duplicate observations that occur near the regression line can slow down convergence considerably. To speed up convergence, specify 'RemoveDuplicates',true if:
  - Your data set contains many duplicate observations.
  - You suspect that a few duplicate observations can fall near the regression line.

However, to maintain the original data set during training, fitrsvm must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify true for data sets containing few duplicates, then fitrsvm consumes close to double the memory of the original data.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

## Algorithms

- For the mathematical formulation of linear and nonlinear SVM regression problems and the solver algorithms, see “Understanding Support Vector Machine Regression” on page 25-2.

- NaN, `<undefined>`, empty character vector (''), empty string (""), and `<missing>` values indicate missing data values. `fitrsvm` removes entire rows of data corresponding to a missing response. When normalizing weights, `fitrsvm` ignores any weight corresponding to an observation with at least one missing predictor. Consequently, observation box constraints might not equal `BoxConstraint`.

- `fitrsvm` removes observations that have zero weight.

- If you set 'Standardize',true and 'Weights', then `fitrsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitrsvm` standardizes predictor $j$ ($x_j$) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*},$$

- $$\mu_j^* = \frac{1}{\sum_k w_k} \sum_k w_k x_{jk}.$$  

- $x_{jk}$ is observation $k$ (row) of predictor $j$ (column).

- $$(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k \left(x_{jk} - \mu_j^*\right)^2.$$  

- $v_1 = \sum_j w_j.$

- $v_2 = \sum_j (w_j)^2.$
• If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.

• The PredictorNames property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then PredictorNames is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.

• The ExpandedPredictorNames property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then ExpandedPredictorNames is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

• Similarly, the Beta property stores one beta coefficient for each predictor, including the dummy variables.

• The SupportVectors property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then SupportVectors is an m-by-5 matrix.

• The X property stores the training data as originally input. It does not include the dummy variables. When the input is a table, X contains only the columns used as predictors.

• For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.

• For a variable having k ordered levels, the software creates k – 1 dummy variables. The jth dummy variable is -1 for levels up to j, and +1 for levels j + 1 through k.

• The names of the dummy variables stored in the ExpandedPredictorNames property indicate the first level with the value +1. The software stores k – 1 additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k.

• All solvers implement $L1$ soft-margin minimization.

• Let $p$ be the proportion of outliers that you expect in the training data. If you set 'OutlierFraction', $p$, then the software implements robust learning. In other words, the software attempts to remove 100$p$% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

**Introduced in R2015b**
**fitrtree**

Fit binary regression decision tree

**Syntax**

```matlab
tree = fitrtree(Tbl,ResponseVarName)
```

```matlab
tree = fitrtree(Tbl,formula)
```

```matlab
tree = fitrtree(Tbl,Y)
```

```matlab
tree = fitrtree(X,Y)
```

```matlab
tree = fitrtree(___ , Name, Value)
```

**Description**

`tree = fitrtree(Tbl,ResponseVarName)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) contained in `Tbl.ResponseVarName`. `tree` is a binary tree where each branching node is split based on the values of a column of `Tbl`.

`tree = fitrtree(Tbl,formula)` returns a regression tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitrtree(Tbl,Y)` returns a regression tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

`tree = fitrtree(X,Y)` returns a regression tree based on the input variables `X` and output `Y`. `tree` is a binary tree where each branching node is split based on the values of a column of `X`.

`tree = fitrtree(___ , Name, Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify observation weights or train a cross-validated model.
Examples

Construct a Regression Tree

Load the sample data.

load carsmall;

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...
    'categoricalpredictors',2,'MinParentSize',20,...
    'PredictorNames',{'W','C'});
```

```
tree = 
    RegressionTree
    PredictorNames: {'W'  'C'}
    ResponseName: 'Y'
    CategoricalPredictors: 2
    ResponseTransform: 'none'
    NumObservations: 94

Properties, Methods
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])
mileage4K = 3×1
```

```
    19.2778
    19.2778
    14.3889
```
Control Regression Tree Depth

You can control the depth of trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitrtree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

The default values of the tree-depth controllers for growing regression trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a regression tree using the default values for tree-depth control. Cross validate the model using 10-fold cross validation.

```matlab
rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');
```

Draw a histogram of the number of imposed splits on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

```matlab
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);
figure;
histogram(mdlDefaultNumSplits)
```
view(MdlDefault.Trained{1},'Mode','graph')
The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross validate the model using 10-fold cross validation.

```matlab
Mdl7 = fitrtree(X,MPG,'MaxNumSplits',7,'CrossVal','on'); view(Mdl7.Trained{1},'Mode','graph')
```
Compare the cross validation MSEs of the models.

\[
\text{mseDefault} = \text{kfoldLoss(MdlDefault)}
\]

mseDefault = 27.7277

\[
\text{mse7} = \text{kfoldLoss(Mdl7)}
\]

mse7 = 28.3833

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

32-2537
Optimize Regression Tree

This example shows how to optimize hyperparameters automatically using `fitrtree`. The example uses the `carsmall` data.

Load the `carsmall` data.

```matlab
load carsmall
```

Use `Weight` and `Horsepower` as predictors for `MPG`. Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```matlab
X = [Weight,Horsepower];
Y = MPG;
rng default
Mdl = fitrtree(X,Y,'OptimizeHyperparameters','auto',
               'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',
               'expected-improvement-plus'))
```

Properties, Methods

Unbiased Predictor Importance Estimates

Load the carsmall data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider Cylinders, Mfg, and Model_Year as categorical variables.

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);

Display the number of categories represented in the categorical variables.
numCylinders = numel(categories(Cylinders))
numCylinders = 3
numMfg = numel(categories(Mfg))
numMfg = 28
numModelYear = numel(categories(Model_Year))
numModelYear = 3

Because there are 3 categories only in Cylinders and Model_Year, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

Mdl = fitrtree(X,'MPG','PredictorSelection','curvature','Surrogate','on');

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
In this case, Displacement is the most important predictor, followed by Horsepower.

**Input Arguments**

Tbl — Sample data

`table`

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

**ResponseVarName — Response variable name**
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

**formula — Explanatory model of response and subset of predictor variables**
character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

**Y — Response data**
numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.  

32-2545
The software considers NaN values in Y to be missing values. fitrtree does not use observations with missing values for Y in the fit.

Data Types: single | double

X — Predictor data
numeric matrix

Predictor data, specified as numeric matrix. Each column of X represents one variable, and each row represents one observation.

fitrtree considers NaN values in X as missing values. fitrtree does not use observations with all missing values for X the fit. fitrtree uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'CrossVal','on','MinParentSize',30 specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

Model Parameters

CategoricalPredictors — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.
### Value Description

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), `fitrtree` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (X), `fitrtree` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: single | double | logical | char | string | cell

#### MergeLeaves — Leaf merge flag

'off' (default) | 'on'

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and 'on' or 'off'.

If `MergeLeaves` is 'on', then `fitrtree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, `fitrtree` does not merge leaves.

Example: `'MergeLeaves','off'"
**MinParentSize — Minimum number of branch node observations**
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitrtree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize,2*MinLeafSize).

Example: 'MinParentSize',8

Data Types: single | double

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames contains the names of all predictor variables.

- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitrtree uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

PredictorSelection — Algorithm used to select the best split predictor
'splits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allsplits'</td>
<td>Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].</td>
</tr>
<tr>
<td>'curvature'</td>
<td>Curvature test on page 32-2560 — Selects the split predictor that minimizes the p-value of chi-square tests of independence between each predictor and the response [2]. Training speed is similar to standard CART.</td>
</tr>
<tr>
<td>'interaction-curvature'</td>
<td>Interaction test on page 32-2561 — Chooses the split predictor that minimizes the p-value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the p-value of a chi-square test of independence between each pair of predictors and response [2]. Training speed can be slower than standard CART.</td>
</tr>
</tbody>
</table>

For 'curvature' and 'interaction-curvature', if all tests yield p-values greater than 0.05, then fitrtree stops splitting nodes.

**Tip**

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see predictorImportance.
• Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test.

• Prediction speed is unaffected by the value of 'PredictorSelection'.

For details on how fitrtree selects split predictors, see “Node Splitting Rules” on page 32-2563.

Example: 'PredictorSelection','curvature'

**Prune — Flag to estimate optimal sequence of pruned subtrees**

'on' (default) | 'off'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If Prune is 'on', then fitrtree grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, fitrtree grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to prune.

Example: 'Prune','off'

**PruneCriterion — Pruning criterion**

'mse' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

**QuadraticErrorTolerance — Quadratic error tolerance**

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below QuadraticErrorTolerance*QED, where QED is the quadratic error for the entire data computed before the decision tree is grown.
Example: 'QuadraticErrorTolerance', 1e-4

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

**ResponseTransform — Response transformation**

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @(y)y, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using myfunction = @(y)exp(y). Then, you can specify the response transformation as 'ResponseTransform', myfunction.

Data Types: char | string | function_handle

**SplitCriterion — Split criterion**

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

**Surrogate — Surrogate decision splits flag**

'off' (default) | 'on' | 'all' | positive integer

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer.
• When 'on', fitrtree finds at most 10 surrogate splits at each branch node.
• When set to a positive integer, fitrtree finds at most the specified number of surrogate splits at each branch node.
• When set to 'all', fitrtree finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate','on'

Data Types: single | double | char | string

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The software weights the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors when training the model.

fitrtree normalizes the weights in each class to add up to 1.

Data Types: single | double | char | string

Cross Validation

CrossVal — Cross-validation flag
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', fitrtree grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four options
('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Example: 'CrossVal','on'

**CVPartition — Partition for cross-validation tree**
cvp = cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout — Fraction of data for holdout validation**

holdout = 0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

**KFold — Number of folds**

kfold = 10 (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

leaveout = 'off' (default) | 'on'

"leaveout" — Leave-one-out cross-validation flag

'off' (default) | 'on'

"leaveout" is a flag to specify whether to use one row of training data, and use the rest of the data for testing. The default is 'off', which means cross-validation is not performed. Use the 'Leaveout' name-value pair argument to specify the leave-one-out cross-validation flag.
Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

Hyperparameters

**MaxNumSplits — Maximal number of decision splits**

`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. `fitrtree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Tree Depth Control” on page 32-2566.

Example: 'MaxNumSplits',5

Data Types: `single` | `double`

**MinLeafSize — Minimum number of leaf node observations**

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: 'MinLeafSize',3

Data Types: `single` | `double`

**NumVariablesToSample — Number of predictors for split**

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NumVariablesToSample',3
Data Types: single | double

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize
'structured' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

• 'none' — Do not optimize.
• 'auto' — Use {'MinLeafSize'}.
• 'all' — Optimize all eligible parameters.
• String array or cell array of eligible parameter names.
• Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrtree by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrtree are:

• MaxNumSplits — fitrtree searches among integers, by default log-scaled in the range [1,max(2,NumObservations-1)].
• MinLeafSize — fitrtree searches among integers, by default log-scaled in the range [1,max(2,floor(NumObservations/2))].
• NumVariablesToSample — fitrtree does not optimize over this hyperparameter. If you pass NumVariablesToSample as a parameter name, fitrtree simply uses the full number of predictors. However, fitrensemble does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,
load carsmall
params = hyperparameters('fitrtree', [Horsepower, Weight], MPG);
params(1).Range = [1, 30];

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Regression Tree” on page 32-2538.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.
<table>
<thead>
<tr>
<th>Field Name</th>

</tr>
</tbody>
</table>
Field Name | Values | Default
---|---|---
**UseParallel** | Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-9. | false

**Repartition** | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. | false

true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations.

Use no more than one of the following three field names.

**CVPartition** | A cvpartition object, as created by cvpartition. | 'Kfold',5 if you do not specify any cross-validation field

**Holdout** | A scalar in the range (0,1) representing the holdout fraction. | 

**Kfold** | An integer greater than 1. | 

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

**Output Arguments**

tree — Regression tree
regression tree object

Regression tree, returned as a regression tree object. Using the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.
Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

**Definitions**

**Curvature Test**

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable $x$ and $y$ is conducted using this process.

1. If $x$ is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
2. For each level in the partitioned predictor $j = 1...J$ and class in the response $k = 1,...,K$, compute the weighted proportion of observations in class $k$

$$
\hat{p}_{jk} = \sum_{i=1}^{n} I(y_i = k)w_i.
$$

where $w_i$ is the weight of observation $i$, $\sum w_i = 1$, $I$ is the indicator function, and $n$ is the sample size. If all observations have the same weight, then $\hat{p}_{jk} = \frac{n_{jk}}{n}$, where $n_{jk}$ is the number of observations in level $j$ of the predictor that are in class $k$.
3. Compute the test statistic

$$
t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \frac{(\hat{p}_{jk} - \hat{p}_{j+k})^2}{\hat{p}_{j+k} \hat{p}_{j+k}}
$$
\begin{align*}
    \hat{\pi}_{j+} &= \sum_k \hat{\pi}_{jk} , \text{ that is, the marginal probability of observing the predictor at level } j. \\
    \hat{\pi}_{+k} &= \sum_j \hat{\pi}_{jk} , \text{ that is the marginal probability of observing class } k. \text{ If } n \text{ is large enough, then } t \text{ is distributed as a } \chi^2 \text{ with } (K - 1)(J - 1) \text{ degrees of freedom.}
\end{align*}

4 If the \( p \)-value for the test is less than 0.05, then reject the null hypothesis that there is no association between \( x \) and \( y \).

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant \( p \)-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

For more details on how the curvature test applies to growing regression trees, see “Node Splitting Rules” on page 32-2563 and [3].

**Interaction Test**

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables \( x_1 \) and \( x_2 \) with respect to \( y \) is conducted using this process.

1 If \( x_1 \) or \( x_2 \) is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2 Create the nominal variable \( z \) with \( J = J_1 J_2 \) levels that assigns an index to observation \( i \) according to which levels of \( x_1 \) and \( x_2 \) it belongs. Remove any levels of \( z \) that do not correspond to any observations.

3 Conduct a curvature test on page 32-2560 between \( z \) and \( y \).

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then
standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-2560, “Node Splitting Rules” on page 32-2563 and [2].

**Predictive Measure of Association**

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2087 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose \( x_j \) and \( x_k \) are predictor variables \( j \) and \( k \), respectively, and \( j \neq k \). At node \( t \), the predictive measure of association between the optimal split \( x_j < u \) and a surrogate split \( x_k < v \) is

\[
\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L,L_k} - P_{R,R_k})}{\min(P_L, P_R)}.
\]

- \( P_L \) is the proportion of observations in node \( t \), such that \( x_j < u \). The subscript \( L \) stands for the left child of node \( t \).
- \( P_R \) is the proportion of observations in node \( t \), such that \( x_j \geq u \). The subscript \( R \) stands for the right child of node \( t \).
- \( P_{L,L_k} \) is the proportion of observations at node \( t \), such that \( x_j < u \) and \( x_k < v \).
- \( P_{R,R_k} \) is the proportion of observations at node \( t \), such that \( x_j \geq u \) and \( x_k \geq v \).
- Observations with missing values for \( x_j \) or \( x_k \) do not contribute to the proportion calculations.

\( \lambda_{jk} \) is a value in \((-\infty,1]\). If \( \lambda_{jk} > 0 \), then \( x_k < v \) is a worthwhile surrogate split for \( x_j < u \).
Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2562.

Tip

• By default, Prune is 'on'. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to prune.
• After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

Node Splitting Rules

fitrtree uses these processes to determine how to split node $t$.

• For standard CART (that is, if PredictorSelection is 'allpairs') and for all predictors $x_i$, $i = 1,...,p$:

1. fitrtree computes the weighted, mean-square error (MSE) of the responses in node $t$ using

$$
\varepsilon_t = \sum_{j \in T} w_j (y_j - \bar{y}_t)^2.
$$
$w_j$ is the weight of observation $j$, and $T$ is the set of all observation indices in node $t$. If you do not specify Weights, then $w_j = 1/n$, where $n$ is the sample size.

2. `fitrtree` estimates the probability that an observation is in node $t$ using

$$P(T) = \sum_{j \in T} w_j.$$ 

3. `fitrtree` sorts $x_i$ in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitrtree` records any indices corresponding to missing values in the set $T_U$, which is the unsplit set.

4. `fitrtree` determines the best way to split node $t$ using $x_i$ by maximizing the reduction in MSE ($\Delta I$) over all splitting candidates. That is, for all splitting candidates in $x_i$:

   a. `fitrtree` splits the observations in node $t$ into left and right child nodes ($t_L$ and $t_R$, respectively).

   b. `fitrtree` computes $\Delta I$. Suppose that for a particular splitting candidate, $t_L$ and $t_R$ contain observation indices in the sets $T_L$ and $T_R$, respectively.

      - If $x_i$ does not contain any missing values, then the reduction in MSE for the current splitting candidate is

      $$\Delta I = P(T)\epsilon_t - P(T_L)\epsilon_{t_L} - P(T_R)\epsilon_{t_R}.$$ 

      - If $x_i$ contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is

      $$\Delta I_U = P(T - T_U)\epsilon_t - P(T_L)\epsilon_{t_L} - P(T_R)\epsilon_{t_R}.$$ 

      $T - T_U$ is the set of all observation indices in node $t$ that are not missing.

   • If you use surrogate decision splits on page 32-2563, then:

      i. `fitrtree` computes the predictive measures of association on page 32-2562 between the decision split $x_j < u$ and all possible decision splits $x_k < v, j \neq k$.

      ii. `fitrtree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
iii  *fitrtree* decides the child node assignments for observations with a missing value for $x_i$ using the surrogate split. If the surrogate predictor also contains a missing value, then *fitrtree* uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for *fitrtree* to split two different observations at node $t$ using two different surrogate splits. For example, suppose the predictors $x_1$ and $x_2$ are the best and second best surrogates, respectively, for the predictor $x_i$, $i \notin \{1,2\}$, at node $t$. If observation $m$ of predictor $x_i$ is missing (i.e., $x_{mi}$ is missing), but $x_{m1}$ is not missing, then $x_1$ is the surrogate predictor for observation $x_{mi}$. If observations $x_{(m+1),1}$ and $x_{(m+1),2}$ are missing, but $x_{(m+1),2}$ is not missing, then $x_2$ is the surrogate predictor for observation $m+1$.

iv  *fitrtree* uses the appropriate MSE reduction formula. That is, if *fitrtree* fails to assign all missing observations in node $t$ to children nodes using surrogate splits, then the MSE reduction is $\Delta I_U$. Otherwise, *fitrtree* uses $\Delta I$ for the MSE reduction.

c  *fitrtree* chooses the candidate that yields the largest MSE reduction.

*fitrtree* splits the predictor variable at the cut point that maximizes the MSE reduction.

- For the curvature test (that is, if `PredictorSelection` is `'curvature'`):
  1  *fitrtree* computes the residuals $r_{ti} = y_{ti} - \bar{y}_t$ for all observations in node $t$.

  $$
  \bar{y}_t = \frac{1}{\text{weight}} \sum_{i} w_{i} y_{ti},
  $$
  which is the weighted average of the responses in node $t$. The weights are the observation weights in `Weights`.

  2  *fitrtree* assigns observations to one of two bins according to the sign of the corresponding residuals. Let $z_t$ be a nominal variable that contains the bin assignments for the observations in node $t$.

  3  *fitrtree* conducts curvature tests on page 32-2560 between each predictor and $z_t$. For regression trees, $K = 2$.

- If all $p$-values are at least 0.05, then *fitrtree* does not split node $t$.
- If there is a minimal $p$-value, then *fitrtree* chooses the corresponding predictor to split node $t$.
- If more than one $p$-value is zero due to underflow, then *fitrtree* applies standard CART to the corresponding predictors to choose the split predictor.
If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

For the interaction test (that is, if `PredictorSelection` is 'interaction-curvature'):  

1. For observations in node \( t \), `fitrtree` conducts curvature tests between each predictor and the response and interaction tests between each pair of predictors and the response.
   
   - If all \( p \)-values are at least 0.05, then `fitrtree` does not split node \( t \).
   - If there is a minimal \( p \)-value and it is the result of a curvature test, then `fitrtree` chooses the corresponding predictor to split node \( t \).
   - If there is a minimal \( p \)-value and it is the result of an interaction test, then `fitrtree` chooses the split predictor using standard CART on the corresponding pair of predictors.
   - If more than one \( p \)-value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.

2. If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

**Tree Depth Control**

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'mse' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using MSE. This specification amounts to merging leaves coming from the same parent node whose MSE is at most the sum of the MSE of its two leaves.

- To accommodate `MaxNumSplits`, `fitrtree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitrtree` follows this procedure:

1. Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
2. Sort the branch nodes by their impurity gains.
3. Unsplit the number of least successful branches.
4. Return the decision tree grown so far.
This procedure produces maximally balanced trees.

• The software splits branch nodes layer by layer until at least one of these events occurs:
  • There are MaxNumSplits branch nodes.
  • A proposed split causes the number of observations in at least one branch node to be fewer than MinParentSize.
  • A proposed split causes the number of observations in at least one leaf node to be fewer than MinLeafSize.
  • The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see PruneCriterion), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
  • For values 'curvature' or 'interaction-curvature' of PredictorSelection, all tests yield p-values greater than 0.05.

MaxNumSplits and MinLeafSize do not affect splitting at their default values. Therefore, if you set 'MaxNumSplits', splitting might stop due to the value of MinParentSize, before MaxNumSplits splits occur.

Parallelization

Topics
“Splitting Categorical Predictors” on page 19-31

Introduced in R2014a
fitSVMPosterior

Fit posterior probabilities

Syntax

ScoreSVMModel = fitSVMPosterior(SVMModel)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)
ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)

ScoreSVMModel = fitSVMPosterior(___ ,Name,Value)

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(___)  

Description

ScoreSVMModel = fitSVMPosterior(SVMModel) returns ScoreSVMModel, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier SVMModel, and by cross validation using the stored predictor data (SVMModel.X) and the class labels (SVMModel.Y). The transformation function computes the posterior probability that an observation is classified into the positive class (SVMModel.Classnames(2)).

• If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2580.
• If the classes are perfectly separable, the transformation function is the step function on page 32-2580.
• In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2581. fitSVMPosterior is not appropriate for one-class learning.
• If SVMModel is a ClassificationSVM classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, SVMModel must be a ClassificationPartitionedModel classifier. SVMModel specifies the cross-validation method.

• The software stores the optimal transformation function in ScoreSVMModel.ScoreTransform.

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName) returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier SVMModel. The software estimates the score transformation function using predictor data in the table TBL and class labels TBL.ResponseVarName.

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y) returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier SVMModel. The software estimates the score transformation function using predictor data in the table TBL and class labels Y.

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y) returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier SVMModel. The software estimates the score transformation function using predictor data X and class labels Y.

ScoreSVMModel = fitSVMPosterior(___,Name,Value) uses additional options specified by one or more Name,Value pair arguments provided SVMModel is a ClassificationSVM classifier. For example, you can specify the number of folds to use in k-fold cross validation.

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(___) additionally returns the transformation function parameters (ScoreTransform) using any of the input arguments in the previous syntaxes.

Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

load fisheriris
classKeep = ~strcmp(species,'virginica');
The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).
rng(1);
CVSVMModel = fitcsvm(X,y,'CrossVal','on');

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

fitSVMPosterior does the following:

• Uses the data that the software stored in CVSVMModel to fit the transformation function
• Warns whenever the classes are separable
• Stores the step function in ScoreCVSVMModel.ScoreTransform

Display the score function type and its parameter values.

ScoreParameters

ScoreParameters = struct with fields:
    Type: 'step'
    LowerBound: -0.8431
    UpperBound: 0.6897
    PositiveClassProbability: 0.5000

ScoreParameters is a structure array with four fields:

• The score transformation function type (Type)
• The score corresponding to the negative class boundary (LowerBound)
• The score corresponding to the positive class boundary (UpperBound)
• The positive class probability (PositiveClassProbability)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.
Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the ionosphere data set.

load ionosphere

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true,...    'CrossVal','on');
ScoreTransform = CVSVMModel.ScoreTransform

ScoreTransform = 'none'

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform

ScoreTransform = @(S)sigmoid(S,-9.481576e-01,-1.218300e-01)

ScoreParameters

ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -0.9482
    Intercept: -0.1218

ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing ScoreCVSVMModel to kfoldPredict.
Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```matlab
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```matlab
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```matlab
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreCVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```matlab
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans=10×2 table
  ObservationIndex    PosteriorProbability
     6                   0.17378
```

32-2574
Input Arguments

**SVMMModel** — Trained SVM classifier
ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier, specified as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

If SVMMModel is a ClassificationSVM classifier, then you can set optional name-value pair arguments.

If SVMMModel is a CompactClassificationSVM classifier, then you must input predictor data X and class labels Y.

**TBL** — Sample data
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMMModel using sample data contained in a table, then the input data for fitSVMPosterior must also be in a table.
If you set 'Standardize',true in fitcsvm when training SVMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: table

**X — Predictor data**

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows in X must be equal.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software fits the transformation function parameter estimates using standardized data.

Data Types: double | single

**ResponseVarName — Response variable name**

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify ResponseVarName as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.Response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors
Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example: 'KFold', 8 performs 8-fold cross validation when SVMModel is a ClassificationSVM classifier.

CVPARTITION — Cross-validation partition

[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPARTITION' and a cvpartition partition object as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPARTITION'.

The crossval name-value pair argument of fitcsvm splits the data into subsets using cvpartition.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPARTITION', cvp.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.
You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1
Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'Leaveout', 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

**Output Arguments**

**ScoreSVMModel — Trained SVM classifier**

ClassificationSVM classifier | CompactClassificationSVM classifier |
ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.
The ScoreSVMModel classifier type is the same as the SVMModel classifier type.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize',true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

**ScoreTransform — Optimal score-to-posterior-probability transformation function parameters**

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field Type is:

- sigmoid, then ScoreTransform has these fields:
  - Slope — The value of $A$ in the sigmoid function on page 32-2580
  - Intercept — The value of $B$ in the sigmoid function

- step, then ScoreTransform has these fields:
  - PositiveClassProbability: the value of $\pi$ in the step function on page 32-2580. $\pi$ represents:
    - The probability that an observation is in the positive class.
    - The posterior probability that a score is in the interval $(LowerBound,UpperBound)$.

- LowerBound: the value $\max s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class PositiveClassProbability to scores. Any observation with a score less than LowerBound has posterior probability of being the positive class 0.

- UpperBound: the value $\min s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class PositiveClassProbability. Any observation with a score greater than UpperBound has posterior probability of being the positive class 1.

- constant, then ScoreTransform.PredictedClass contains the name of the class prediction.
This result is the same as `SVMMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

**Definitions**

**Sigmoid Function**

The sigmoid function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$  

If the value of the Type field of `ScoreTransform` is sigmoid, then parameters $A$ and $B$ correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

**Step Function**

The step function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \begin{cases} 
0; & s < \max_{y_k=-1} s_k \\
\pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=-1} s_k \\
1; & s_j > \min_{y_k=+1} s_k 
\end{cases}$$

where:

- $s_j$ is the score of observation $j$.
- $+1$ and $-1$ denote the positive and negative classes, respectively.
- $\pi$ is the prior probability that an observation is in the positive class.
If the value of the Type field of ScoreTransform is step, then the quantities $\max_{y_k=-1} s_k$ and $\min s_k$ correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

- This process describes one way to predict positive class posterior probabilities.

1. Train an SVM classifier by passing the data to fitcsvm. The result is a trained SVM classifier, such as SVMModel, that stores the data. The software sets the score transformation function property (SVMModel.ScoreTransformation) to none.

2. Pass the trained SVM classifier SVMModel to fitSVMPosterior or fitPosterior. The result, such as, ScoreSVMModel, is the same trained SVM classifier as SVMModel, except the software sets ScoreSVMModel.ScoreTransformation to the optimal score transformation function.

3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (ScoreSVMModel) to predict. The second column in the second output argument of predict stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

If you skip step 2, then predict returns the positive class score rather than the positive class posterior probability.
• After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to fitPosterior or fitSVMPosterior and its ScoreTransform property is not none, then the software:

• Displays a warning
• Resets the original transformation function to 'none' before estimating the new one

Introduced in R2014a
**fitted**

**Class:** GeneralizedLinearMixedModel

Fitted responses from generalized linear mixed-effects model

**Syntax**

mufit = fitted(glme)
mufit = fitted(glme,Name,Value)

**Description**

mufit = fitted(glme) returns the fitted conditional response of the generalized linear mixed-effects model glme.

mufit = fitted(glme,Name,Value) returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

**Input Arguments**

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name, Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
Conditional — Indicator for conditional response

true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Contributions from both fixed effects and random effects (conditional)</td>
</tr>
<tr>
<td>false</td>
<td>Contribution from only fixed effects (marginal)</td>
</tr>
</tbody>
</table>

To obtain fitted marginal response values, fitted computes the conditional mean of the response with the empirical Bayes predictor vector of random effects $b$ set equal to 0. For more information, see “Conditional and Marginal Response” on page 32-2587

Example: 'Conditional',false

Output Arguments

mufit — Fitted response values

$n$-by-1 vector

Fitted response values, returned as an $n$-by-1 vector, where $n$ is the number of observations.

Examples

Plot Observed Versus Fitted Values

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new
manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) $$

This corresponds to the generalized linear mixed-effects model

$$ \log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i, $$

where

- $$ \text{defects}_{ij} $$ is the number of defects observed in the batch produced by factory $$ i $$ during batch $$ j $$.
• $\mu_{ij}$ is the mean number of defects corresponding to factory $i$ (where $i = 1, 2, ..., 20$) during batch $j$ (where $j = 1, 2, ..., 5$).

• newprocess$_{ij}$, time_dev$_{ij}$, and temp_dev$_{ij}$ are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, newprocess$_{ij}$ indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• supplier_C$_{ij}$ and supplier_B$_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma^2_b)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ...
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');

Generate the fitted conditional mean values for the model.

mufit = fitted(glme);

Create a scatterplot of the observed values versus fitted values.

figure
scatter(mfr.defects,mufit)
title('Residuals versus Fitted Values')
xlabel('Fitted Values')
ylabel('Residuals')
```
Definitions

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an `n-by-p` fixed-effects design matrix `X` and an `n-by-q` random-effects design matrix `Z`. Also, suppose the
estimated \( p \)-by-1 fixed-effects vector is \( \hat{\beta} \), and the \( q \)-by-1 empirical Bayes predictor vector of random effects is \( \hat{b} \).

The fitted conditional response corresponds to the 'Conditional',true name-value pair argument, and is defined as

\[
\hat{\mu}_{\text{cond}} = g^{-1}(\hat{\eta}_{\text{ME}}),
\]

where \( \hat{\eta}_{\text{ME}} \) is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

\[
\hat{\eta}_{\text{ME}} = X\hat{\beta} + Z\hat{b} + \delta.
\]

The fitted marginal response corresponds to the 'Conditional',false name-value pair argument, and is defined as

\[
\hat{\mu}_{\text{mar}} = g^{-1}(\hat{\eta}_{\text{FE}}),
\]

where \( \hat{\eta}_{\text{FE}} \) is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

\[
\hat{\eta}_{\text{FE}} = X\hat{\beta} + \delta.
\]

fitted

**Class:** LinearMixedModel

Fitted responses from a linear mixed-effects model

**Syntax**

```matlab
yfit = fitted(lme)
yfit = fitted(lme,Name,Value)
```

**Description**

`yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response from the linear mixed-effects model `lme`.

**Input Arguments**

- `lme` — Linear mixed-effects model
  LinearMixedModel object
  Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmmatrix`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

32-2589
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Conditional — Indicator for conditional response**

*true* (default) | *false*

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

- **true**
  - Contribution from both fixed effects and random effects (conditional)

- **false**
  - Contribution from only fixed effects (marginal)

Example: 'Conditional',false

Data Types: logical

**Output Arguments**

*`yfit` — Fitted response values*

*n*-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

**Examples**

**Compute Fitted Conditional and Marginal Responses**

Load the sample data.

```
load flu
```

The *flu* dataset array has a *Date* variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).
To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate','IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Region is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, `I[MidAtl]` is the dummy variable representing the region MidAtl. For details, see “Dummy Indicator Variables” on page 2-60.

The corresponding model is

\[
y_{im} = \beta_0 + \beta_1 I[\text{MidAt}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SA}]_i
+ \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \epsilon_{im}, \quad m = 1, 2, ..., 52,
\]

where \(y_{im}\) is the observation \(i\) for level \(m\) of grouping variable Date, \(\beta_j, j = 0, 1, ..., 8\), are the fixed-effects coefficients, with \(\beta_0\) being the coefficient for region NE. \(b_{0m}\) is the random effect for level \(m\) of the grouping variable Date, and \(\epsilon_{im}\) is the observation error for observation \(i\). The random effect has the prior distribution, \(b_{0m} \sim N(0, \sigma^2)\) and the error term has the distribution, \(\epsilon_{im} \sim N(0, \sigma^2)\).

```matlab
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)');
lme =
Linear mixed-effects model fit by ML
```

Upper
The $P$-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions WNCentral and ESCentral are significantly different relative to the flu rates in region NE.

The confidence limits for the standard deviation of the random-effects term, $\sigma_b$, do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the compare method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region WNCentral in week 10/9/2005 is

$$\hat{y}_{\text{WNCentral},10/9/2005} = \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005}$$

$$= 1.2233 + 0.23687 - 0.1718$$

$$= 1.28837.$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```matlab
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```matlab
y_hat = 1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for $\beta_0$ and `beta(4)` corresponds to the estimate for $\beta_3$. You can simply display the fitted value using the fitted method.

```matlab
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

32-2593
The estimated marginal response for region WNCentral in week 10/9/2005 is

\[\hat{y}_{\text{WNCentral}, 10/9/2005} = \beta_0 + \beta_3 I[\text{WNCentral}]\]
\[= 1.2233 + 0.23687\]
\[= 1.46017.\]

Compute the fitted marginal response.

```matlab
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

ans = 1.4602

---

**Plot Residuals vs. Fitted Values**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'));
weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```matlab
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```matlab
F = fitted(lme);
R = residuals(lme);
```
Plot the residuals versus the fitted values.

```matlab
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```matlab
figure()
gscatter(F,R,Program)
```
Definitions

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, lme, has an $n$-by-$p$ fixed-effects design matrix $X$ and an $n$-by-$q$ random-effects design matrix $Z$. Also, suppose the $p$-by-1 estimated fixed-
effects vector is $\hat{\beta}$, and the $q$-by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is $\hat{b}$.

The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

beta = fixedEffects(glme)
[beta,betanames] = fixedEffects(glme)
[beta,betanames,stats] = fixedEffects(glme)
[___] = fixedEffects(glme,Name,Value)

Description

beta = fixedEffects(glme) returns the estimated fixed-effects coefficients, beta, of the generalized linear mixed-effects model glme.

[beta,betanames] = fixedEffects(glme) also returns the names of estimated fixed-effects coefficients in betanames. Each name corresponds to a fixed-effects coefficient in beta.

[beta,betanames,stats] = fixedEffects(glme) also returns a table of statistics, stats, related to the estimated fixed-effects coefficients of glme.

[___] = fixedEffects(glme,Name,Value) returns any of the output arguments in previous syntaxes using additional options specified by one or more Name,Value pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the t-statistic.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object
Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Alpha — Confidence level**

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value $\alpha$, the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

**DFMethod — Method for computing approximate degrees of freedom**

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'residual'</code></td>
<td>The degrees of freedom value is assumed to be constant and equal to $n - p$, where $n$ is the number of observations and $p$ is the number of fixed effects.</td>
</tr>
<tr>
<td><code>'none'</code></td>
<td>The degrees of freedom is set to infinity.</td>
</tr>
</tbody>
</table>

Example: `'DFMethod','none'`
Output Arguments

**beta — Estimated fixed-effects coefficients**
vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

**betanames — Names of fixed-effects coefficients**
table

Names of fixed-effects coefficients in `beta`, returned as a table.

**stats — Fixed-effects estimates and related statistics**
dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

<table>
<thead>
<tr>
<th>Column Name</th>

<td>Upper</td>
<td>Upper limit of a 95% confidence interval for the fixed-effects coefficient</td>
</tr>
</tbody>
</table>

When fitting a model using `fitglme` and one of the maximum likelihood fit methods (‘Laplace’ or ‘ApproximateLaplace’), if you specify the ‘CovarianceMethod’ name-value pair argument as ‘conditional’, then `SE` does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify ‘CovarianceMethod’ as ‘JointHessian’.
When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

**Examples**

**Estimate Fixed-Effects Coefficients**

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the
coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log(\mu_{ij}) = \beta_0 + \beta_1\text{newprocess}_{ij} + \beta_2\text{time_dev}_{ij} + \beta_3\text{temp_dev}_{ij} + \beta_4\text{supplier}_C_{ij} + \beta_5\text{supplier}_B_{ij} + b_i, \]

where

- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
- \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, \ldots, 20 \)) during batch \( j \) (where \( j = 1, 2, \ldots, 5 \)).
- \( \text{newprocess}_{ij}, \text{time_dev}_{ij}, \text{and temp_dev}_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, \( \text{newprocess}_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.
- \( \text{supplier}_C_{ij} \) and \( \text{supplier}_B_{ij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).
- \( b_i \sim N(0, \sigma_b^2) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ... 'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```matlab
[beta,betanames,stats] = fixedEffects(glme);
stats
```
stats =

</tbody>
</table>

The returned results indicate, for example, that the estimated coefficient for temp_dev is \(-0.28317\). Its large \(P\)-value, 0.76907, indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries Lower and Upper indicate that the 95% confidence interval for the coefficient for temp_dev is \([-2.1926, 1.6263]\). This interval contains 0, which supports the conclusion that temp_dev is not statistically significant at the 5% significance level.

[beta,betanames] = fixedEffects(lme) also returns the names of estimated fixed-effects coefficients in betanames. Each name corresponds to a fixed-effects coefficient in beta.

[beta,betanames,stats] = fixedEffects(lme) also returns the estimated fixed-effects coefficients of the linear mixed-effects model lme and related statistics in stats.

[beta,betanames,stats] = fixedEffects(lme,Name,Value) also returns the estimated fixed-effects coefficients of the linear mixed-effects model lme and related statistics with additional options specified by one or more Name,Value pair arguments.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmmatrix.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Alpha — Confidence level**
0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

**DFMethod — Method for computing approximate degrees of freedom**

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for the t-statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

- **'residual'**
  
  Default. The degrees of freedom are assumed to be constant and equal to n – p, where n is the number of observations and p is the number of fixed effects.

- **'satterthwaite'**
  
  Satterthwaite approximation.

- **'none'**
  
  All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod','satterthwaite'
Output Arguments

**beta — Fixed-effects coefficients estimates**

*vector*

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

**betanames — Names of fixed-effects coefficients**

*table*

Names of fixed-effects coefficients in `beta`, returned as a table.

**stats — Fixed-effects estimates and related statistics**

*dataset array*

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

**Display Fixed-Effects Coefficient Estimates and Names**

Load the sample data.
load(fullfile(matlabroot,'examples','stats','weight.mat'));

The data set weight contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define Subject and Program as categorical variables.

tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

[beta,betanames] = fixedEffects(lme)

Compute Coefficient Estimates and Related Statistics

Load the sample data.

load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

tbl = table(Acceleration,Horsepower,Model_Year,MPG);

Fit the model.

lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');

Compute the fixed-effects coefficients estimates and related statistics.

[~,~,stats] = fixedEffects(lme)

stats =
  Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
    Name                  Estimate    SE          tStat    DF   pValue

-0.18382    -0.15527

The small \( p \)-values (under \( p \)Value) indicate that all fixed-effects coefficients are significant.
Load the sample data.

load(fullfile(matlabroot,'examples','stats','shift.mat'));

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

[~,~,stats] = fixedEffects(lme,'alpha',0.01)

stats =

Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01

LinearMixedModel | coefCI | coefTest | fitlme | randomEffects
**fpdf**

*F* probability density function

**Syntax**

\[ Y = \text{fpdf}(X, V1, V2) \]

**Description**

\[ Y = \text{fpdf}(X, V1, V2) \] computes the *F* pdf at each of the values in *X* using the corresponding numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *X*, *V1*, and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. *V1* and *V2* parameters must contain real positive values, and the values in *X* must lie on the interval [0, Inf].

The probability density function for the *F* distribution is

\[
y = f(x | v_1, v_2) = \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{v_1/2} x^{-v_2/2} \left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{-\frac{v_1+v_2}{2}}
\]

**Examples**

\[
y = \text{fpdf}(1:6, 2, 2)
\]
\[
y =
\begin{array}{cccccccc}
0.2500 & 0.1111 & 0.0625 & 0.0400 & 0.0278 & 0.0204
\end{array}
\]

\[
z = \text{fpdf}(3, 5:10, 5:10)
\]
\[
z =
\begin{array}{cccccccc}
0.0689 & 0.0659 & 0.0620 & 0.0577 & 0.0532 & 0.0487
\end{array}

Introduced before R2006a
fracfact

Fractional factorial design

Syntax

X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)

Description

X = fracfact(gen) creates the two-level fractional factorial design defined by the generator gen.

[X,conf] = fracfact(gen) returns a cell array of character vectors containing the confounding pattern for the design.

[X,conf] = fracfact(gen,Name,Value) creates a fractional factorial designs with additional options specified by one or more Name,Value pair arguments.

Input Arguments

gen

Either a string array or cell array of character vectors where each element contains one “word,” or a character array or string scalar consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents value 1, 'b' represents value 2, ..., 'A' represents value 27, ..., 'Z' represents value 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a 2^K full-factorial design. K is the number of letters of the alphabet in gen.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

FactorNames

String array or cell array specifying the name for each factor.

Default: {'X1','X2',...}

MaxInt

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- N = 2^K, where K is the number of letters of the alphabet in gen.
- P is the number of words in gen.

Because X is a two-level design, the components of X are ±1. For the meaning of X, see “Fractional Factorial Designs” on page 27-5.

conf

Cell array of character vectors containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:
\[ x = \text{fracfact('a b c abc')} \]

\[
x =
\begin{bmatrix}
-1 & -1 & -1 & -1 \\
-1 & -1 & 1 & 1 \\
-1 & 1 & -1 & 1 \\
-1 & 1 & 1 & -1 \\
1 & -1 & -1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 \\
1 & 1 & 1 & 1
\end{bmatrix}
\]

Find generators for a six-factor design that uses four factors and achieves resolution IV using \text{fracfactgen}. Use the result to specify the design:

\[
generators = \text{fracfactgen('a b c d e f',4,4)} \]

\[
generators =
\begin{bmatrix}
'a' \\
'b' \\
'c' \\
'd' \\
'bcd' \\
'acd'
\end{bmatrix}
\]

\[
x = \text{fracfact(generators)}
\]

\[
x =
\begin{bmatrix}
-1 & -1 & -1 & -1 & -1 & -1 \\
-1 & -1 & -1 & 1 & 1 & 1 \\
-1 & -1 & 1 & -1 & 1 & 1 \\
-1 & -1 & 1 & 1 & -1 & -1 \\
-1 & 1 & -1 & -1 & 1 & -1 \\
-1 & 1 & -1 & 1 & -1 & 1 \\
-1 & 1 & 1 & -1 & -1 & 1 \\
-1 & 1 & 1 & 1 & -1 & -1 \\
1 & -1 & -1 & -1 & -1 & 1 \\
1 & -1 & -1 & 1 & 1 & -1 \\
1 & -1 & 1 & -1 & 1 & -1 \\
1 & -1 & 1 & 1 & -1 & 1 \\
1 & 1 & -1 & -1 & 1 & 1 \\
1 & 1 & -1 & 1 & -1 & -1 \\
1 & 1 & 1 & -1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]

Topics

“Fractional Factorial Designs” on page 27-5

Introduced before R2006a
fracfactgen

Fractional factorial design generators

Syntax

generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)

Description

generators = fracfactgen(terms) uses the Franklin-Bailey algorithm to find
generators for the smallest two-level fractional-factorial design for estimating linear
model terms specified by terms. terms is a character vector or string scalar consisting of
words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a'-'z'
for the first 26 factors, and, if necessary, 'A'-'Z' for the remaining factors. For example,
terms = 'a b c ab ac'. Single-letter words indicate main effects to be estimated;
multiple-letter words indicate interactions. Alternatively, terms is an m-by-n matrix of 0s
and 1s where m is the number of model terms to be estimated and n is the number of
factors. For example, if terms contains rows [0 1 0 0] and [1 0 0 1], then the factor
b and the interaction between factors a and d are included in the model. generators is
a cell array of character vectors with one generator per cell. Pass generators to
fracfact to produce the fractional-factorial design and corresponding confounding
pattern.

generators = fracfactgen(terms,k) returns generators for a two-level fractional-
factorial design with 2^k-runs, if possible. If k is [], fracfactgen finds the smallest
design.

generators = fracfactgen(terms,k,R) finds a design with resolution R, if possible.
The default resolution is 3.

A design of resolution R is one in which no n-factor interaction is confounded with any
other effect containing less than R - n factors. Thus a resolution III design does not
confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

generators = fracfactgen(terms,k,R,basic) also accepts a vector basic specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in terms.

**Examples**

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

generators = fracfactgen('a b c d',3,4)

```
generators =
'a'
'b'
'c'
'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dF =
-1 -1 -1 -1
-1 -1 1  1
-1  1 -1  1
-1  1  1 -1
  1 -1 -1  1
  1 -1  1 -1
  1  1 -1 -1
  1  1  1  1
confounding =
```

32-2618
The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

“Fractional Factorial Designs” on page 27-5

Introduced in R2006a
friedman

Friedman’s test

Syntax

p = friedman(x,reps)
p = friedman(x,reps,displayopt)
[p,tbl] = friedman(__)
[p,tbl,stats] = friedman(__)

Description

p = friedman(x,reps) returns the p-value for the nonparametric Friedman's test to compare column effects in a two-way layout. friedman tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

p = friedman(x,reps,displayopt) enables the ANOVA table display when displayopt is 'on' (default) and suppresses the display when displayopt is 'off'.

[p,tbl] = friedman(__) returns the ANOVA table (including column and row labels) in cell array tbl.

[p,tbl,stats] = friedman(__) also returns a structure stats that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.
load popcorn
popcorn

popcorn = 6×3

5.5000  4.5000  3.5000
5.5000  4.5000  4.0000
6.0000  4.0000  3.0000
6.5000  5.0000  4.0000
7.0000  5.5000  5.0000
7.0000  5.0000  4.5000

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix popcorn are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

p = friedman(popcorn,3)
The small value of $p = 0.001$ indicates the popcorn brand affects the yield of popcorn.

### Input Arguments

$x$ — Sample data matrix

Sample data for the hypothesis test, specified as a matrix. The columns of $x$ represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more
than one observation for each combination of factors, input reps indicates the number of replicates in each “cell,” which must be constant.

Data Types: single | double

**reps — Number of replicates per cell**

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: single | double

**displayopt — ANOVA table display option**

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If displayopt is 'on', then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if reps is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the Edit menu.
Output Arguments

p — \( p \)-value
scalar value in the range \([0, 1]\)

\( p \)-value of the test, returned as a scalar value in the range \([0, 1]\). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \( p \) cast doubt on the validity of the null hypothesis.

tbl — ANOVA table
cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the \( p \) value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the Edit menu.

stats — Test data
structure

Test data, returned as a structure. friedman evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the multcompare function to perform such tests by supplying stats as the input value.
Definitions

Friedman’s Test

Friedman’s test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman’s test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input reps indicates the number of replicates in each “cell,” which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (reps=2). The subscripts indicate row, column, and replicate, respectively.

\[
\begin{bmatrix}
  x_{111} & x_{121} & x_{131} \\
  x_{112} & x_{122} & x_{132} \\
  x_{211} & x_{221} & x_{231} \\
  x_{212} & x_{222} & x_{232} \\
\end{bmatrix}
\]

Friedman’s test assumes a model of the form

\[x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}\]

where \(\mu\) is an overall location parameter, \(\alpha_i\) represents the column effect, \(\beta_j\) represents the row effect, and \(\varepsilon_{ijk}\) represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The \(p\) that \texttt{friedman} returns is the \(p\) value for the null hypothesis that \(\alpha_i = 0\). If the \(p\) value is near zero, this casts doubt on the null hypothesis. A sufficiently small \(p\) value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical \(p\) value to determine whether a result is “statistically significant” is left
to the researcher. It is common to declare a result significant if the $p$ value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in $X$:

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

**frnd**

$F$ random numbers

**Syntax**

\[
R = \text{frnd}(V1,V2) \\
R = \text{frnd}(V1,V2,m,n,...) \\
R = \text{frnd}(V1,V2,[m,n,...])
\]

**Description**

\( R = \text{frnd}(V1,V2) \) generates random numbers from the $F$ distribution with numerator degrees of freedom $V1$ and denominator degrees of freedom $V2$. $V1$ and $V2$ can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for $V1$ or $V2$ is expanded to a constant array with the same dimensions as the other input. $V1$ and $V2$ parameters must contain real positive values.

\( R = \text{frnd}(V1,V2,m,n,...) \) or \( R = \text{frnd}(V1,V2,[m,n,...]) \) generates an $m$-by-$n$-by-... array containing random numbers from the $F$ distribution with parameters $V1$ and $V2$. $V1$ and $V2$ can each be scalars or arrays of the same size as $R$.

**Examples**

\[
n1 = \text{frnd}(1:6,1:6) \\
n1 =
  \begin{bmatrix}

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

Topics
“F Distribution” on page B-42

Introduced before R2006a
**fscnca**

Feature selection using neighborhood component analysis for classification

**Syntax**

```matlab
mdl = fscnca(X,Y)
mdl = fscnca(X,Y,Name,Value)
```

**Description**

`mdl = fscnca(X,Y)` performs feature selection for classification using the predictors in `X` and responses in `Y`.

`fscnca` learns the feature weights by using a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fscnca(X,Y,Name,Value)` performs feature selection for classification with additional options specified by one or more name-value pair arguments.

**Examples**

**Detect Relevant Features in Data Using NCA for Classification**

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```matlab
rng(0,'twister'); \% For reproducibility
N = 100;
X = rand(N,20);
y = -ones(N,1);
y(X(:,3).*X(:,9)./X(:,15) < 0.4) = 1;
```

Fit the neighborhood component analysis model for classification.

```matlab
mdl = fscnca(X,y,'Solver','sgd','Verbose',1);
```
### Tuning initial learning rate

- **NumTuningIterations** = 20, **TuningSubsetSize** = 100

</tr>
</tbody>
</table>

Two norm of the final step = 2.946e-01
Relative two norm of the final step = 6.588e-02, TolX = 1.000e-06
EXIT: Iteration or pass limit reached.

Plot the selected features. The weights of the irrelevant features should be close to zero.
```matlab
figure()
plot(mdl.FeatureWeights,'ro')
grid on
xlabel('Feature index')
ylabel('Feature weight')
```

The code above plots the feature weights against their indices. The `fscnca` function correctly detects the relevant features.
Identify Relevant Features for Classification

Load sample data

```matlab
load ovariancancer;
whos
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>grp</td>
<td>216x1</td>
<td>26784</td>
<td>cell</td>
<td></td>
</tr>
<tr>
<td>obs</td>
<td>216x4000</td>
<td>3456000</td>
<td>single</td>
<td></td>
</tr>
</tbody>
</table>

This example uses the high-resolution ovarian cancer data set that was generated using the WCX2 protein array. The data is from the FDA-NCI Clinical Proteomics Program Databank. After some preprocessing steps, the data set has two variables: `obs` and `grp`. The `obs` variable consists 216 observations with 4000 features. Each element in `grp` defines the group to which the corresponding row of `obs` belongs.

Divide data into training and test sets

Use `cvpartition` to divide data into a training set of size 160 and a test set of size 56. Both the training set and the test set have roughly the same group proportions as in `grp`.

```matlab
rng(1); % For reproducibility
cvp = cvpartition(grp,'holdout',56)
Xtrain = obs(cvp.training,:);
ytrain = grp(cvp.training,:);
Xtest  = obs(cvp.test,:);
ytest  = grp(cvp.test,:);
```

```matlab
cvp =

Hold-out cross validation partition
NumObservations: 216
NumTestSets: 1
TrainSize: 160
TestSize: 56
```

Determine if feature selection is necessary

Compute generalization error without fitting.
nca = fscnca(Xtrain,ytrain,'FitMethod','none');
L = loss(nca,Xtest,ytest)

L =

0.0893

This option computes the generalization error of the neighborhood component analysis (NCA) feature selection model using the initial feature weights (in this case the default feature weights) provided in fscnca.

Fit NCA without regularization parameter (Lambda = 0)

nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Lambda',0,...
          'Solver','sgd','Standardize',true);
L = loss(nca,Xtest,ytest)

L =

0.0714

The improvement on the loss value suggests that feature selection is a good idea. Tuning the \( \lambda \) value usually improves the results.

**Tune the regularization parameter for NCA using five-fold cross-validation**

Tuning \( \lambda \) means finding the \( \lambda \) value that produces the minimum classification loss. To tune \( \lambda \) using cross-validation:

1. Partition the training data into five folds and extract the number of validation (test) sets. For each fold, cvpartition assigns four-fifths of the data as a training set, and one-fifth of the data as a test set.

   cvp = cvpartition(ytrain,'kfold',5);
   numvalidsets = cvp.NumTestSets;

Assign \( \lambda \) values and create an array to store the loss function values.

   n = length(ytrain);
   lambdavals = linspace(0,20,20)/n;
   lossvals = zeros(length(lambdavals),numvalidsets);
2. Train the NCA model for each \( \lambda \) value, using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this process for all folds and all \( \lambda \) values.

```matlab
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fscnca(X,y,'FitMethod','exact', ...
                     'Solver','sgd','Lambda',lambdavals(i), ...
                     'IterationLimit',30,'GradientTolerance',1e-4, ...
                     'Standardize',true);

        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','classiferror');
    end
end
```

Compute the average loss obtained from the folds for each \( \lambda \) value.

```matlab
meanloss = mean(lossvals,2);
```

Plot the average loss values versus the \( \lambda \) values.

```matlab
figure()
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```
Find the best lambda value that corresponds to the minimum average loss.

\[
[~, idx] = \min(\text{meanloss}) \quad \text{Find the index}
\]
\[
\text{bestlambda} = \text{lambdavals}(idx) \quad \text{Find the best lambda value}
\]
\[
\text{bestloss} = \text{meanloss}(idx)
\]

\[
idx = 2
\]

\[
\text{bestlambda} = fscnca
\]
bestloss = 0.0250

**Fit the nca model on all data using best $\lambda$ and plot the feature weights**

Use the solver lbfgs and standardize the predictor values.

```matlab
c = fscnca(Xtrain,ytrain,'FitMethod','exact','Solver','sgd',...
    'Lambda',bestlambda,'Standardize',true,'Verbose',1);
```

```

\[ L = \]

single

0

### Input Arguments

**X** — Predictor variable values

\( n \)-by-\( p \) matrix

Predictor variable values, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables.

Data Types: single | double

**Y** — Class labels

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length \( n \) | character matrix with \( n \) rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length \( n \), or character matrix with \( n \) rows, where \( n \) is the number of observations. Element \( i \) or row \( i \) of \( Y \) is the class label corresponding to row \( i \) of \( X \) (observation \( i \)).

Data Types: single | double | logical | char | string | cell | categorical

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**,** Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name**1,** Value**1,** ...,** Name**N,** Value**N.
Example: 'Solver','sgd','Weights',W,'Lambda',0.0003 specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector W, and sets the regularization parameter at 0.0003.

Fitting Options

FitMethod — Method for fitting the model
'exact' (default) | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following:

• 'exact' — Performs fitting using all of the data.
• 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to fscnca.
• 'average' — Divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the NumPartitions name-value pair argument.

Example: 'FitMethod','none'

NumPartitions — Number of partitions
max(2,min(10,n)) (default) | integer between 2 and n

Number of partitions to split the data for using with 'FitMethod','average' option, specified as the comma-separated pair consisting of 'NumPartitions' and an integer value between 2 and n, where n is the number of observations.

Example: 'NumPartitions',15

Data Types: double | single

Lambda — Regularization parameter
1/n (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of 'Lambda' and a nonnegative scalar.

As the number of observations n increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Identify Relevant Features for Classification” on page 32-2631 and “Tune Regularization Parameter to Detect Features Using NCA for Classification” to learn how to tune the regularization parameter.
Example: 'Lambda', 0.002
Data Types: double | single

**LengthScale — Width of the kernel**

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of 'LengthScale' and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using 'Standardize', true and setting 'LengthScale', 1.

Example: 'LengthScale', 1.5
Data Types: double | single

**InitialFeatureWeights — Initial feature weights**

ones(p, 1) (default) | p-by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p-by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using rand(p, 1) can give better quality solutions.

Data Types: double | single

**Weights — Observation weights**

n-by-1 vector of 1s (default) | n-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: double | single

**Prior — Prior probabilities for each class**

'empirical' (default) | 'uniform' | structure
Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'empirical' — fscnca obtains the prior class probabilities from class frequencies.
- 'uniform' — fscnca sets all class probabilities equal.
- Structure with two fields:
  - ClassProbs — Vector of class probabilities. If these are numeric values with a total greater than 1, fscnca normalizes them to add up to 1.
  - ClassNames — Class names corresponding to the class probabilities in ClassProbs.

Example: 'Prior','uniform'

**Standardize — Indicator for standardizing predictor data**

false (default) | true

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either false or true. For more information, see “Impact of Standardization” on page 15-127.

Example: 'Standardize',true

Data Types: logical

**Verbose — Verbosity level indicator**

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose',1

Data Types: double | single
**Solver — Solver type**
'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for \( n \leq 1000 \), and 'sgd' for \( n > 1000 \).
Example: 'solver','minibatch-lbfgs'

**LossFunction — Loss function**
'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following.

- 'classiferror' — Misclassification error

\[
l(y_i, y_j) = \begin{cases} 
1 & \text{if } y_i \neq y_j, \\
0 & \text{otherwise.} 
\end{cases}
\]

- @lossfun — Custom loss function handle. A loss function has this form.

```matlab
function L = lossfun(Yu,Yv)
% calculation of loss
...
```

Yu is a \( u \)-by-1 vector and Yv is a \( v \)-by-1 vector. L is a \( u \)-by-\( v \) matrix of loss values such that \( L(i,j) \) is the loss value for \( Yu(i) \) and \( Yv(j) \).

The objective function for minimization includes the loss function \( l(y_i, y_j) \) as follows:

\[
f(w) = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{p} w_r^2,
\]
where \( w \) is the feature weight vector, \( n \) is the number of observations, and \( p \) is the number of predictor variables. \( p_{ij} \) is the probability that \( x_j \) is the reference point for \( x_i \). For details, see “NCA Feature Selection for Classification” on page 15-121.

Example: 'LossFunction',@lossfun

**CacheSize — Memory size**

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize',1500MB

Data Types: double | single

**LBFGS Options**

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20

Data Types: double | single

**InitialStepSize — Initial step size**

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

**LineSearchMethod — Line search method**

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:
• 'weakwolfe' — Weak Wolfe line search
• 'strongwolfe' — Strong Wolfe line search
• 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

MaxLineSearchIterations — Maximum number of line search iterations
20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25

Data Types: double | single

GradientTolerance — Relative convergence tolerance
1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar.

Example: 'GradientTolerance',0.000002

Data Types: double | single

SGD Options

InitialLearningRate — Initial learning rate for 'sgd' solver
'auto' (default) | positive real scalar

Initial learning rate for the 'sgd' solver, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive real scalar.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

The default 'auto' means that the initial learning rate is determined using experiments on small subsets of data. Use the NumTuningIterations name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the TuningSubsetSize name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.
For solver type 'minibatch-lbfgs', you can set 'InitialLearningRate' to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the Iteration versus the Objective values saved in the mdl.FitInfo property.

You can use the refit method with 'InitialFeatureWeights' equal to mdl.FeatureWeights to start from the current solution and run additional iterations.

Example: 'InitialLearningRate', 0.9
Data Types: double | single

**MiniBatchSize — Number of observations to use in each batch for the 'sgd' solver**

*min(10,n) (default) | positive integer value from 1 to n*

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n.

Example: 'MiniBatchSize', 25
Data Types: double | single

**PassLimit — Maximum number of passes for solver 'sgd'**

*5 (default) | positive integer*

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit', 10
Data Types: double | single

**NumPrint — Frequency of batches for displaying convergence summary**

*10 (default) | positive integer value*

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-
batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5
Data Types: double | single

**NumTuningIterations — Number of tuning iterations**

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations',15
Data Types: double | single

**TuningSubsetSize — Number of observations to use for tuning initial learning rate**

min(100,n) (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to n. This option is valid only for 'InitialLearningRate','auto'.

Example: 'TuningSubsetSize',25
Data Types: double | single

**SGD or LBFGS Options**

**IterationLimit — Maximum number of iterations**

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: 'IterationLimit',250
Data Types: double | single
StepTolerance — Convergence tolerance on the step size
1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance',0.000005

Data Types: double | single

Mini-Batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step
10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for classification
FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

FeatureSelectionNCAClassification | loss | predict | refit

Topics

“Tune Regularization Parameter to Detect Features Using NCA for Classification”
“Neighborhood Component Analysis (NCA) Feature Selection” on page 15-121

Introduced in R2016b
fsrnca

Feature selection using neighborhood component analysis for regression

Syntax

mdl = fsrnca(X,Y)
mdl = fsrnca(X,Y,Name,Value)

Description

mdl = fsrnca(X,Y) performs feature selection for regression using the predictors in X and responses in Y.

fsrnca learns the feature weights by a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

mdl = fsrnca(X,Y,Name,Value) performs feature selection for regression with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Regression

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = 1 + X(:,3)*5 + sin(X(:,9)./X(:,15)) + 0.25*randn(N,1));

Fit the neighborhood component analysis model for regression.

mdl = fsrnca(X,y,'Verbose',1,'Lambda',0.5/N);
Plot the selected features. The weights of the irrelevant features should be close to zero.

```matlab
figure()
plot(mdl.FeatureWeights,'ro')
```
grid on
xlabel('Feature index')
ylabel('Feature weight')

fsrnca correctly detects the relevant predictors for this response.

Tune Regularization Parameter in NCA for Regression

Load the sample data.

load robotarm.mat
The robotarm (pumadyn32nm) dataset is created using a robot arm simulator with 7168 training observations and 1024 test observations with 32 features [1][2]. This is a preprocessed version of the original data set. The data are preprocessed by subtracting off a linear regression fit, followed by normalization of all features to unit variance.

Perform neighborhood component analysis (NCA) feature selection for regression with the default $\lambda$ (regularization parameter) value.

```matlab
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...  
    'Solver','lbfgs');
```

Plot the selected values.

```matlab
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```
More than half of the feature weights are nonzero. Compute the loss using the test set as a measure of the performance by using the selected features.

\[ L = \text{loss(nca,Xtest,ytest)} \]

\[ L = 0.0837 \]

Try improving the performance. Tune the regularization parameter \( \lambda \) for feature selection using five-fold cross-validation. Tuning \( \lambda \) means finding the \( \lambda \) value that produces the minimum regression loss. To tune \( \lambda \) using cross-validation:
1. Partition the data into five folds. For each fold, \texttt{cvpartition} assigns 4/5th of the data as a training set, and 1/5th of the data as a test set.

```matlab
rng(1) % For reproducibility
n = length(ytrain);
cvp = cvpartition(length(ytrain),'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign the \( \lambda \) values for the search. Multiplying response values by a constant increases the loss function term by a factor of the constant. Therefore, including the \( \text{std}(ytrain) \) factor in the \( \lambda \) values balances the default loss function ('mad', mean absolute deviation) term and the regularization term in the objective function. In this example, the \( \text{std}(ytrain) \) factor is one because the loaded sample data is a preprocessed version of the original data set.

```matlab
lambdavals = linspace(0,50,20)*std(ytrain)/n;
```

Create an array to store the loss values.

```matlab
lossvals = zeros(length(lambdavals),numvalidsets);
```

2. Train the NCA model for each \( \lambda \) value, using the training set in each fold.

3. Compute the regression loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this for each \( \lambda \) value and each fold.

```matlab
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y,'FitMethod','exact', ... 
                      'Solver','minibatch-lbfgs','Lambda',lambdavals(i), ... 
                      'GradientTolerance',1e-4,'IterationLimit',30);
        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','mse');
    end
end
```
Compute the average loss obtained from the folds for each $\lambda$ value.

$$\text{meanloss} = \text{mean(lossvals,2)};$$

Plot the mean loss versus the $\lambda$ values.

```matlab
figure
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```
Find the $\lambda$ value that gives the minimum loss value.

$$[~,\text{idx}] = \min(\text{meanloss})$$

bestlambda = lambdavals(idx)
bestloss = meanloss(idx)

idx =

17

bestlambda =
Fit the NCA feature selection model for regression using the best λ value.

```matlab
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
    'Solver','lbfgs','Lambda',bestlambda);
```

Plot the selected features.

```matlab
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```
Most of the feature weights are zero. \texttt{fsrnca} identifies the four most relevant features.

Compute the loss for the test set.

\[
\text{L} = \text{loss}(\text{nca}, \text{Xtest}, \text{ytest})
\]

\[
\text{L} = 0.0571
\]
Tuning the regularization parameter, \( \lambda \), eliminated more of the irrelevant features and improved the performance.

**Compare NCA and ARD Feature Selection**

This example uses the Abalone data [3] [4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height', ...    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
```

```
ans =
7×9 table
   Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRings
     ___    ______    ________    ______    _______    _______    _______    ________    __________
     'M'    0.455     0.365       0.095      0.514     0.2245      0.101      0.15       15
     'M'     0.35     0.265        0.09     0.2255     0.0995     0.0485      0.07        7
     'F'     0.53      0.42       0.135      0.677     0.2565     0.1415      0.33       20
     'M'     0.44     0.365       0.125      0.516     0.2155      0.114     0.155       10
     'I'     0.33     0.255        0.08      0.205     0.0895     0.0395     0.055        7
     'I'    0.425       0.3       0.095     0.3515      0.141     0.0775      0.12        8
     'F'     0.53     0.415        0.15     0.7775      0.237     0.1415      0.33
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, the number of shell rings, shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Prepare the predictor and response variables for `fsrnca`. The last column of `tbl` contains the number of shell rings, which is the response variable. The first predictor variable, sex, is categorical. You must create dummy variables.
y = table2array(tbl(:,end));
X(:,1:3) = dummyvar(categorical(tbl.Sex));
X = [X,table2array(tbl(:,2:end-1))];

Use four-fold cross-validation to tune the regularization parameter in the NCA model. First partition the data into four folds.

rng('default') % For reproducibility
n = length(y);
cvp = cvpartition(n,'kfold',4);
numtestsets = cvp.NumTestSets;

cvpartition divides the data into four partitions (folds). In each fold, about three-fourths of the data is assigned as a training set and one-fourth is assigned as a test set.

Generate a variety of λ (regularization parameter) values for fitting the model to determine the best λ value. Create a vector to collect the loss values from each fit.

lambdavals = linspace(0,25,20)*std(y)/n;
lossvals = zeros(length(lambdavals),numtestsets);

The rows of lossvals corresponds to the λ values and the columns correspond to the folds.

Fit the NCA model for regression using fsrnca to the data from each fold using each λ value. Compute the loss for each model using the test data from each fold.

for i = 1:length(lambdavals)
    for k = 1:numtestsets
        Xtrain = X(cvp.training(k),:);
        ytrain = y(cvp.training(k),:);
        Xtest = X(cvp.test(k),:);
        ytest = y(cvp.test(k),:);

        nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
                     'Solver','lbfgs','Lambda',lambdavals(i),'Standardize',true);

        lossvals(i,k) = loss(nca,Xtest,ytest,'LossFunction','mse');
    end
end

Compute the average loss for the folds, that is, compute the mean in the second dimension of lossvals.

meanloss = mean(lossvals,2);
Plot the $\lambda$ values versus the mean loss from the four folds.

```matlab
figure
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```

Find the $\lambda$ value that minimizes the mean loss.

```matlab
[~,idx] = min(meanloss);
bestlambda = lambdavals(idx)
```

```
bestlambda = 32
```

32-2664
0.0071

Compute the best loss value.

bestloss = meanloss(idx)

bestloss =

4.7799

Fit the NCA model on all of the data using the best $\lambda$ value.

nca = fsrnca(X,y,'FitMethod','exact','Solver','lbfgs', ...  
    'Verbose',1,'Lambda',bestlambda,'Standardize',true);

Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
<table>

Compute the regression loss on the training data (resubstitution loss) for the trained model.

L = resubLoss(gprMdl)

L =

    4.0306
The smallest cross-validated loss using `fsrnca` is comparable to the loss obtained using a GPR model with an ARD kernel.

**Input Arguments**

\( X \) — **Predictor variable values**

\( n \)-by-\( p \) matrix

Predictor variable values, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables.

Data Types: `single` | `double`

\( Y \) — **Response values**

numeric real vector of length \( n \)

Response values, specified as a numeric real vector of length \( n \), where \( n \) is the number of observations.

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','sgd','Weights',W,'Lambda',0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector \( W \), and sets the regularization parameter at 0.0003.

**Fitting Options**

**FitMethod** — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.
• 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to fsrnca.
• 'average' — Divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the NumPartitions name-value pair argument.

Example: 'FitMethod','none'

NumPartitions — Number of partitions
max(2,min(10,n)) (default) | integer between 2 and n

Number of partitions to split the data for using with 'FitMethod','average' option, specified as the comma-separated pair consisting of 'NumPartitions' and an integer value between 2 and n, where n is the number of observations.

Example: 'NumPartitions',15
Data Types: double | single

Lambda — Regularization parameter
1/n (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of 'Lambda' and a nonnegative scalar.

As the number of observations n increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Tune Regularization Parameter in NCA for Regression” on page 32-2654 to learn how to tune the regularization parameter.

Example: 'Lambda',0.002
Data Types: double | single

LengthScale — Width of the kernel
1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of 'LengthScale' and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using 'Standardize',true and setting 'LengthScale',1.

Example: 'LengthScale',1.5
Data Types: double | single

**InitialFeatureWeights — Initial feature weights**

*ones(p,1)* (default) | p-by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p-by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using *rand(p,1)* can give better quality solutions.

Data Types: double | single

**Weights — Observation weights**

n-by-1 vector of 1s (default) | n-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: double | single

**Standardize — Indicator for standardizing predictor data**

false (default) | true

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either false or true. For more information, see “Impact of Standardization” on page 15-127.

Example: 'Standardize',true

Data Types: logical

**Verbose — Verbosity level indicator**

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:
- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose',1

Data Types: double | single

Solver — Solver type
'slbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for n ≤ 1000, and 'sgd' for n > 1000.

Example: 'solver','minibatch-lbfgs'

LossFunction — Loss function
'mad' (default) | 'mse' | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following:

- 'mad' — Mean absolute deviation
  \[ l(y_i, y_j) = |y_i - y_j|. \]
- 'mse' — Mean squared error
  \[ l(y_i, y_j) = (y_i - y_j)^2. \]
• 'epsiloninsensitive' — \(\varepsilon\)-insensitive loss function

\[
l(y_i, y_j) = \max(0, |y_i - y_j| - \varepsilon).
\]

This loss function is more robust to outliers than mean squared error or mean absolute deviation.

• \@lossfun — Custom loss function handle. A loss function has this form.

```matlab
function L = lossfun(Yu,Yv)
% calculation of loss
...
```

\(Y_u\) is a \(u\)-by-1 vector and \(Y_v\) is a \(v\)-by-1 vector. \(L\) is a \(u\)-by-\(v\) matrix of loss values such that \(L(i,j)\) is the loss value for \(Y_u(i)\) and \(Y_v(j)\).

The objective function for minimization includes the loss function \(l(y_i, y_j)\) as follows:

\[
f(w) = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{P} w_r^2,
\]

where \(w\) is the feature weight vector, \(n\) is the number of observations, and \(p\) is the number of predictor variables. \(p_{ij}\) is the probability that \(x_j\) is the reference point for \(x_i\). For details, see “NCA Feature Selection for Regression” on page 15-125.

Example: 'LossFunction',@lossfun

**Epsilon — Epsilon value**

\(\text{iqr}(Y)/13.49\) (default) | nonnegative real scalar

Epsilon value for the 'LossFunction', 'epsiloninsensitive' option, specified as the comma-separated pair consisting of 'LossFunction' and a nonnegative real scalar. The default value is an estimate of the sample standard deviation using the interquartile range of the response variable.

Example: 'Epsilon', 0.1

Data Types: double | single

**CacheSize — Memory size**

1000MB (default) | integer
Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize',1500MB

Data Types: double | single

**LBFGS Options**

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20

Data Types: double | single

**InitialStepSize — Initial step size**

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

**LineSearchMethod — Line search method**

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

**MaxLineSearchIterations — Maximum number of line search iterations**

20 (default) | positive integer
Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25

Data Types: double | single

**GradientTolerance — Relative convergence tolerance**

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar.

Example: 'GradientTolerance',0.000002

Data Types: double | single

**SGD Options**

**InitialLearningRate — Initial learning rate for 'sgd' solver**

'auto' (default) | positive real scalar

Initial learning rate for the 'sgd' solver, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive real scalar.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

The default 'auto' means that the initial learning rate is determined using experiments on small subsets of data. Use the NumTuningIterations name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the TuningSubsetSize name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type 'minibatch-lbfgs', you can set 'InitialLearningRate' to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the Iteration versus the Objective values saved in the mdl.FitInfo property.

You can use the refit method with 'InitialFeatureWeights' equal to mdl.FeatureWeights to start from the current solution and run additional iterations.
Example: 'InitialLearningRate', 0.9
Data Types: double | single

**MiniBatchSize** — Number of observations to use in each batch for the 'sgd' solver

min(10, n) (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n.

Example: 'MiniBatchSize', 25
Data Types: double | single

**PassLimit** — Maximum number of passes for solver 'sgd'

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit', 10
Data Types: double | single

**NumPrint** — Frequency of batches for displaying convergence summary

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint', 5
Data Types: double | single

**NumTuningIterations** — Number of tuning iterations

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate', 'auto'.

32-2676
Example: 'NumTuningIterations', 15
Data Types: double | single

**TuningSubsetSize — Number of observations to use for tuning initial learning rate**

\[
\min(100, n) \text{ (default)} \mid \text{positive integer value from 1 to } n
\]

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to \( n \). This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'TuningSubsetSize', 25
Data Types: double | single

**SGD or LBFGS Options**

**IterationLimit — Maximum number of iterations**

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into \( k \) mini-batches, then every epoch is equivalent to \( k \) iterations.

Example: 'IterationLimit', 250
Data Types: double | single

**StepTolerance — Convergence tolerance on the step size**

\[ \text{1e-6 (default)} \mid \text{positive real scalar} \]

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance', 0.000005
Data Types: double | single
Mini-batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step

10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, returned as a FeatureSelectionNCARegression object.

“Neighborhood Component Analysis (NCA) Feature Selection” on page 15-121

Introduced in R2016b
\textbf{fstat}

\textit{F} mean and variance

\textbf{Syntax}

\[ [M,V] = \text{fstat}(V1,V2) \]

\textbf{Description}

\[ [M,V] = \text{fstat}(V1,V2) \] returns the mean of and variance for the \textit{F} distribution with numerator degrees of freedom \( V1 \) and denominator degrees of freedom \( V2 \). \( V1 \) and \( V2 \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( M \) and \( V \). A scalar input for \( V1 \) or \( V2 \) is expanded to a constant arrays with the same dimensions as the other input. \( V1 \) and \( V2 \) parameters must contain real positive values.

The mean of the \textit{F} distribution for values of \( \nu_2 \) greater than 2 is

\[
\frac{\nu_2}{\nu_2 - 2}
\]

The variance of the \textit{F} distribution for values of \( \nu_2 \) greater than 4 is

\[
\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}
\]

The mean of the \textit{F} distribution is undefined if \( \nu_2 \) is less than 3. The variance is undefined for \( \nu_2 \) less than 5.

\textbf{Examples}

\texttt{fstat} returns \texttt{NaN} when the mean and variance are undefined.
[m,v] = fstat(1:5,1:5)

m = 
    NaN  NaN  3.0000  2.0000  1.6667
v = 
    NaN  NaN  NaN  NaN  8.8889

**fsurfht**

Interactive contour plot

**Syntax**

```matlab
fsurfht(fun,xlims,ylims)
fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)
```

**Description**

`fsurfht(fun,xlims,ylims)` is an interactive contour plot of the function specified by the text variable `fun`. The x-axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y-axis limits are specified by `ylims` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z-values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x-axis and y-axis.

**Examples**

Plot the Gaussian likelihood function for the `gas.mat` data.

```matlab
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```matlab
function z = gauslike(mu,sigma,p1)
    n = length(p1);
    z = ones(size(mu));
    for i = 1:n
        z = z .* (normpdf(p1(i),mu,sigma));
    end
```
The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters $\mu$ and $\sigma$ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

\[ \text{fsurfht('gauslike',}[112 \ 118], [3 \ 5], \text{price1}) \]

The sample mean is the $x$ value at the maximum, but the sample standard deviation is not the $y$ value at the maximum.

\[
\text{mumax} = \text{mean(price1)} \\
\text{mumax} = 115.1500 \\
\text{sigmamax} = \text{std(price1)}*\text{sqrt(19/20)}
\]
sigmamax =
    3.7719

Introduced before R2006a
fullfact

Full factorial design

Syntax

dFF = fullfact(levels)

Description

dFF = fullfact(levels) gives factor settings dFF for a full factorial design with \( n \) factors, where the number of levels for each factor is given by the vector levels of length \( n \). dFF is \( m \)-by-\( n \), where \( m \) is the number of treatments in the full-factorial design. Each row of dFF corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

dFF = fullfact([2 4])
dFF =
   1 1
   2 1
   1 2
   2 2
   1 3
   2 3
   1 4
   2 4

Introduced before R2006a
**gagerr**

Gage repeatability and reproducibility study

**Syntax**

```matlab
gagerr(y,{part,operator})
gagerr(y,GROUP)
gagerr(y,part)
gagerr(...,param1,val1,param2,val2,...)
[TABLE, stats] = gagerr(...)
```

**Description**

`gagerr(y,{part,operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, string arrays, or cell arrays of character vectors. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 \times \text{standard deviation}) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If NDC > 5, the measurement system is capable.
- If NDC < 2, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
To determine the capability of a measurement system using PRR, use the following guidelines:

- If PRR < 10%, the measurement system is capable.
- If PRR > 30%, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

\( \text{gagerr}(y, \text{GROUP}) \) performs a gage R&R study on measurements in \( y \) with \( \text{part} \) and \( \text{operator} \) represented in \( \text{GROUP} \). \( \text{GROUP} \) is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in \( \text{GROUP} \) should be the same as the number of elements in \( y \).

\( \text{gagerr}(y, \text{part}) \) performs a gage R&R study on measurements in \( y \) without operator information. The assumption is that all variability is contributed by \( \text{part} \).

\( \text{gagerr}(\ldots, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \ldots) \) performs a gage R&R study using one or more of the following parameter name/value pairs:

- 'spec' — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If PTR < 0.1, the measurement system is capable.
- If PTR > 0.3, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

- 'printtable' — A value 'on' or 'off' that indicates whether the tabular output should be printed in the command window or not. The default value is 'on'.
- 'printgraph' — A value 'on' or 'off' that indicates whether the bar graph should be plotted or not. The default value is 'on'.
- 'randomoperator' — A logical value, true or false, that indicates whether the effect of \( \text{operator} \) is random or not. The default value is true.
- 'model' — The model to use, specified by one of:
  - 'linear' — Main effects only (default)
• 'interaction' — Main effects plus two-factor interactions
• 'nested' — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

• ndc — Number of distinct categories
• prr — Percentage of gage R&R of total variations
• ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y, operators do on the parts.

rng(1234,'twister')               % for reproducibility
y = randn(100,1);                 % measurements
part = ceil(3*rand(100,1));       % parts
operator = ceil(4*rand(100,1));   % operators

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

gagerr(y,{part, operator},'randomoperator',true)

“Grouping Variables” on page 2-57

Introduced in R2006b
**gamcdf**

Gamma cumulative distribution function

**Syntax**

```
gamcdf(x,a,b)
[p,plo,pup] = gamcdf(x,a,b,pcov,alpha)
[p,plo,pup] = gamcdf(__,'upper')
```

**Description**

gamcdf(x,a,b) returns the gamma cdf at each of the values in x using the corresponding shape parameters in a and scale parameters in b. x, a, and b can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in a and b must be positive, and the values in x must lie on the interval [0 Inf].

[p,plo,pup] = gamcdf(x,a,b,pcov,alpha) produces confidence bounds for p when the input parameters a and b are estimates. pcov is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. alpha has a default value of 0.05, and specifies 100*(1-alpha)% confidence bounds. plo and pup are arrays of the same size as p containing the lower and upper confidence bounds.

[p,plo,pup] = gamcdf(__,'upper') returns the complement of the gamma cdf at each value in x, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The gamma cdf is

\[
p = F(x | a,b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-t/b} dt
\]

The result, p, is the probability that a single observation from a gamma distribution with parameters a and b will fall in the interval [0 x].
gammainc is the gamma distribution with \( b \) fixed at 1.

**Examples**

**Compute Gamma Distribution CDF**

The mean of the gamma distribution is the product of the parameters, \( ab \). In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```matlab
a = 1:6;
b = 5:10;
prob = gamcdf(a.*b,a,b)
```

```
prob = 1x6
     0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

Topics
“Gamma Distribution” on page B-45

Introduced before R2006a
gamfit

Gamma parameter estimates

Syntax

phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)

Description

phat = gamfit(data) returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector data.

[phat,pci] = gamfit(data) returns MLEs and 95% percent confidence intervals. The first row of pci is the lower bound of the confidence intervals; the last row is the upper bound.

[phat,pci] = gamfit(data,alpha) returns 100(1 - alpha)% confidence intervals. For example, alpha = 0.01 yields 99% confidence intervals.

[...] = gamfit(data,alpha,censoring) accepts a Boolean vector of the same size as data that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

[...] = gamfit(data,alpha,censoring,freq) accepts a frequency vector of the same size as data. freq typically contains integer frequencies for the corresponding elements in data, but may contain any nonnegative values.

[...] = gamfit(data,alpha,censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an options structure which can be created using the function statset. Enter statset('gamfit') to see the names and default values of the parameters that gamfit accepts in the options structure.
Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```matlab
a = 2; b = 4;
data = gamrnd(a,b,100,1);

[p,ci] = gamfit(data)
p =
    2.1990  3.7426
ci =
    1.6840  2.8298
    2.7141  4.6554
```

Topics
“Gamma Distribution” on page B-45

Introduced before R2006a
gaminv

Gamma inverse cumulative distribution function

Syntax

$X = \text{gaminv}(P, A, B)$

$[X, XL0, XUP] = \text{gaminv}(P, A, B, \text{pcov}, \text{alpha})$

Description

$X = \text{gaminv}(P, A, B)$ computes the inverse of the gamma cdf with shape parameters in $A$ and scale parameters in $B$ for the corresponding probabilities in $P$. $P$, $A$, and $B$ can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in $A$ and $B$ must all be positive, and the values in $P$ must lie on the interval $[0, 1]$.

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} \, dt$$

$[X, XL0, XUP] = \text{gaminv}(P, A, B, \text{pcov}, \text{alpha})$ produces confidence bounds for $X$ when the input parameters $A$ and $B$ are estimates. $\text{pcov}$ is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. $\text{alpha}$ has a default value of 0.05, and specifies $100(1-\alpha)\%$ confidence bounds. $XL0$ and $XUP$ are arrays of the same size as $X$ containing the lower and upper confidence bounds.
Examples

This example shows the relationship between the gamma cdf and its inverse function.

```matlab
a = 1:5;
b = 6:10;
x = gaminv(gamcdf(1:5,a,b),a,b)
x =
   1.0000  2.0000  3.0000  4.0000  5.0000
```

Algorithms

There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

gamlike

Gamma negative log-likelihood

Syntax

\[
n\log L = \text{gamlike}(\text{params}, \text{data})
\]

\[
[n\log L, \text{AVAR}] = \text{gamlike}(\text{params}, \text{data})
\]

Description

\(n\log L = \text{gamlike}(\text{params}, \text{data})\) returns the negative of the gamma log-likelihood of the parameters, \(\text{params}\), given \(\text{data}\). \(\text{params}(1)=A\), shape parameters, and \(\text{params}(2)=B\), scale parameters. The parameters in \(\text{params}\) must all be positive.

\([n\log L, \text{AVAR}] = \text{gamlike}(\text{params}, \text{data})\) also returns \(\text{AVAR}\), which is the asymptotic variance-covariance matrix of the parameter estimates when the values in \(\text{params}\) are the maximum likelihood estimates. \(\text{AVAR}\) is the inverse of Fisher's information matrix. The diagonal elements of \(\text{AVAR}\) are the asymptotic variances of their respective parameters.

\([...\] = \text{gamlike}(\text{params}, \text{data}, \text{censoring})\) accepts a Boolean vector of the same size as \(\text{data}\) that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

\([...\] = \text{gamfit}(\text{params}, \text{data}, \text{censoring}, \text{freq})\) accepts a frequency vector of the same size as \(\text{data}\). \(\text{freq}\) typically contains integer frequencies for the corresponding elements in \(\text{data}\), but may contain any non-negative values.

\(\text{gamlike}\) is a utility function for maximum likelihood estimation of the gamma distribution. Since \(\text{gamlike}\) returns the negative gamma log-likelihood function, minimizing \(\text{gamlike}\) using \text{fminsearch} is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the \text{gamfit} function:
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
   0.0788    -0.1104
  -0.1104    0.1955

Introduced before R2006a
gampdf
Gamma probability density function

Syntax

Y = gampdf(X,A,B)

Description

Y = gampdf(X,A,B) computes the gamma pdf at each of the values in X using the corresponding shape parameters in A and scale parameters in B. X, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in A and B must all be positive, and the values in X must lie on the interval [0 Inf].

The gamma pdf is

\[ y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} \]

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and \( \chi^2 \) functions are special cases of the gamma function.

Examples

The exponential distribution is a special case of the gamma distribution.

\[ \text{mu} = 1:5; \]
\[ y = \text{gampdf}(1,1,\text{mu}) \]
$y = 
0.3679\ 0.3033\ 0.2388\ 0.1947\ 0.1637$

y1 = expdf(1,\mu)
y1 = 
0.3679\ 0.3033\ 0.2388\ 0.1947\ 0.1637$

gamrnd

Gamma random numbers

Syntax

\[ R = \text{gamrnd}(A,B) \]
\[ R = \text{gamrnd}(A,B,m,n,...) \]
\[ R = \text{gamrnd}(A,B,[m,n,...]) \]

Description

\( R = \text{gamrnd}(A,B) \) generates random numbers from the gamma distribution with shape parameters in \( A \) and scale parameters in \( B \). \( A \) and \( B \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for \( A \) or \( B \) is expanded to a constant array with the same dimensions as the other input. The parameters in \( A \) and \( B \) must be positive.

\( R = \text{gamrnd}(A,B,m,n,...) \) or \( R = \text{gamrnd}(A,B,[m,n,...]) \) generates an \( m \)-by-\( n \)-by-... array containing random numbers from the gamma distribution with parameters \( A \) and \( B \). \( A \) and \( B \) can each be scalars or arrays of the same size as \( R \).

Examples

\[ n1 = \text{gamrnd}(1:5,6:10) \]
\[ n1 = \]
\[ 9.1132 \quad 12.8431 \quad 24.8025 \quad 38.5960 \quad 106.4164 \]

\[ n2 = \text{gamrnd}(5,10,[1 5]) \]
\[ n2 = \]
\[ 30.9486 \quad 33.5667 \quad 33.6837 \quad 55.2014 \quad 46.8265 \]

\[ n3 = \text{gamrnd}(2:6,3,1,5) \]
\[ n3 = \]
\[ 12.8715 \quad 11.3068 \quad 3.0982 \quad 15.6012 \quad 21.6739 \]
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Introduced before R2006a
gamstat

Gamma mean and variance

Syntax

[M,V] = gamstat(A,B)

Description

[M,V] = gamstat(A,B) returns the mean of and variance for the gamma distribution with shape parameters in A and scale parameters in B. A and B can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of M and V. A scalar input for A or B is expanded to a constant array with the same dimensions as the other input. The parameters in A and B must be positive.

The mean of the gamma distribution with parameters A and B is AB. The variance is AB^2.

Examples

[m,v] = gamstat(1:5,1:5)
m =
1 4 9 16 25
v =
1 8 27 64 125

[m,v] = gamstat(1:5,1./(1:5))
m =
1 1 1 1 1
v =
1.0000 0.5000 0.3333 0.2500 0.2000

ge

Class: qrandstream

Greater than or equal relation for handles

Syntax

h1 >= h2

Description

h1 >= h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise >= result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = ge(h1, h2) stores the result in a logical array of the same dimensions.

See Also

eq | gt | le | lt | ne | qrandstream
GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A GeneralizedLinearMixedModel object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the predict function and generate random data at new design points using the random function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using fitglme(tbl,formula). For more information, see fitglme.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using formula.

Data Types: table

formula — Formula for model specification

character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

32-2709
Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For a full description, see Formula on page 32-2725.

Example: 'y ~ treatment +(1|block)'

Properties

**Coefficients — Estimates of fixed-effects coefficients**

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t-statistic for a test that the coefficient is equal to 0
- **DF** — Degrees of freedom associated with the t statistic
- **pValue** — p-value for the t-statistic
- **Lower** — Lower confidence limit
- **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

**CoefficientCovariance — Covariance of estimated fixed-effects vector**

matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

**CoefficientNames — Names of fixed-effects coefficients**

cell array of character vectors

Names of fixed-effects coefficients, stored as a cell array of character vectors. The label for the coefficient of the constant term is (Intercept). The labels for other coefficients
indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: cell

**DFE — Degrees of freedom for error**

Positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If \( n \) is the number of observations and \( p \) is the number of fixed-effects coefficients, then DFE is equal to \( n - p \).

Data Types: double

**Dispersion — Model dispersion parameter**

Scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation \( i \), the conditional variance of the response \( y_i \) given the conditional mean \( \mu_i \) and the dispersion parameter \( \sigma^2 \), in a generalized linear mixed-effects model is

\[
\text{var}\left( y_i \mid \mu_i, \sigma^2 \right) = \frac{\sigma^2}{w_i} v(\mu_i),
\]

where \( w_i \) is the \( i \)th observation weight and \( v \) is the variance function for the specified conditional distribution of the response. The Dispersion property contains an estimate of \( \sigma^2 \) for the specified GLME model. The value of Dispersion depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of Dispersion is equal to \( \sigma^2 = 1.0 \).

- If FitMethod is MPL or REMPL and the 'DispersionFlag' name-value pair argument in fitglme is true, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If FitMethod is ApproximateLaplace or Laplace, then the 'DispersionFlag' name-value pair argument in fitglme does not apply, and the dispersion parameter is
fixed at 1.0 for binomial and Poisson distributions. For all other distributions, 
Dispersion is estimated from data.

Data Types: double

**DispersionEstimated** — Flag indicating if dispersion parameter was estimated

true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is 
  fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and 
  DispersionEstimated is false. For other distributions, the dispersion parameter is 
  estimated from the data, and DispersionEstimated is true.

- If `FitMethod` is `MPL` or `REML`, and the 'DispersionFlag' name-value pair 
  argument in `fitglme` is specified as true, then the dispersion parameter is estimated 
  for all distributions, including binomial and Poisson distributions, and 
  DispersionEstimated is true.

- If `FitMethod` is `MPL` or `REML`, and the 'DispersionFlag' name-value pair 
  argument in `fitglme` is specified as false, then the dispersion parameter is fixed at 
  its theoretical value for binomial and Poisson distributions, and 
  DispersionEstimated is false. For distributions other than binomial and Poisson, 
  the dispersion parameter is estimated from the data, and DispersionEstimated is 
  true.

Data Types: logical

**Distribution** — Response distribution name

'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:

- 'Normal' — Normal distribution
- 'Binomial' — Binomial distribution
- 'Poisson' — Poisson distribution
- 'Gamma' — Gamma distribution
- 'InverseGaussian' — Inverse Gaussian distribution

**FitMethod** — Method used to fit the model

'MPL' | 'REML' | 'ApproximateLaplace' | 'Laplace'
Method used to fit the model, stored as one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REML' — Restricted maximum pseudo likelihood
- 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- 'Laplace' — Maximum likelihood using the Laplace method

**Formula — Model specification formula**

Object

Model specification formula, stored as an object. The model specification formula uses Wilkinson’s notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula on page 32-2725.

**Link — Link function characteristics**

Structure

Link function characteristics, stored as a structure containing the following fields. The link is a function $G$ that links the distribution parameter $\mu$ to the linear predictor $\eta$ as follows: $G(\mu) = \eta$.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the link function</td>
</tr>
<tr>
<td>Link</td>
<td>Function that defines $G$</td>
</tr>
<tr>
<td>Derivative</td>
<td>Derivative of $G$</td>
</tr>
<tr>
<td>SecondDerivative</td>
<td>Second derivative of $G$</td>
</tr>
<tr>
<td>Inverse</td>
<td>Inverse of $G$</td>
</tr>
</tbody>
</table>

Data Types: struct

**LogLikelihood — Log of likelihood function**

Scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.
• If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.
• If you use 'MPL', then LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
• If you use 'REML', then LogLikelihood is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: double

ModelCriterion — Model criterion
table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIC</td>
<td>Akaike information criterion</td>
</tr>
<tr>
<td>BIC</td>
<td>Bayesian information criterion</td>
</tr>
</tbody>
</table>
| LogLikelihood | • For a model fit using 'Laplace' or 'ApproximateLaplace', LogLikelihood is the maximized log likelihood.  
                   • For a model fit using 'MPL', LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.  
                   • For a model fit using 'REML', LogLikelihood is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.  |
| Deviance   | -2 times LogLikelihood                                                       |

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.
Data Types: double

**NumEstimatedCoefficients — Number of estimated fixed-effects coefficients**

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumObservations — Number of observations**

Number of observations used in the fit, stored as a positive integer value. **NumObservations** is the number of rows in the table or dataset array tbl, minus rows excluded using the 'Exclude' name-value pair of fitglme or rows containing NaN values.

Data Types: double

**NumPredictors — Number of predictors**

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumVariables — Total number of variables**

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array tbl, then **NumVariables** is the total number of variables in tbl, including the response variable. **NumVariables** includes variables, if any, that are not used as predictors or as the response.

Data Types: double

**ObservationInfo — Information about the observations**

Information about the observations used in the fit, stored as a table. **ObservationInfo** has one row for each observation and the following columns.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>The weight value for the observation. The default value is 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>If the observation was excluded from the fit using the 'Exclude' name-value pair argument in fitglme, then Excluded is true, or 1. Otherwise, Excluded is false, or 0.</td>
</tr>
<tr>
<td>Missing</td>
<td>If the observation was excluded from the fit because any response or predictor value is missing, then Missing is true. Otherwise, Missing is false. Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the &lt;undefined&gt; value for categorical arrays.</td>
</tr>
<tr>
<td>Subset</td>
<td>If the observation was used in the fit, then Subset is true. If the observation was not used in the fit because it is missing or excluded, then Subset is false.</td>
</tr>
<tr>
<td>BinomSize</td>
<td>Binomial size for each observation. This column only applies when fitting a binomial distribution.</td>
</tr>
</tbody>
</table>

**Data Types:** `table`

**ObservationNames — Names of observations**

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array `tbl` that contains observation names, then `ObservationNames` uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

**Data Types:** `cell`
**PredictorNames — Names of predictors**  
cell array of character vectors

Names of the variables used as predictors in the fit, stored as a cell array of character vectors that has the same length as NumPredictors.

Data Types: cell

**ResponseName — Name of response variable**  
character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: char

**Rsquared — Proportion of variability in the response explained by the fitted model**  
structure

Proportion of variability in the response explained by the fitted model, stored as a structure. Rsquared contains the $R^2$-squared value of the fitted model, also known as the multiple correlation coefficient. Rsquared contains the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ordinary</td>
<td>R-squared value, stored as a scalar value in a structure.</td>
</tr>
<tr>
<td></td>
<td>Rsquared.Ordinary = $1 - \frac{SSE}{SST}$</td>
</tr>
<tr>
<td>Adjusted</td>
<td>R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.</td>
</tr>
<tr>
<td></td>
<td>Rsquared.Adjusted = $1 - \left(\frac{SSE}{SST}\right) \left(\frac{DFT}{DFE}\right)$,</td>
</tr>
<tr>
<td></td>
<td>where DFE = $n - p$, DFT = $n - 1$, $n$ is the total number of observations, and $p$ is the number of fixed-effects coefficients.</td>
</tr>
</tbody>
</table>

Data Types: struct

**SSE — Error sum of squares**  
positive scalar value
Error sum of squares, stored as a positive scalar value. SSE is the weighted sum of the squared conditional residuals, and is calculated as

\[ SSE = \sum_{i=1}^{n} w_i^{\text{eff}} (y_i - f_i)^2, \]

where \( n \) is the number of observations, \( w_i^{\text{eff}} \) is the \( i \)th effective weight, \( y_i \) is the \( i \)th response, and \( f_i \) is the \( i \)th fitted value.

The \( i \)th effective weight is calculated as

\[ w_i^{\text{eff}} = \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{\theta}))}, \]

where \( v_i \) is the variance term for the \( i \)th observation, \( \hat{\beta} \) and \( \hat{\theta} \) are estimated values of \( \beta \) and \( b \), respectively.

The \( i \)th fitted value is calculated as

\[ f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{\theta} + \delta_i), \]

where \( x_i^T \) is the \( i \)th row of the fixed-effects design matrix \( X \), and \( z_i^T \) is the \( i \)th row of the random-effects design matrix \( Z \). \( \delta_i \) is the \( i \)th offset value.

Data Types: double

**SSR — Regression sum of squares**

positive scalar value

Regression sum of squares, stored as a positive scalar value. SSR is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. SSR is calculated as

\[ SSR = \sum_{i=1}^{N} w_i^{\text{eff}} (f_i - \bar{f})^2, \]
where \( n \) is the number of observations, \( w_{i}^{\text{eff}} \) is the \( i \)th effective weight, \( f_{i} \) is the \( i \)th fitted value, and \( \bar{f} \) is a weighted average of the fitted values.

The \( i \)th effective weight is calculated as

\[
w_{i}^{\text{eff}} = \left\{ \frac{w_{i}}{v_{i}\left(\mu_{i}\left(\hat{\beta}, \hat{b}\right)\right)} \right\},
\]

where \( \hat{\beta} \) and \( \hat{b} \) are estimated values of \( \beta \) and \( b \), respectively.

The \( i \)th fitted value is calculated as

\[
f_{i} = g^{-1}\left(x_{i}^{T}\hat{\beta} + z_{i}^{T}\hat{b} + \delta_{i}\right),
\]

where \( x_{i}^{T} \) is the \( i \)th row of the fixed-effects design matrix \( X \), and \( z_{i}^{T} \) is the \( i \)th row of the random-effects design matrix \( Z \). \( \delta_{i} \) is the \( i \)th offset value.

The weighted average of fitted values is calculated as

\[
\bar{f} = \left[ \frac{\sum_{i=1}^{n} w_{i}^{\text{eff}} f_{i}}{\sum_{i=1}^{n} w_{i}^{\text{eff}}} \right].
\]

Data Types: double

**SST — Total sum of squares**

positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as \( \text{SST} = \text{SSE} + \text{SSR} \).

Data Types: double

**VariableInfo — Information about the variables**
table
Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Class</strong></td>
<td>Class of the variable ('double', 'cell', 'nominal', and so on).</td>
</tr>
</tbody>
</table>
| **Range**   | Value range of the variable.  
  - For a numerical variable, `Range` is a two-element vector of the form `[min, max]`.  
  - For a cell or categorical variable, `Range` is a cell or categorical array containing all unique values of the variable. |
| **InModel** | If the variable is a predictor in the fitted model, `InModel` is true.  
  If the variable is not in the fitted model, `InModel` is false. |
| **IsCategorical** | If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then `IsCategorical` is true.  
  If the variable is a continuous predictor, then `IsCategorical` is false. |

Data Types: `table`

**VariableNames — Names of the variables**

`cell` array of character vectors

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of character vectors.

Data Types: `cell`

**Variables — Variables**

`table`
Variables, stored as a table. If the fit is based on a table or dataset array tbl, then Variables is identical to tbl.

Data Types: table

Methods

- **anova**: Analysis of variance for generalized linear mixed-effects model
- **coefCI**: Confidence intervals for coefficients of generalized linear mixed-effects model
- **coefTest**: Hypothesis test on fixed and random effects of generalized linear mixed-effects model
- **compare**: Compare generalized linear mixed-effects models
- **covarianceParameters**: Extract covariance parameters of generalized linear mixed-effects model
- **designMatrix**: Fixed- and random-effects design matrices
- **fitted**: Fitted responses from generalized linear mixed-effects model
- **fixedEffects**: Estimates of fixed effects and related statistics
- **plotResiduals**: Plot residuals of generalized linear mixed-effects model
- **predict**: Predict response of generalized linear mixed-effects model
- **random**: Generate random responses from fitted generalized linear mixed-effects model
- **randomEffects**: Estimates of random effects and related statistics
- **refit**: Refit generalized linear mixed-effects model
- **residuals**: Residuals of fitted generalized linear mixed-effects model
- **response**: Response vector of generalized linear mixed-effects model

Examples

**Fit a Generalized Linear Mixed-Effects Model**

Load the sample data.
load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i,
\]

where
• $\text{defects}_{ij}$ is the number of defects observed in the batch produced by factory $i$ during batch $j$.

• $\mu_{ij}$ is the mean number of defects corresponding to factory $i$ (where $i = 1, 2, ..., 20$) during batch $j$ (where $j = 1, 2, ..., 5$).

• $\text{newprocess}_{ij}$, $\text{time\_dev}_{ij}$, and $\text{temp\_dev}_{ij}$ are the measurements for each variable that correspond to factory $i$ during batch $j$. For example, $\text{newprocess}_{ij}$ indicates whether the batch produced by factory $i$ during batch $j$ used the new process.

• $\text{supplier\_C}_{ij}$ and $\text{supplier\_B}_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory $i$ during batch $j$.

• $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory $i$ that accounts for factory-specific variation in quality.

```matlab
glme = fitglme(mfr,'defects ~ 1 + newprocess + time\_dev + temp\_dev + supplier + (1|factory)', ...
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Display the model.

```matlab
disp(glme)
```

Generalized linear mixed-effects model fit by ML

Model information:

- Number of observations 100
- Fixed effects coefficients 6
- Random effects coefficients 20
- Covariance parameters 1
- Distribution Poisson
- Link Log
- FitMethod Laplace

Formula:

```
defects ~ 1 + newprocess + time\_dev + temp\_dev + supplier + (1 | factory)
```

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

**Formula** indicates the model specification using Wilkinson’s notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The **Fixed effects coefficients** table indicates that **fitglme** returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and
column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the \( t \)-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and \( p \)-value that correspond to the \( t \)-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only factory), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, \texttt{std} indicates that \texttt{fitglme} returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by \texttt{fitglme} does not provide confidence intervals for the random-effects parameters. To compute and display these values, use \texttt{covarianceParameters}.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form \( 'y \sim \text{terms}' \). For generalized linear mixed-effects models, this formula is in the form \( 'y \sim \text{fixed} + (\text{random1}|\text{grouping1}) + \ldots + (\text{randomR}|\text{groupingR})' \), where \text{fixed} and \text{random} contain the fixed-effects and the random-effects terms, respectively, and \( R \) is the number of grouping variables in the model.

Suppose a table \texttt{tbl} contains the following:

- A response variable, \( y \)
- Predictor variables, \( X_j \), which can be continuous or grouping variables
- Grouping variables, \( g_1, g_2, \ldots, g_R \)

where the grouping variables in \( X_j \) and \( g_r \) can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form \( 'y \sim \text{fixed} + (\text{random}_1|g_1) + \ldots + (\text{random}_R|g_R)' \), the term \text{fixed} corresponds to a specification of the fixed-effects design matrix \( X \),
random_1 is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly random_1 is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>X^k, where k is a positive integer</td>
<td>X, X^2, ..., X^k</td>
</tr>
<tr>
<td>X1 + X2</td>
<td>X1, X2</td>
</tr>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1.*X2 only</td>
</tr>
<tr>
<td>- X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>
<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>Formula</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>`'y ~ 1 + (1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (X1</td>
<td>g1)'`</td>
</tr>
<tr>
<td>`'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>`'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>
</tbody>
</table>

“Generalized Linear Mixed-Effects Models” on page 12-65
GeneralizedLinearModel class

Superclasses:

Generalized linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the predict or feval methods.

Construction

mdl = fitglm(tbl) or mdl = fitglm(X,y) creates a generalized linear model of a table or dataset array tbl, or of the responses y to a data matrix X. For details, see fitglm.

mdl = stepwiseglm(tbl) or mdl = stepwiseglm(X,y) creates a generalized linear model of a table or dataset array tbl, or of the responses y to a data matrix X, with unimportant predictors excluded. For details, see stepwiseglm.

Input Arguments

tbl — Input data
table | dataset array

Input data, specified as a table or dataset array. When modelspec is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables“ on page 2-57). The response must be numeric or logical.
To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

**X — Predictor variables**

matrix

Predictor variables, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables. Each column of \( X \) represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in \( X \).

Data Types: `single` | `double` | `logical`

**y — Response variable**

vector

Response variable, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations. Each entry in \( y \) is the response for the corresponding row of \( X \).

Data Types: `single` | `double` | `logical`

**Properties**

**CoefficientCovariance — Covariance matrix of coefficient estimates**

numeric matrix

Covariance matrix of coefficient estimates, specified as a \( p \)-by-\( p \) matrix of numeric values. \( p \) is the number of coefficients in the fitted model.

**CoefficientNames — Coefficient names**

cell array of character vectors

Coefficient names, specified as a cell array of character vectors containing a label for each coefficient.

**Coefficients — Coefficient values**

table
Coefficient values, specified as a table. **Coefficients** has one row for each coefficient and the following columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t statistic for a test that the coefficient is zero
- **pValue** — p-value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is

```matlab
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

**Deviance — Deviance of the fit**

numeric value

Deviance of the fit, specified as a numeric value. Deviance is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 32-2746.

**DFE — Degrees of freedom for error**

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer value.

**Diagnostics — Diagnostic information**

table

Diagnostic information for the model, specified as a table. Diagnostics can help identify outliers and influential observations. **Diagnostics** contains the following fields:
<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
<th>Utility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leverage</td>
<td>Diagonal elements of HatMatrix</td>
<td>Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with $p$ coefficients and $n$ observations, the average value of Leverage is $p/n$. An observation with Leverage larger than $2*p/n$ can be an outlier.</td>
</tr>
<tr>
<td>CooksDistance</td>
<td>Cook's measure of scaled change in fitted values</td>
<td>CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.</td>
</tr>
<tr>
<td>HatMatrix</td>
<td>Projection matrix to compute fitted from observed responses</td>
<td>HatMatrix is an $n$-by-$n$ matrix such that $\text{Fitted} = \text{HatMatrix} \times \text{Y}$, where Y is the response vector and Fitted is the vector of fitted response values.</td>
</tr>
</tbody>
</table>

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

\[
\text{Yfit} = \text{glm.Fitted.LinearPredictor} \\
\text{Y} = \text{glm.Fitted.LinearPredictor} + \text{glm.Residuals.LinearPredictor}
\]

**Dispersion — Scale factor of the variance of the response structure**

Scale factor of the variance of the response, specified as a structure. Dispersion multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where $p$ is the probability parameter and $n$ is the sample size parameter. If Dispersion is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If Dispersion is larger than 1, the data are “overdispersed” relative to the binomial distribution.

**DispersionEstimated — Flag to indicate use of dispersion scale factor**

Logical value

32-2731
Flag to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`, specified as a logical value. If `DispersionEstimated` is false, `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be false only for 'binomial' or 'poisson' distributions.
- Set `DispersionEstimated` by setting the `DispersionFlag` name-value pair in `fitglm`.

**Distribution — Generalized distribution information**
structure

Generalized distribution information, specified as a structure with the following fields relating to the generalized distribution:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gaussian'.</td>
</tr>
<tr>
<td>DevianceFunction</td>
<td>Function that computes the components of the deviance as a function of the fitted parameter values and the response values.</td>
</tr>
<tr>
<td>VarianceFunction</td>
<td>Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is true, <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors.</td>
</tr>
</tbody>
</table>

**Fitted — Fitted response values based on input data**
table

Fitted (predicted) values based on the input data, specified as a table with one row for each observation and the following columns:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response</td>
<td>Predicted values on the scale of the response.</td>
</tr>
<tr>
<td>LinearPredictor</td>
<td>Predicted values on the scale of the linear predictor. These are the same as the link function applied to the <code>Response</code> fitted values.</td>
</tr>
<tr>
<td>Probability</td>
<td>Fitted probabilities (this column is included only with the binomial distribution).</td>
</tr>
</tbody>
</table>
To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector $f$ of fitted values on the response scale is

$$f = mdl.Fitted.Response$$

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

**Formula — Model information**

LinearFormula object | NonLinearFormula object

Model information, specified as a LinearFormula object or NonLinearFormula object. If you fit a linear or generalized linear regression model, then `Formula` is a LinearFormula object. If you fit a nonlinear regression model, then `Formula` is a NonLinearFormula object.

**Link — Link function**

structure

Link function, specified as a structure with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the link function, or '' if you specified the link as a function handle rather than a character vector.</td>
</tr>
<tr>
<td>LinkFunction</td>
<td>The function that defines $f$, a function handle.</td>
</tr>
<tr>
<td>DevianceFunction</td>
<td>Derivative of $f$, a function handle.</td>
</tr>
<tr>
<td>VarianceFunction</td>
<td>Inverse of $f$, a function handle.</td>
</tr>
</tbody>
</table>

The link is a function $f$ that links the distribution parameter $\mu$ to the fitted linear combination $Xb$ of the predictors:

$$f(\mu) = Xb.$$  

**LogLikelihood — Log likelihood**

numeric value

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.
ModelCriterion — Criterion for model comparison

Structure

Criterion for model comparison, specified as a structure with the following fields:

- **AIC** — Akaike information criterion. $AIC = -2\log L + 2m$, where $\log L$ is the loglikelihood and $m$ is the number of estimated parameters.

- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + \frac{2m(m+1)}{n-m-1}$, where $n$ is the number of observations.

- **BIC** — Bayesian information criterion. $BIC = -2\log L + m\log(n)$.

- **CAIC** — Consistent Akaike information criterion. $CAIC = -2\log L + m(\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

**NumCoefficients** — Number of model coefficients

Positive integer

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

**NumEstimatedCoefficients** — Number of estimated coefficients

Positive integer

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.
NumObservations — Number of observations
positive integer

Number of observations the fitting function used in fitting, specified as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the Exclude name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables
positive integer

Number of predictor variables used to fit the model, specified as a positive integer.

NumVariables — Number of variables
positive integer

Number of variables in the input data, specified as a positive integer. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo — Observation information
table

Observation information, specified as a n-by-4 table, where n is equal to the number of rows of input data. The four columns of ObservationInfo contain the following:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>Observation weights. Default is all 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>Logical value, 1 indicates an observation that you excluded from the fit with the Exclude name-value pair.</td>
</tr>
<tr>
<td>Missing</td>
<td>Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.</td>
</tr>
<tr>
<td>Subset</td>
<td>Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.</td>
</tr>
</tbody>
</table>

ObservationNames — Observation names
cell array of character vectors

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.
- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

**Offset — Offset variable**

numeric vector

Offset variable, specified as a numeric vector with the same length as the number of rows in the data. `Offset` is passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was

\[ \mu \sim \text{Offset} + (\text{terms involving real predictors}) \]

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor \( A \). By using the log link function and by specifying \( \log(A) \) as an offset, you can force the model to satisfy this theoretical constraint.

**PredictorNames — Names of predictors used to fit the model**

cell array of character vectors

Names of predictors used to fit the model, specified as a cell array of character vectors.

**Residuals — Residuals for fitted model**

Table

Residuals for the fitted model, specified as a table with one row for each observation and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw</td>
<td>Observed minus fitted values.</td>
</tr>
<tr>
<td>LinearPredictor</td>
<td>Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.</td>
</tr>
<tr>
<td>Pearson</td>
<td>Raw residuals divided by the estimated standard deviation of the response.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Anscombe</td>
<td>Residuals defined on transformed data with the transformation chosen to remove skewness.</td>
</tr>
<tr>
<td>Deviance</td>
<td>Residuals based on the contribution of each observation to the deviance.</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```matlab
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain `NaN` values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

**ResponseName — Response variable name**

character vector

Response variable name, specified as a character vector.

**Rsquared — R-squared value for the model**

structure

R-squared value for the model, specified as a structure.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

For a generalized linear model, `Rsquared` is a structure with five fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
• Adjusted — R-squared adjusted for the number of coefficients
• LLR — Log-likelihood ratio
• Deviance — Deviance
• AdjGeneralized — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

\[
R^2 = \frac{SSR}{SST} = 1 - \frac{SSE}{SST}.
\]

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in \( \text{mdl} \) is

\[
r_2 = \text{mdl.Rsquared.Adjusted}
\]

**SSE — Sum of squared errors**

numeric value

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]

**SSR — Regression sum of squares**

numeric value

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]

**SST — Total sum of squares**

numeric value

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector \( y \) from \( \text{mean}(y) \).

The Pythagorean theorem implies

\[
SST = SSE + SSR.
\]
\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**Steps — Stepwise fitting information**

Structure

Stepwise fitting information, specified as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Formula representing the starting model</td>
</tr>
<tr>
<td>Lower</td>
<td>Formula representing the lower bound model, these terms that must remain in the model</td>
</tr>
<tr>
<td>Upper</td>
<td>Formula representing the upper bound model, model cannot contain more terms than Upper</td>
</tr>
<tr>
<td>Criterion</td>
<td>Criterion used for the stepwise algorithm, such as 'sse'</td>
</tr>
<tr>
<td>PEnter</td>
<td>Value of the parameter, such as 0.05</td>
</tr>
<tr>
<td>PRemove</td>
<td>Value of the parameter, such as 0.10</td>
</tr>
<tr>
<td>History</td>
<td>Table representing the steps taken in the fit</td>
</tr>
</tbody>
</table>

The History table has one row for each step including the initial fit, and the following variables (columns).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Action taken during this step, one of:</td>
</tr>
<tr>
<td></td>
<td>• 'Start' — First step</td>
</tr>
<tr>
<td></td>
<td>• 'Add' — A term is added</td>
</tr>
<tr>
<td></td>
<td>• 'Remove' — A term is removed</td>
</tr>
<tr>
<td>TermName</td>
<td>• 'Start' step: The starting model specification</td>
</tr>

The structure is empty unless you use `stepwiselm` or `stepwiseglm` to fit the model.

**VariableInfo — Information about input variables**

table

Information about input variables contained in `Variables`, specified as a table with one row for each model term and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Character vector giving variable class, such as <code>'double'</code></td>
</tr>
<tr>
<td>Range</td>
<td>Cell array giving variable range:</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector $[\min, \max]$, the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Cell array of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Logical vector, where <code>true</code> indicates the variable is in the model</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Logical vector, where <code>true</code> indicates a categorical variable</td>
</tr>
</tbody>
</table>

**VariableNames — Names of variables used in fit**

cell array of character vectors

Names of variables used in fit, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

**Variables — Data used to fit the model**

table

Data used to fit the model, specified as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of
the data from that table or dataset array. Otherwise, Variables is a table created from
the input data matrix \( X \) and response vector \( y \).

**Methods**

- `addTerms`: Add terms to generalized linear model
- `compact`: Compact generalized linear regression model
- `fit`: Create generalized linear regression model
- `plotDiagnostics`: Plot diagnostics of generalized linear regression model
- `plotResiduals`: Plot residuals of generalized linear regression model
- `removeTerms`: Remove terms from generalized linear model
- `step`: Improve generalized linear regression model by adding or removing terms
- `stepwise`: Create generalized linear regression model by stepwise regression

**Inherited Methods**

- `coefCI`: Confidence intervals of coefficient estimates of generalized linear model
- `coefTest`: Linear hypothesis test on generalized linear regression model coefficients
- `devianceTest`: Analysis of deviance
- `disp`: Display generalized linear regression model
- `feval`: Evaluate generalized linear regression model prediction
- `plotSlice`: Plot of slices through fitted generalized linear regression surface
- `predict`: Predict response of generalized linear regression model
- `random`: Simulate responses for generalized linear regression model

**Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

**Fit a Generalized Linear Model**

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```matlab
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```matlab
modelSpec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```matlab
mdl = fitglm(ds,modelSpec,'Distribution','binomial')
```

```
mdl =
Generalized linear regression model:
  logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
  Distribution = Binomial

Estimated Coefficients:
  Estimate SE tStat pValue
(Intercept)  -6.0492  19.749 -0.3063 0.75938
Sex_Male    -2.2859  12.424 -0.18399 0.85402
Age         0.11691  0.50977 0.22934 0.81861
Weight      0.031109 0.15208 0.20455 0.83792
Sex_Male:Age 0.020734 0.20681 0.10025 0.92014
Sex_Male:Weight 0.01216 0.053168 0.22871 0.8191
Age:Weight  -0.00071959 0.0038964 -0.18468 0.85348
```

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large \( p \)-value indicates the model might not differ statistically from a constant.
Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);

Fit a generalized linear model using the Poisson distribution.

mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =
Generalized linear regression model:
    log(y) ~ 1 + x5 + x10 + x15
    Distribution = Poisson

Estimated Coefficients:

Hat Matrix

The hat matrix $H$ is defined in terms of the data matrix $X$ and a diagonal weight matrix $W$:

$$
H = X(X^TWX)^{-1}X^TW^T.
$$

$W$ has diagonal elements $w_i$:

$$
w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},
$$

where

- $g$ is the link function mapping $y_i$ to $x_i b$.
- $g'$ is the derivative of the link function $g$.
- $V$ is the variance function.
- $\mu_i$ is the $i$th mean.

The diagonal elements $H_{ii}$ satisfy
\[ 0 \leq h_{ii} \leq 1 \]
\[ \sum_{i=1}^{n} h_{ii} = p, \]

where \( n \) is the number of observations (rows of \( X \)), and \( p \) is the number of coefficients in the regression model.

**Leverage**

The leverage of observation \( i \) is the value of the \( i \)th diagonal term, \( h_{ii} \), of the hat matrix \( H \). Because the sum of the leverage values is \( p \) (the number of coefficients in the regression model), an observation \( i \) can be considered to be an outlier if its leverage substantially exceeds \( p/n \), where \( n \) is the number of observations.

**Cook’s Distance**

The Cook’s distance \( D_i \) of observation \( i \) is

\[ D_i = w_i \frac{e_i^2}{p\hat{\phi}^2} \frac{1}{(1-h_{ii})^2}, \]

where

- \( \hat{\phi} \) is the dispersion parameter (estimated or theoretical).
- \( e_i \) is the linear predictor residual, \( g(y_i) - x_i\hat{\beta} \), where
  - \( g \) is the link function.
  - \( y_i \) is the observed response.
  - \( x_i \) is the observation.
  - \( \hat{\beta} \) is the estimated coefficient vector.
- \( p \) is the number of coefficients in the regression model.
- \( h_{ii} \) is the \( i \)th diagonal element of the Hat Matrix on page 32-2744 \( H \).
Deviance

Deviance of a model $M_1$ is twice the difference between the loglikelihood of that model and the saturated model, $M_S$. The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are $n$ observations $y_i$, $i = 1, 2, \ldots, n$, with potentially different values for $X_i^T \beta$, then you can define a saturated model with $n$ parameters. Let $L(b, y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model $M_1$ is

$$-2\left(\log L(b_1, y) - \log L(b_S, y)\right),$$

where $b_1$ are the estimated parameters for model $M_1$ and $b_S$ are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where $n$ is the number of parameters in the saturated model and $p$ is the number of parameters in model $M_1$.

If $M_1$ and $M_2$ are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances $D_1$ and $D_2$ of these models. The difference of the deviances is

$$D = D_2 - D_1 = -2\left(\log L(b_2, y) - \log L(b_S, y)\right) + 2\left(\log L(b_1, y) - \log L(b_S, y)\right)$$

$$= -2\left(\log L(b_2, y) - \log L(b_1, y)\right).$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom $v$ equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can get the $p$-value for this test using $1 - \text{chi2cdf}(D, V)$, where $D = D_2 - D_1$.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
The predict and random functions support code generation.
When you fit a model by using fitglm or stepwiseglm, the following restrictions apply.

- Code generation does not support categorical predictors. You cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the 'CategoricalVars' name-value pair argument. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.
- The Link, Derivative, and Inverse fields of the 'Link' name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 31-2.

Topics
“Generalized Linear Model Workflow” on page 12-40
“Generalized Linear Models” on page 12-12

Introduced in R2012a
**generateCode**

**Package:** classreg.learning.coder.config.svm

Generate C/C++ code using coder configurer

After training a machine learning model, create a coder configurer for the model by using `learnerCoderConfigurer`. Modify the properties of the configurer to specify code generation options. Then use `generateCode` to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use `generateCode` for the highlighted step.

![Code Generation Workflow](image)

**Syntax**

```matlab
generateCode(configurer)
generateCode(configurer,cfg)
generateCode(__,'OutputPath',outputPath)
```

**Description**

`generateCode(configurer)` generates a MEX function for the `predict` and `update` functions of a machine learning model by using `configurer`. The generated MEX function is named `outputFileName`, which is the file name stored in the `OutputFileName` property of `configurer`. 
To generate a MEX function, `generateCode` first generates the following MATLAB files required to generate code and stores them in the current folder:

- `predict.m`, `update.m`, and `initialize.m` — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`.
- A MAT-file that includes machine learning model information — `generateCode` uses the `saveCompactModel` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadCompactModel` function.

After generating the necessary MATLAB files, `generateCode` creates the MEX function and the code for the MEX function in the `codegen\mex\outputFileName` folder and copies the MEX function to the current folder.

`generateCode(configurer, cfg)` generates C/C++ code using the build type specified by `cfg`.

`generateCode(____,'OutputPath', outputPath)` specifies the folder path for the output files in addition to any of the input arguments in previous syntaxes.
`generateCode` generates the MATLAB files in the folder specified by `outputPath` and generates C/C++ code in the folder `outputPath\codegen\type\outputFileName` where `type` is the build type specified by `cfg`.

## Examples

### Generate Code Using Coder Configurer

Train a machine learning model and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```matlab
load carsmall
X = [Horsepower, Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.
Create a coder configurer for the RegressionSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

```matlab
configurer = learnerCoderConfigurer(Mdl,X)
```

```matlab
configurer = RegressionSVMCoderConfigurer with properties:

Update Inputs:
   Alpha: [1×1 LearnerCoderInput]
   SupportVectors: [1×1 LearnerCoderInput]
   Scale: [1×1 LearnerCoderInput]
   Bias: [1×1 LearnerCoderInput]

Predict Inputs:
   X: [1×1 LearnerCoderInput]

Code Generation Parameters:
   NumOutputs: 1
   OutputFileName: 'RegressionSVMMModel'
```

(configurer is a RegressionSVMCoderConfigurer object, which is a coder configurer of a RegressionSVM object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use mex -setup to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use generateCode to generate code for the predict and update functions of the RegressionSVM model with default settings.

```matlab
generateCode(configurer)
```

These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMMModel.mat'

generateCode generates these files for code generation.
generateCode generates the MATLAB files required to generate code, including the two entry-point functions predict.m and update.m for the predict and update functions of the RegressionSVM model (Mdl), respectively. Then generateCode creates a MEX function named RegressionSVMModel for the two entry-point functions and the code for the MEX function in the codegen\mex\RegressionSVMModel folder and copies the MEX function to the current folder.

Display the contents of the predict.m, update.m, and initialize.m files.

```matlab
type predict.m % Display contents of predict.m

function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:17:23
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m % Display contents of update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:17:23
initialize('update',varargin{:});
end

type initialize.m % Display contents of initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:17:23
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       Scale
        %                       Bias

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
```
Specify Build Type

Train a machine learning model and generate code by using the coder configurer of the trained model. When generating code, specify the build type and other configuration options using a code generation configuration object.

Load the ionosphere data set and train a binary support vector machine (SVM) classification model.

```matlab
load ionosphere
Mdl = fitcsvm(X,Y);```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```matlab
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Create a code generation configuration object by using `coder.config`. Specify 'dll' to generate a dynamic library and specify the `GenerateReport` property as `true` to enable the code generation report.

```matlab
cfg = coder.config('dll');
cfg.GenerateReport = true;
```
To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` and the configuration object `cfg` to generate code. Also, specify the output folder path.

```matlab
generateCode(configurer, cfg, 'OutputPath', 'testPath')
```

Specified folder does not exist. Folder has been created.
These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
generateCode generates these files for code generation.
Code generation successful: View report

generateCode creates the specified folder. The function also generates the MATLAB files required to generate code and stores them in the folder. Then `generateCode` generates C code in the `testPath\codegen\dll\ClassificationSVMModel` folder.

**Update Model Parameters in Generated Code**

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

**Train Model**

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```matlab
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.
Create CoderConfigurer

Create a coder configurer for the ClassificationSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

configurer = learnerCoderConfigurer(Mdl,X(1:50,:),'NumOutputs',2);

configurer is a ClassificationSVMCoderConfigurer object, which is a coder configurer of a ClassificationSVM object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of X so that the generated code accepts any number of observations. Modify the SizeVector and VariableDimensions attributes. The SizeVector attribute specifies the upper bound of the predictor data size, and the VariableDimensions attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is Inf and the size is variable, meaning that X can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. X contains 34 predictors, so the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be false.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of SupportVectors so that you can update the support vectors in the generated code.
configurer.SupportVectors.SizeVector = [250 34];

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

configurer.SupportVectors.VariableDimensions = [true false];

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the `ClassificationSVM` model with default settings.

```matlab
generateCode(configurer)
```

These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

generateCode generates these files for code generation.

```matlab
generateCode generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of the `ClassificationSVM` model (Mdl), respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

**Verify Generated Code**

Pass some predictor data to verify whether the `predict` function of Mdl and the `predict` function in the MEX function return the same labels. To call an entry-point
function in a MEX function that has more than one entry point, specify the function name as the first input argument.

[label, score] = predict(Mdl, X);
[label_mex, score_mex] = ClassificationSVMModel('predict', X);

Compare label and label_mex by using isequal.

isequal(label, label_mex)
ans = logical
  1

isequal returns logical 1 (true) if all the inputs are equal. The comparison confirms that the predict function of Mdl and the predict function in the MEX function return the same labels.

score_mex might include round-off differences compared with score. In this case, compare score_mex and score, allowing a small tolerance.

find(abs(score - score_mex) > 1e-8)
ans =
   0×1 empty double column vector

The comparison confirms that score and score_mex are equal within the tolerance 1e–8.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

retrainedMdl = fitcsvm(X, Y);

Extract parameters to update by using validatedUpdateInputs. This function detects the modified model parameters in retrainedMdl and validates whether the modified parameter values satisfy the coder attributes of the parameters.

params = validatedUpdateInputs(configurer, retrainedMdl);

Update parameters in the generated code.

ClassificationSVMModel('update', params)
Verify Generated Code

Compare the outputs from the predict function of `retrainedMdl` and the predict function in the updated MEX function.

```matlab
labels = predict(retrainedMdl,X);
label_mex = ClassificationSVMModel('predict',X);
isequal(labels,label_mex)

ans = logical
  1

find(abs(score-score_mex) > 1e-8)
ans =

  0×1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Input Arguments

`configurer` — Coder configurer
coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

This table shows coder configurer objects corresponding to the supported machine learning models.

<table>
<thead>
<tr>
<th>Model</th>
<th>Coder Configurer Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support vector machine (SVM) classification</td>
<td>ClassificationSVMCoderConfigurer</td>
</tr>
<tr>
<td>SVM regression</td>
<td>RegressionSVMCoderConfigurer</td>
</tr>
</tbody>
</table>

`cfg` — Build type
'mex' (default) | 'dll' | 'lib' | code generation configuration object

32-2757
Build type, specified as 'mex', 'dll', 'lib', or a code generation configuration object created by coder.config.

generateCode generates C/C++ code using one of the following build types.

- 'mex' — Generates a MEX function that has a platform-dependent extension. A MEX function is a C/C++ program that is executable from the Command Window. Before generating a C/C++ library for deployment, generate a MEX function to verify that the generated code provides the correct functionality.
- 'dll' — Generate a dynamic C/C++ library.
- 'lib' — Generate a static C/C++ library.
- Code generation configuration object created by coder.config — Generate C/C++ code using the code generation configuration object to customize code generation options. You can specify the build type and other configuration options using the object. For example, modify the GenerateReport parameter to enable the code generation report, and modify the TargetLang parameter to generate C++ code. The default value of the TargetLang parameter is 'C', generating C code.

```matlab
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.TargetLang = 'C++';
```

For details, see the -config option of codegen, coder.config, and “Configure Build Settings” (MATLAB Coder).

generateCode generates C/C++ code in the folder `outputPath\codegen\type \outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the `OutputFileName` property of `configurer`.

**outputPath — Folder path for output files**
current folder (default) | character vector | string scalar

Folder path for the output files of generateCode, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
• The path also cannot contain non-7-bit ASCII characters, such as Japanese characters. If the specified folder does not exist, then `generateCode` creates the folder.

`generateCode` searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then `generateCode` generates the files. Otherwise, `generateCode` does not generate any MATLAB files.

`generateCode` generates C/C++ code in the folder `outputPath\codegen\type\outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the `OutputFileName` property of `configurer`.

Example: 'C:\myfiles'

Data Types: char | string

**Limitations**

• The `generateCode` function uses the `saveCompactModel`, `loadCompactModel`, and `codegen` functions, so the code generation limitations of these functions also apply to the `generateCode` function. For details, see the function reference pages `saveCompactModel`, `loadCompactModel`, and `codegen`.

• For the code generation usage notes and limitations of a machine learning model and its object functions, see the Code Generation sections of the corresponding reference pages.

<table>
<thead>

</tr>
</tbody>
</table>

**Alternative Functionality**

• If you want to modify the MATLAB files (`predict.m`, `update.m`, and `initialize.m`) according to your code generation workflow, then use `generateFiles` to generate these files and use `codegen` to generate code.

Introduced in R2018b
**generateFiles**

**Package:** classreg.learning.coder.config.svm

Generate MATLAB files for code generation using coder configurer

**Syntax**

```matlab
generateFiles(configurer)
generateFiles(configurer,'OutputPath',outputPath)
```

**Description**

`generateFiles(configurer)` generates the MATLAB files required to generate C/C++ code by using the coder configurer `configurer`, and saves the generated files in the current folder.

To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`.

`generateFiles` generates the following MATLAB files:

- **`predict.m`, `update.m`, and `initialize.m`** — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`. You can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project.

- A MAT-file that includes machine learning model information — `generateFiles` uses the `saveCompactModel` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadCompactModel` function.

After you generate these files, generate C/C++ code by using `codegen` and the prepared `codegen` argument stored in the `CodeGenerationArguments` property of a coder configurer.
If the folder already includes all four MATLAB files, then generateFiles does not generate any files.

generateFiles(configurer,'OutputPath',outputPath) generates the MATLAB files in the folder specified by outputPath.

**Examples**

**Generate MATLAB® Files for Code Generation**

Train a machine learning model and then generate the MATLAB files required to generate C/C++ code for the predict and update functions of the model by using a coder configurer.

Load the ionosphere data set and train a binary support vector machine (SVM) classification model.

```matlab
load ionosphere
Mdl = fitcsvm(X,Y);
```

Mdl is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` object.

```matlab
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Use `generateFiles` to generate the MATLAB files required to generate C/C++ code for the predict and update functions of the model.

```matlab
generateFiles(configurer)
```

generateFiles generates `predict.m`, `update.m`, `initialize.m`, and `ClassificationSVMModel.mat` (a MAT-file that includes machine learning model information).

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files.

```matlab
type predict.m % Display contents of predict.m
```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 27-Aug-2018 19:46:31
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m % Display contents of update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 27-Aug-2018 19:46:31
initialize('update',varargin{:});
end

type initialize.m % Display contents of initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 27-Aug-2018 19:46:31
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('ClassificationSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       SupportVectorLabels
        %                       Scale
        %                       Bias
        %                       Prior
        %                       Cost

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
Generate C/C++ code by using codegen and the prepared codegen argument stored in the CodeGenerationArguments property of configurer.

```matlab
cfArgs = configurer.CodeGenerationArguments;
codegen(cfArgs{:})
```

### Input Arguments

**configurer — Coder configurer**

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

This table shows coder configurer objects corresponding to the supported machine learning models.

<table>
<thead>
<tr>
<th>Model</th>
<th>Coder Configurer Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support vector machine (SVM) classification</td>
<td>ClassificationSVMCoderConfigurer</td>
</tr>
<tr>
<td>SVM regression</td>
<td>RegressionSVMCoderConfigurer</td>
</tr>
</tbody>
</table>

**outputPath — Folder path for output files**

current folder (default) | character vector | string scalar

Folder path for the output files of `generateFiles`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateFiles` creates the folder.
generateFiles searches the specified folder for the four MATLAB files: predict.m, update.m, initialize.m, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then generateFiles generates the files. Otherwise, generateFiles does not generate any MATLAB files.

Example: 'C:\myfiles'

Data Types: char | string

Alternative Functionality

• To customize the code generation workflow, use generateFiles and codegen. If you do not need to customize your workflow, use generateCode. In addition to generating the four MATLAB files generated by generateFiles, the generateCode function also generates the C/C++ code.

Introduced in R2018b
geocdf

Geometric cumulative distribution function

Syntax

\[ y = \text{geocdf}(x,p) \]
\[ y = \text{geocdf}(x,p,'\text{upper}') \]

Description

\[ y = \text{geocdf}(x,p) \] returns the cumulative distribution function (cdf) of the geometric distribution at each value in \( x \) using the corresponding probabilities in \( p \). \( x \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( p \) must lie on the interval \([0, 1]\).

\[ y = \text{geocdf}(x,p,'\text{upper}') \] returns the complement of the geometric distribution cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at \( x \) equal to 3. The probability of success (tossing a heads) \( p \) in any given trial is 0.5.
x = 3;
p = 0.5;
y = geocdf(x,p)
y = 0.9375

The returned value of $y$ indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

Definitions

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x | p) = 1 - (1 - p)^{x+1} ; x = 0, 1, 2, \ldots,$$

where $p$ is the probability of success, and $x$ is the number of failures before the first success. The result $y$ is the probability of observing up to $x$ trials before a success, when the probability of success in any given trial is $p$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

cdf | geoinv | geopdf | geornd | geostat | mle

Topics

“Geometric Distribution” on page B-61

Introduced before R2006a
geoinv

Geometric inverse cumulative distribution function

Syntax

\[ x = \text{geoinv}(y,p) \]

Description

\[ x = \text{geoinv}(y,p) \] returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in \( y \) using the corresponding probabilities in \( p \).

geoinv returns the smallest positive integer \( x \) such that the geometric cdf evaluated at \( x \) is equal to or exceeds \( y \). You can think of \( y \) as the probability of observing \( x \) successes in a row in independent trials, where \( p \) is the probability of success in each trial.

\( y \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for \( p \) or \( y \) is expanded to a constant array with the same dimensions as the other input. The values in \( p \) and \( y \) must lie on the interval \([0, 1]\).

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial \( p \) equals 0.03, while the probability of observing \( x \) failures in a row before observing a success \( y \) equals 0.1.
\[ y = 0.1; \]
\[ p = 0.03; \]
\[ x = \text{geoinv}(y,p) \]

\[ x = 3 \]

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of \( x \) equal to 2 and 3, given the probability of success for each trial \( p \) equal to 0.03.

\[ y_2 = \text{geocdf}(2,p) \quad \% \text{cdf for } x = 2 \]

\[ y_2 = 0.0873 \]

\[ y_3 = \text{geocdf}(3,p) \quad \% \text{cdf for } x = 3 \]

\[ y_3 = 0.1147 \]

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

**Extended Capabilities**

Introduced before R2006a
geomean

Geometric mean

Syntax

m = geomean(X)
m = geomean(X,'all')
m = geomean(X,dim)
m = geomean(X,vecdim)

Description

m = geomean(X) calculates the geometric mean on page 32-2774 of a sample. For vectors, geomean(X) is the geometric mean of the elements in X. For matrices, geomean(X) is a row vector containing the geometric means of each column. For N-dimensional arrays, geomean operates along the first nonsingleton dimension of X.

m = geomean(X,'all') returns the geometric mean of all elements of X.

m = geomean(X,dim) takes the geometric mean along the operating dimension dim of X.

m = geomean(X,vecdim) returns the geometric mean over the dimensions specified in the vector vecdim. Each element of vecdim represents a dimension of the input array X. The output m has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and m. For example, if X is a 2-by-3-by-4 array, then geomean(X,[1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the geometric mean of the elements on the corresponding page of X.

Examples

Compare Geometric and Arithmetic Mean

Set the random seed for reproducibility of the results.
rng('default')

Create a matrix of exponential random numbers with 5 rows and 4 columns.

```matlab
X = exprnd(1,5,4)
```

```
X = 5×4
    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
   2.0637    0.6035    0.0438    0.0880
   0.0906    0.0434    0.7228    0.2329
   0.4583    0.0357    0.2228    0.0414
```

Compute the geometric and arithmetic means of the columns of `X`.

```matlab
geometric = geomean(X)
```

```
geometric = 1×4
    0.2805    0.3083    0.2079    0.2698
```

```matlab
arithmetic = mean(X)
```

```
arithmetic = 1×4
    0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than or equal to the geometric mean.

**Geometric Mean of All Values**

Find the geometric mean of all the values in an array.

Create a 3-by-5-by-2 array `X`.

```matlab
X = reshape(1:30,[3 5 2])
```

```
X(:,:,1) =
    0.2805    0.3083    0.2079    0.2698
```

```matlab
X(:,:,1) =
    0.5833    0.8577    0.5734    0.6357
```
Find the geometric mean of the elements of \( X \).

\[ m = \text{geomean}(X, 'all') \]

\[ m = 12.0445 \]

### Definitions

#### Geometric Mean

The geometric mean of a sample \( X \) is

\[
m = \left[ \prod_{i=1}^{n} x_i \right]^{1/n}
\]

where \( n \) is the number of values in \( X \).

### Extended Capabilities

#### Tall Arrays

Calculate with arrays that have more rows than fit in memory.
This function supports tall arrays with the limitations:

- The following syntaxes are not supported.
  - \( m = \text{geomean}(X,'all') \)
  - \( m = \text{geomean}(X,\text{vecdim}) \)

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
  - \( m = \text{geomean}(X,'all') \)
  - \( m = \text{geomean}(X,\text{vecdim}) \)

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The following syntaxes do not support GPU arrays as input arguments.
  - \( m = \text{geomean}(X,'all') \)
  - \( m = \text{geomean}(X,\text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**

“Geometric Distribution” on page B-61
Introduced before R2006a
geopdf

Geometric probability density function

Syntax

\( y = \text{geopdf}(x,p) \)

Description

\( y = \text{geopdf}(x,p) \) returns the probability density function (pdf) of the geometric distribution at each value in \( x \) using the corresponding probabilities in \( p \). \( x \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( p \) must lie on the interval \([0,1]\).

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distribution at \( x \) equal to 3. The probability of success (tossing a heads) \( p \) in any given trial is 0.5.

\[
\begin{align*}
x &= 3; \\
p &= 0.5; \\
y &= \text{geopdf}(x,p)
\end{align*}
\]

\( y = 0.0625 \)

The returned value of \( y \) indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.
Definitions

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

\[ y = f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \ldots \]

where \( p \) is the probability of success, and \( x \) is the number of failures before the first success. The result \( y \) is the probability of observing exactly \( x \) trials before a success, when the probability of success in any given trial is \( p \). For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Geometric Distribution” on page B-61
Introduced before R2006a
geornd

Geometric random numbers

Syntax

\[ r = \text{geornd}(p) \]
\[ r = \text{geornd}(p,m,n,...) \]
\[ r = \text{geornd}(p,[m,n,...]) \]

Description

\( r = \text{geornd}(p) \) generates random numbers from a geometric distribution with probability parameter \( p \). \( p \) can be a vector, a matrix, or a multidimensional array. The size of \( r \) is equal to the size of \( p \). The parameters in \( p \) must lie in the interval \([0,1]\).

\( r = \text{geornd}(p,m,n,...) \) or \( r = \text{geornd}(p,[m,n,...]) \) generates a multidimensional \( m \)-by-\( n \)-by-\( ... \) array containing random numbers from the geometric distribution with probability parameter \( p \). \( p \) can be a scalar or an array of the same size as \( r \).

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant \( p \).

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter \( p \) equal to 0.01.

\[
\begin{align*}
\text{rng default} & \quad \% \text{ For reproducibility} \\
p &= 0.01; \\
r1 &= \text{geornd}(0.01)
\end{align*}
\]
r1 = 20

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success $p$ equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter $p$ equal to 0.01.

$r2 = \text{geornd}(p,1,5)$

$r2 = \begin{bmatrix} 9 & 205 & 9 & 45 & 231 \end{bmatrix}$

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success $p$ equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities $p$.

$p = [0.01 \ 0.1 \ 0.5]$;

$r3 = \text{geornd}(p,[1 \ 3])$

$r3 = \begin{bmatrix} 127 & 5 & 0 \end{bmatrix}$

Each element of the returned 1-by-3 array $r3$ contains one random number generated from the geometric distribution described by the corresponding parameter in $P$. For example, the first element in $r3$ represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success $p$ equal to 0.01. The second element in $r3$ represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success $p$ equal to 0.1. The third element in $r3$ represents an experiment in which zero failures were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success $p$ equal to 0.5.
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

• The output is nonscalar.
• An input parameter is invalid for the distribution.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“Geometric Distribution” on page B-61

Introduced before R2006a
geostat

Geometric mean and variance

Syntax

\[ [m,v] = \text{geostat}(p) \]

Description

\[ [m,v] = \text{geostat}(p) \] returns the mean \( m \) and variance \( v \) of a geometric distribution with corresponding probability parameters in \( p \). \( p \) can be a vector, a matrix, or a multidimensional array. The parameters in \( p \) must lie in the interval \([0, 1]\).

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

\[ p = 1./(1:6) \]

\[ p = 1\times6 \]

\[
\begin{array}{ccccccc}
1.0000 & 0.5000 & 0.3333 & 0.2500 & 0.2000 & 0.1667 \\
\end{array}
\]

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

\[ [m,v] = \text{geostat}(1./(1:6)) \]

\[ m = 1\times6 \]

\[
\begin{array}{ccccccc}
0 & 1.0000 & 2.0000 & 3.0000 & 4.0000 & 5.0000 \\
\end{array}
\]
The returned values indicate that, for example, the mean of a geometric distribution with probability parameter $p$ equal to 1/3 is 2, and its variance is 6.

**Definitions**

**Geometric Distribution Mean and Variance**

The mean of the geometric distribution is

$$\text{mean} = \frac{1 - p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1 - p}{p^2},$$

where $p$ is the probability of success.

**Extended Capabilities**

GapEvaluation

Package: clustering.evaluation
Superclasses:
Gap criterion clustering evaluation object

Description

GapEvaluation is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using evalclusters.

Construction

eva = evalclusters(x,clust,'Gap') creates a gap criterion clustering evaluation object.

eva = evalclusters(x,clust,'Gap',Name,Value) creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data
matrix

Input data, specified as an N-by-P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm
'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.
'kmeans' Cluster the data in x using the \textit{kmeans} clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.

'linkage' Cluster the data in x using the \textit{clusterdata} agglomerative clustering algorithm, with 'Linkage' set to 'ward'.

'gmdistribution' Cluster the data in x using the \textit{gmdistribution} Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form \texttt{C = clustfun(DATA,K)}, where \texttt{DATA} is the data to be clustered, and \texttt{K} is the number of clusters. The output of \texttt{clustfun} must be one of the following:

- A vector of integers representing the cluster index for each observation in \texttt{DATA}. There must be \texttt{K} unique values in this vector.
- A numeric \texttt{n}\texttimes\texttt{K} matrix of score for \texttt{n} observations and \texttt{K} classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify \texttt{clust} as a \texttt{n}\texttimes\texttt{K} matrix containing the proposed clustering solutions. \texttt{n} is the number of observations in the sample data, and \texttt{K} is the number of proposed clustering solutions. Column \texttt{j} contains the cluster indices for each of the \texttt{N} points in the \texttt{j}\textsuperscript{th} clustering solution.

Data Types: \texttt{single | double | char | string | function_handle}

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name\textsubscript{1},Value\textsubscript{1},...,Name\textsubscript{N},Value\textsubscript{N}}.

Example: 'KList',[1:5],'Distance','cityblock' specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

\textbf{B — Number of reference data sets}
\texttt{100 (default) | positive integer value}
Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B',150`

Data Types: `single` | `double`

**Distance — Distance metric**
`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | `function` | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

- `'sqEuclidean'` : Squared Euclidean distance
- `'Euclidean'` : Euclidean distance
- `'cityblock'` : Sum of absolute differences
- `'cosine'` : One minus the cosine of the included angle between points (treated as vectors)
- `'correlation'` : One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using a function handle (MATLAB). The distance function must be of the form

\[
d2 = \text{distfun}(XI,XJ),
\]

where `XI` is a 1-by-`n` vector corresponding to a single row of the input matrix `X`, and `XJ` is an `m_2`-by-`n` matrix corresponding to multiple rows of `X`. `distfun` must return an `m_2`-by-1 vector of distances `d2`, whose `k`th element is the distance between `XI` and `XJ(k,:)`.

Distance only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- When `clust` is `'kmeans'` or `'gmdistribution'`, `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
• If `clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
• In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance','Euclidean'

Data Types: single | double | char | string | function_handle

**KList — List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name or a function handle. When criterion is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]

Data Types: single | double

**ReferenceDistribution — Reference data generation method**

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA' Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x.

'uniform' Generate reference data uniformly over the range of each feature in the data matrix x.

Example: 'ReferenceDistribution','uniform'

**SearchMethod — Method for selecting optimal number of clusters**

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.
Evaluate each proposed number of clusters in \( K \text{List} \) and select the smallest number of clusters satisfying

\[
\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),
\]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, \( \text{GAPMAX} \) is the largest gap value, and \( \text{SE}(\text{GAPMAX}) \) is the standard error corresponding to the largest gap value.

Evaluate each proposed number of clusters in \( K \text{List} \) and select the smallest number of clusters satisfying

\[
\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),
\]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, and \( \text{SE}(K + 1) \) is the standard error of the clustering solution with \( K + 1 \) clusters.

Example: 'SearchMethod','globalMaxSE'

**Properties**

**B**

Number of data sets generated from the reference distribution, stored as a positive integer value.

**ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

**CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name.
**CriterionValues**

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

**Distance**

Distance metric used for clustering data, stored as a valid distance metric name.

**ExpectedLogW**

Expectation of the natural logarithm of $W$ based on the generated reference data, stored as a vector of scalar values. $W$ is the within-cluster dispersion computed using the distance metric `Distance`.

**InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

**LogW**

Natural logarithm of $W$ based on the input data, stored as a vector of scalar values. $W$ is the within-cluster dispersion computed using the distance metric `Distance`.

**Missing**

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix $x$ is not used in the clustering solution.

**NumObservations**

Number of observations in the data matrix $X$, minus the number of missing (NaN) values in $X$, stored as a positive integer value.

**OptimalK**

Optimal number of clusters, stored as a positive integer value.
**OptimalY**

Optimal clustering solution corresponding to OptimalK, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, OptimalY is empty.

**ReferenceDistribution**

Reference data generation method, stored as a valid reference distribution name.

**SE**

Standard error of the natural logarithm of W with respect to the reference data for each number of clusters in InspectedK, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance metric Distance.

**SearchMethod**

Method for determining the optimal number of clusters, stored as a valid search method name.

**StdLogW**

Standard deviation of the natural logarithm of W with respect to the reference data for each number of clusters in InspectedK. W is the within-cluster dispersion computed using the distance metric Distance.

**X**

Data used for clustering, stored as a matrix of numerical values.

**Methods**

- increaseB 
  Increase reference data sets
Inherited Methods

addK  Evaluate additional numbers of clusters
plot  Plot clustering evaluation object criterion values
compact  Compact clustering evaluation object

Examples

Evaluate Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

load fisheriris

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using kmeans.

rng('default');  % For reproducibility
ev = evalclusters(meas,'kmeans','gap','KList',[1:6])
ev =
    GapEvaluation with properties:
        NumObservations: 150
        InspectedK: [1 2 3 4 5 6]
        CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
        OptimalK: 5

The OptimalK value indicates that, based on the gap criterion, the optimal number of clusters is five.

Plot the gap criterion values for each number of clusters tested.

plot(eva)
Based on the plot, the maximum value of the gap criterion occurs at six clusters. However, the value at five clusters is within one standard error of the maximum, so the suggested optimal number of clusters is five.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```matlab
figure
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgkc','xod^*');
```
The plot shows cluster 4 in the lower-left corner, completely separated from the other four clusters. Cluster 4 contains flowers with the smallest petal widths and lengths. Cluster 2 is in the upper-right corner and contains flowers with the largest petal widths and lengths. Cluster 5 is next to cluster 2 and contains flowers with similar petal widths as the flowers in cluster 2, but smaller petal lengths than the flowers in cluster 2. Clusters 1 and 3 are near the center of the plot and contain flowers with measurements between the extremes.
Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

\[
Gap_n (k) = E_n^* \{ \log (W_k) \} - \log (W_k),
\]

where \( n \) is the sample size, \( k \) is the number of clusters being evaluated, and \( W_k \) is the pooled within-cluster dispersion measurement

\[
W_k = \sum_{r=1}^{k} \frac{1}{2n_r} D_r,
\]

where \( n_r \) is the number of data points in cluster \( r \), and \( D_r \) is the sum of the pairwise distances for all points in cluster \( r \).

The expected value \( E_n^* \{ \log (W_k) \} \) is determined by Monte Carlo sampling from a reference distribution, and \( \log (W_k) \) is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Topics

Class Attributes (MATLAB)
Property Attributes (MATLAB)
get

Class: dataset

Access dataset array properties

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})

Description

get(A) displays a list of property/value pairs for the dataset array A.

s = get(A) returns the values in a scalar structure s with field names given by the properties.

p = get(A,PropertyName) returns the value of the property specified by PropertyName.

p = get(A,{PropertyName1,PropertyName2,...}) allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs),'%-d'));
iris = dataset({nominal(species),'species'},...
    {meas,'SL','SW','PL','PW'},...
    'ObsNames',NameObs);

get(iris)
    Description: ''
    Units: {}
    DimNames: {'Observations' 'Variables'}
    UserData: []
    ObsNames: {150x1 cell}
    VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
    'Obs1'
    'Obs2'
    'Obs3'

getlabels

Access nominal or ordinal array labels

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

\[ \text{labels} = \text{getlabels}(A) \]

**Description**

\( \text{labels} = \text{getlabels}(A) \) returns the labels of the levels in the nominal or ordinal array \( A \) as a cell array of character vectors, labels. If \( A \) is an ordinal array, \text{getlabels} returns the labels in the order of the levels.

**Input Arguments**

- \( A \) — **Nominal or ordinal array**
  - nominal array | ordinal array

  Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

**See Also**

- getlevels  
- nominal  
- ordinal

**Topics**

- “Change Category Labels” on page 2-9
Introduced in R2007a
getlevels

Access nominal or ordinal array levels

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

\[ L = \text{getlevels}(A) \]

**Description**

\[ L = \text{getlevels}(A) \] returns the levels in the nominal or ordinal array \( A \). \( L \) is a vector of the same type as \( A \).

**Input Arguments**

\( A \) — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

**See Also**

getlabels | nominal | ordinal

gevcdf

Generalized extreme value cumulative distribution function

Syntax

p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')

Description

p = gevcdf(x,k,sigma,mu) returns the cdf of the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu, evaluated at the values in x. The size of p is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

p = gevcdf(x,k,sigma,mu,'upper') returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for k, sigma, and mu are 0, 1, and 0, respectively.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblcdf function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evcdf function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution has positive density only for values of X such that k*(X-mu)/sigma > -1.

gevfit

Generalized extreme value parameter estimates

Syntax

parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)

Description

parmhat = gevfit(X) returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. parmhat(1) is the shape parameter, k, parmhat(2) is the scale parameter, sigma, and parmhat(3) is the location parameter, mu.

[parmhat,parmci] = gevfit(X) returns 95% confidence intervals for the parameter estimates.

[parmhat,parmci] = gevfit(X,alpha) returns 100(1-alpha)% confidence intervals for the parameter estimates.

[...] = gevfit(X,alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gevfit') for parameter names and default values. Pass in [] for alpha to use the default values.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wb1fit function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evfit function.
The mean of the GEV distribution is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). The GEV distribution is defined for \( k^*(X-mu)/sigma > -1 \).

geinv

Generalized extreme value inverse cumulative distribution function

Syntax

\[ X = \text{geinv}(P,k,sigma,mu) \]

Description

\[ X = \text{geinv}(P,k,sigma,mu) \] returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter \( k \), scale parameter \( sigma \), and location parameter \( mu \), evaluated at the values in \( P \). The size of \( X \) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for \( k \), \( sigma \), and \( mu \) are 0, 1, and 0, respectively.

When \( k < 0 \), the GEV is the type III extreme value distribution. When \( k > 0 \), the GEV distribution is the type II, or Frechet, extreme value distribution. If \( w \) has a Weibull distribution as computed by the \text{wblinv} function, then \(-w\) has a type III extreme value distribution and \(1/w\) has a type II extreme value distribution. In the limit as \( k \) approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the \text{evinv} function.

The mean of the GEV distribution is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). The GEV distribution has positive density only for values of \( X \) such that \( k*(X-mu)/sigma > -1 \).

Generalized extreme value negative log-likelihood

**Syntax**

\[
\text{nlogL} = \text{gevlike}(\text{params},\text{data})
\]

\[
[\text{nlogL,ACOV}] = \text{gevlike}(\text{params},\text{data})
\]

**Description**

\[
\text{nlogL} = \text{gevlike}(\text{params},\text{data})
\] returns the negative of the log-likelihood \(\text{nlogL}\) for the generalized extreme value (GEV) distribution, evaluated at parameters \(\text{params}\). \(\text{params}(1)\) is the shape parameter, \(k\), \(\text{params}(2)\) is the scale parameter, \(\sigma\), and \(\text{params}(3)\) is the location parameter, \(\mu\).

\[
[\text{nlogL,ACOV}] = \text{gevlike}(\text{params},\text{data})
\] returns the inverse of Fisher's information matrix, \(\text{ACOV}\). If the input parameter values in \(\text{params}\) are the maximum likelihood estimates, the diagonal elements of \(\text{ACOV}\) are their asymptotic variances. \(\text{ACOV}\) is based on the observed Fisher's information, not the expected information.

When \(k < 0\), the GEV is the type III extreme value distribution. When \(k > 0\), the GEV distribution is the type II, or Frechet, extreme value distribution. If \(w\) has a Weibull distribution as computed by the \(\text{wbllike}\) function, then \(-w\) has a type III extreme value distribution and \(1/w\) has a type II extreme value distribution. In the limit as \(k\) approaches \(0\), the GEV is the mirror image of the type I extreme value distribution as computed by the \(\text{evlike}\) function.

The mean of the GEV distribution is not finite when \(k \geq 1\), and the variance is not finite when \(k \geq 1/2\). The GEV distribution has positive density only for values of \(X\) such that \(k*(X-\mu)/\sigma > -1\).

gevpdf

Generalized extreme value probability density function

Syntax

Y = gevpdf(X,k,sigma,mu)

Description

Y = gevpdf(X,k,sigma,mu) returns the pdf of the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu, evaluated at the values in X. The size of Y is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k, sigma, and mu are 0, 1, and 0, respectively.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblpdf function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evcdf function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution has positive density only for values of X such that k*(X-mu)/sigma > -1.

Introduced before R2006a
gevrnd

Generalized extreme value random numbers

Syntax

R = gevrnd(k,sigma,mu)
R = gevrnd(k,sigma,mu,m,n,...)
R = gevrnd(k,sigma,mu,[m,n,...])

Description

R = gevrnd(k,sigma,mu) returns an array of random numbers chosen from the
generalized extreme value (GEV) distribution with shape parameter k, scale parameter
sigma, and location parameter, mu. The size of R is the common size of the input
arguments if all are arrays. If any parameter is a scalar, the size of R is the size of the
other parameters.

R = gevrnd(k,sigma,mu,m,n,...) or R = gevrnd(k,sigma,mu,[m,n,...])
generates an m-by-n-by-... array containing random numbers from the GEV distribution
with parameters k, sigma, and mu. The k, sigma, mu parameters can each be scalars or
arrays of the same size as R.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV
distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull
distribution as computed by the wblrnd function, then -w has a type III extreme value
distribution and 1/w has a type II extreme value distribution. In the limit as k approaches
0, the GEV is the mirror image of the type I extreme value distribution as computed by
the evrnd function.

The mean of the GEV distribution is not finite when k \geq 1, and the variance is not finite
when k \geq 1/2. The GEV distribution has positive density only for values of X such that
k*(X-mu)/sigma > -1.

gevstat

Generalized extreme value mean and variance

Syntax

[M,V] = gevstat(k,sigma,mu)

Description

[M,V] = gevstat(k,sigma,mu) returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu. The sizes of M and V are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k, sigma, and mu are 0, 1, and 0, respectively.

When k < 0, the GEV is the type III extreme value distribution. When k > 0, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblstat function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evstat function.

The mean of the GEV distribution is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. The GEV distribution has positive density only for values of X such that k*(X-mu)/sigma > -1.

“Generalized Extreme Value Distribution” on page B-50

Introduced before R2006a
gline

Interactively add line to plot

Syntax

gline(h)
gline
hline = gline(...)  

Description

gline(h) allows you to draw a line segment in the figure with handle h by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

gline with no input arguments defaults to h = gcf and draws in the current figure.

hline = gline(...) returns the handle hline to the line.

Examples

Use gline to connect two points in a plot:

```matlab
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```
See Also

Introduced before R2006a
glmfit

Generalized linear model regression

Syntax

\[ b = \text{glmfit}(X,y,distr) \]
\[ b = \text{glmfit}(X,y,distr,param1,val1,param2,val2,...) \]
\[ [b,dev] = \text{glmfit}(...) \]
\[ [b,dev,stats] = \text{glmfit}(...) \]

Description

\[ b = \text{glmfit}(X,y,distr) \] returns a \((p + 1)\)-by-1 vector \(b\) of coefficient estimates for a generalized linear regression of the responses in \(y\) on the predictors in \(X\), using the distribution \(distr\). \(X\) is an \(n\)-by-\(p\) matrix of \(p\) predictors at each of \(n\) observations. \(distr\) can be any of the following: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, \(y\) is an \(n\)-by-1 vector of observed responses. For the binomial distribution, \(y\) can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

**Note** By default, glmfit adds a first column of 1s to \(X\), corresponding to a constant term in the model. Do not enter a column of 1s directly into \(X\). You can change the default behavior of glmfit using the 'constant' parameter, below.

glmfit treats NaNs in either \(X\) or \(y\) as missing values, and ignores them.

\[ b = \text{glmfit}(X,y,distr,param1,val1,param2,val2,...) \] additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.
<table>

</thead>
</table>
| structure array having these fields: | - 'Link' — Link function  
- 'Derivative' — Derivative of the link function  
- 'Inverse' — Inverse of the link function  
The value of each field is a character vector corresponding to a function that is on the path or a function handle (created using @). | Custom-defined link function, its derivative, and its inverse. |
| 'estdisp'   | 'on'                   | Estimates a dispersion parameter for the binomial or Poisson distribution.    |
|             | 'off' (Default for binomial or Poisson distribution) | Uses the theoretical value of 1.0 for those distributions. |
| 'offset'    | Vector                 | Used as an additional predictor variable, but with a coefficient value fixed at 1.0. |
| 'weights'   | Vector of prior weights, such as the inverses of the relative variance of each observation | |
| 'constant'  | 'on' (default)        | Includes a constant term in the model. The coefficient of the constant term is the first element of b. |
|             | 'off'                  | Omit the constant term.                                                     |

\[b, dev\] = glmfit(...) returns dev, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test
whether the model with more terms is significantly better than the model with fewer terms.

\[ [b, \text{dev}, \text{stats}] = \text{glmfit}(...) \] returns \text{dev} and \text{stats}.

\text{stats} is a structure with the following fields:

- \text{beta} — Coefficient estimates \( b \)
- \text{dfe} — Degrees of freedom for error
- \text{sfit} — Estimated dispersion parameter
- \text{s} — Theoretical or estimated dispersion parameter
- \text{estdisp} — 0 when the 'estdisp' name-value pair argument value is 'off' and 1 when the 'estdisp' name-value pair argument value is 'on'.
- \text{covb} — Estimated covariance matrix for \( B \)
- \text{se} — Vector of standard errors of the coefficient estimates \( b \)
- \text{coeffcorr} — Correlation matrix for \( b \)
- \text{t} — \( t \) statistics for \( b \)
- \text{p} — \( p \)-values for \( b \)
- \text{resid} — Vector of residuals
- \text{residp} — Vector of Pearson residuals
- \text{residd} — Vector of deviance residuals
- \text{resida} — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then \text{stats.s} is set equal to \text{stats.sfit}. Also, the elements of \text{stats.se} differ by the factor \text{stats.s} from their theoretical values.

**Examples**

**Fit Generalized Linear Model with Probit Link**

Enter the sample data.

\[
x = [2100 2300 2500 2700 2900 3100 ... 3300 3500 3700 3900 4100 4300]';
\]
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';

Each y value is the number of successes in the corresponding number of trials in n, and x contains the predictor variable values.

Fit a probit regression model for y on x.

b = glmfit(x,[y n], 'binomial', 'link', 'probit');

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

yfit = glmval(b,x, 'probit', 'size', n);
plot(x, y./n, 'o', x, yfit./n, '-','LineWidth', 2)
Use Custom-Defined Link Function

Load the sample data.

load fisheriris

The column vector, species, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

\[
X = \text{meas}(51:\text{end},:);
\]
\[
y = \text{strcmp}('\text{versicolor}', \text{species}(51:\text{end}));
\]

Define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

\[
\text{link} = @(\mu) \log(\mu ./ (1-\mu));
\]
\[
\text{derlink} = @(\mu) 1 ./ (\mu .* (1-\mu));
\]
\[
\text{invlink} = @(\text{resp}) 1 ./ (1 + \exp(-\text{resp}));
\]
\[
F = \{\text{link}, \text{derlink}, \text{invlink}\};
\]

Fit a logistic regression using glmfit with the link function you defined.

\[
b = \text{glmfit}(X,y, '\text{binomial}', '\text{link}', F)
\]

\[
b = 5\times1
\]
\[
\begin{array}{c}
42.6378 \\
3.8152 \\
6.6809 \\
-9.4294 \\
-18.2861 \\
\end{array}
\]

Now, fit a generalized linear model using the logit link function and compare the results.

\[
b = \text{glmfit}(X,y, '\text{binomial}', '\text{link}', '\text{logit}')
\]

\[
b = 5\times1
\]

Introduced before R2006a
glmval

Generalized linear model values

Syntax

yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)

Description

yhat = glmval(b,X,link) computes predicted values for the generalized linear model with link function link and predictors X. Distinct predictor variables should appear in different columns of X. b is a vector of coefficient estimates as returned by the glmfit function. link can be any of the character vectors, string scalars, or custom-defined link functions used as values for the 'link' name-value pair argument in the glmfit function.

Note By default, glmval adds a first column of 1s to X, corresponding to a constant term in the model. Do not enter a column of 1s directly into X. You can change the default behavior of glmval using the 'constant' parameter, below.

[yhat,dylo,dyhi] = glmval(b,X,link,stats) also computes 95% confidence bounds for the predicted values. When the stats structure output of the glmfit function is specified, dylo and dyhi are also returned. dylo and dyhi define a lower confidence bound of yhat-dylo, and an upper confidence bound of yhat+dyhi. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

[...] = glmval(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'confidence' — the confidence level for the confidence bounds</td>
<td>A scalar between 0 and 1</td>
</tr>
<tr>
<td>'size' — the size parameter (N) for a binomial model</td>
<td>A scalar, or a vector with one value for each row of X</td>
</tr>
<tr>
<td>'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0</td>
<td>A vector</td>
</tr>
</tbody>
</table>
| 'constant'                | • 'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b.  
|                           | • 'off' — Omit the constant term                                       |
| 'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false) | true or false                                                         |

**Examples**

**Fit Generalized Linear Model with Probit Link**

Enter the sample data.

```matlab
x = [2100 2300 2500 2700 2900 3100 3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in the corresponding number of trials in n, and x contains the predictor variable values.

Fit a probit regression model for y on x.

```matlab
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.
Use Custom-Defined Link Function

Enter sample data.

```matlab
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```
Each y value is the number of successes in corresponding number of trials in n, and x contains the predictor variable values.

Now define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

\[
\text{link} = @(\mu) \text{norminv}(\mu);
\]
\[
\text{derlink} = @(\mu) 1 ./ \text{normpdf}(\text{norminv}(\mu));
\]
\[
\text{invlink} = @(\text{resp}) \text{normcdf}(\text{resp});
\]
\[
F = \{\text{link}, \text{derlink}, \text{invlink}\};
\]

Fit a generalized linear model for y on x using the link function you defined.

\[
b = \text{glmfit}(x, [y \ n], 'binomial', 'link', F);
\]

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

\[
yfit = \text{glmval}(b, x, F, 'size', n);
\]
\[
\text{plot}(x, y ./ n, 'o', x, yfit ./ n, '-', 'LineWidth', 2)
\]
Generate Code from Function That Predicts Responses Given New Data

Train a generalized linear model, and then generate code from a function that classifies new observations based on the model. This example is based on the “Use Custom-Defined Link Function” on page 32-2829 example.

Enter the sample data.

```matlab
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```
Suppose that the inverse normal pdf is an appropriate link function for the problem.

Define a function named `myInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the standard normal cdf.

```matlab
function in = myInvNorm(mu) %#codegen
%myInvNorm Inverse of standard normal cdf for code generation
% myInvNorm is a GLM link function that accepts a numeric vector mu, and
% returns in, which is a numeric vector of corresponding values of the
% inverse of the standard normal cdf.
% in = norminv(mu);
end
```

Define another function named `myDInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the derivative of the link function.

```matlab
function din = myDInvNorm(mu) %#codegen
%myDInvNorm Derivative of inverse of standard normal cdf for code generation
% myDInvNorm corresponds to the derivative of the GLM link function
% myInvNorm. myDInvNorm accepts a numeric vector mu, and returns din,
% which is a numeric vector of corresponding derivatives of the inverse
% of the standard normal cdf.
% din = 1./normpdf(norminv(mu));
end
```

Define another function named `myInvInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the link function.

```matlab
function iin = myInvInvNorm(mu) %#codegen
%myInvInvNorm Standard normal cdf for code generation
% myInvInvNorm is the inverse of the GLM link function myInvNorm.
% myInvInvNorm accepts a numeric vector mu, and returns iin, which is a
% numeric vector of corresponding values of the standard normal cdf.
% iin = normcdf(norminv(mu));
end
```
iin = normcdf(mu);
end

Create a structure array that specifies each of the link functions. Specifically, the structure array contains fields named 'Link', 'Derivative', and 'Inverse'. The corresponding values are the names of the functions.

link = struct('Link','myInvNorm','Derivative','myDInvNorm',...
    'Inverse','myInvInvNorm')

link =
    struct with fields:
        Link: 'myInvNorm'
        Derivative: 'myDInvNorm'
        Inverse: 'myInvInvNorm'

Fit a GLM for y on x using the link function link. Additionally, return the structure array of statistics.

[b,~,stats] = glmfit(x,[y n],'binomial','link',link);

b is a 2-by-1 vector of regression coefficients.

In your current working folder, define a function called classifyGLM.m that:

• Accepts measurements with columns corresponding to those in x, regression coefficients whose dimensions correspond to b, a link function, the structure of GLM statistics, and any valid glmval name-value pair argument

• Returns predictions and confidence interval margins of error

function [yhat,lo,hi] = classifyGLM(b,x,link,varargin) %#codegen
%CLASSIFYGLM Classify measurements using GLM model
%CLASSIFYGLM classifies the n observations in the n-by-1 vector x using
%the GLM model with regression coefficients b and link function link,
%and then returns the n-by-1 vector of predicted values in yhat.
%CLASSIFYGLM also returns margins of error for the predictions using
%additional information in the GLM statistics structure stats.
narginchk(3,Inf);
if(isstruct(varargin{1}))
    stats = varargin{1};
    [yhat,lo,hi] = glmval(b,x,link,stats,varargin{2:end});
else
    yhat = glmval(b,x,link,varargin{:});
end
end

Generate a MEX function from classifyGLM.m. Because C uses static typing, codegen must determine the properties of all variables in MATLAB® files at compile time. To ensure that the MEX function can use the same inputs, use the -args argument to specify the following in the order given:

- Regression coefficients b as a compile-time constant
- In-sample observations x
- Link function as a compile-time constant
- Resulting GLM statistics as a compile-time constant
- Name 'Confidence' as a compile-time constant
- Confidence level 0.9

To designate arguments as compile-time constants, use coder.Constant.

codegen -config:mex classifyGLM -args {coder.Constant(b),x,coder.Constant(link),coder.Constant(stats),coder.Constant('Confidence'),0.9}
codegen generates the MEX file classifyGLM_mex.mexw64 in your current folder. The file extension depends on your platform.

Compare predictions using glmval and classifyGLM_mex. Specify name-value pair arguments in the same order as in the -args argument in the call to codegen.

[yhat1,melo1,mehi1] = glmval(b,x,link,stats,'Confidence',0.9);
[yhat2,melo2,mehi2] = classifyGLM_mex(b,x,link,stats,'Confidence',0.9);

comp1 = (yhat1 - yhat2)'*(yhat1 - yhat2);
agree1 = comp1 < eps
comp2 = (melo1 - melo2)'*(melo1 - melo2);
agree2 = comp2 < eps
comp3 = (mehi1 - mehi2)'*(mehi1 - mehi2);
agree3 = comp3 < eps
agree1 =
    logical 1

agree2 =
    logical 1

agree3 =
    logical 1

The generated MEX function produces the same results as `predict`.

Topics
“Introduction to Code Generation” on page 31-2

Introduced before R2006a
**glyphplot**

Glyph plot

**Syntax**

```matlab
glyphplot(X)
glyphplot(X,'glyph','face')
glyphplot(X,'glyph','face','features',f)
glyphplot(X,...,'grid',[rows,cols])
glyphplot(X,...,'grid',[rows,cols],'page',p)
glyphplot(X,...,'centers',C)
glyphplot(X,...,'centers',C,'radius',r)
glyphplot(X,...,'obslabels',labels)
glyphplot(X,...,'standardize',method)
glyphplot(X,...,'prop1',val1,...)
h = glyphplot(X,...)
```

**Description**

`glyphplot(X)` creates a star plot from the multivariate data in the n-by-p matrix `X`. Rows of `X` correspond to observations, columns to variables. A star plot represents each observation as a “star” whose `i`th spoke is proportional in length to the `i`th coordinate of that observation. `glyphplot` standardizes `X` by shifting and scaling each column separately onto the interval \([0,1]\) before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in `X` as missing values, and does not plot the corresponding rows of `X`.

`glyphplot(X,'glyph','star')` is a synonym for `glyphplot(X)`.

`glyphplot(X,'glyph','face')` creates a face plot from `X`. A face plot represents each observation as a “face,” whose `i`th facial feature is drawn with a characteristic proportional to the `i`th coordinate of that observation. The features are described in “Face Features” on page 32-2839.

`glyphplot(X,'glyph','face','features',f)` creates a face plot where the `i`th element of the index vector `f` defines which facial feature will represent the `i`th column of `X`.
X. f must contain integers from 0 to 17, where 0 indicate that the corresponding column
of X should not be plotted. See “Face Features” on page 32-2839 for more information.

glyphplot(X,...,'grid',[rows,cols]) organizes the glyphs into a rows-by-cols
grid.

glyphplot(X,...,'grid',[rows,cols],'page',p) organizes the glyph into one or
more pages of a rows-by-cols grid, and displays the page p. If p is a vector, glyphplot
displays multiple pages in succession. If p is 'all', glyphplot displays all pages. If p is
'scroll', glyphplot displays a single plot with a scrollbar.

glyphplot(X,...,'centers',C) creates a plot with each glyph centered at the
locations in the n-by-2 matrix C.

glyphplot(X,...,'centers',C,'radius',r) creates a plot with glyphs positioned
using C, and scale the glyphs so the largest has radius r.

glyphplot(X,...,'obslabels',labels) labels each glyph with the text in labels.
By default, the glyphs are labelled 1:N. Use '' for blank labels.

glyphplot(X,...,'standardize',method) standardizes X before making the plot.
Choices for method are

• 'column' — Maps each column of X separately onto the interval [0,1]. This is the
default.
• 'matrix' — Maps the entire matrix X onto the interval [0,1].
• 'PCA' — Transforms X to its principal component scores, in order of decreasing
eigenvalue, and maps each one onto the interval [0,1].
• 'off' — No standardization. Negative values in X may make a star plot
uninterpretable.

glyphplot(X,...,prop1,val1,...) sets properties to the specified property values
for all line graphics objects created by glyphplot.

h = glyphplot(X,...) returns a matrix of handles to the graphics objects created by
glyphplot. For a star plot, h(:,1) and h(:,2) contain handles to the line objects for
each star's perimeter and spokes, respectively. For a face plot, h(:,1) and h(:,2)
contain object handles to the lines making up each face and to the pupils, respectively.
h(:,3) contains handles to the text objects for the labels, if present.
**Face Features**

The following table describes the correspondence between the columns of the vector $f$, the value of the 'Features' input parameter, and the facial features of the glyph plot. If $X$ has fewer than 17 columns, unused features are displayed at their default value.

<table>
<thead>
<tr>
<th>Column</th>
<th>Facial Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Size of face</td>
</tr>
<tr>

**Introduced before R2006a**
gmdistribution

Create Gaussian mixture model

Description

A gmdistribution object stores a Gaussian mixture distribution, also called a Gaussian mixture model (GMM), which is a multivariate distribution that consists of multivariate Gaussian distribution components. Each component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Creation

You can create a gmdistribution model object in two ways.

- Use the gmdistribution function (described here) to create a gmdistribution model object by specifying the distribution parameters.
- Use the fitgmdist function to fit a gmdistribution model object to data given a fixed number of components.

Syntax

```matlab
gm = gmdistribution(mu,sigma)
gm = gmdistribution(mu,sigma,p)
```

Description

`gm = gmdistribution(mu,sigma)` creates a gmdistribution model object using the specified means `mu` and covariances `sigma` with equal mixing proportions.

`gm = gmdistribution(mu,sigma,p)` specifies the mixing proportions of multivariate Gaussian distribution components.
**Input Arguments**

**mu — Means**  
*k*-by-`m` numeric matrix

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. `mu(i,:)` is the mean of component `i`.

Data Types: `single` | `double`

**sigma — Covariances**  
numeric vector | numeric matrix | numeric array

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, `sigma` is one of the values in this table.

Data Types: `single` | `double`

**p — Mixing proportions of mixture components**  
numeric vector of length *k*

Mixing proportions of mixture components, specified as a numeric vector of length *k*, where *k* is the number of components. The default is a row vector of (1/*k*)s, which sets equal proportions. If `p` does not sum to 1, `gmdistribution` normalizes it.

Data Types: `single` | `double`
Properties

Distribution Parameters

**mu — Means**

*k*-by-*m* numeric matrix

This property is read-only.

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. *mu*(i,:) is the mean of component *i*.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `mu` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

**Sigma — Covariances**

numeric vector | numeric matrix | numeric array

This property is read-only.

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, Sigma is one of the values in this table.

<table>

</tbody>
</table>
• If you create a gmdistribution object by using the gmdistribution function, then the sigma input argument of gmdistribution sets this property.
• If you fit a gmdistribution object to data by using the fitgmdist function, then fitgmdist estimates this property.

Data Types: single | double

ComponentProportion — Mixing proportions of mixture components
1-by-k numeric vector

This property is read-only.

Mixing proportions of mixture components, specified as a 1-by-k numeric vector.

• If you create a gmdistribution object by using the gmdistribution function, then the p input argument of gmdistribution sets this property.
• If you fit a gmdistribution object to data by using the fitgmdist function, then fitgmdist estimates this property.

Data Types: single | double

Distribution Characteristics

CovarianceType — Type of covariance matrices
'diagonal' | 'full'

This property is read-only.

Type of covariance matrices, specified as either 'diagonal' or 'full'.

• If you create a gmdistribution object by using the gmdistribution function, then the type of covariance matrices in the sigma input argument of gmdistribution sets this property.
• If you fit a gmdistribution object to data by using the fitgmdist function, then the 'CovarianceType' name-value pair argument of fitgmdist sets this property.

DistributionName — Distribution name
'gaussian mixture distribution' (default)

This property is read-only.
Distribution name, specified as 'gaussian mixture distribution'.

**NumComponents — Number of mixture components**

positive integer

This property is read-only.

Number of mixture components, $k$, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the $k$ input argument of `fitgmdist` sets this property.

Data Types: `single` | `double`

**NumVariables — Number of variables**

positive integer

This property is read-only.

Number of variables in the multivariate Gaussian distribution components, $m$, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the input data $X$ of `fitgmdist` sets this property.

Data Types: `double`

**SharedCovariance — Flag indicating shared covariance**

`true` | `false`

This property is read-only.

Flag indicating whether a covariance matrix is shared across mixture components, specified as `true` or `false`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
• If you fit a gmdistribution object to data by using the fitgmdist function, then the 'SharedCovariance' name-value pair argument of fitgmdist sets this property.

Data Types: logical

Properties for Fitted Object

The following properties apply only to a fitted object you create by using fitgmdist. The values of these properties are empty if you create a gmdistribution object by using the gmdistribution function.

**AIC — Akaike Information Criterion**

`scalar`

This property is read-only.

Akaike information criterion (AIC), specified as a scalar: $AIC = 2*N\log L + 2*p$, where $N\log L$ is the negative loglikelihood (the NegativeLogLikelihood property) and $p$ is the number of estimated parameters.

AIC is a model selection tool you can use to compare multiple models fit to the same data. AIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with a smaller value of AIC is better.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: `single` | `double`

**BIC — Bayes Information Criterion**

`scalar`

This property is read-only.

Bayes information criterion (BIC), specified as a scalar: $BIC = 2*N\log L + p*\log(n)$, where $N\log L$ is the negative loglikelihood (the NegativeLogLikelihood property), $n$ is the number of observations, and $p$ is the number of estimated parameters.

BIC is a model selection tool you can use to compare multiple models fit to the same data. BIC is a likelihood-based measure of model fit that includes a penalty for complexity,
specifically, the number of parameters. When you compare multiple models, a model with the lowest BIC value is the best fitting model.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

**Converged — Flag indicating convergence**

`true` | `false`

This property is read-only.

Flag indicating whether the Expectation-Maximization (EM) algorithm is converged when fitting a Gaussian mixture model, specified as `true` or `false`.

You can change the optimization options by using the `'Options'` name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `logical`

**NegativeLogLikelihood — Negative loglikelihood**

`scalar`

This property is read-only.

Negative loglikelihood of the fitted Gaussian mixture model given the input data `X` of `fitgmdist`, specified as a scalar.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

**NumIterations — Number of iterations**

`positive integer`

This property is read-only.

Number of iterations in the Expectation-Maximization (EM) algorithm, specified as a positive integer.
You can change the optimization options, including the maximum number of iterations allowed, by using the 'Options' name-value pair argument of fitgmdist.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: double

**ProbabilityTolerance — Tolerance for posterior probabilities**

nonnegative scalar value in range $[0, 1e-6]$.

This property is read-only.

Tolerance for posterior probabilities, specified as a nonnegative scalar value in the range $[0, 1e-6]$.

The 'ProbabilityTolerance' name-value pair argument of fitgmdist sets this property.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: single | double

**RegularizationValue — Regularization parameter value**

nonnegative scalar

This property is read-only.

Regularization parameter value, specified as a nonnegative scalar.

The 'RegularizationValue' name-value pair argument of fitgmdist sets this property.

This property is empty if you create a gmdistribution object by using the gmdistribution function.

Data Types: single | double

**Object Functions**

cdf Cumulative distribution function for Gaussian mixture distribution
cluster Construct clusters from Gaussian mixture distribution
Examples

Create Gaussian Mixture Distribution Using `gmdistribution`

Create a two-component bivariate Gaussian mixture distribution by using the `gmdistribution` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

\[
\mu = \begin{bmatrix} 1 & 2 \\ -3 & -5 \end{bmatrix};
\]

\[
sigma = \text{cat}(3,\begin{bmatrix} 2 & 0.5 \\ 1 & 1 \end{bmatrix}) \% \text{1-by-2-by-2 array}
\]

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,:)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object. By default, the `gmdistribution` function creates an equal proportion mixture.

\[
\text{gm} = \text{gmdistribution}([\mu \sigma])
\]

`gm` =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean: 1  2

Component 2:
Mixing proportion: 0.500000
Mean: -3 -5

List the properties of the gm object.

properties(gm)

Properties for class gmdistribution:

NumVariables
DistributionName
NumComponents
ComponentProportion
SharedCovariance
NumIterations
RegularizationValue
NegativeLogLikelihood
CovarianceType
mu
Sigma
AIC
BIC
Converged
ProbabilityTolerance

You can access these properties by using dot notation. For example, access the ComponentProportion property, which represents the mixing proportions of mixture components.

gm.ComponentProportion

ans = 1x2

0.5000    0.5000

A gmdistribution object has properties that apply only to a fitted object. The fitted object properties are AIC, BIC, Converged, NegativeLogLikelihood, NumIterations, ProbabilityTolerance, and RegularizationValue. The values of the fitted object properties are empty if you create an object by using the
gmdistribution function and specifying distribution parameters. For example, access the NegativeLogLikelihood property by using dot notation.

```matlab
gm.NegativeLogLikelihood
ans =
```

After you create a `gmdistribution` object, you can use the object functions. Use `cdf` and `pdf` to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use `random` to generate random vectors. Use `cluster`, `mahal`, and `posterior` for cluster analysis.

Visualize the object by using `pdf` and `ezsurf`.

```matlab
ezsurf(@(x,y)pdf(gm,[x y]),[-10 10],[-10 10])```
Fit Gaussian Mixture Model to Data Using `fitgmdist`

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

\[
\text{mu1} = [1 \ 2]; \quad \% \text{Mean of the 1st component}
\]
\sigma_1 = \begin{bmatrix} 2 & 0 \\ 0 & 0.5 \end{bmatrix}; \quad \text{% Covariance of the 1st component}
\mu_2 = [-3 -5]; \quad \text{% Mean of the 2nd component}
\sigma_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}; \quad \text{% Covariance of the 2nd component}

Generate an equal number of random variates from each component, and combine the two sets of random variates.

rng('default') \quad \text{% For reproducibility}
\text{r1} = \text{mvnrnd}(\mu_1, \sigma_1, 1000);
\text{r2} = \text{mvnrnd}(\mu_2, \sigma_2, 1000);
\text{X} = [\text{r1}; \text{r2}];

The combined data set \text{X} contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to \text{X}.

\text{gm} = \text{fitgmdist}(\text{X}, 2)

\text{gm} =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean: \begin{bmatrix} -2.9617 \\ -4.9727 \end{bmatrix}

Component 2:
Mixing proportion: 0.500000
Mean: \begin{bmatrix} 0.9539 \\ 2.0261 \end{bmatrix}

List the properties of the \text{gm} object.

\text{properties(gm)}

Properties for class \text{gmdistribution}:

- NumVariables
- DistributionName
- NumComponents
- ComponentProportion
- SharedCovariance
- NumIterations
- RegularizationValue
- NegativeLogLikelihood
- CovarianceType
mu
Sigma
AIC
BIC
Converged
ProbabilityTolerance

You can access these properties by using dot notation. For example, access the NegativeLogLikelihood property, which represents the negative loglikelihood of the data X given the fitted model.

gm.NegativeLogLikelihood

ans = 7.0584e+03

After you create a gmdistribution object, you can use the object functions. Use cdf and pdf to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use random to generate random variates. Use cluster, mahal, and posterior for cluster analysis.

Plot X by using scatter. Visualize the fitted model gm by using pdf and ezcontour.

scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
ezcontour(@(x,y)pdf(gm,[x y]),[-8 6],[-8 6])

Topics

“Gaussian Mixture Models” on page 5-145
Introduced in R2007b
**gname**

Add case names to plot

**Syntax**

```
gname(cases)
gname
h = gname(cases,line_handle)
```

**Description**

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array, string array, or cell array of character vectors, in which each row of the character array or each element of the string array or cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a string array, cell array of character vectors, or character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.
Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```matlab
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```

Click the point at the top of the graph to display its label, “New York.”

**gpcdf**

Generalized Pareto cumulative distribution function

**Syntax**

\[ p = \text{gpcdf}(x,k,sigma,theta) \]
\[ p = \text{gpcdf}(x,k,sigma,theta,'upper') \]

**Description**

\[ p = \text{gpcdf}(x,k,sigma,theta) \] returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter \( k \), scale parameter \( sigma \), and threshold (location) parameter, \( theta \), evaluated at the values in \( x \). The size of \( p \) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

\[ p = \text{gpcdf}(x,k,sigma,theta,'upper') \] returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for \( k \), \( sigma \), and \( theta \) are 0, 1, and 0, respectively.

When \( k = 0 \) and \( theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and \( theta = sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to \( sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for

\[ x > theta, \text{ or, when} \]

\[ k < 0, \quad 0 \leq \frac{x - theta}{sigma} \leq -\frac{1}{k}. \]

Introduced before R2006a
gpfit

Generalized Pareto parameter estimates

Syntax

parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)

Description

parmhat = gpfit(x) returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in x. parmhat(1) is the tail index (shape) parameter, k and parmhat(2) is the scale parameter, sigma. gpfit does not fit a threshold (location) parameter.

[parmhat,parmci] = gpfit(x) returns 95% confidence intervals for the parameter estimates.

[parmhat,parmci] = gpfit(x,alpha) returns 100(1-alpha)% confidence intervals for the parameter estimates.

[...] = gpfit(x,alpha,options) specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to statset. See statset('gpfit') for parameter names and default values.

Other functions for the generalized Pareto, such as gpcdf allow a threshold parameter, theta. However, gpfit does not estimate theta. It is assumed to be known, and subtracted from x before calling gpfit.

When k = 0 and theta = 0, the GP is equivalent to the exponential distribution. When k > 0 and theta = sigma/k, the GP is equivalent to a Pareto distribution with a scale parameter equal to sigma/k and a shape parameter equal to 1/k. The mean of the GP is not finite when k ≥ 1, and the variance is not finite when k ≥ 1/2. When k ≥ 0, the GP has positive density for
k > \theta, or, when k < 0, for

\[ 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k} \]

**gpinv**

Generalized Pareto inverse cumulative distribution function

**Syntax**

\[ x = \text{gpinv}(p,k,sigma,theta) \]

**Description**

\[ x = \text{gpinv}(p,k,sigma,theta) \] returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter \( k \), scale parameter \( sigma \), and threshold (location) parameter \( theta \), evaluated at the values in \( p \). The size of \( x \) is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for \( k \), \( sigma \), and \( theta \) are 0, 1, and 0, respectively.

When \( k = 0 \) and \( theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and \( theta = sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to \( sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for

\[ x > theta, \text{ or, when} \]

\[ k < 0, \quad 0 \leq \frac{x-\theta}{\sigma} \leq \frac{1}{k}. \]

**gplike**

Generalized Pareto negative loglikelihood

**Syntax**

```matlab
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

**Description**

`nlogL = gplike(params,data)` returns the negative of the loglikelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

\[ x > \theta, \text{ or, when} \]

\[ k < 0, \quad 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}. \]

*Introduced before R2006a*
gplotmatrix
Matrix of scatter plots by group

Syntax

\[
gplotmatrix(x, [], group) \\
gplotmatrix(x, y, group) \\
gplotmatrix(x, y, group, clr, sym, siz) \\
gplotmatrix(x, y, group, clr, sym, siz, doleg) \\
gplotmatrix(x, [], group, clr, sym, siz, doleg, dispopt) \\
gplotmatrix(x, [], group, clr, sym, siz, doleg, 'variable', xnam) \\
gplotmatrix(x, y, group, clr, sym, siz, doleg, [], xnam, ynam) \\
\]

[\text{h,ax,bigax}]= \text{gplotmatrix}(___)

Description

gplotmatrix(x, [], group) creates a matrix of scatter plots of the data in \(x\), grouped by the grouping variable in \(group\). Each individual set of axes in the resulting figure contains a scatter plot of a column of \(x\) against another column of \(x\). It also plots the outlines of the grouped histograms in the diagonals.

gplotmatrix(x, y, group) creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of \(x\) against a column of \(y\). All plots are grouped by the grouping variable \(group\).

\(x\) and \(y\) are matrices with the same number of rows. If \(x\) has \(p\) columns and \(y\) has \(q\) columns, the figure contains a \(p\)-by-\(q\) matrix of scatter plots. If you omit \(y\) or specify it as the empty matrix, [], \text{gplotmatrix} creates a square matrix of scatter plots of columns of \(x\) against each other.

\(group\) is a grouping variable that can be a categorical variable, vector, character array, string array, or cell array of character vectors. \(group\) must have the same number of rows as \(x\) and \(y\). Points with the same value of \(group\) are placed in the same group, and appear on the graph with the same marker and color. Alternatively, \(group\) can be a cell array containing several grouping variables (such as \{\text{g1 g2 g3}\}); in that case, observations are in the same group if they have common values of all grouping variables.
gplotmatrix(x,y,group,clr,sym,siz) specifies the color, marker type, and size for each group. clr is a character array or string array of colors recognized by the plot function. sym is a character array or string array of symbols recognized by the plot command, with the default value '. '. siz is a vector of sizes, with the default value determined based on the number of observations. If you do not specify enough values for all groups, gplotmatrix cycles through the specified values as needed.

gplotmatrix(x,y,group,clr,sym,siz,doleg) controls whether a legend is displayed on the graph (doleg is 'on', the default) or not (doleg is 'off').

gplotmatrix(x,[],group,clr,sym,siz,doleg,dispopt) controls what appears along the diagonals of a plot matrix of x. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, 'stairs' to display the outlines of grouped histograms (default if there is more than one group), 'grpbars' to plot grouped histogram bars.

gplotmatrix(x,[],group,clr,sym,siz,doleg,'variable',xnam) displays the variable names along the diagonal of the plot matrix of x. It also uses these column names to label the x- and y-axes.

gplotmatrix(x,y,group,clr,sym,siz,doleg,[],xnam,ynam) labels the x- and y-axes using the column names specified in xnam and ynam.

xnam and ynam must be character arrays, string arrays, or cell arrays of character vectors, with one name for each column of x and y, respectively.

[h,ax,bigax] = gplotmatrix(__) returns three arrays of handles for any of the previous input arguments. h is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in the input argument group. ax is a matrix of handles to the axes of the individual plots. If dispopt is 'hist', 'stairs', or 'grpbars', ax contains one extra row of handles to invisible axes in which the histograms are plotted. bigax is a handle to big (invisible) axes framing the entire plot matrix. bigax is fixed to point to the current axes, so a subsequent title, xlabel, or ylabel command will produce labels that are centered with respect to the entire plot matrix.

Examples
Create Grouped Data Scatter Plot Matrix

Load the sample data.

load discrim;

The ratings array contains rating values for 329 U.S. cities in the nine different categories listed in the categories array. The group array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, climate and housing, with categories 4 (crime) and 7 (arts). Specify group as the grouping variable to visually distinguish the data for large and small cities.

figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```matlab
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br', '.o', [], 'on', '', categories(1:2,:),...
categories([4 7],:));
```

Introduced before R2006a
**gprnd**

Generalized Pareto random numbers

**Syntax**

\[ r = \text{gprnd}(k, \sigma, \theta) \]
\[ r = \text{gprnd}(k, \sigma, \theta, m, n, \ldots) \]
\[ R = \text{gprnd}(K, \sigma, \theta, [m, n, \ldots]) \]

**Description**

The function `gprnd(k, sigma, theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter \( k \), scale parameter \( \sigma \), and threshold (location) parameter, \( \theta \). The size of \( r \) is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of \( r \) is the size of the other parameters.

\[ r = \text{gprnd}(k, \sigma, \theta, m, n, \ldots) \text{ or } R = \text{gprnd}(K, \sigma, \theta, [m, n, \ldots]) \]

generates an \( m \)-by-\( n \)-by-... array. The \( k \), \( \sigma \), \( \theta \) parameters can each be scalars or arrays of the same size as \( r \).

When \( k = 0 \) and \( \theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and \( \theta = \sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to \( \sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for

\[ x > \theta, \text{ or, when} \]
\[ 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k} \]
References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

gpstat

Generalized Pareto mean and variance

Syntax

\[ [m,v] = \text{gpstat}(k,\sigma,\theta) \]

Description

\[ [m,v] = \text{gpstat}(k,\sigma,\theta) \]

returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter \( k \), scale parameter \( \sigma \), and threshold (location) parameter, \( \theta \).

The default value for \( \theta \) is 0.

When \( k = 0 \) and \( \theta = 0 \), the GP is equivalent to the exponential distribution. When \( k > 0 \) and \( \theta = \sigma/k \), the GP is equivalent to a Pareto distribution with a scale parameter equal to \( \sigma/k \) and a shape parameter equal to \( 1/k \). The mean of the GP is not finite when \( k \geq 1 \), and the variance is not finite when \( k \geq 1/2 \). When \( k \geq 0 \), the GP has positive density for \( x > \theta \), or when

\[
k < 0, \quad 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.
\]

Introduced before R2006a
growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)

Description

B = growTrees(B,ntrees) grows ntrees new trees and appends them to those trees already stored in the ensemble B.

B = growTrees(B,ntrees,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'NumPrint' Specifies that a diagnostic message showing training progress should display after every value training cycles (grown trees). Default is no diagnostic messages.
'Options'

A struct that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- **'UseParallel'** — If true and if a parpool of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is false, or serial computation.

- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.

- **Streams** — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case

  - You have an open Parallel pool
  - **UseParallel** is true
  - **UseSubstreams** is false

In that case, use a cell array the same size as the Parallel pool.
Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

**grp2idx**

Create index vector from grouping variable

**Syntax**

\[
\begin{align*}
[g, gN] &= \text{grp2idx}(s) \\
[g, gN, gL] &= \text{grp2idx}(s)
\end{align*}
\]

**Description**

\[
\begin{align*}
[g, gN] &= \text{grp2idx}(s) \text{ creates an index vector } g \text{ from the grouping variable } s. \text{ The output } g \text{ is a vector of integer values from 1 up to the number } K \text{ of distinct groups. } gN \text{ is a cell array of character vectors representing the list of group names.} \\
[g, gN, gL] &= \text{grp2idx}(s) \text{ also returns a column vector } gL \text{ representing the list of the group levels with the same data type as } s.
\end{align*}
\]

**Examples**

**Create Index Vector from Categorical Vector**

Create a categorical vector by using `discretize` and convert it to an index vector by using `grp2idx`.

Load the `hospital` data set and convert the ages in `hospital.Age` to categorical values representing the ages by decade.

```matlab
load hospital 
edges = 0:10:100; % Bin edges 
labels = strcat(num2str((0:10:90),'%d'),{'s'}); % Labels for the bins 
s = discretize(hospital.Age,edges,'Categorical',labels);
```

Display the ages and the groups of ages for the first five samples.

```matlab
ages = hospital.Age(1:5)
```
ages = 5×1
38
43
38
40
49

groups = s(1:5)
groups = 5x1 categorical array
30s
40s
30s
40s
40s

Create an index vector from the categorical vector s.
[g,gN,gL] = grp2idx(s);

Display the index values corresponding to the first five samples.
g(1:5)
ans = 5×1
4
5
4
5
5

Reproduce the input argument s using the output gL.
gL(g(1:5))
ans = 5x1 categorical array
30s
40s
30s
40s
40s

Use `gN(g)` to reproduce the input argument `s` as a cell array of character vectors.

```matlab
gN(g(1:5))
```

```matlab
ans = 5x1 cell array
    {'30s' }    
    {'40s' }    
    {'30s' }    
    {'40s' }    
    {'40s' }
```

**Input Arguments**

`s — Grouping variable

categorical vector | numeric vector | logical vector | datetime vector | duration vector | string array | cell array of character vectors | character array

Grouping variable, specified as a categorical, numeric, logical, datetime, or duration vector, a string array, a cell array of character vectors, or a character array with each row representing a group label.

*grp2idx* treats NaNs (numeric, duration, or logical), '' (empty character arrays or cell arrays of character vectors), "" (empty strings), <missing> values (string), <undefined> values (categorical), and NaTs (datetime) in `s` as missing values and returns NaNs in the corresponding rows of `g`. The outputs `gN` and `gL` do not include entries for missing values.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | string | cell | categorical | datetime | duration

**Output Arguments**

`g — Group index

positive integer vector`
Group index, returned as a positive integer vector with values from 1 up to the number \( K \) of distinct groups in \( s \).

\[ gN \] — List of group names

cell array of character vectors

List of group names, returned as a cell array of character vectors.

The order of \( gN \) depends on the data type of the grouping variable \( s \).

- For numeric and logical vectors, the order is the sorted order of \( s \).
- For categorical vectors, the order is the order of categories\( (s) \).
- For other data types, the order is the order of first appearance in \( s \).

\( gN(g) \) reproduces the contents of \( s \) in a cell array.

\[ gL \] — List of group levels

categorical vector | numeric vector | logical vector | datetime vector | duration vector | cell array of character vectors | character array

List of group levels, returned as the same data type as \( s \): a categorical, numeric, logical, datetime, or duration vector, a cell array of character vectors, or a character array with each row representing a group label. (The software treats string arrays as cell arrays of character vectors.)

The set of groups and their order in \( gL \) are the same as those in \( gN \), but \( gL \) has the same data type as \( s \).

If \( s \) is a character matrix, then \( gL(g, :) \) reproduces \( s \); otherwise, \( gL(g) \) reproduces \( s \).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The input argument `s` can be a numeric, logical, or character vector or a cell array of character vectors. Code generation does not support a categorical, datetime, or duration vector or a string array for the input argument.

• In the generated code, the second and third outputs, `gN` and `gL`, are identical. `gN` and `gL` have the same data type as the input argument `s`.

**Introduced before R2006a**
grpstats

Summary statistics organized by group

Syntax

`statarray = grpstats(tbl,groupvar)`  
`statarray = grpstats(tbl,groupvar,whichstats)`  
`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)`

`means = grpstats(X,group)`  
`[stats1,...,statsN] = grpstats(X,group,whichstats)`  
`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)`

`grpstats(X,group,alpha)`

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a string array or cell array of character vectors containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`. 
\texttt{statarray = grpstats(tbl,groupvar,\textit{whichstats})} returns the group values for the summary statistics types specified in \textit{whichstats}.

\texttt{statarray = grpstats(tbl,groupvar,\textit{whichstats},Name,Value)} uses additional options specified by one or more Name,Value pair arguments.

\texttt{means = grpstats(X,\textit{group})} returns a column vector or matrix with the means of the groups of the data in the matrix or vector \textit{X} determined by the values of the grouping variable or variables, \textit{group}. The rows of \textit{means} correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in \textit{means} for each value of the grouping variable. \textit{grpstats} sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If \textit{group} is a string array or cell array of grouping variables, then there is a row in \textit{means} for each observed unique combination of values of the grouping variables. \textit{grpstats} sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If \textit{X} is a matrix, then \textit{means} is a matrix with the same number of columns as \textit{X}. Each column of \textit{means} has the group means for the corresponding column of \textit{X}.

\texttt{[\textit{stats1,...,statsN}] = grpstats(X,\textit{group},\textit{whichstats})} returns column vectors or arrays with group values for the summary statistic types specified in \textit{whichstats}.

\texttt{[\textit{stats1,...,statsN}] = grpstats(X,\textit{group},\textit{whichstats},'Alpha',\textit{alpha})} specifies the significance level for confidence and prediction intervals.

\textit{grpstats(X,\textit{group},\textit{alpha})} plots the means of the groups of data in the vector or matrix \textit{X} determined by the values of the grouping variable, \textit{group}. The grouping variable values are on the horizontal plot axis. Each group mean has $100 \times (1 - \alpha)$% confidence intervals.

- If \textit{X} is a matrix, then \textit{grpstats} plots the means and confidence intervals for each column of \textit{X}.
- If \textit{group} is a cell array of grouping variables, then \textit{grpstats} plots the means and confidence intervals for the groups of data in \textit{X} determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of
grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

**Examples**

**Dataset Array Summary Statistics Organized by Group**

Load the sample data.

```matlab
toolbox('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```matlab
dsa = hospital(:,{'Sex','Age','Weight','Smoker'});
```

Sex is a nominal array, with levels Male and Female. The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean for the numeric and logical arrays, Age, Weight, and Smoker, grouped by the levels in Sex.

```matlab
statarray = grpstats(dsa,'Sex')
```

```
statarray =
    Sex     GroupCount    mean_Age    mean_Weight    mean_Smoker
Female    Female       53         37.717        130.47         0.24528
Male      Male         47         38.915        180.53         0.44681
```

`statarray` is a dataset array with two rows, corresponding to the levels in Sex. GroupCount is the number of observations in each group. The means of Age, Weight, and Smoker, grouped by Sex, are given in mean_Age, mean_Weight, and mean_Smoker.

Compute the mean for Age and Weight, grouped by the values in Smoker.

```matlab
statarray = grpstats(dsa,'Smoker','mean','DataVars',{'Age','Weight'})
```

```
statarray =
         Smoker    GroupCount    mean_Age    mean_Weight
false         66         37.97        149.91
true          32
```

32-2890
In this case, not all variables in `dsa` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```matlab
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
    'DataVars','Weight')
```

```matlab
statarray =
    Sex    Smoker    GroupCount    min_Weight    max_Weight
Female_0    Female    false     40            111           147
Female_1    Female    true      13            115           146
Male_0      Male      false     26            158           194
Male_1      Male      true      21            164           202
```

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```matlab
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
    'DataVars','Weight','VarNames',{'Gender','Smoker',...
    'GroupCount','LowestWeight','HighestWeight'})
```

```matlab
statarray =
    Gender    Smoker    GroupCount    LowestWeight    HighestWeight
Female_0    Female    false     40            111             147
Female_1    Female    true      13            115             146
Male_0      Male      false     26            158             194
Male_1      Male      true      21            164             202
```
Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

load('hospital')

The dataset array hospital has 100 observations and 7 variables.

Create a dataset array with only the variables Age, Weight, and Smoker.

dsa = hospital(:,{'Age','Weight','Smoker'});

The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, Age, Weight, and Smoker, with no grouping.

statarray = grpstats(dsa,[],{'mean','min','max'})

statarray =

<table>
<thead>
<tr>
<th>GroupCount</th>
<th>mean_Age</th>
<th>min_Age</th>
<th>max_Age</th>
<th>mean_Weight</th>
<th>min_Weight</th>
<th>max_Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>100</td>
<td>38.28</td>
<td>25</td>
<td>50</td>
<td>154</td>
<td>111</td>
</tr>
<tr>
<td></td>
<td></td>
<td>202</td>
<td>0.34</td>
<td>false</td>
<td></td>
<td>true</td>
</tr>
</tbody>
</table>

The observation name All indicates that all observations in dsa were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

load('carsmall')

All variables are measured for 100 cars. Origin is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). Cylinders has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.
means = grpstats(Acceleration,Origin)
means = 6×1
   14.4377
   18.0500
   15.8867
   16.3778
   16.6000
   15.5000

means is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.
means = grpstats(Acceleration,{Origin,Cylinders})
means = 10×1
   17.0818
   16.5267
   11.6406
   18.0500
   15.9143
   15.5000
   16.3375
   16.7000
   16.6000
   15.5000

There are 18 possible combinations of grouping variable values because Origin has 6 unique values and Cylinders has 3 unique values. Only 10 of the possible combinations appear in the data, so means is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},{'mean','gname'})
means = 10×1
The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

**Multiple Summary Statistics for a Matrix Organized by Group**

Load the sample data.

```matlab
load carsmall
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum and maximum acceleration grouped by country of origin.

```matlab
[grpMin,grpMax,grp] = grpstats(Acceleration,Origin,{'min','max','gname'})
```

`grpMin` = 6×1
The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

**Plot Prediction Intervals for a New Observation in Each Group**

Load the sample data.

```matlab
load('carsmall')
```

The variable Weight was measured for 100 cars. The variable Model_Year has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```matlab
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```
Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

\[ \text{ngrps} = \text{length(grp)}; \quad \% \text{Number of groups} \]
\[ \text{errorbar}((1: \text{ngrps})', \text{means}, \text{pred(:,2)} - \text{means}) \]
\[ \text{xlim}([0.5 \ 3.5]) \]
\[ \text{set(gca,'xtick',1:ngrps,'xticklabel',grp)} \]
\[ \text{title('90\% Prediction Intervals for Weight by Year')} \]

**Plot Group Means and Confidence Intervals**

Load the sample data.
load('carsmall')

The variables 

**Acceleration** and **Weight** are the acceleration and weight values measured for 100 cars. The variable 

**Cylinders** is the number of cylinders in each car. The variable **Model_Year** has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by **Cylinders**, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```
The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and 95% confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.

\[ \text{grpstats([Acceleration, Weight/1000], Cylinders, 0.05)} \]
The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model_Year. Specify 95% confidence intervals.

\[
grpstats(Acceleration,\{\text{Cylinders, Model\_Year}\}, 0.05)\]
ans = 8×1

16.1875
16.8667
16.7036
15.5000
17.0000
16.0333
11.0217
13.2222

There are nine possible combinations of grouping variable values because there are three unique values in Cylinders and three unique values in Model_Year. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

**Input Arguments**

**tbl — Input data**

table | dataset array

Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in `tbl` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

**groupvar — Identifiers for the grouping variables**

ccharactervector | stringarray | cellarrayofcharactervectors | vectoreffpositiveintegers
| logicalvector | [ ]

Identifiers for the grouping variables in the input data, `tbl`, specified as one of the following:
Character vector, string array, or cell array of character vectors  
Names of the grouping variables
Positive integer or vector of positive integers  
Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in tbl  
Logical indicator with value true for grouping variables and false otherwise
[]  
No groups (returns summary statistics for all data)

Any variable that is identified by groupvar as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors.

For example, consider an input table, tbl, with six variables. The fourth variable is named Gender. To be a valid grouping variable, the data type of Gender might be a string array, a cell array of character vectors, or a nominal array, with the unique values Male and Female. To specify the variable Gender as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl,'Gender')`
- `statarray = grpstats(tbl,4)`
- `statarray = grpstats(tbl,logical([0 0 0 1 0 0]))`

Data Types: double | logical | char | string | cell

**whichstats — Types of summary statistics**

character vector | string scalar | function handle | string array | cell array of character vectors and function handles

Types of summary statistics to compute, specified as a character vector, a string scalar, a function handle, a string array, or a cell array of character vectors and function handles. Use a cell array to specify multiple types of summary statistics.

Values include:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mean'</td>
<td>Mean</td>
</tr>
<tr>
<td>'sem'</td>
<td>Standard error of the mean</td>
</tr>
</tbody>
</table>
'numel'  Count, or number, of non-NaN elements
'gname'  Group name
'std'    Standard deviation
'var'    Variance
'min'    Minimum
'max'    Maximum
'range'  Range
'meanci' 95% confidence interval for the mean
'predci' 95% prediction interval for a new observation

Example: [stat1,stat2] = grpstats(X,group,{'mean','sem'})

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time grpstats calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an nvals-by-1 column vector for descriptive statistics of length nvals (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-ncols row vector, or an nvals-by-ncols matrix, where ncols is the number of columns in the input data matrix.

Example: [stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

Example: stat1 = grpstats(X,group,@(x)sum(x,1))

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in whichstats, you can use alpha to specify the significance level for the confidence or prediction intervals. If you specify
alpha, then `grpstats` returns $100 \times (1 - \alpha)\%$ confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals ($\alpha = 0.05$).

- Use `alpha` with the syntax on page 32-2888 to plot group means and corresponding $100 \times (1 - \alpha)\%$ confidence intervals.

**Data Types:** double

**X — Input data**

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

**Data Types:** double | single

**group — Grouping variable**

categorical array | logical or numeric vector | datetime or duration vector | string array | cell array of character vectors | []

Grouping variable, specified as a categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a string array or cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

**Data Types:** single | double | logical | char | string | cell | categorical | datetime | duration
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'DataVars', [1, 3, 4], 'Alpha', 0.01 specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

Alpha — Significance level
0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

When you include 'meanci' or 'predci' in whichstats, you can use Alpha to specify the significance level for confidence or prediction intervals. If you specify the value \( \alpha \), then grpstats returns \( 100 \times (1 - \alpha) \) % confidence or prediction intervals.

If you do not specify a value for Alpha, then grpstats returns 95% intervals (\( \alpha = 0.05 \)).
Example: 'Alpha', 0.1
Data Types: double

DataVars — Variable names or columns
string array | cell array of character vectors | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data tbl you want to compute summary statistics for, specified as the comma-separated pair consisting of 'DataVars' and a string array, cell array of character vectors, vector of positive integers, or logical vector. Use a character vector or string scalar to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (true if you want to compute summary statistics, false otherwise).

You must specify DataVars if there are any variables in tbl (other than the grouping variables specified in groupvar) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.
Example: 'DataVars', {'Height', 'Weight'}
Data Types: double | string | cell | char

**VarNames — Variable names for output**
string array | cell array of character vectors

Variable names for the output `statarray`, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: 'VarNames', {'Gender','GroupCount','MaleMean','FemaleMean'}
Data Types: string | cell

**Output Arguments**

**statarray — Group summary statistics**
table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is `ngrpvars + 1 + ndatavars×nstats`, where `ngrpvars` is the number of variables in `groupvar`, `ndatavars` is the number of variables for which summary statistics are computed, and `nstats` is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`. 

32-2905
means — Group means
column vector | array

Group means for the groups of data in the vector or matrix X determined by the levels of group, returned as an ngroups-by-ncols array. Here, ngroups is the number of unique values in the grouping variable, and ncols is the number of columns in X. If X is a vector, then means is a column vector.

stats1,...,statsN — Group summary statistics
column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix X determined by the levels of group, returned as ngroups-by-ncols arrays. Here, ngroups is the number of unique values in the grouping variable, and ncols is the number of columns in X. You must specify an output argument for each type of summary statistic specified in whichstats.

If a summary statistic type in whichstats returns a value of length nvals (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an ngroups-by-ncols-by-nvals array.

Algorithms

- grpstats treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- grpstats ignores empty group names.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.
• The `whichstats` option cannot be specified as a function handle. In addition to the current built-in options, `whichstats` can also be:
  • 'Count' — Number of non-NaNs.
  • 'NNZ' — Number of nonzeros and non-NaNs.
  • 'Kurtosis' — Compute kurtosis.
  • 'Skewness' — Compute skewness.
  • 'all-stats' — Compute all summary statistics.

• Group order is not guaranteed to be the same as the in-memory `grpstats` computation. Specify 'gname' as the `whichstats` option to return the order of rows of the summary statistics. For example `[means,grpname] = grpstats(x,bins, {'mean','gname'})` returns the means of groups in `x` in the same order that the groups appear in `grpname`.

• Summary statistics for nonnumeric variables return NaNs.
• `grpstats` always operates on the first dimension.
• If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable `GroupLabel` that contains the same information.

For more information, see “Tall Arrays” (MATLAB).

**Introduced before R2006a**
**grpstats**

**Class:** RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

**Syntax**

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

**Description**

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

**Input Arguments**

- **rm** — Repeated measures model
  RepeatedMeasuresModel object

  Repeated measures model, returned as a `RepeatedMeasuresModel` object.

  For properties and methods of this object, see `RepeatedMeasuresModel`.

- **g** — Name of grouping factor or factors
  character vector | string array | cell array of character vectors

  Name of grouping factor or factors, specified as a character vector, string array, or cell array of character vectors.

  Example: 'Drug'

  Example: {'Drug','Sex'}
Data Types: char | string | cell

**stats — Statistics to compute**

character vector | string scalar | function handle | string array | cell array of multiple character vectors and function handles

Statistics to compute, specified as one of the following:

- Character vector or string scalar specifying the name of the statistics to compute. Names can be one of the following.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mean'</td>
<td>Mean</td>
</tr>
<tr>
<td>'sem'</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>'numel'</td>
<td>Count or number of elements</td>
</tr>
<tr>
<td>'gname'</td>
<td>Group name</td>
</tr>
<tr>
<td>'std'</td>
<td>Standard deviation</td>
</tr>
<tr>
<td>'var'</td>
<td>Variance</td>
</tr>
<tr>
<td>'min'</td>
<td>Minimum</td>
</tr>
<tr>
<td>'max'</td>
<td>Maximum</td>
</tr>
<tr>
<td>'range'</td>
<td>Maximum minus minimum</td>
</tr>
<tr>
<td>'meanci'</td>
<td>95% confidence interval for the mean</td>
</tr>
<tr>
<td>'predci'</td>
<td>95% prediction interval for a new observation</td>
</tr>
</tbody>
</table>

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.

- A string array or cell array of character vectors and function handles.

Example: `@median`
Example: `@skewness`
Example: `'gname'`
Example: `{'gname','range','predci'}`
Output Arguments

\texttt{statstbl} — Statistics values for each group\newline\texttt{table}

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

\begin{verbatim}
load fisheriris
\end{verbatim}

The column vector, \texttt{species} consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix \texttt{meas} consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

\begin{verbatim}
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4],{'VarNames',{'Measurements'}});
\end{verbatim}

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

\begin{verbatim}
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
\end{verbatim}

Compute group counts, mean, and standard deviation with respect to species.

\begin{verbatim}
grpstats(rm,'species')
\end{verbatim}

\begin{verbatim}
ans=3×4 table
    species    GroupCount    mean    std
    _________    _________    ______    ______
    'setosa'  200      2.5355    1.8483
    'versicolor'  200      3.573    1.7624
    'virginica'  200      4.285    1.9154
\end{verbatim}
Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

\[
grpstats(rm,'species',{\text{'gname','range','predci'}})
\]

\[
\text{ans=3x5 table}
\]

<table>
<thead>
<tr>
<th>species</th>
<th>gname</th>
<th>GroupCount</th>
<th>range</th>
<th>predci</th>
</tr>
</thead>
<tbody>
<tr>
<td>'setosa'</td>
<td>'setosa'</td>
<td>200</td>
<td>5.7</td>
<td>-1.1185</td>
</tr>
<tr>
<td>'versicolor'</td>
<td>'versicolor'</td>
<td>200</td>
<td>6</td>
<td>0.088976</td>
</tr>
<tr>
<td>'virginica'</td>
<td>'virginica'</td>
<td>200</td>
<td>6.5</td>
<td>0.4985</td>
</tr>
</tbody>
</table>

**Statistics for Data Grouped by Two Factors**

Load the sample data.

\[
\text{load repeatedmeas}
\]

The table \textit{between} includes the between-subject variables age, IQ, group, gender, and eight repeated measures \(y_1\) through \(y_8\) as responses. The table \textit{within} includes the within-subject variables \(w_1\) and \(w_2\). This is simulated data.

Fit a repeated measures model, where the repeated measures \(y_1\) through \(y_8\) are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

\[
\text{rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within)};
\]

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors Group and Gender.

\[
\text{GS = grpstats(rm,{'Group','Gender'},{'mean','std',@skewness,@kurtosis}})
\]

\[
\text{GS=6x7 table}
\]

<table>
<thead>
<tr>
<th>Group</th>
<th>Gender</th>
<th>GroupCount</th>
<th>mean</th>
<th>std</th>
<th>skewness</th>
<th>kurtosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Female</td>
<td>40</td>
<td>16.554</td>
<td>21.498</td>
<td>0.35324</td>
<td>3.7807</td>
</tr>
<tr>
<td>A</td>
<td>Male</td>
<td>40</td>
<td>9.8335</td>
<td>20.602</td>
<td>-0.38722</td>
<td>2.7834</td>
</tr>
<tr>
<td>B</td>
<td>Female</td>
<td>40</td>
<td>11.261</td>
<td>25.779</td>
<td>-0.49177</td>
<td>4.1484</td>
</tr>
</tbody>
</table>
B      Male          40         3.6078    24.646     0.55447     2.7966
C      Female        40        -11.335    27.186      1.7499     6.1429
C      Male          40        -14.028    31.984      1.7362      5.141

Tips

- `grpstats` computes results separately for each group. The results do not depend on
  the fitted repeated measures model. It computes the results on all available data,
  without omitting entire rows that contain NaNs.

See Also

`fitrm` | `plot`
gscatter

Scatter plot by group

Syntax

gscatter(x,y,g)
gscatter(x,y,g,clr,sym,siz)
gscatter(x,y,g,clr,sym,siz,doleg)
gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)

h = gscatter(____)

Description

gscatter(x,y,g) creates a scatter plot of x and y, grouped by g. The inputs x and y are vectors of the same size.

gscatter(x,y,g,clr,sym,siz) specifies the marker color clr, symbol sym, and size siz for each group.

gscatter(x,y,g,clr,sym,siz,doleg) controls whether a legend is displayed on the graph. gscatter creates a legend by default.

gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam) specifies the names to use for the x-axis and y-axis labels. If you do not provide xnam and ynam, and the x and y inputs are variables with names, then gscatter labels the axes with the variable names.

h = gscatter(____) returns graphics handles corresponding to the groups in g, using any of the input arguments in the previous syntaxes.

Examples
**Scatter Plot with Default Settings**

Load the carsmall data set.

```matlab
load carsmall
```

Plot the Displacement values on the x-axis and the Horsepower values on the y-axis. `gscatter` uses the variable names as the default labels for the axes. Group the data points by Model Year.

```matlab
gscatter(Displacement,Horsepower,Model_Year)
```
**Scatter Plot with One Grouping Variable**

Load the `discrim` data set.

```matlab
load discrim
```

The data set contains ratings of cities according to nine factors such as climate, housing, education, and health. The matrix `ratings` contains the ratings information.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```matlab
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')
xlabel('climate')
ylabel('housing')
```
Scatter Plot with Multiple Grouping Variables

Load the hospital data set.

```matlab
load hospital
```

Plot the ages and weights of the hospital patients. Group the patients according to their gender and smoker status. Use the o symbol to represent nonsmokers and the * symbol to represent smokers.

```matlab
x = hospital.Age;
y = hospital.Weight;
```
g = {hospital.Sex,hospital.Smoker};
gscatter(x,y,g,'rkgb','o*','on',['Age','Weight'])
legend('Location','northeastoutside')

Create and Modify Scatter Plot

Load the carbig data set.
load carbig

Create a scatter plot comparing Acceleration to MPG. Group data points based on Origin.
h = gscatter(Acceleration,MPG,Origin)

h =
  7x1 Line array:

   Line    (USA)
   Line    (France)
   Line    (Japan)
   Line    (Germany)
   Line    (Sweden)
   Line    (Italy)
   Line    (England)

Display the Line object corresponding to the group labeled (Japan).

jgroup = h(3)

jgroup =
  Line (Japan) with properties:

      Color: [0.2857 1 0]
    LineStyle: 'none'
    LineWidth: 0.5000
      Marker: '.'
      MarkerSize: 15
    MarkerFaceColor: 'none'
        XData: [1x79 double]
        YData: [1x79 double]
        ZData: [1x0 double]

Show all properties

Change the marker color for the Japan group to black.

jgroup.Color = 'k';
**Input Arguments**

**x — x-axis values**  
numeric vector

x-axis values, specified as a numeric vector. x must have the same size as y.  
Data Types: single | double

**y — y-axis values**  
numeric vector
y-axis values, specified as a numeric vector. \( y \) must have the same size as \( x \).

Data Types: single | double

**g — Grouping variable**

categorical vector | logical vector | numeric vector | character array | string array | cell array of character vectors | cell array

Grouping variable, specified as a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors. Alternatively, \( g \) can be a cell array containing several grouping variables (such as \{g1 g2 g3\}), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group appear on the scatter plot with the same marker color, symbol, and size.

Example: `species`

Example: `{Cylinders,Origin}`

Data Types: categorical | logical | single | double | char | string | cell

**clr — Marker colors**

character vector or string scalar of colors | matrix of RGB triplet values

Marker colors, specified as either a character vector or string scalar of colors recognized by the `plot` function or a matrix of RGB triplet values. Each RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range \([0,1]\).

This table lists the available color characters and their equivalent RGB triplet values.

<table>
<thead>
<tr>
<th>Long Name</th>
<th>Short Name</th>
<th>RGB Triplet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow</td>
<td>'y'</td>
<td>[1 1 0]</td>
</tr>
<tr>
<td>Magenta</td>
<td>'m'</td>
<td>[1 0 1]</td>
</tr>
<tr>
<td>Cyan</td>
<td>'c'</td>
<td>[0 1 1]</td>
</tr>
<tr>
<td>Red</td>
<td>'r'</td>
<td>[1 0 0]</td>
</tr>
<tr>
<td>Green</td>
<td>'g'</td>
<td>[0 1 0]</td>
</tr>
<tr>
<td>Blue</td>
<td>'b'</td>
<td>[0 0 1]</td>
</tr>
<tr>
<td>White</td>
<td>'w'</td>
<td>[1 1 1]</td>
</tr>
</tbody>
</table>

32-2920
<table>
<thead>
<tr>
<th>Long Name</th>
<th>Short Name</th>
<th>RGB Triplet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black</td>
<td>'k'</td>
<td>[0 0 0]</td>
</tr>
</tbody>
</table>

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: 'rgb'
Example: [0 0 1; 0 0 0]

Data Types: char | string | single | double

### `sym` — Marker symbols

'. ' (default) | character vector or string scalar of symbols

Marker symbols, specified as a character vector or string scalar of symbols recognized by the `plot` function. This table lists the available marker symbols.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'o'</td>
<td>Circle</td>
</tr>
<tr>
<td>'+'</td>
<td>Plus sign</td>
</tr>
<tr>
<td>'*'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'. '</td>
<td>Point</td>
</tr>
<tr>
<td>'x'</td>
<td>Cross</td>
</tr>
<tr>
<td>'s'</td>
<td>Square</td>
</tr>
<tr>
<td>'d'</td>
<td>Diamond</td>
</tr>
<tr>
<td>'^'</td>
<td>Upward-pointing triangle</td>
</tr>
<tr>
<td>'v'</td>
<td>Downward-pointing triangle</td>
</tr>
<tr>
<td>'&gt;'</td>
<td>Right-pointing triangle</td>
</tr>
<tr>
<td>'&lt;'</td>
<td>Left-pointing triangle</td>
</tr>
<tr>
<td>'p'</td>
<td>Five-pointed star (pentagram)</td>
</tr>
<tr>
<td>'h'</td>
<td>Six-pointed star (hexagram)</td>
</tr>
<tr>
<td>'none'</td>
<td>No markers</td>
</tr>
</tbody>
</table>

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.
Example: 'o+*v'
Data Types: char | string

**siz — Marker sizes**
positive numeric vector

Marker sizes, specified as a positive numeric vector in points. The default value is determined by the number of observations. If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.
Example: [6 12]
Data Types: single | double

**doleg — Option to include legend**
'on' (default) | 'off'

Option to include a legend, specified as either 'on' or 'off'. By default, the legend is displayed on the graph.

**xnam — x-axis label**

x variable name (default) | character vector | string scalar

x-axis label, specified as a character vector or string scalar.
Data Types: char | string

**ynam — y-axis label**

y variable name (default) | character vector | string scalar

y-axis label, specified as a character vector or string scalar.
Data Types: char | string

### Output Arguments

**h — Graphics handles**
array of Line objects

Graphics handles, returned as an array of Line objects. Each Line object corresponds to one of the groups in `g`. You can use dot notation to query and set properties of the line objects. For a list of Line object properties, see Chart Line.

Introduced before R2006a
gt

**Class:** qrandstream

Greater than relation for handles

**Syntax**

\[ h1 > h2 \]

**Description**

\[ h1 > h2 \] performs element-wise comparisons between handle arrays \( h1 \) and \( h2 \). \( h1 \) and \( h2 \) must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise > result.

If one of \( h1 \) or \( h2 \) is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

\[ tf = gt(h1, h2) \] stores the result in a logical array of the same dimensions.

“Quasi-Random Point Sets” on page 7-17
haltonset

**Class:** haltonset

Construct Halton quasi-random point set

**Syntax**

```plaintext
p = haltonset(d)
p = haltonset(d, prop1, val1, prop2, val2, ...)
```

**Description**

```plaintext
p = haltonset(d) constructs a d-dimensional point set p of the haltonset on page 32-2925 class, with default property settings.

p = haltonset(d, prop1, val1, prop2, val2, ...) specifies property name/value pairs used to construct p.

The object p returned by haltonset encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the Skip and Leap properties and by limits on the size of point set indices (maximum value of $2^{53}$). Values of the point set are not generated and stored in memory until you access p using `net` or parenthesis indexing.
```

**Examples**

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```plaintext
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)
p = Halton point set in 3 dimensions (8.918019e+013 points)
Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : none
```
Use **scramble** to apply reverse-radix scrambling:

```matlab
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+13 points)
    Properties:
      Skip : 1000
      Leap : 100
      ScrambleMethod : RR2
```

Use **net** to generate the first four points:

```matlab
X0 = net(p,4)
X0 =
    0.0928  0.6950  0.0029
    0.6958  0.2958  0.8269
    0.3013  0.6497  0.4141
    0.9087  0.7883  0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```matlab
X = p(1:3:11,:)
X =
    0.0928  0.6950  0.0029
    0.9087  0.7883  0.2166
    0.3843  0.9840  0.9878
    0.6831  0.7357  0.7923
```

**Introduced in R2008a**
**harmmean**

Harmonic mean

**Syntax**

\[
\begin{align*}
m &= \text{harmmean}(X) \\
m &= \text{harmmean}(X, 'all') \\
m &= \text{harmmean}(X, \text{dim}) \\
m &= \text{harmmean}(X, \text{vecdim})
\end{align*}
\]

**Description**

\(m = \text{harmmean}(X)\) calculates the harmonic mean on page 32-2931 of a sample. For vectors, \(\text{harmmean}(X)\) is the harmonic mean of the elements in \(X\). For matrices, \(\text{harmmean}(X)\) is a row vector containing the harmonic means of each column. For \(N\)-dimensional arrays, \(\text{harmmean}\) operates along the first nonsingleton dimension of \(X\).

\(m = \text{harmmean}(X, 'all')\) returns the harmonic mean of all elements of \(X\).

\(m = \text{harmmean}(X, \text{dim})\) takes the harmonic mean along the operating dimension \(\text{dim}\) of \(X\).

\(m = \text{harmmean}(X, \text{vecdim})\) returns the harmonic mean over the dimensions specified in the vector \(\text{vecdim}\). Each element of \(\text{vecdim}\) represents a dimension of the input array \(X\). The output \(m\) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \(X\) and \(m\). For example, if \(X\) is a 2-by-3-by-4 array, then \(\text{harmmean}(X, [1 \ 2])\) returns a 1-by-1-by-4 array. Each element of the output array is the harmonic mean of the elements on the corresponding page of \(X\).

**Examples**

**Compare Harmonic and Arithmetic Mean**

Set the random seed for reproducibility of the results.
rng('default')

Create a matrix of exponential random numbers with 5 rows and 4 columns.

\[
X = \text{exprnd}(1,5,4)
\]

\[
X = \begin{bmatrix}
0.2049 & 2.3275 & 1.8476 & 1.9527 \\
0.0989 & 1.2783 & 0.0298 & 0.8633 \\
2.0637 & 0.6035 & 0.0438 & 0.0880 \\
0.0906 & 0.0434 & 0.7228 & 0.2329 \\
0.4583 & 0.0357 & 0.2228 & 0.0414
\end{bmatrix}
\]

Compute the harmonic and arithmetic means of the columns of \(X\).

\[
\text{harmonic} = \text{harmmean}(X)
\]

\[
\text{harmonic} = \begin{bmatrix}
0.1743 \\
0.0928 \\
0.0797 \\
0.1205
\end{bmatrix}
\]

\[
\text{arithmetic} = \text{mean}(X)
\]

\[
\text{arithmetic} = \begin{bmatrix}
0.5833 \\
0.8577 \\
0.5734 \\
0.6357
\end{bmatrix}
\]

The arithmetic mean is greater than or equal to the harmonic mean.

**Harmonic Mean of All Values**

Find the harmonic mean of all the values in an array.

Create a 3-by-5-by-2 array \(X\).

\[
X = \text{reshape}(1:30,[3 \ 5 \ 2])
\]

\[
X = 
X(:,:,1) = 
\]

32-2930
Find the harmonic mean of the elements of X.

\[ m = \text{harmmean}(X, 'all') \]

\[ m = 7.5094 \]

**Definitions**

**Harmonic Mean**

The harmonic mean of a sample X is

\[ m = \frac{n}{\sum_{i=1}^{n} \frac{1}{x_i}} \]

where \( n \) is the number of values in X.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.
This function supports tall arrays with the limitations:

- The following syntaxes are not supported.
  - \( m = \text{harmmean}(X, \text{'all'}) \)
  - \( m = \text{harmmean}(X, \text{vecdim}) \)

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
  - \( m = \text{harmmean}(X, \text{'all'}) \)
  - \( m = \text{harmmean}(X, \text{vecdim}) \)

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The following syntaxes do not support GPU arrays as input arguments.
  - \( m = \text{harmmean}(X, \text{'all'}) \)
  - \( m = \text{harmmean}(X, \text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
hist3

Bivariate histogram plot

Syntax

hist3(X)
hist3(X,'Nbins',nbins)
hist3(X,'Ctrs',ctrs)
hist3(X,'Edges',edges)
hist3(___,Name,Value)
hist3(ax,___)

N = hist3(__)
[N,c] = hist3(__)

Description

hist3(X) creates a bivariate histogram plot of X(:,1) and X(:,2) using 10-by-10 equally spaced bins. The hist3 function displays the bins as 3-D rectangular bars, and the height of each bar indicates the number of elements in the bin.

hist3(X,'Nbins',nbins) specifies the number of bins in each dimension of the histogram. This syntax is equivalent to hist3(X,nbins).

hist3(X,'Ctrs',ctrs) specifies the centers of the bins in each dimension of the histogram. This syntax is equivalent to hist3(X,ctrs).

hist3(X,'Edges',edges) specifies the edges of the bins in each dimension.

hist3(___,Name,Value) specifies graphical properties using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, 'FaceAlpha',0.5 creates a semitransparent histogram. For a list of properties, see Surface Properties.
hist3(ax,___) plots into the axes specified by ax instead of the current axes (gca). The option ax can precede any of the input argument combinations in the previous syntaxes.

N = hist3(___) returns the number of elements in X that fall in each bin. This syntax does not create a histogram.

[N,c] = hist3(___) also returns the bin centers. This syntax does not create a histogram.

Examples

Histogram of Vectors

Load the sample data.

load carbig

Create a bivariate histogram with the default settings.

X = [MPG,Weight];
hist3(X)
xlabel('MPG')
ylabel('Weight')
Specify Centers of Histogram Bins

Create a bivariate histogram on the bins specified by the bin centers, and count the number of elements in each bin.

Load the sample data.

load carbig

Create a bivariate histogram. Specify the centers of the histogram bins using a two-element cell array.
$$X = [\text{MPG}, \text{Weight}];$$
$$\text{hist3}(X, \text{'Ctrs'}, \{0:10:50 \ 2000:500:5000\})$$
$$\text{xlabel('MPG')}$$
$$\text{ylabel('Weight')}$$

Count the number of elements in each bin.

$$N = \text{hist3}(X, \text{'Ctrs'}, \{0:10:50 \ 2000:500:5000\})$$

$$N = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & 3 & 16 & 26 & 6 \\
6 & 34 & 50 & 49 & 27 & 10 & 0 \\
70 & 49 & 11 & 3 & 0 & 0 & 0
\end{bmatrix}$$
Color Histogram Bars by Height

Load the sample data.

load carbig

Create a bivariate histogram. Specify graphical properties to color the histogram bars by height representing the frequency of the observations.

X = [MPG,Weight];
hist3(X,'CDataMode','auto','FaceColor','interp')
xlabel('MPG')
ylabel('Weight')
Tiled Histogram View

Load the sample data.

load carbig

Create a bivariate tiled histogram. Specify graphical properties to color the top surface of the histogram bars by the frequency of the observations. Change the view to two-dimensional.

X = [MPG,Weight];
hist3(X,'CdataMode','auto')
xlabel('MPG')
ylabel('Weight')
colorbar
view(2)

Adjust Graphical Properties

Create a bivariate histogram and adjust its graphical properties by using the handle of the histogram surface object.

Load the sample data.

load carbig
Create a bivariate histogram with 7 bins in each dimension.

\[
X = [\text{MPG}, \text{Weight}];
\]
\[
\text{hist3}(X, \text{''Nbins'',}[7 \ 7])
\]
\[
\text{xlabel(',\text{MPG}')}
\]
\[
\text{ylabel(',\text{Weight}')}
\]

The \text{hist3} function creates a bivariate histogram, which is a type of surface plot. Find the handle of the surface object and adjust the face transparency.

\[
s = \text{findobj(gca, } \text{''Type'',} \text{''Surface'');}
\]
\[
s.\text{FaceAlpha} = 0.65;
\]
Plot Histogram with Intensity Map

Create a bivariate histogram and add the 2-D projected view of intensities to the histogram.

Load the seamount data set (a seamount is an underwater mountain). The data set consists of a set of longitude (x) and latitude (y) locations, and the corresponding seamount elevations (z) measured at those coordinates. This example uses x and y to draw a bivariate histogram.

load seamount
Draw a bivariate histogram.

\[
\text{hist3([x,y])}
\]
\[
\text{xlabel('Longitude')}
\]
\[
\text{ylabel('Latitude')}
\]
\[
\text{hold on}
\]

Count the number of elements in each bin.

\[
N = \text{hist3([x,y])};
\]

Generate a grid to draw the 2-D projected view of intensities by using \texttt{pcolor}.

\[
N_{\text{pcolor}} = N';
\]
\[
N_{\text{pcolor}}(\text{size}(N_{\text{pcolor}},1)+1,\text{size}(N_{\text{pcolor}},2)+1) = 0;
\]
xl = linspace(min(x), max(x), size(N_pcolor, 2)); % Columns of N_pcolor
yl = linspace(min(y), max(y), size(N_pcolor, 1)); % Rows of N_pcolor

Draw the intensity map by using pcolor. Set the z-level of the intensity map to view the histogram and the intensity map together.

h = pcolor(xl, yl, N_pcolor);
colormap('hot') % Change color scheme
colorbar % Display colorbar
h.ZData = -max(N_pcolor(:))*ones(size(N_pcolor));
ax = gca;
ax.ZTick(ax.ZTick < 0) = [];
title('Seamount Location Histogram and Intensity Map');
Input Arguments

\( X \) — Data to distribute among bins

\( m\text{-by-2 numeric matrix} \)

Data to distribute among the bins, specified as an \( m\text{-by-2 numeric matrix} \), where \( m \) is the number of data points. Corresponding elements in \( X(:,1) \) and \( X(:,2) \) specify the \( x \) and \( y \) coordinates of 2-D data points.

\texttt{hist3} ignores all \texttt{NaN} values. Similarly, \texttt{hist3} ignores \texttt{Inf} and \texttt{–Inf} values unless you explicitly specify \texttt{Inf} or \texttt{–Inf} as a bin edge by using the \texttt{edges} input argument.

Data Types: \texttt{single} | \texttt{double}

\( \texttt{nbins} \) — Number of bins

[10 10] (default) | \texttt{two-element vector of positive integers}

Number of bins in each dimension, specified as a two-element vector of positive integers. \( \texttt{nbins}(1) \) specifies the number of bins in the first dimension, and \( \texttt{nbins}(2) \) specifies the number of bins in the second dimension.

Example: [10 20]

Data Types: \texttt{single} | \texttt{double}

\( \texttt{ctrs} \) — Bin centers

\texttt{two-element cell array of numeric vectors}

Bin centers in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. \( \texttt{ctrs}(1) \) and \( \texttt{ctrs}(2) \) are the positions of the bin centers in the first and second dimensions, respectively.

\texttt{hist3} assigns rows of \( X \) falling outside the range of the grid to the bins along the outer edges of the grid.

Example: \{0:10:100 0:50:500\}

Data Types: \texttt{cell}

\( \texttt{edges} \) — Bin edges

\texttt{two-element cell array of numeric vectors}
Bin edges in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `edges{1}` and `edges{2}` are the positions of the bin edges in the first and second dimensions, respectively.

The value `X(k,:)` is in the `(i,j)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`.

The last bins in each dimension also include the last (outer) edge. For example, `X(k,:)` falls into the `(I,j)`th bin if `edges{1}(I–1) ≤ X(k,1) ≤ edges{1}(I)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`, where `I` is the length of `edges{1}`. Also, `X(k,:)` falls into the `(i,J)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(J–1) ≤ X(k,2) ≤ edges{2}(J)`, where `J` is the length of `edges{2}`.

`hist3` does not count rows of `X` falling outside the range of the grid. Use `–Inf` and `Inf` in `edges` to include all non-`NaN` values.

Example: `{0:10:100 0:50:500}

Data Types: cell

**ax — Target axes**
current axes (gca) (default) | Axes object

Target axes, specified as an axes object. If you do not specify an `Axes` object, then the `hist3` function uses the current axes (`gca`). For details, see `Axes Properties`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `hist3(X,'FaceColor','interp','CDataMode','auto')` colors the histogram bars according to the height of the bars.

The graphical properties listed here are only a subset. For a full list, see `Surface Properties`.

**CDataMode — Selection mode for vertex colors**

'`manual`' (default) | 'auto'
Selection mode for CData (vertex colors), specified as the comma-separated pair consisting of 'CDataMode' and one of these values:

- 'manual' — Use manually specified values in the CData property. The default color in CData is light steel blue corresponding to an RGB triple value of [0.75 0.85 0.95].
- 'auto' — Use the ZData values to set the colors. ZData contains the z-coordinate data for the eight corners of each bar.

Example: 'CDataMode','auto'

EdgeColor — Edge line color
[0 0 0] (default) | 'none' | 'flat' | 'interp' | RGB triplet | 'r' | 'g' | 'b' |...

Edge line color, specified as the comma-separated pair consisting of 'EdgeColor' and one of these values:

- 'none' — Do not draw the edges.
- 'flat' — Use a different color for each edge based on the values in the CData property.
- 'interp' — Use interpolated coloring for each edge based on the values in the CData property.
- RGB triplet or color name — Use the specified color for all the edges. This option does not use the color values in the CData property.

The default color of [0 0 0] corresponds to black edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7]. Alternatively, you can specify some common colors by name. This table lists the long and short color name options and the equivalent RGB triplet values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Equivalent RGB Triplet</th>
</tr>
</thead>
<tbody>
<tr>
<td>'red' or 'r'</td>
<td>Red</td>
<td>[1 0 0]</td>
</tr>
<tr>
<td>'green' or 'g'</td>
<td>Green</td>
<td>[0 1 0]</td>
</tr>
<tr>
<td>'blue' or 'b'</td>
<td>Blue</td>
<td>[0 0 1]</td>
</tr>
<tr>
<td>'yellow' or 'y'</td>
<td>Yellow</td>
<td>[1 1 0]</td>
</tr>
<tr>
<td>'magenta' or 'm'</td>
<td>Magenta</td>
<td>[1 0 1]</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
<td>Equivalent RGB Triplet</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
<td>------------------------</td>

<tr>
<td>'cyan'</td>
<td>Cyan</td>
<td>[0 1 1]</td>
</tr>
<tr>
<td>'white'</td>
<td>White</td>
<td>[1 1 1]</td>
</tr>
<tr>
<td>'black'</td>
<td>Black</td>
<td>[0 0 0]</td>
</tr>
</tbody>
</table>

Example: 'EdgeColor', 'blue'

**FaceAlpha — Face transparency**

1 (default) | scalar in the range [0,1] | 'flat' | 'interp' | 'texturemap'

Face transparency, specified as the comma-separated pair consisting of 'FaceAlpha' and one of these values:

- Scalar in the range [0,1] — Use uniform transparency across all the faces. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the AlphaData property.
- 'flat' — Use a different transparency for each face based on the values in the AlphaData property. The transparency value at the first vertex determines the transparency for the entire face. This value applies only when you specify the AlphaData property and set the FaceColor property to 'flat'.
- 'interp' — Use interpolated transparency for each face based on the values in the AlphaData property. The transparency varies across each face by interpolating the values at the vertices. This value applies only when you specify the AlphaData property and set the FaceColor property to 'interp'.
- 'texturemap' — Transform the data in AlphaData so that it conforms to the surface.

Example: 'FaceAlpha', 0.5

**FaceColor — Face color**

'flat' (default) | 'interp' | 'none' | 'texturemap' | RGB triplet | 'r' | 'g' | 'b' | ...

Face color, specified as the comma-separated pair consisting of 'FaceColor' and one of these values:

- 'flat' — Use a different color for each face based on the values in the CData property.
- 'interp' — Use interpolated coloring for each face based on the values in the CData property.
- 'none' — Do not draw the faces.
- 'texturemap' — Transform the color data in CData so that it conforms to the surface.
- RGB triplet or color name — Use the specified color for all the faces. This option does not use the color values in the CData property.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$. Alternatively, you can specify some common colors by name. This table lists the long and short color name options and the equivalent RGB triplet values.

<table>
<thead>
<tr>

<tr>
<td>'magenta' or 'm'</td>
<td>Magenta</td>
<td>[1 0 1]</td>
</tr>
<tr>
<td>'cyan' or 'c'</td>
<td>Cyan</td>
<td>[0 1 1]</td>
</tr>
<tr>
<td>'white' or 'w'</td>
<td>White</td>
<td>[1 1 1]</td>
</tr>
<tr>
<td>'black' or 'k'</td>
<td>Black</td>
<td>[0 0 0]</td>
</tr>
</tbody>
</table>

Example: 'FaceColor','interp'

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and one of the options in this table.

<table>
<thead>
<tr>
<th>Line Style</th>
<th>Description</th>
<th>Resulting Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>

<td>_ . . . .</td>
</tr>
<tr>
<td>'none'</td>
<td>No line</td>
<td>No line</td>
</tr>
</tbody>
</table>

Example: 'LineStyle',':'

**LineWidth — Line width**

0.5 (default) | positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points.

Example: 'LineWidth',0.75

Data Types: single | double

**Output Arguments**

**N — Number of elements in each bin**
numeric matrix

Number of elements in X that fall in each bin, returned as a numeric matrix.

**c — Bin centers**
two-element cell array of numeric vectors

Bin centers in each dimension, returned as a two-element cell array of numeric vectors. c{1} and c{2} are the positions of the bin centers in the first and second dimensions, respectively.

**Tips**

The hist3 function creates a bivariate histogram, which is a type of surface plot. You can specify surface properties using one or more name-value pair arguments. Also, you can
change the appearance of the histogram by changing the surface property values after you create a histogram. Get the handle of the surface object by using `s = findobj(gca,'Type','Surface')`, and then use `s` to modify the surface properties. For an example, see “Adjust Graphical Properties” on page 32-2939. For a list of properties, see Surface Properties.

**Alternative Functionality**

The `histogram2` function enables you to create a bivariate histogram using a `Histogram2` object. You can use the name-value pair arguments of `histogram2` to use normalization ('Normalization'), adjust the width of the bins in each dimension ('BinWidth'), and display the histogram as a rectangular array of tiles instead of 3-D bars ('DisplayStyle').

### histfit

Histogram with a distribution fit

### Syntax

- `histfit(data)`
- `histfit(data,nbins)`
- `histfit(data,nbins,dist)`
- `h = histfit(___)`

### Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit(___)` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

### Examples

#### Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```
Construct a histogram with a normal distribution fit.

\texttt{histfit(r)}

\texttt{histfit} uses \texttt{fitdist} to fit a distribution to data. Use \texttt{fitdist} to obtain parameters used in fitting.

\texttt{pd = fitdist(r,'Normal')}

\texttt{pd =}
\begin{verbatim}
NormalDistribution

Normal distribution
mu = 10.1231   [9.89244, 10.3537]
\end{verbatim}
The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

**Histogram for a Given Number of Bins**

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```matlab
histfit(r,6)
```
Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```matlab
rng default; % For reproducibility
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```matlab
histfit(b,10,'beta')
```
Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```matlab
rng default; % For reproducibility
b = betarnd(3,10,[100,1]);

Construct a histogram using 10 bins with a smoothing function fit.

histfit(b,10,'kernel')
```
Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```matlab
rng default % for reproducibility
r = normrnd(10,1,100,1);

Construct a histogram with a normal distribution fit.

h = histfit(r,10,'normal')
```
h =
    2x1 graphics array:
    Bar
    Line

Change the bar colors of the histogram.

h(1).FaceColor = [.8 .8 1];
Change the color of the density curve.

\[ h(2).\text{Color} = [.2 \ .2 \ .2]; \]
**Input Arguments**

**data** — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`
Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`
**nbins — Number of bins**

positive integer | [ ]

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [ ] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`
Example: `y = histfit(x,10,'gamma')`
Example: `y = histfit(x,[],'weibull')`

Data Types: `double` | `single`

**dist — Distribution to fit**

'normal' (default) | character vector | string scalar

Distribution to fit to the histogram, specified as a character vector or string scalar. The following table shows the supported distributions.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Output Arguments**

**h — Handles for the plot**

plot handle

Handles for the plot, returned as a vector, where h(1) is the handle to the histogram, and h(2) is the handle to the density curve. `histfit` normalizes the density to match the total area under the curve with that of the histogram.

**Algorithms**

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

Introduced before R2006a
hmmdecode

Hidden Markov model posterior state probabilities

Syntax

PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)

Description

PSTATES = hmmdecode(seq,TRANS,EMIS) calculates the posterior state probabilities, PSTATES, of the sequence seq, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i, given the observed sequence of symbols, sym. You specify the model by a transition probability matrix, TRANS, and an emissions probability matrix, EMIS. TRANS(i,j) is the probability of transition from state i to state j. EMIS(k,seq) is the probability that symbol seq is emitted from state k.

PSTATES is an array with the same length as seq and one row for each state in the model. The (i,j)th element of PSTATES gives the probability that the model is in state i at the jth step, given the sequence seq.

Note The function hmmdecode begins with the model in state 1 at step 0, prior to the first emission. hmmdecode computes the probabilities in PSTATES based on the fact that the model begins in state 1.

[PSTATES,logpseq] = hmmdecode(...) returns logpseq, the logarithm of the probability of sequence seq, given transition matrix TRANS and emission matrix EMIS.

[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...) returns the forward and backward probabilities of the sequence scaled by S.
hmmdecode(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

**Examples**

```matlab
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];
[seq,states] = hmmgenerate(100,trans,emis);
pStates = hmmdecode(seq,trans,emis);
[seq,states] = hmmgenerate(100,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'})
pStates = hmmdecode(seq,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'});
```

**Introduced before R2006a**
hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)

Description

[TRANS,EMIS] = hmmestimate(seq,states) calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.

hmmestimate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmestimate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

hmmestimate(...,'Pseudoemissions',PSEUDOE) specifies pseudocount emission values in the matrix PSEUDOE. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the \( i \rightarrow k \) emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

hmmestimate(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for
transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size \( m \times m \), where \( m \) is the number of states in the hidden Markov model. If the \( i \rightarrow j \) transition does not occur in states, you can set \( \text{PSEUDOTR}(i,j) \) to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

**Pseudotransitions and Pseudoemissions**

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence states, or the emission might never occur in the sequence seq. In either case, the algorithm returns a probability of 0 for the given transition or emission in TRANS or EMIS. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of PSEUDO\( E \) or \( \text{PSEUDOTR} \) to 1. For example, if the transition \( i \rightarrow j \) does not occur in states, set \( \text{PSEUDOTR}(i,j) = 1 \). This forces \( \text{TRANS}(i,j) \) to be positive. If you have an estimate for the expected number of transitions \( i \rightarrow j \) in a sequence of the same length as states, and the actual number of transitions \( i \rightarrow j \) that occur in seq is substantially less than what you expect, you can set \( \text{PSEUDOTR}(i,j) \) to the expected number. This increases the value of \( \text{TRANS}(i,j) \). For transitions that do occur in states with the frequency you expect, set the corresponding entry of \( \text{PSEUDOTR} \) to 0, which does not increase the corresponding entry of TRANS.

If you do not know the sequence of states, use hmmtrain to estimate the model parameters.

**Examples**

```plaintext
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

32-2965

hmmdecode | hmmgenerate | hmmtrain | hmmviterbi

Introduced before R2006a
hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

```
[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence seq of emission symbols
- A random sequence states of states

The length of both seq and states is len. TRANS(i,j) is the probability of transition from state i to state j. EMIS(k,l) is the probability that symbol l is emitted from state k.

Note The function hmmgenerate begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1, with probability T_{i1}, and generates an emission a_{k1} with probability E_{i1k1}. hmmgenerate returns i_1 as the first entry of states, and a_{k1} as the first entry of seq.
```

hmmgenerate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be specified as a numeric array, a string array, or a cell array of character vectors. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmgenerate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be specified as a numeric array, a string array, or a cell array of
character vectors. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output states is be 1 with probability 0.95 and 2 with probability 0.05.

**Examples**

```matlab
trans = [0.95, 0.05; 0.10, 0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6; 1/10 1/10 1/10 1/10 1/10 1/2];

[seq, states] = hmmgenerate(100, trans, emis)
[seq, states] = hmmgenerate(100, trans, emis,...
    'Symbols', {'one', 'two', 'three', 'four', 'five', 'six'},...
    'Statenames', {'fair'; 'loaded'})
```

**See Also**

hmmdecode | hmmestimate | hmmtrain | hmmviterbi

**Introduced before R2006a**
hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)

Description

[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS) estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. seq can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. TRGUESS and EMITGUESS are initial estimates of the transition and emission probability matrices. TRGUESS(i,j) is the estimated probability of transition from state i to state j. EMITGUESS(i,k) is the estimated probability that symbol k is emitted from state i.

hmmtrain(...,'Algorithm',algorithm) specifies the training algorithm. algorithm can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

hmmtrain(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmtrain(...,'Tolerance',tol) specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is 1e-4.
hmmtrain(...,'Maxiterations',maxiter) specifies the maximum number of iterations for the estimation process. The default maximum is 100.

hmmtrain(...,'Verbose',true) returns the status of the algorithm at each iteration.

hmmtrain(...,'Pseudoemissions',PSEUDOE) specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size m-by-n, where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

hmmtrain(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size m-by-m, where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in states, you can set PSEUDOTR(i,j) to be a positive number representing an estimate of the expected number of such transitions in the sequence states.

If you know the states corresponding to the sequences, use hmmestimate to estimate the model parameters.

**Tolerance**

The input argument 'tolerance' controls how many steps the hmmtrain algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for tolerance:

- The log likelihood that the input sequence seq is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of 'tolerance' is 1e-6. Increasing the tolerance decreases the number of steps the hmmtrain algorithm executes before it terminates.
maxiterations

The maximum number of iterations, 'maxiterations', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes maxiter iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

Examples

trans = [0.95,0.05; 
         0.10,0.90];
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6; 
         1/10, 1/10, 1/10, 1/10, 1/10, 1/2];

seq1 = hmmgenerate(100,trans,emis);
seq2 = hmmgenerate(200,trans,emis);
seqs = {seq1,seq2};
[estTR,estE] = hmmtrain(seqs,trans,emis);

**hmmviterbi**

Hidden Markov model most probable state path

**Syntax**

```matlab
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

**Description**

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

**Note** The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

**Examples**

```matlab
trans = [0.95,0.05;
         0.10,0.90];
```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
    1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
estimatedStates = hmmviterbi(seq,trans,emis);

[seq,states] = ...
    hmmgenerate(100,trans,emis,...
        'Statenames',{'fair';'loaded'});
estimatesStates = ...
    hmmviterbi(seq,trans,emis,...
        'Statenames',{'fair';'loaded'});

Introduced before R2006a
horzcat

**Class:** dataset

Horizontal concatenation for dataset arrays

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

ds = horzcat(ds1, ds2, ...)

**Description**

ds = horzcat(ds1, ds2, ...) horizontally concatenates the dataset arrays ds1, ds2, .... You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and horzcat includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. horzcat concatenates by matching observation names when present, or by position for datasets that do not have observation names.

cat | vertcat
hougen

Hougen-Watson model

Syntax

yhat = hougen(beta,x)

Description

yhat = hougen(beta,x) returns the predicted values of the reaction rate, yhat, as a function of the vector of parameters, beta, and the matrix of data, X. beta must have 5 elements and X must have three columns.

hougen is a utility function for rsmdemo.

The model form is:

\[ \hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3} \]

Introduced before R2006a
hygecdf

Hypergeometric cumulative distribution function

Syntax

\[
\text{hygecdf}(x,M,K,N) \\
\text{hygecdf}(x,M,K,N, 'upper')
\]

Description

\text{hygecdf}(x,M,K,N) \text{ computes the hypergeometric cdf at each of the values in } x \text{ using the corresponding size of the population, } M, \text{ number of items with the desired characteristic in the population, } K, \text{ and number of samples drawn, } N. \text{ Vector or matrix inputs for } x, M, K, \text{ and } N \text{ must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.}

\text{hygecdf}(x,M,K,N, 'upper') \text{ returns the complement of the hypergeometric cdf at each value in } x, \text{ using an algorithm that more accurately computes the extreme upper tail probabilities.}

The hypergeometric cdf is

\[
p = F(x | M, K, N) = \sum_{i=0}^{x} \binom{K}{i} \binom{M-K}{N-i} \binom{M}{N}
\]

The result, \( p \), is the probability of drawing up to \( x \) of a possible \( K \) items in \( N \) drawings without replacement from a group of \( M \) objects.

Examples
Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

\[ p = \text{hygecdf}(2, 100, 20, 10) \]

\[ p = 0.6812 \]

cdf | hygeinv | hygepdf | hygernd | hygestat

Introduced before R2006a
hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

hygeinv(P,M,K,N)

Description

hygeinv(P,M,K,N) returns the smallest integer $X$ such that the hypergeometric cdf evaluated at $X$ equals or exceeds $P$. You can think of $P$ as the probability of observing $X$ defective items in $N$ drawings without replacement from a group of $M$ items where $K$ are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```matlab
x = hygeinv(0.99,1000,10,50)
x =
   3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```matlab
x = hygeinv(0.50,1000,10,50)
x =
   0
```
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

hygecdf | hygepdf | hygernd | hygestat | icdf

Introduced before R2006a
hygepdf

Hypergeometric probability density function

Syntax

Y = hygepdf(X,M,K,N)

Description

Y = hygepdf(X,M,K,N) computes the hypergeometric pdf at each of the values in X using the corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. X, M, K, and N can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in M, K, and N must all be positive integers, with N ≤ M. The values in X must be less than or equal to all the parameter values.

The hypergeometric pdf is

\[ y = f(x \mid M, K, N) = \binom{K}{x} \frac{\binom{M - K}{N - x} \binom{M}{x}}{\binom{M}{N}} \]

The result, y, is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?
\[ p = \text{hygepdf}(0:5, 100, 20, 10) \]
\[ p = 0.0951 \ 0.2679 \ 0.3182 \ 0.2092 \ 0.0841 \ 0.0215 \]

*Introduced before R2006a*
hygernd

Hypergeometric random numbers

Syntax

R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])

Description

R = hygernd(M,K,N) generates random numbers from the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. M, K, and N can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of R. A scalar input for M, K, or N is expanded to a constant array with the same dimensions as the other inputs.

R = hygernd(M,K,N,m,n,...) or R = hygernd(M,K,N,[m,n,...]) generates an m-by-n-by-... array. The M, K, N parameters can each be scalars or arrays of the same size as R.

Examples

numbers = hygernd(1000,40,50)
numbers =
    1
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

Introduced before R2006a
hygestat

Hypergeometric mean and variance

Syntax

\[[M,N,V] = \text{hygestat}(M,K,N)\]

Description

\[[M,N,V] = \text{hygestat}(M,K,N)\] returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, \(M\), number of items with the desired characteristic in the population, \(K\), and number of samples drawn, \(N\). Vector or matrix inputs for \(M\), \(K\), and \(N\) must have the same size, which is also the size of \(MN\) and \(V\). A scalar input for \(M\), \(K\), or \(N\) is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters \(M\), \(K\), and \(N\) is \(NK/M\), and the variance is \(NK(M-K)(M-N)/[M^2(M-1)]\).

Examples

The hypergeometric distribution approaches the binomial distribution, where \(p = K/M\), as \(M\) goes to infinity.

\[[m,v] = \text{hygestat}(10.^(1:4),10.^(0:3),9)\]

\(m = \)

\(0.9000 \ 0.9000 \ 0.9000 \ 0.9000\
\(v = \)

\(0.0900 \ 0.7445 \ 0.8035 \ 0.8094\)

\[[m,v] = \text{binostat}(9,0.1)\]

\(m = \)

\(0.9000\)

\(v = \)

\(0.8100\)

Introduced before R2006a
**hyperparameters**

Variable descriptions for optimizing a fit function

**Syntax**

```matlab
VariableDescriptions = hyperparameters(FitFcnName,predictors, response)
VariableDescriptions = hyperparameters(FitFcnName,predictors, response,LearnerType)
```

**Description**

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response)` returns the default variables for the given fit function. These are the variables that apply when you set the `OptimizeHyperparameters` name-value pair to 'auto'.

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response,LearnerType)` returns the variables for an ensemble fit with specified learner type. This syntax applies when `FitFcnName` is 'fitcecoc', 'fitcensemble', or 'fitrensemble'.

**Examples**

**Obtain Default Hyperparameters**

Obtain the default hyperparameters for the `fitcsvm` classifier.

Load the `ionosphere` data.

```matlab
load ionosphere
```

Obtain the hyperparameters.
VariableDescriptions = hyperparameters('fitcsvm',X,Y);

Examine all the hyperparameters.

for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end

1

optimizableVariable with properties:

    Name: 'BoxConstraint'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1

2

optimizableVariable with properties:

    Name: 'KernelScale'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1

3

optimizableVariable with properties:

    Name: 'KernelFunction'
    Range: {'gaussian' 'linear' 'polynomial'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 0

4

optimizableVariable with properties:

    Name: 'PolynomialOrder'
    Range: [2 4]
    Type: 'integer'
Transform: 'none'
Optimize: 0

5

optimizableVariable with properties:

    Name: 'Standardize'
    Range: {'true' 'false'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 0

Change the PolynomialOrder hyperparameter to have a wider range and to be used in an optimization.

VariableDescriptions(4).Range = [2,5];
VariableDescriptions(4).Optimize = true;
disp(VariableDescriptions(4))

    optimizableVariable with properties:

        Name: 'PolynomialOrder'
        Range: [2 5]
        Type: 'integer'
        Transform: 'none'
        Optimize: 1

**Obtain Ensemble Hyperparameters**

Obtain the default hyperparameters for the fitrensemble ensemble regression function.

Load the carsmall data.
load carsmall

Use Horsepower and Weight as predictor variables, and MPG as the response variable.

X = [Horsepower Weight];
Y = MPG;

Obtain the default hyperparameters for a Tree learner.
VariableDescriptions = hyperparameters('fitensemble',X,Y,'Tree');

Examine all the hyperparameters.

for ii = 1:length(VariableDescriptions)
    disp(ii), disp(VariableDescriptions(ii))
end

1

optimizableVariable with properties:
    Name: 'Method'
    Range: {'Bag' 'LSBoost'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 1

2

optimizableVariable with properties:
    Name: 'NumLearningCycles'
    Range: [10 500]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1

3

optimizableVariable with properties:
    Name: 'LearnRate'
    Range: [1.0000e-03 1]
    Type: 'real'
    Transform: 'log'
    Optimize: 1

4

optimizableVariable with properties:
    Name: 'MinLeafSize'
    Range: [1 50]
    Type: 'integer'
Change the `MaxNumSplits` hyperparameter to have a wider range and to be used in an optimization.

```matlab
VariableDescriptions(5).Range = [1,200];
VariableDescriptions(5).Optimize = true;
disp(VariableDescriptions(5))
```

```matlab
optimizableVariable with properties:
    Name: 'MaxNumSplits'
    Range: [1 200]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```
**Input Arguments**

**FitFcnName — Name of fitting function**

<table>
<thead>
<tr>
<th>FitFcnName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fitcdiscr'</td>
<td>Discriminant classifier fit function.</td>
</tr>
<tr>
<td>'fitcecoc'</td>
<td>Error-correcting output code (ECOC) classifier fit function.</td>
</tr>
<tr>
<td>'fitcensemble'</td>
<td>Ensemble classifier fit function.</td>
</tr>
<tr>
<td>'fitckernel'</td>
<td>Kernel regression fit function.</td>
</tr>
<tr>
<td>'fitcknn'</td>
<td>k-nearest neighbors (k-NN) classifier fit function.</td>
</tr>
<tr>
<td>'fitclinear'</td>
<td>Linear regression fit function.</td>
</tr>
<tr>
<td>'fitcnb'</td>
<td>Naive Bayes classifier fit function.</td>
</tr>
<tr>
<td>'fitcsvm'</td>
<td>Support vector machine (SVM) classifier fit function.</td>
</tr>
<tr>
<td>'fitctree'</td>
<td>Classification tree fit function.</td>
</tr>
<tr>
<td>'fitrensemble'</td>
<td>Ensemble regression fit function.</td>
</tr>
<tr>
<td>'fitrgp'</td>
<td>Gaussian process regression fit function.</td>
</tr>
<tr>
<td>'fitrkernel'</td>
<td>Kernel regression fit function.</td>
</tr>
<tr>
<td>'fitrlinear'</td>
<td>Linear regression fit function.</td>
</tr>
<tr>
<td>'fitrsvm'</td>
<td>Support vector machine (SVM) regression fit function.</td>
</tr>
<tr>
<td>'fitrtree'</td>
<td>Regression tree fit function.</td>
</tr>
</tbody>
</table>

Name of fitting function, specified as one of the listed classification or regression fit function names.

If `FitFcnName` is 'fitcecoc', 'fitcensemble', or 'fitrensemble', then also specify the learner type in the **LearnerType** argument.

Example: 'fitctree'

**predictors — Predictor data**

matrix with D predictor columns | table with D predictor columns

Predictor data, specified as a matrix with D predictor columns or as a table with D predictor columns, where D is the number of predictors.

Example: X

Data Types: double | logical | char | string | table | cell | categorical | datetime

**response — Class labels or numeric response**

grouping variable | scalar

Class labels or numeric response, specified as a grouping variable (see “Grouping Variables” on page 2-57) or as a scalar.

Example: Y

Data Types: single | double | logical | char | string | cell

**LearnerType — Learner type for ensemble fit**

'Discriminant' | 'KNN' | 'Linear' | 'SVM' | 'Tree' | template of a listed learner

Learner type for ensemble fit, specified as 'Discriminant', 'KNN', 'Linear', 'SVM', 'Tree', or a template of a listed learner. Use this argument when **FitFcnName** is 'fitcecoc', 'fitcensemble', or 'fitrensemble'.
For 'fitcensemble' you can use only 'Discriminant', 'KNN', 'Tree', or an associated template.

For 'fitrensemble', you can use only 'Tree' or templateTree.

Example: 'Tree'

Output Arguments

VariableDescriptions — Variable descriptions
vector of optimizableVariable objects

Variable descriptions, returned as a vector of optimizableVariable objects. The variables have their default parameters set, such as range and variable type. All eligible variables exist in the descriptions, but the variables unused in the 'auto' setting have their Optimize property set to false. You can update the variables by using dot notation, as shown in “Examples” on page 32-0.

Introduced in R2016b
icdf

**Package:** prob

Inverse cumulative distribution function

**Syntax**

\[
x = \text{icdf('name','p,A)}
\]

\[
x = \text{icdf('name','p,A,B)}
\]

\[
x = \text{icdf('name','p,A,B,C)}
\]

\[
x = \text{icdf('name','p,A,B,C,D)}
\]

\[
x = \text{icdf(pd,'p)}
\]

**Description**

\[
x = \text{icdf('name','p,A)}\] returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the probability values in p.

\[
x = \text{icdf('name','p,A,B)}\] returns the icdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the probability values in p.

\[
x = \text{icdf('name','p,A,B,C)}\] returns the icdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the probability values in p.

\[
x = \text{icdf('name','p,A,B,C,D)}\] returns the icdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the probability values in p.

\[
x = \text{icdf(pd,'p)}\] returns the icdf function of the probability distribution object pd, evaluated at the probability values in p.
Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, $\mu$, equal to 0 and the standard deviation, $\sigma$, equal to 1.

```matlab
mu = 0;
sigma = 1;
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector $p$ to contain the probability values at which to calculate the icdf.

```matlab
p = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in $p$.

```matlab
x = icdf(pd,p)
x = 1x5
    -1.2816   -0.6745         0    0.6745    1.2816
```

Each value in $x$ corresponds to a value in the input vector $p$. For example, at the value $p$ equal to 0.9, the corresponding icdf value $x$ is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for $\mu$ and $\sigma$.

```matlab
x2 = icdf('Normal',p,mu,sigma)
x2 = 1x5
    -1.2816   -0.6745         0    0.6745    1.2816
```

The icdf values are the same as those computed using the probability distribution object.
Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, $\lambda$, equal to 2.

```matlab
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector $p$ to contain the probability values at which to calculate the icdf.

```matlab
p = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the Poisson distribution at the values in $p$.

```matlab
x = icdf(pd,p)
```

```
x = 1x5
     0     1     2     3     4
```

Each value in $x$ corresponds to a value in the input vector $p$. For example, at the value $p$ equal to 0.9, the corresponding icdf value $x$ is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter $\lambda$.

```matlab
x2 = icdf('Poisson',p,lambda)
```

```
x2 = 1x5
     0     1     2     3     4
```

The icdf values are the same as those computed using the probability distribution object.

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```matlab
pd = makedist('Normal')
```
pd = NormalDistribution
    Normal distribution
    mu = 0
    sigma = 1

Determine the critical values at the 5% significance level for a test statistic with a
standard normal distribution, by computing the upper and lower 2.5% values.

x = icdf(pd, [.025, .975])
x = 1x2
    -1.9600  1.9600

Plot the cdf and shade the critical regions.

p = normspec(x, 0, 1, 'outside')
Input Arguments

'name' — Probability distribution name
classic vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

Example: 'Normal'

**p — Probability values at which to evaluate icdf**

scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values in the range [0,1].

If one or more of the input arguments p, A, B, C, and D are arrays, then the array sizes must be the same. In this case, icdf expands each scalar input into a constant array of the same size as the array inputs.

Example: [0.1, 0.25, 0.5, 0.75, 0.9]

Data Types: single | double

**A — First probability distribution parameter**

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments p, A, B, C, and D are arrays, then the array sizes must be the same. In this case, icdf expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**B — Second probability distribution parameter**

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.
If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

**C — Third probability distribution parameter**

`scalar value` | `array of scalar values`

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

**D — Fourth probability distribution parameter**

`scalar value` | `array of scalar values`

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs.

Data Types: `single` | `double`

**pd — Probability distribution**

`probability distribution object`

Probability distribution, specified as a probability distribution object created with a function or app in this table.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>makedist</code></td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td><code>fitdist</code></td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
</tbody>
</table>
### Function or App | Description
---|---
**Distribution Fitter** | Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

**paretotails** | Create a piecewise distribution object that has generalized Pareto distributions in the tails.

---

#### Output Arguments

**x — icdf values**

scalar value | array of scalar values

icdf values, returned as a scalar value or an array of scalar values. x is the same size as p after any necessary scalar expansion. Each element in x is the icdf value of the distribution, specified by the corresponding elements in the distribution parameters (A, B, C, and D) or specified by the probability distribution object (pd), evaluated at the corresponding element in p.

#### Alternative Functionality

icdf is a generic function that accepts either a distribution by its name 'name' or a probability distribution object pd. It is faster to use a distribution-specific function, such as norminv for the normal distribution and binoinv for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-16.

#### Extended Capabilities

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include coder.Constant('Normal') in the -args value of codegen.

• Code generation does not support the probability distribution object (pd) input argument.

“Working with Probability Distributions” on page 5-3
“Supported Distributions” on page 5-16

Introduced before R2006a
inconsistent

Inconsistency coefficient

Syntax

\[
Y = \text{inconsistent}(Z) \\
Y = \text{inconsistent}(Z,d)
\]

Description

\(Y = \text{inconsistent}(Z)\) returns the inconsistency coefficient for each link of the hierarchical cluster tree \(Z\) generated by the \text{linkage} function. \text{inconsistent} calculates the inconsistency coefficient for each link by comparing its height with the average height of other links at the same level of the hierarchy. The larger the coefficient, the greater the difference between the objects connected by the link. For more information, see “Algorithms” on page 32-3009.

\(Y = \text{inconsistent}(Z,d)\) returns the inconsistency coefficient for each link in the tree \(Z\) by searching to a depth \(d\) below each link.

Examples

Inconsistency Coefficient Calculation

Examine an inconsistency coefficient calculation for a hierarchical cluster tree.

Load the \text{examgrades} data set.

```
load examgrades
```

Create a hierarchical cluster tree.

```
Z = \text{linkage}(\text{grades});
```
Create a matrix of inconsistency coefficient information using `inconsistent`. Examine the information for the 84th link.

```matlab
Y = inconsistent(Z);
Y(84,:)
```

```plaintext
ans = 1x4
    7.2741 0.3624 3.0000 0.5774
```

The fourth column of Y contains the inconsistency coefficient, which is computed using the mean in the first column of Y and the standard deviation in the second column of Y.

Because the rows of Y correspond to the rows of Z, examine the 84th link in Z.

```matlab
Z(84,:)
```

```plaintext
ans = 1x3
   190.0000 203.0000  7.4833
```

The 84th link connects the 190th and 203rd clusters in the tree and has a height of 7.4833. The 190th cluster corresponds to the link of index \(190 - 120 = 70\), where 120 is the number of observations. The 203rd cluster corresponds to the 83rd link.

By default, `inconsistent` uses two levels of the tree to compute Y. Therefore, it uses only the 70th, 83rd, and 84th links to compute the inconsistency coefficient for the 84th link. Compare the values in `Y(84,:)` with the corresponding computations by using the link heights in Z.

```matlab
mean84 = mean([Z(70,3) Z(83,3) Z(84,3)])
std84 = std([Z(70,3) Z(83,3) Z(84,3)])
inconsistent84 = (Z(84,3) - mean84) / std84
```

```plaintext
mean84 = 7.2741
std84 = 0.3624
inconsistent84 = 0.5774
```
Compute Inconsistency Coefficient

Create the sample data.

\[ X = \text{gallery('uniformdata',}[10 \ 2],12); \]
\[ Y = \text{pdist}(X); \]

Generate the hierarchical cluster tree.

\[ Z = \text{linkage}(Y,'\text{single}'); \]

Generate a dendrogram plot of the hierarchical cluster tree.

\[ \text{dendrogram}(Z) \]
Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

\[ W = \text{inconsistent}(Z, 3) \]

\[
W = \begin{bmatrix}
0.1313 & 0 & 1.0000 & 0 \\
0.1386 & 0 & 1.0000 & 0 \\
0.1463 & 0.0109 & 2.0000 & 0.7071 \\
0.2391 & 0 & 1.0000 & 0 \\
0.1951 & 0.0568 & 4.0000 & 0.9425 \\
0.2308 & 0.0543 & 4.0000 & 0.9320 \\
0.2395 & 0.0748 & 4.0000 & 0.7636 \\
0.2654 & 0.0945 & 4.0000 & 0.9203 \\
0.3769 & 0.0950 & 3.0000 & 1.1040 \\
\end{bmatrix}
\]

### Input Arguments

**Z — Agglomerative hierarchical cluster tree**

numeric matrix

Agglomerative hierarchical cluster tree, specified as a numeric matrix returned by `linkage`. Z is an \((m - 1)\)-by-3 matrix, where \(m\) is the number of observations. Columns 1 and 2 of Z contain cluster indices linked in pairs to form a binary tree. \(Z(I, 3)\) contains the linkage distances between the two clusters merged in row \(Z(I, :)\).

Data Types: single | double

**d — Depth**

2 (default) | positive integer scalar

Depth, specified as a positive integer scalar. For each link \(k\), `inconsistent` calculates the corresponding inconsistency coefficient using all the links in the tree within \(d\) levels below \(k\).

Data Types: single | double
Output Arguments

**Y — Inconsistency coefficient information**

numeric matrix

Inconsistency coefficient information, returned as an \((m - 1)\)-by-4 matrix, where the \((m - 1)\) rows correspond to the rows of \(Z\). This table describes the columns of \(Y\).

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mean of the heights of all the links included in the calculation</td>
</tr>
<tr>
<td>2</td>
<td>Standard deviation of the heights of all the links included in the calculation</td>
</tr>
<tr>
<td>3</td>
<td>Number of links included in the calculation</td>
</tr>
<tr>
<td>4</td>
<td>Inconsistency coefficient</td>
</tr>
</tbody>
</table>

Data Types: double

**Algorithms**

For each link \(k\), the inconsistency coefficient is calculated as

\[
Y(k, 4) = (Z(k, 3) - Y(k, 1)) / Y(k, 2),
\]

where \(Y\) is the inconsistency coefficient information for links in the hierarchical cluster tree \(Z\).

For links that have no further links below them, the inconsistency coefficient is set to 0.

“Hierarchical Clustering” on page 16-4

Introduced before R2006a
increaseB

**Class:** clustering.evaluation.GapEvaluation  
**Package:** clustering.evaluation

Increase reference data sets

**Syntax**

eva_out = increaseB(eva,nref)

**Description**

eva_out = increaseB(eva,nref) returns a gap criterion clustering evaluation object eva_out that uses the same evaluation criteria as the input object eva and an additional number of reference data sets as specified by nref.

**Input Arguments**

**eva** — Clustering evaluation data
clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using evalclusters.

**nref** — Number of additional reference data sets
positive integer value

Number of additional reference data sets, specified as a positive integer value.

**Output Arguments**

**eva_out** — Updated clustering evaluation data
clustering evaluation object
Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

**Examples**

**Evaluate Clustering Solutions Using Additional Reference Data**

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```matlab
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```matlab
rng('default') % For reproducibility
ev = evalclusters(meas,'kmeans','gap','klist',1:5,'B',50)
ev =
```

```matlab
GapEvaluation with properties:

  NumObservations: 150
  InspectedK: [1 2 3 4 5]
  CriterionValues: [0.0870 0.5822 0.8766 1.0007 1.0465]
  OptimalK: 4
```
The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is four.

The value of the B property of `eva` shows 50 reference data sets.

```matlab
eva.B
ans = 50
```

Increase the number of reference data sets by 100, for a total of 150 sets.

```matlab
eva = increaseB(eva,100)
eva =
    GapEvaluation with properties:
      NumObservations: 150
      InspectedK: [1 2 3 4 5]
      CriterionValues: [0.0794 0.5850 0.8738 1.0034 1.0508]
        OptimalK: 5
```

The returned results now indicate that the optimal number of clusters is five.

The value of the B property of `eva` now shows 150 reference data sets.

```matlab
eva.B
ans = 150
```

**See Also**

`evalclusters`
interactionplot

Interaction plot for grouped data

Syntax

interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)

Description

interactionplot(Y,GROUP) displays the two-factor interaction plot for the group means of matrix Y with groups defined by entries in GROUP, which can be a cell array or a matrix. Y is a numeric matrix or vector. If Y is a matrix, the rows represent different observations and the columns represent replications of each observation. If Y is a vector, the rows give the means of each entry in GROUP. If GROUP is a cell array, then each cell of GROUP must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If GROUP is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as Y. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position \((i,j)\) is the interaction of the two variables whose names are given at row diagonal \((i,i)\) and column diagonal \((j,j)\), respectively.

interactionplot(Y,GROUP,'varnames',VARNAMES) displays the interaction plot with user-specified grouping variable names VARNAMES. VARNAMES is a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ... .

[h,AX,bigax] = interactionplot(...) returns a handle h to the figure window, a matrix AX of handles to the subplot axes, and a handle bigax to the big (invisible) axes framing the subplots.
Examples

Display Interaction Plots

Randomly generate data for a response variable \( y \).

```matlab
rng default; % For reproducibility
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```matlab
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```matlab
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

Introduced in R2006b
**intersect**

**Class:** dataset

Set intersection for dataset array observations

---

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

---

**Syntax**

- `C = intersect(A,B)`
- `C = intersect(A,B,vars)`
- `C = intersect(A,B,vars,setOrder)`
- `[C,iA,iB] = intersect(___)`

**Description**

- `C = intersect(A,B)` for dataset arrays A and B returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array C are in sorted order.

- `C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array C are sorted by those variables.

The values for variables not specified in `vars` for each observation in C are taken from the corresponding observations in A. If there are multiple observations in A that correspond to an observation in C, then those values are taken from the first occurrence.

- `C = intersect(A,B,vars,setOrder)` returns the observations in C in the order specified by `setOrder`.

- `[C,iA,iB] = intersect(___)` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in A or B, then
intersect returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A, B
Input dataset arrays.

vars
String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. vars indicates the variables in A and B that intersect considers.

Specify vars as [] to use its default value of all variables.

setOrder
Flag indicating the sorting order for the observations in C. The possible values of setOrder are:

'sorted' Observations in C are in sorted order (default).
'stable' Observations in C are in the same order that they appear in A.

Output Arguments

C
Dataset array with the common set of observations in A and B, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

iA
Index vector, indicating the observations in A that are common to B. The vector iA contains the index to the first occurrence of any repeated observations in A.
iB

Index vector, indicating the observations in B that are common to A. The vector iB contains the index to the first occurrence of any repeated observations in B.

Examples

Intersection of Two Dataset Arrays

Load sample data.

A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'));
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'),'Sheet',2);

Return the intersection and index vectors.

[C,iA,iB] = intersect(A,B);

C =

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>sex</th>
<th>age</th>
<th>wgt</th>
<th>smoke</th>

</thead>
<tbody>
<tr>
<td>'TRW-072'</td>
<td>'WHITE'</td>
<td>'m'</td>
<td>39</td>
<td>202</td>
<td>1</td>
</tr>
</tbody>
</table>

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

A(iA,:)

ans =

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>sex</th>
<th>age</th>
<th>wgt</th>

Topics

“Merge Dataset Arrays” on page 2-104
“Dataset Arrays” on page 2-137
invpred

Inverse prediction

Syntax

\[ X_0 = \text{invpred}(X,Y,Y_0) \]
\[ [X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0) \]
\[ [X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0,\text{name1},\text{val1},\text{name2},\text{val2},...) \]

Description

\[ X_0 = \text{invpred}(X,Y,Y_0) \] accepts vectors \( X \) and \( Y \) of the same length, fits a simple regression, and returns the estimated value \( X_0 \) for which the height of the line is equal to \( Y_0 \). The output, \( X_0 \), has the same size as \( Y_0 \), and \( Y_0 \) can be an array of any size.

\[ [X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0) \] also computes 95% inverse prediction intervals. \( DXLO \) and \( DXUP \) define intervals with lower bound \( X_0-DXLO \) and upper bound \( X_0+DXUP \). Both \( DXLO \) and \( DXUP \) have the same size as \( Y_0 \).

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to \(-\infty\) or \(+\infty\), and some may extend over the entire real line.

\[ [X_0,DXLO,DXUP] = \text{invpred}(X,Y,Y_0,\text{name1},\text{val1},\text{name2},\text{val2},...) \] specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'alpha'</td>
<td>A value between 0 and 1 specifying a confidence level of ( 100%(1-\alpha) ). Default is ( \alpha=0.05 ) for 95% confidence.</td>
</tr>
<tr>
<td>Name</td>
<td>Value</td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>'predopt'</td>
<td>Either 'observation', the default value to compute the intervals for $X_0$ at which a new observation could equal $Y_0$, or 'curve' to compute intervals for the $X_0$ value at which the curve is equal to $Y_0$.</td>
</tr>
</tbody>
</table>

**Examples**

**Inverse Prediction**

Generate sample data.

```matlab
x = 4*rand(25,1);
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```matlab
scatter(x,y)
```
Predict the x value for a given y value of 20.

\[ x_0 = \text{invpred}(x, y, 20) \]

\[ x_0 = 1.9967 \]

**Introduced before R2006a**
### iqr

**Package:** prob

Interquartile range

#### Syntax

- `r = iqr(x)`
- `r = iqr(x,'all')`
- `r = iqr(x,dim)`
- `r = iqr(x,vecdim)`
- `r = iqr(pd)`

#### Description

- `r = iqr(x)` returns the interquartile range of the values in `x`.
  - If `x` is a vector, then `r` is the difference between the 75th and the 25th percentiles of the data contained in `x`.
  - If `x` is a matrix, then `r` is a row vector containing the difference between the 75th and the 25th percentiles of the sample data in each column of `x`.
  - If `x` is a multidimensional array, then `iqr` operates along the first nonsingleton dimension of `x`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

- `r = iqr(x,'all')` returns the interquartile range of all the values in `x`.

- `r = iqr(x,dim)` returns the interquartile range along the dimension of `x` specified by `dim`.

- `r = iqr(x,vecdim)` returns the interquartile range over the dimensions specified by `vecdim`. For example, if `x` is a matrix, then `iqr(x,[1 2])` is the interquartile range of all the elements of `x` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.
\[ r = \text{iqr}(pd) \] returns the interquartile range of the probability distribution \( pd \).

**Examples**

**Compute the Interquartile Range**

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values \( \mu \) equal to 10 and \( \sigma \) equal to 1.

```matlab
rng default  % For reproducibility
x = normrnd(10,1,4)
```

\[
\begin{align*}
4 \times 4 \\
11.8339 & 8.6923 & 12.7694 & 9.9369 \\
7.7412 & 9.5664 & 8.6501 & 10.7147 \\
\end{align*}
\]

Compute the interquartile range for each column of data.

```matlab
r = iqr(x)
```

\[
1 \times 4 \\
2.2086 & 1.2013 & 2.5969 & 0.8541
\]

Compute the interquartile range for each row of data.

```matlab
r2 = iqr(x,2)
```

\[
4 \times 1 \\
1.7237 \\
2.9870 \\
1.9449 \\
1.8797
\]
**Compute Interquartile Range of Multidimensional Array**

Compute the interquartile range of a multidimensional array over multiple dimensions by specifying the 'all' and `vecdim` input arguments.

Create a 3-by-4-by-2 array `X`.

```matlab
X = reshape(1:24,[3 4 2])
```

```plaintext
X(:,:,1) =
1     4     7    10
2     5     8    11
3     6     9    12

X(:,:,2) =
13    16    19    22
14    17    20    23
15    18    21    24
```

Compute the interquartile range of all the values in `X`.

```matlab
rall = iqr(X,'all')
```

```plaintext
rall = 12
```

Compute the interquartile range of each page of `X`. Specify the first and second dimensions as the operating dimensions along which the interquartile range is calculated.

```matlab
rpage = iqr(X,[1 2])
```

```plaintext
rpage =
rpage(:,:,1) =
6

rpage(:,:,2) =
6
```
For example, \( \text{rpage}(1,1,1) \) is the interquartile range of all the elements in \( X(:,:,1) \).

Compute the interquartile range of the elements in each \( X(i,:, :) \) slice by specifying the second and third dimensions as the operating dimensions.

\[
rrow = \text{iqr}(X,[2 3])
\]

\[
rrow = 3\times1
\]

\[
12
12
12
\]

For example, \( rrow(3) \) is the interquartile range of all the elements in \( X(3,:, :) \).

### Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, \( \mu \), equal to 0 and the standard deviation, \( \sigma \), equal to 1.

\[
pd = \text{makedist}('Normal','mu',0,'sigma',1);
\]

Compute the interquartile range of the standard normal distribution.

\[
r = \text{iqr}(pd)
\]

\[
r = 1.3490
\]

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities \( y \) equal to 0.75 and 0.25.

\[
r2 = \text{icdf}(pd,0.75) - \text{icdf}(pd,0.25)
\]

\[
r2 = 1.3490
\]

### Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students’ exam grade data.
load examgrades;
x = grades(:,1);

Create a normal distribution object by fitting it to the data.

pd = fitdist(x,'Normal')

pd =
    NormalDistribution

    Normal distribution
    mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]

Compute the interquartile range of the fitted distribution.

r = iqr(pd)

r = 11.7634

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use icdf to determine the 75th and 25th percentiles of the students' grades.

y = icdf(pd,[0.25,0.75])

y = 1×2
    69.1266   80.8900

Calculate the difference between the 75th and 25th percentiles. This yields the same result as iqr.

y(2)-y(1)

ans = 11.7634

Use boxplot to visualize the interquartile range.

boxplot(x)
The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

**Input Arguments**

**x — Input array**  
vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: single | double
**dim — Dimension**  
positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix `x`, when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of `x`. When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of `x`. For `n`-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `x`.

Data Types: `single` | `double`

**vecdim — Vector of dimensions**  
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `x`. The output `r` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `x` and `r`.

For example, if `x` is a 2-by-3-by-3 array, then `iqr(x,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the interquartile range of the elements on the corresponding page of `x`.

![Diagram of 3D array](image)

Data Types: `single` | `double`

**pd — Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.
<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td>Distribution Fitter</td>
<td>Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
</tbody>
</table>

**Output Arguments**

\[ r \rightarrow \text{Interquartile range values} \]

scalar | vector | matrix | multidimensional array

Interquartile range values, returned as a scalar, vector, matrix, or multidimensional array.

- If you input an array \( x \), then the dimensions of \( r \) depend on whether the 'all', dim, or vecdim input arguments are specified. Each interquartile range value in \( r \) is the difference between the 75th and the 25th percentiles of the specified data contained in \( x \).
- If you input a probability distribution \( pd \), then the scalar value of \( r \) is the difference between the values of the 75th and 25th percentiles of the probability distribution.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
  - \( r = \text{iqr}(x,'all') \)
  - \( r = \text{iqr}(x,\text{vecdim}) \)

32-3031
• \( r = \text{iqr}(pd) \)

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • \( r = \text{iqr}(x, 'all') \)
  • \( r = \text{iqr}(x, \text{vecdim}) \)
  • \( r = \text{iqr}(pd) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced before R2006a**
isbranch

Class: classregtree

(Removed) Test node for branch

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

ib = isbranch(t)
ib = isbranch(t,nodes)

Description

ib = isbranch(t) returns an n-element logical vector ib that is true for each branch node and false for each leaf node.

ib = isbranch(t,nodes) takes a vector nodes of node numbers and returns a vector of logical values for the specified nodes.

References

See Also

classregtree | cutvar | numnodes
isempty

Class: dataset

True for empty dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

tf = isempty(A)

Description

tf = isempty(A) returns true (1) if A is an empty dataset and false (0) otherwise. An empty array has no elements, that is prod(size(A))==0.

See Also

size
islevel

Determine if levels are in nominal or ordinal array

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

```matlab
tf = islevel(levels,A)
```

**Description**

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

**Input Arguments**

- **A** — Nominal or ordinal array
  
  Nominal array | Ordinal array
  
  Nominal or ordinal array, specified as a nominal or ordinal array object created with `nominal` or `ordinal`.

- **levels** — Levels to test
  
  Character vector | String array | Cell array of character vectors | 2-D character matrix
  
  Levels to test, specified as a character vector, string array, cell array of character vectors, or 2-D character matrix.

  Data Types: `char` | `string` | `cell`
Output Arguments

**tf — Level indicator**

logical array

Level indicator, returned as a logical array of the same size as `levels`. `tf` has the value 1 (true) when the corresponding element of `levels` is the label of a level in the nominal or ordinal array `A`, even if the level contains no elements. Otherwise, `tf` has the value 0 (false).

**See Also**

`isequal` | `ismember` | `nominal` | `ordinal`

**Introduced in R2007a**
ismember

Class: dataset

Dataset array elements that are members of set

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember( ___ )

Description

LiA = ismember(A,B) for dataset arrays A and B returns a vector of logical values the same length as A. The output vector, LiA, has value 1 (true) in the elements that correspond to observations in A that are also present in B, and 0 (false) otherwise.

LiA = ismember(A,B,vars) returns a vector of logical values the same length as A. The output vector, LiA, has value 1 (true) in the elements that correspond to observations in A that are also present in B for the variables specified in vars only, and 0 (false) otherwise.

[LiA,LocB] = ismember( ___ ) also returns a vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, or 0 if there is no such observation. You can use any of the previous input arguments.
Input Arguments

A
Query dataset array, containing the observations to be found in B.

B
Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in vars, the corresponding element of LiA is 1.

vars
String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. vars indicates which variables to match observations on in A and B.

Output Arguments

LiA
Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in A is present in B. Otherwise, LiA has value 0 (false).

If you specify vars, LiA has value 1 when the corresponding observation in A is present in B for the variables in vars only.

LocB
Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in vars.

Examples

Find Observations That Are Members of a Dataset Array
Load sample data.
```matlab
load('hospital')
B = hospital(1:50,1:5);

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)

A =
    LastName       Sex    Age  Weight  Smoker
    YLN-495      'COLEMAN'  Male   39    188     false
    LQW-768      'TAYLOR'    Female  31    132     false
    DGC-290      'BUTLER'    Male   38    184      true
    DAU-529      'REED'      Male   50    186      true
    REV-997     'ALEXANDER'  Male   25    171      true
    QEQ-082       'COX'    Female   28    111     false
    AGR-528     'SIMMONS'    Male   45    181     false
    PUE-347      'YOUNG'    Female   25    114     false
    HVR-372     'RUSSELL'    Male   44    188      true
    XUE-826     'JACKSON'    Male   25    174     false

Check which observations in A are present in B.

LiA = ismember(A,B)

LiA = 10x1 logical array

ismissing

Class: dataset

Find dataset array elements with missing values

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

I = ismissing(ds)
I = ismissing(ds,Name,Value)

**Description**

I = ismissing(ds) returns a logical array that indicates which elements in the dataset array, ds, contain a missing value. By default, ismissing recognizes NaN as a missing value in numeric variables, '' as a missing value in character variables, and <undefined> as a missing value in categorical arrays.

- ds2 = ds(~any(I,2),:) creates a new dataset array containing only the complete observations in ds.
- ds2 = ds(:,~any(I,1)) creates a new dataset array containing only the variables from ds with no missing values.

I = ismissing(ds,Name,Value) returns missing value indices with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

ds
dataset array
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**NumericTreatAsMissing**

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a `NaN` value as a missing value.

**Default:**

**StringTreatAsMissing**

Character vector, string array, or cell array of character vectors to treat as missing value indicators in character `ds` variables. `ismissing` always treats `' ' as a missing value.

**Output Arguments**

**I**

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value 1 for elements that contain a missing value.

**See Also**

dataset | isempty | isnan | isundefined | replaceWithMissing

**Topics**

“Clean Messy and Missing Data” on page 2-118

“Dataset Arrays” on page 2-137
isvalid

Class: qrandstream

Test handle validity

Syntax

tf = isvalid(h)

Description

tf = isvalid(h) performs an element-wise check for validity on the handle elements of h. The result is a logical array of the same dimensions as h, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also
delete|qrandstream
**iwishrnd**

Inverse Wishart random numbers

**Syntax**

\[
W = \text{iwishrnd}(\text{Tau}, df)
W = \text{iwishrnd}(\text{Tau}, df, \text{DI})
\begin{bmatrix} W, \text{DI} \end{bmatrix} = \text{iwishrnd}(\text{Tau}, df)
\]

**Description**

\(W = \text{iwishrnd}(\text{Tau}, df)\) generates a random matrix \(W\) from the inverse Wishart distribution with parameters \(\text{Tau}\) and \(df\). The inverse of \(W\) has the Wishart distribution with covariance matrix \(\Sigma = \text{inv}(\text{Tau})\) and with \(df\) degrees of freedom. \(\text{Tau}\) is a symmetric and positive definite matrix.

\(W = \text{iwishrnd}(\text{Tau}, df, \text{DI})\) expects \(\text{DI}\) to be the transpose of the inverse of the Cholesky factor of \(\text{Tau}\), so that \(\text{DI}'\times\text{DI} = \text{inv}(\text{Tau})\), where \(\text{inv}\) is the MATLAB inverse function. \(\text{DI}\) is lower-triangular and the same size as \(\text{Tau}\). If you call \(\text{iwishrnd}\) multiple times using the same value of \(\text{Tau}\), it is more efficient to supply \(\text{DI}\) instead of computing it each time.

\(\begin{bmatrix} W, \text{DI} \end{bmatrix} = \text{iwishrnd}(\text{Tau}, df)\) returns \(\text{DI}\) so you can use it as an input in future calls to \(\text{iwishrnd}\).

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter \(\tau\) so that the mean of the output matrix is \(\text{Tau}/(df-d-1)\) where \(d\) is the dimension of \(\text{Tau}\).

**See Also**

\text{wishrnd}

**Topics**

“Inverse Wishart Distribution” on page B-79
Introduced before R2006a
jackknife

Jackknife sampling

Syntax

jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)

Description

jackstat = jackknife(jackfun,X) draws jackknife data samples from the n-by-p data array X, computes statistics on each sample using the function jackfun, and returns the results in the matrix jackstat. jackknife regards each row of X as one data sample, so there are n data samples. Each of the n rows of jackstat contains the results of applying jackfun to one jackknife sample. jackfun is a function handle specified with @. Row i of jackstat contains the results for the sample consisting of X with the ith row omitted:

s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);

If jackfun returns a matrix or array, then this output is converted to a row vector for storage in jackstat. If X is a row vector, it is converted to a column vector.

jackstat = jackknife(jackfun,X,Y,...) accepts additional arguments to be supplied as inputs to jackfun. They may be scalars, column vectors, or matrices. jackknife creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to jackfun unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

jackstat = jackknife(jackfun,...,'Options',option) provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set 'Options' as a structure you create with statset. jackknife uses the following field in the structure:
'UseParallel'  If true, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is false, meaning serial computation.

**Examples**

Estimate the bias of the MLE variance estimator of random samples taken from the vector y using jackknife. The bias has a known formula in this problem, so you can compare the jackknife value to this formula.

```matlab
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var,y,1);
n = length(y);
bias = -sigma^2/n % known bias formula
jbias = (n-1)*(mean(m)-var(y,1)) % jackknife bias estimate
```

```matlab
bias =
    -0.2500

jbias =
    -0.3378
```

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)
For more information, see the 'Options' name-value pair argument.

See Also
bootstrap | histogram | ksdensity | random | randsample

Topics
“Jackknife Resampling” on page 3-18

Introduced in R2006a
**jbtest**

Jarque-Bera test

**Syntax**

\[
h = \text{jbtest}(x) \\
h = \text{jbtest}(x,\alpha) \\
h = \text{jbtest}(x,\alpha,\text{mctol}) \\
[h,p] = \text{jbtest}(___) \\
[h,p,jbstat,critval] = \text{jbtest}(___)
\]

**Description**

\( h = \text{jbtest}(x) \) returns a test decision for the null hypothesis that the data in vector \( x \) comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test on page 32-3053. The alternative hypothesis is that it does not come from such a distribution. The result \( h \) is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

\( h = \text{jbtest}(x,\alpha) \) returns a test decision for the null hypothesis at the significance level specified by \( \alpha \).

\( h = \text{jbtest}(x,\alpha,\text{mctol}) \) returns a test decision based on a \( p \)-value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error on page 32-3053 less than or equal to \( \text{mctol} \).

\([h,p] = \text{jbtest}(___)\) also returns the \( p \)-value \( p \) of the hypothesis test, using any of the input arguments from the previous syntaxes.

\([h,p,jbstat,critval] = \text{jbtest}(___)\) also returns the test statistic \( jbstat \) and the critical value \( \text{critval} \) for the test.

**Examples**
**Test for a Normal Distribution**

Load the data set.

```matlab
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```matlab
h = jbttest(MPG)
```

```matlab
h = 1
```

The returned value of \( h = 1 \) indicates that \texttt{jbttest} rejects the null hypothesis at the default 5% significance level.

**Test the Hypothesis at a Different Significance Level**

Load the data set.

```matlab
load carbig
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```matlab
[h,p] = jbttest(MPG,0.01)
```

```matlab
h = 1
```

```matlab
p = 0.0022
```

The returned value of \( h = 1 \), and the returned \( p \)-value less than \( \alpha = 0.01 \) indicate that \texttt{jbttest} rejects the null hypothesis.

**Test for a Normal Distribution Using Monte Carlo Simulation**

Load the data set.

```matlab
load carbig
```
Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact $P$-value.

$$[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)$$

$h = 1$

$p = 0.0022$

$ jbstat = 18.2275$

$critval = 5.8461$

The returned value of $h = 1$ indicates that $jbtest$ rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, $jbstat$, is larger than the critical value, $critval$, which indicates rejection of the null hypothesis.

**Input Arguments**

**$x$ — Sample data**  
vector

Sample data for the hypothesis test, specified as a vector. $jbtest$ treats NaN values in $x$ as missing values and ignores them.

Data Types: single | double

**$alpha$ — Significance level**  
0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If $alpha$ is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, $jbtest$ looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use $mctol$.

Example: 0.01

Data Types: single | double

**$mctol$ — Maximum Monte Carlo standard error**  
nonnegative scalar value
Maximum Monte Carlo standard error on page 32-3053 for the \( p \)-value, \( p \), specified as a nonnegative scalar value. If you specify a value for \( \text{mctol} \), \( \text{jbtest} \) computes a Monte Carlo approximation for \( p \) directly, rather than interpolating into a table of precomputed values. \( \text{jbtest} \) chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for \( p \) less than \( \text{mctol} \).

If you specify a value for \( \text{mctol} \), you must also specify a value for \( \text{alpha} \). You can specify \( \text{alpha} \) as [ ] to use the default value of 0.05.

Example: \( 0.0001 \)

Data Types: \( \text{single} \) | \( \text{double} \)

**Output Arguments**

\( \text{h} \) — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If \( h = 1 \), this indicates the rejection of the null hypothesis at the \( \text{alpha} \) significance level.
- If \( h = 0 \), this indicates a failure to reject the null hypothesis at the \( \text{alpha} \) significance level.

\( p \) — \( p \)-value

scalar value in the range (0,1)

\( p \)-value of the test, returned as a scalar value in the range (0,1). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \( p \) cast doubt on the validity of the null hypothesis.

\( \text{jbtest} \) warns when \( p \) is not found within the tabulated range of \([0.001,0.50]\), and returns either the smallest or largest tabulated value. In this case, you can use \( \text{mctol} \) to compute a more accurate \( p \)-value.

\( \text{jbstat} \) — Test statistic

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.
critval — Critical value
nonnegative scalar value

Critical value for the Jarque-Bera test at the alpha significance level, returned as a nonnegative scalar value. If alpha is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, jbtest looks up the critical value for the test in a table of precomputed values. If you use mctol, jbtest determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when jbstat > critval.

Definitions

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

\[ JB = \frac{n}{6} \left( s^2 + \frac{(k-3)^2}{4} \right), \]

where \( n \) is the sample size, \( s \) is the sample skewness, and \( k \) is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p-value.

The Monte Carlo standard error is calculated as

\[ SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{mcreps}}, \]
where \( \hat{p} \) is the estimated \( p \)-value of the hypothesis test, and \( mcreps \) is the number of Monte Carlo replications performed. \( jbtest \) chooses the number of Monte Carlo replications, \( mcreps \), large enough to make the Monte Carlo standard error for \( \hat{p} \) less than the value specified for \( mctol \).

**Algorithms**

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see \texttt{lillietest}) for small samples. \( jbtest \), by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

**References**

\texttt{adtest} | \texttt{ktest} | \texttt{lillietest}

**Introduced before R2006a**
johnsrnd

Johnson system random numbers

Syntax

\[ r = \text{johnsrnd}(\text{quantiles}, m, n) \]
\[ r = \text{johnsrnd}(\text{quantiles}) \]
\[ [r, \text{type}] = \text{johnsrnd}(...) \]
\[ [r, \text{type}, \text{coefs}] = \text{johnsrnd}(...) \]

Description

\[ r = \text{johnsrnd}(\text{quantiles}, m, n) \] returns an \( m \)-by-\( n \) matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by \( \text{quantiles} \). \( \text{quantiles} \) is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles \([-1.5 -0.5 0.5 1.5]\). In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities \([0.067 0.309 0.691 0.933]\). \( \text{quantiles} \) may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

**Note** Because \( r \) is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

\[ r = \text{johnsrnd}(\text{quantiles}) \] returns a scalar value.

\[ r = \text{johnsrnd}(\text{quantiles}, m, n, ...) \text{ or } r = \text{johnsrnd}(\text{quantiles}, [m, n, ...]) \] returns an \( m \)-by-\( n \)-by-... array.

\[ [r, \text{type}] = \text{johnsrnd}(...) \] returns the type of the specified distribution within the Johnson system. \( \text{type} \) is 'SN', 'SL', 'SB', or 'SU'. Set \( m \) and \( n \) to zero to identify the distribution type without generating any random values.
The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution on page B-130)
- 'SL' — Exponential transformation (lognormal distribution on page B-95)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

\[ [r, \text{type}, \text{coefs}] = \text{johnsrnd}(...) \] returns coefficients coefs of the transformation that defines the distribution. coefs is \([\gamma, \eta, \epsilon, \lambda]\). If \(z\) is a standard normal random variable and \(h\) is one of the transformations defined above, \(r = \lambda h((z-\gamma)/\eta) + \epsilon\) is a random variate from the distribution type corresponding to \(h\).

### Examples

#### Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```matlab
rng default;  % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```
Generate random values skewed to the right.

```matlab
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```
Generate random values that match some sample data well in the right-hand tail.

load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]

ans = 2x4

16.7000  18.2086  19.5376  21.7263
16.6986  18.2220  19.9078  22.0918

Determine the distribution type and the coefficients.
[r, type, coefs] = johnsrnd([qnorm; q], 0)
r = 

    []
type = 'SU'
coefs = 1×4
    1.0920   0.5829  18.4382   1.4494

Topics
“Generating Data Using Flexible Families of Distributions” on page 7-26

Introduced in R2006a
join

Class: dataset

Merge observations

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)

Description

C = join(A,B) creates a dataset array C by merging observations from the two dataset arrays A and B. join performs the merge by first finding key variables, that is, pairs of dataset variables, one in A and one in B, that share the same name. Each observation in B must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from A. join then uses these key variables to define a many-to-one correspondence between observations in A and those in B. join uses this correspondence to replicate the observations in B and combine them with the observations in A to create C.

C = join(A,B,keys) performs the merge using the variables specified by keys as the key variables in both A and B. keys is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

C contains one observation for each observation in A. Variables in C include all of the variables from A, as well as one variable corresponding to each variable in B (except for
the keys from B). If A and B contain variables with identical names, join adds the suffix '_left' and '_right' to the corresponding variables in C.

C = join(A,B,param1,val1,param2,val2,...) specifies optional parameter name/value pairs to control how the dataset variables in A and B are used in the merge. Parameters are:

- 'Keys' — Specifies the variables to use as keys in both A and B.
- 'LeftKeys' — Specifies the variables to use as keys in A.
- 'RightKeys' — Specifies the variables to use as keys in B.

You may provide either the 'Keys' parameter, or both the 'LeftKeys' and 'RightKeys' parameters. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. 'LeftKeys' or 'RightKeys' must both specify the same number of key variables, and join pairs the left and right keys in the order specified.

- 'LeftVars' — Specifies which variables from A to include in C. By default, join includes all variables from A.
- 'RightVars' — Specifies which variables from B to include in C. By default, join includes all variables from B except the key variables.

You can use 'LeftVars' or 'RightVars' to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

[C,IB] = join(...) returns an index vector IB, where join constructs C by horizontally concatenating A(:,LeftVars) and B(IB,RightVars). join can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

C = join(A,B,'Type',TYPE,...) performs the join operation specified by TYPE. TYPE is one of 'inner', 'leftouter', 'rightouter', 'fullouter', or 'outer' (which is a synonym for 'fullouter'). For an inner join, C only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, C also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains variables corresponding to the key variables from both A and B, and join sorts the observations in C by the key values.
For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. join sorts the observations in the result C by the key values.

\[
C = \text{join}(A, B, \text{'Type'}, \text{'TYPE'}, \text{'MergeKeys'}, \text{true}, \ldots) \]

includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, join creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to true overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to false is equivalent to not passing in the 'MergeKeys' parameter.

\[
[C, IA, IB] = \text{join}(A, B, \text{'Type'}, \text{'TYPE'}, \ldots) \]

returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, join constructs C by horizontally concatenating A(IA,LeftVars) and B(IB,RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

**Examples**

Create a dataset array from Fisher's iris data:

```matlab
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs),'%-d'));
iris = dataset({nominal(species),'species'},... 
    {meas,'SL','SW','PL','PW'},... 
    'ObsNames',NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```matlab
snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},{[38;108;70],'cc'})
CC =
    species      cc
    setosa       38
    versicolor   108
    virginica    70
```
Broadcast the data in CC to the rows of iris using the key variable species in each dataset:

```matlab
iris2 = join(iris, CC);
iris2([1 2 51 52 101 102], :)
ans =
    species     SL     SW     PL     PW     cc
  Obs1      setosa    5.1    3.5    1.4    0.2     38
  Obs2      setosa    4.9     3    1.4    0.2     38
  Obs51     versicolor    7    3.2    4.7    1.4    108
  Obs52     versicolor    6.4    3.2    4.5    1.5    108
  Obs101    virginica    6.3    3.3    6.0    2.5     70
  Obs102    virginica    5.8    2.7    5.1    1.9     70
```

Create two datasets and join them using the 'MergeKeys' flag:

```matlab
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17],...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7],...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
    'MergeKeys',true)
```

```matlab
a =

    Key1      Var1
      'a'       1
```
| 'b' | 2  |
| 'c' | 3  |
| 'e' | 11 |
| 'h' | 17 |

\[ b = \]

**KDDtreeSearcher**

Create Kd-tree nearest neighbor searcher

**Description**

KDDtreeSearcher model objects store the results of a nearest neighbor search that uses the Kd-tree algorithm. Results include the training data, distance metric and its parameters, and maximum number of data points in each leaf node (that is, the bucket size). The Kd-tree algorithm partitions an n-by-K data set by recursively splitting n points in K-dimensional space into a binary tree.

Once you create a KDDtreeSearcher model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbor search using knnsearch or a radius search using rangesearch. The Kd-tree algorithm is more efficient than the exhaustive search algorithm when K is small (that is, K ≤ 10), the training and query sets are not sparse, and the training and query sets have many observations.

**Creation**

Use either the createns function or the KDDtreeSearcher function (described here) to create a KDDtreeSearcher model object. Both functions use the same syntax except that the createns function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The createns function also creates an ExhaustiveSearcher object. Specify 'NSMethod','kdtree' to create a KDDtreeSearcher object. The default is 'kdtree' if K ≤ 10, the training data is not sparse, and the distance metric is Euclidean, city block, Chebychev, or Minkowski.

**Syntax**

Mdl = KDDtreeSearcher(X)
Mdl = KDDtreeSearcher(X,Name,Value)
**Description**

Mdl = KDTreeSearcher(X) grows a default Kd-tree (Mdl) using the n-by-K numeric matrix of training data (X).

Mdl = KDTreeSearcher(X,Name,Value) specifies additional options using one or more name-value pair arguments. You can specify the maximum number of data points in each leaf node (that is, the bucket size) and the distance metric, and set the distance metric parameter (DistParameter) property. For example, KDTreeSearcher(X,'Distance','minkowski','BucketSize',10) specifies to use the Minkowski distance when searching for nearest neighbors and to use 10 for the bucket size. To specify DistParameter, use the P name-value pair argument.

**Input Arguments**

**X — Training data**

numeric matrix

Training data that grows the Kd-tree, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: single | double

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','minkowski','P',3,'BucketSize',10 specifies to use the following when searching for nearest neighbors: the Minkowski distance, 3 for the Minkowski distance metric exponent, and 10 for the bucket size.

**Distance — Distance metric**

'euclidean' (default) | 'chebychev' | 'cityblock' | 'minkowski'

Distance metric used when you call knnsearch orrangesearch to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and one of these values.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
</tbody>
</table>

For more details, see “Distance Metrics” on page 18-16.

The software does not use the distance metric for creating a KDTreeSearcher model object, so you can alter the distance metric by using dot notation after creating the object.

Example: 'Distance','minkowski'

**P — Exponent for Minkowski distance metric**

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

**BucketSize — Maximum number of data points in each leaf node**

50 (default) | positive integer

Maximum number of data points in each leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer.

Example: 'BucketSize',10

Data Types: single | double

**Properties**

**X — Training data**

numeric matrix
This property is read-only.

Training data that grows the Kd-tree, specified as a numeric matrix. \( X \) has \( n \) rows, each corresponding to an observation (that is, an instance or example), and \( K \) columns, each corresponding to a predictor (that is, a feature).

The input argument \( X \) of \texttt{createns} or \texttt{KDTreeSearcher} sets this property.

Data Types: \texttt{single} | \texttt{double}

**Distance — Distance metric**

\texttt{'chebychev'} | \texttt{'cityblock'} | \texttt{'minkowski'}

Distance metric used when you call \texttt{knnsearch} or \texttt{rangesearch} to find nearest neighbors for future query points, specified as \texttt{'chebychev'}, \texttt{'cityblock'}, \texttt{'euclidean'}, or \texttt{'minkowski'}.

The \texttt{'Distance'} name-value pair argument of \texttt{createns} or \texttt{KDTreeSearcher} sets this property.

The software does not use the distance metric for creating a \texttt{KDTreeSearcher} model object, so you can alter it by using dot notation.

**DistParameter — Distance metric parameter values**

\([]\) | positive scalar

Distance metric parameter values, specified as empty (\texttt{[]}) or a positive scalar.

If \texttt{Distance} is \texttt{'minkowski'}, then \texttt{DistParameter} is the exponent in the Minkowski distance formula. Otherwise, \texttt{DistParameter} is \texttt{[]}, indicating that the specified distance metric formula has no parameters.

The \texttt{'P'} name-value pair argument of \texttt{createns} or \texttt{KDTreeSearcher} sets this property.

You can alter \texttt{DistParameter} by using dot notation, for example, \texttt{Mdl.DistParameter = PNew}, where \texttt{PNew} is a positive scalar.

Data Types: \texttt{single} | \texttt{double}

**BucketSize — Maximum number of data points in each leaf node**

positive integer

This property is read-only.
Maximum number of data points in each leaf node of the Kd-tree, specified as a positive integer.

The 'BucketSize' name-value pair argument of createns or KDTreeSearcher sets this property.

Data Types: single | double

Object Functions

- knnsearch: Find k-nearest neighbors using object
- rangesearch: Find all neighbors within specified distance using object

Examples

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
k = 4
```

X has 150 observations and 4 predictors.

Grow a four-dimensional Kd-tree using the entire data set as training data.

```matlab
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 =  
KDTreeSearcher with properties:  

    BucketSize: 50 
    Distance: 'euclidean' 
    DistParameter: [] 
```
Mdl1 is a KDTreeSearcher model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional Kd-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a Kd-tree by using createns.

Mdl2 = createns(X)

Mdl2 =
KDTreeSearcher with properties:

    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]

Mdl2 is also a KDTreeSearcher model object, and it is equivalent to Mdl1. Because X has four columns and the default distance metric is Euclidean, createns creates a KDTreeSearcher model by default.

To find the nearest neighbors in X to a batch of query data, pass the KDTreeSearcher model object and the query data to knnsearch or rangesearch.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

load fisheriris
X = meas(:,[3 4]); % Predictors

Grow a two-dimensional Kd-tree using createns and the training data. Specify the Minkowski distance metric.

Mdl = createns(X,'Distance','Minkowski')

Mdl =
KDTreeSearcher with properties:
Because \( X \) has two columns and the distance metric is Minkowski, \texttt{createns} creates a \texttt{KDTreeSearcher} model object by default.

Access properties of \texttt{Mdl} by using dot notation. For example, use \texttt{Mdl.DistParameter} to access the Minkowski distance exponent.

\texttt{Mdl.DistParameter}

\texttt{ans = 2}

You can pass query data and \texttt{Mdl} to:

- \texttt{knnsearch} to find indices and distances of nearest neighbors
- \texttt{rangesearch} to find indices of all nearest neighbors within a distance that you specify

**Alter Properties of \texttt{KDTreeSearcher} Model**

Create a \texttt{KDTreeSearcher} model object and alter the \texttt{Distance} property by using dot notation.

Load Fisher's iris data set.

\texttt{load fisheriris}

\texttt{X = meas;}

Grow a default four-dimensional \( Kd \)-tree using the entire data set as training data.

\texttt{Mdl = KDTreeSearcher(X)}

\texttt{Mdl =}

\texttt{KDTreeSearcher with properties:}

\begin{verbatim}
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
\end{verbatim}
Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```matlab
Mdl.Distance = 'minkowski'
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Minkowski distance.

### Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a Kd-tree nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find $k$-nearest neighbors.

Load Fisher's iris data set.

```matlab
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```matlab
rng(1);                     % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```matlab
Mdl = createns(X,'Distance','minkowski')
```
Md\(l = \)
\[\text{KDTreeSearcher with properties:}\]
  
  \[
  \begin{align*}
  \text{BucketSize} & : 50 \\
  \text{Distance} & : 'minkowski' \\
  \text{DistParameter} & : 2 \\
  \text{X: [145x4 double]}
  \end{align*}
\]

Because \(X\) has four columns and the distance metric is Minkowski, \texttt{createns} creates a \texttt{KDTreeSearcher} model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (\(Mdl.X\)) that are the two nearest neighbors of each point in the query data (\(Q\)).

\[\text{IdxNN = knnsearch(Mdl,Q,'K',2)}\]

\[\text{IdxNN = 5x2}\]

\[
\begin{array}{rr}
  17 & 4 \\
  6 & 2 \\
  1 & 12 \\
  89 & 66 \\
  124 & 100 \\
\end{array}
\]

Each row of \(\text{IdxNN}\) corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of \(Q(3,:)\) is \(X(12,:)\).

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The \texttt{knnsearch} and \texttt{rangesearch} functions support code generation.
For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Introduced in R2010a
kfoldEdge

**Package:** classreg.learning.partition

Classification edge for cross-validated ECOC model

**Syntax**

```
edge = kfoldEdge(CVMdl)
dedge = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-3083 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```
Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

\[
t = \text{templateSVM}('\text{Standardize}',1);
\]

\[
\text{CVMdl} = \text{fitcecoc}(X,Y,'\text{CrossVal}','on','\text{Learners}',t,'\text{ClassNames}',\text{classOrder});
\]

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the average of the edges.

\[
edge = \text{kfoldEdge}(\text{CVMdl})
\]

\[
edge = 0.4825
\]

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

### Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. To determine which folds perform poorly, display the edges for each fold.

Load Fisher's iris data set. Specify the predictor data \(X\), the response data \(Y\), and the order of the classes in \(Y\).

\[
\text{load fisheriris}
\]

\[
X = \text{meas};
\]

\[
Y = \text{categorical}(	ext{species});
\]

\[
\text{classOrder} = \text{unique}(Y);
\]

\[
\text{rng}(1); \quad \% \text{For reproducibility}
\]

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

\[
t = \text{templateSVM}('\text{Standardize}',1);
\]

\[
\text{CVMdl} = \text{fitcecoc}(X,Y,'\text{KFold}',8,'\text{Learners}',t,'\text{ClassNames}',\text{classOrder});
\]

Estimate the classification edge for each fold.
edges = kfoldEdge(CVMdl,'Mode','individual')
edges = 8×1
 0.4791
 0.4872
 0.4260
 0.5302
 0.5064
 0.4575
 0.4860
 0.4687

The edges have similar magnitudes across folds. Folds that perform poorly have small edges relative to the other folds.

To return the average classification edge across the folds that perform well, specify the 'Folds' name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Define the following two data sets.
- fullX contains all the predictors.
- partX contains the petal dimensions.

fullX = X;
partX = X(:,3:4);
For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

\[
t = \text{templateSVM('Standardize',1)};
\]

\[
\text{CVMdl} = \text{fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...}
\]

\[
\quad '\text{ClassNames}',\text{classOrder});
\]

\[
\text{PCVMdl} = \text{fitcecoc(partX,Y,'CrossVal','on','Learners',t,...}
\]

\[
\quad '\text{ClassNames}',\text{classOrder});
\]

CVMdl and PCVMdl are \text{ClassificationPartitionedECOC} models. By default, the software implements 10-fold cross-validation.

Estimate the edge for each classifier.

\[
\text{fullEdge} = \text{kfoldEdge(CVMdl)}
\]

\[
\text{fullEdge} = 0.4825
\]

\[
\text{partEdge} = \text{kfoldEdge(PCVMdl)}
\]

\[
\text{partEdge} = 0.4951
\]

The two models have comparable edges.

**Input Arguments**

\text{CVMdl} — Cross-validated ECOC model

\text{ClassificationPartitionedECOC} model

Cross-validated ECOC model, specified as a \text{ClassificationPartitionedECOC} model. You can create a \text{ClassificationPartitionedECOC} model in two ways:

- Pass a trained ECOC model (\text{ClassificationECOC}) to \text{crossval}.
- Train an ECOC model using \text{fitcecoc} and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \text{Name,Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldEdge(CVMdl,'BinaryLoss','hinge') specifies 'hinge' as the binary learner loss function.

**BinaryLoss — Binary learner loss function**

'hamming'|'linear'|'logit'|'exponential'|'binodeviance'|'hinge'|'quadratic'|function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j,s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((\infty,\infty))</td>
<td>( \frac{\log[1 + \exp(-2y_j s_j)]}{2\log(2)} )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((\infty,\infty))</td>
<td>( \exp(-y_j s_j)/2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((\infty,\infty))</td>
<td>( \frac{1 - \text{sign}(y_j s_j)}{2} )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((\infty,\infty))</td>
<td>( \frac{\max(0,1 - y_j s_j)}{2} )</td>
</tr>
<tr>

<td>Linear</td>
<td>((\infty,\infty))</td>
<td>( 1 - y_j s_j/2 )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((\infty,\infty))</td>
<td>( \frac{\log[1 + \exp(-y_j s_j)]}{2\log(2)} )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( \frac{1 - y_j (2s_j - 1)^2}{2} )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:
• $\text{M}$ is the $K$-by-$L$ coding matrix stored in $\text{Mdl.CodingMatrix}$.
• $s$ is the 1-by-$L$ row vector of classification scores.
• $\text{bLoss}$ is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
• $K$ is the number of classes.
• $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

• SVMs or either linear or kernel classification models of SVM learners, then $\text{BinaryLoss}$ is 'hinge'
• Ensembles trained by $\text{AdaboostM1}$ or $\text{GentleBoost}$, then $\text{BinaryLoss}$ is 'exponential'
• Ensembles trained by $\text{LogitBoost}$, then $\text{BinaryLoss}$ is 'binodeviance'
• Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior',1 in $\text{fitcecoc}$), then $\text{BinaryLoss}$ is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the $\text{BinaryLoss}$ property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding', 'lossbased'

Folds — Fold indices for prediction

1:CVMdl.KFold (default) | numeric vector of positive integers
Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.
Example: 'Folds',[1 4 10]
Data Types: single | double

**Mode — Aggregation level for output**

'value' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length $k$ containing one value per fold, where $k$ is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options',statset('UseParallel',1).

**Verbose — Verbosity level**

0 (default) | 1
Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: `single` | `double`

### Output Arguments

**edge** — Classification edge

numeric scalar | numeric column vector

Classification edge on page 32-3083, returned as a numeric scalar or numeric column vector.

If `Mode` is 'average', then `edge` is the average classification edge over all folds. Otherwise, `edge` is a `k`-by-1 numeric column vector containing the classification edge for each fold, where `k` is the number of folds.

### Definitions

#### Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

#### Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.
**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

## References

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2014b
**kfoldEdge**

Classification edge for observations not used for training

**Syntax**

E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)

**Description**

E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification ensemble obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Input Arguments**

ens

Object of class ClassificationPartitionedEnsemble. Create ens with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvsample'. Alternatively, create ens from a classification ensemble with crossval.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
folds
Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

mode
Character vector or string scalar representing the meaning of the output `edge`:

- 'average' — `edge` is a scalar value, the average over all folds.
- 'individual' — `edge` is a vector of length `ens.KFold` with one element per fold.
- 'cumulative' — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element J is obtained by averaging values across all folds for weak learners 1:J in each fold.

Default: 'average'

Output Arguments

E
The average classification margin. E is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Compute K-Fold Edge of Held-Out Observations

Compute the k-fold edge for an ensemble trained on the Fisher iris data.

Load the sample data set.

```matlab
load fisheriris
```

Train an ensemble of 100 boosted classification trees.

```matlab
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Learners',t);
```
Create a cross-validated ensemble from `ens` and find the classification edge.

```matlab
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
E = kfoldEdge(cvens)
E = 3.2066
```

**Definitions**

**Edge**

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

**Score (ensemble)**

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to $\infty$.
- `Bag` scores range from 0 to 1.

kfoldEdge

Package: classreg.learning.partition

Classification edge for cross-validated kernel classification model

Syntax

edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)

Description

dedge = kfoldEdge(CVMdl) returns the classification edge on page 32-3094 obtained by the cross-validated, binary kernel model (ClassificationPartitionedKernel) CVMdl. For every fold, kfoldEdge computes the classification edge for validation-fold observations using a model trained on training-fold observations.

dedge = kfoldEdge(CVMdl,Name,Value) returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds or the aggregation level.

Examples

Estimate k-Fold Cross-Validation Edge

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

load ionosphere

Cross-validate a binary kernel classification model using the data.

CVMdl = fitckernel(X,Y,'Crossval','on')
CVMdl = classificationkernel
   ClassificationPartitionedKernel
   CrossValidatedModel: 'Kernel'
   ResponseName: 'Y'
   NumObservations: 351
   KFold: 10
   Partition: [1x1 cvpartition]
   ClassNames: {'b' 'g'}
   ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification edge.

d = kfoldEdge(CVMdl)

d = 1.5585

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

Feature Selection Using k-Fold Edges

Perform feature selection by comparing k-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

load ionosphere

Randomly choose half of the predictor variables.

rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

\[
\text{CVMdl} = \text{fitckernel}(X,Y,\text{'}CrossVal\text{','on'}); \\
\text{PCVMdl} = \text{fitckernel}(X(:,\text{idxPart}),Y,\text{'}CrossVal\text{','on'});
\]

CVMdl and PCVMdl are ClassificationPartitionedKernel models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the \( k \)-fold edge for each classifier.

\[
\text{fullEdge} = \text{kfoldEdge(CVMdl)} \\
\text{fullEdge} = 1.5142 \\
\text{partEdge} = \text{kfoldEdge(PCVMdl)} \\
\text{partEdge} = 1.8910
\]

Based on the \( k \)-fold edges, the classifier that uses half of the predictors is the better model.

### Input Arguments

- **CVMdl** — Cross-validated, binary kernel classification model
  
  ClassificationPartitionedKernel model object

  Cross-validated, binary kernel classification model, specified as a ClassificationPartitionedKernel model object. You can create a ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

  To obtain estimates, kfoldEdge applies the same data used to cross-validate the kernel classification model (X and Y).

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `kfoldEdge(CVMdl,'Mode','individual')` returns the classification edge for each fold.

**Folds — Fold indices for prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

**Mode — Aggregation level for output**

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length k containing one value per fold, where k is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

**Output Arguments**

**edge — Classification edge**

numeric scalar | numeric column vector

32-3093
Classification edge on page 32-3094, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a \( k \)-by-1 numeric column vector containing the classification edge for each fold, where \( k \) is the number of folds.

**Definitions**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[
m = 2yf(x).
\]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

For kernel classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by
\[ f(x) = T(x)\beta + b. \]

- \( T(\cdot) \) is a transformation of an observation for feature expansion.
- \( \beta \) is the estimated column vector of coefficients.
- \( b \) is the estimated scalar bias.

The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**Introduced in R2018b**
kfoldEdge

**Package:** classreg.learning.partition

Classification edge for cross-validated kernel ECOC model

**Syntax**

\[
\text{edge} = \text{kfoldEdge}(\text{CVMdl})
\]

\[
\text{edge} = \text{kfoldEdge}(\text{CVMdl}, \text{Name}, \text{Value})
\]

**Description**

\[
\text{edge} = \text{kfoldEdge}(\text{CVMdl})\]

returns the classification edge on page 32-3102 obtained by the cross-validated kernel ECOC model (ClassificationPartitionedKernelECOC) \(\text{CVMdl}\). For every fold, \(\text{kfoldEdge}\) computes the classification edge for validation-fold observations using a model trained on training-fold observations.

\[
\text{edge} = \text{kfoldEdge}(\text{CVMdl}, \text{Name}, \text{Value})\]

returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Edge**

Load Fisher's iris data set. \(X\) contains flower measurements, and \(Y\) contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification edges.

edge = kfoldEdge(CVMdl)

edge = 0.4145

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Feature Selection Using k-Fold Edges**

Perform feature selection by comparing k-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

load fisheriris
X = meas;
Y = species;

Randomly choose half of the predictor variables.
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');

CVMdl and PCVMdl are ClassificationPartitionedKernelECOC models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold edge for each classifier.

fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.4092

partEdge = kfoldEdge(PCVMdl)
partEdge = 0.4161

Based on the k-fold edges, the two classifiers are comparable.

### Input Arguments

**CVMdl — Cross-validated kernel ECOC model**

ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners'— Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

32-3098
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example: kfoldEdge(CVMdl, 'BinaryLoss', 'hinge') specifies 'hinge' as the binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>( g(y_j, s_j) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((\infty, \infty))</td>
<td>( \log[1 + \exp(-2y_j s_j)] / [2\log(2)] )</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((\infty, \infty))</td>
<td>( \exp(-y_j s_j) / 2 )</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((\infty, \infty))</td>
<td>( [1 - \text{sign}(y_j s_j)] / 2 )</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((\infty, \infty))</td>
<td>( \max(0, 1 - y_j s_j) / 2 )</td>
</tr>
<tr>

<td>Linear</td>
<td>((\infty, \infty))</td>
<td>( (1 - y_j s_j) / 2 )</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((\infty, \infty))</td>
<td>( \log[1 + \exp(-y_j s_j)] / [2\log(2)] )</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>( [1 - y_j (2s_j - 1)]^2 / 2 )</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss', @customFunction.

customFunction has this form:
\( bLoss = \text{customFunction}(M,s) \)

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \( \text{Mdl.CodingMatrix} \).
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then \( \text{BinaryLoss} \) is 'hinge'. If all binary learners are kernel classification models using logistic regression, then \( \text{BinaryLoss} \) is 'quadratic'.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

- 'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3102.

Example: 'Decoding','lossbased'

**Folds — Fold indices for prediction**

- 1:CVMdl.KFold (default) | numeric vector of positive integers
