Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

**Mode — Aggregation level for output**

- 'average' (default) | 'individual'

32-3100
Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length $k$ containing one value per fold, where $k$ is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

**Options — Estimation options**

Options (default) | [structure array returned by statset]

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options',statset('UseParallel',1).

**Verbose — Verbosity level**

(0 (default) | 1)

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. 
Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

32-3101
Output Arguments

edge — Classification edge
numeric scalar | numeric column vector

Classification edge on page 32-3102, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k-by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j, s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty, \infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty, \infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b
kfoldEdge

Classification edge for observations not used for training

Syntax

e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)

Description

e = kfoldEdge(CVMdl) returns the cross-validated classification edges on page 32-3112 obtained by the cross-validated, binary, linear classification model CVMdl. That is, for every fold, kfoldEdge estimates the classification edge for observations that it holds out when it trains using all other observations.

e contains a classification edge for each regularization strength in the linear classification models that comprise CVMdl.

e = kfoldEdge(CVMdl,Name,Value) uses additional options specified by one or more Name,Value pair arguments. For example, indicate which folds to use for the edge calculation.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model
ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using fitclinear and specifying any one of the cross-validation, name-value pair arguments, for example, CrossVal.

To obtain estimates, kfoldEdge applies the same data used to cross-validate the linear classification model (X and Y).
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Folds — Fold indices to use for classification-score prediction
1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]
Data Types: single | double

Mode — Edge aggregation level
'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns classification edges averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns classification edges for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

Output Arguments

e — Cross-validated classification edges
numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-3112, returned as a numeric scalar, vector, or matrix.
Let \( L \) be the number of regularization strengths in the cross-validated models (that is, \( L \) is \text{numel}(CVMdl.Trained{1}.Lambda)) and \( F \) be the number of folds (stored in CVMdl.KFold).

- If Mode is 'average', then \( e \) is a 1-by-\( L \) vector. \( e(j) \) is the average classification edge over all folds of the cross-validated model that uses regularization strength \( j \).
- Otherwise, \( e \) is an \( F \)-by-\( L \) matrix. \( e(i,j) \) is the classification edge for fold \( i \) of the cross-validated model that uses regularization strength \( j \).

To estimate \( e \), \text{kfoldEdge} uses the data that created CVMdl (see \( X \) and \( Y \)).

### Examples

**Estimate k-Fold Cross-Validation Edge**

Load the NLP data set.

```matlab
load nlpdata
```

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```matlab
rng(1); % For reproducibility
cvmdl = fitclinear(X,Ystats,'CrossVal','on');
```

\( CVMdl \) is a \text{ClassificationPartitionedLinear} \ model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.
e = kfoldEdge(CVMdl)
e = 8.1243

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Feature Selection Using k-fold Edges**

One way to perform feature selection is to compare k-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 32-3107.

load nlpdata
Ystats = Y == 'stats';
X = X';

Create these two data sets:
- **fullX** contains all predictors.
- **partX** contains 1/2 of the predictors chosen at random.

rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

CVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
'ObservationsIn','columns');
PCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
'ObservationsIn','columns');

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Estimate the k-fold edge for each classifier.
fullEdge = kfoldEdge(CVMdl)
fullEdge = 16.5629

partEdge = kfoldEdge(PCVMdl)
partEdge = 13.9030

Based on the \( k \)-fold edges, the classifier that uses all of the predictors is the better model.

**Find Good Lasso Penalty Using \( k \)-fold Edge**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare \( k \)-fold edges.

Load the NLP data set. Preprocess the data as in “Estimate \( k \)-Fold Cross-Validation Edge” on page 32-3107.

load nlpdata
Ystats = Y == 'stats';
X = X';

Create a set of 11 logarithmically-spaced regularization strengths from \( 10^{-8} \) through \( 10^1 \).

Lambda = logspace(-8,1,11);

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to \( 1 \times 10^{-8} \).

rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1x1 cvpartition]
ClassNames: [0 1]
ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedLinear model. Because fitclinear implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

eFolds = kfoldEdge(CVMdl,'Mode','individual')
eFolds = 5×11

<td>0.8127</td>
</tr>
</tbody>
</table>

eFolds is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in Lambda. You can use eFolds to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

e = kfoldEdge(CVMdl)
e = 1×11

| 0.9978 | 0.9978 | 0.9978 | 0.9978 | 0.9978 | 0.9936 | 0.9777 | 0.9140 | 0.8128 |

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```matlab
figure;
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
```
Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

LambdaFinal = Lambda(5);
Train a linear classification model using the entire data set and specify the regularization strength $\text{LambdaFinal}$.

$$\text{MdlFinal} = \text{fitclinear}(X,Y_{\text{stats}},'\text{ObservationsIn}','\text{columns}',...$$

'\text{Learner}','\text{logistic}','\text{Solver}','\text{sparsa}','\text{Regularization}','\text{lasso}',...$

'\text{Lambda}',\text{LambdaFinal});$

To estimate labels for new observations, pass $\text{MdlFinal}$ and the new data to $\text{predict}$.

**Definitions**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

$x$ is an observation. If the true label of $x$ is the positive class, then $y$ is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation $x$. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.
**Classification Score**

For linear classification models, the raw classification score for classifying the observation \(x\), a row vector, into the positive class is defined by

\[
f_j(x) = x\beta_j + b_j.
\]

For the model with regularization strength \(j\), \(\beta_j\) is the estimated column vector of coefficients (the model property \(\text{Beta}(\cdot,j)\)) and \(b_j\) is the estimated, scalar bias (the model property \(\text{Bias}(j)\)).

The raw classification score for classifying \(x\) into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

ClassificationLinear | ClassificationPartitionedLinear | edge | kfoldMargin | kfoldPredict

**Introduced in R2016a**
**kfoldEdge**

Classification edge for observations not used for training

**Syntax**

```matlab
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

**Description**

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

**Input Arguments**

- **CVMdl** — Cross-validated, ECOC model composed of linear classification models
  
  ClassificationPartitionedLinearECOC model object

  Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model object using `fitcecoc` and by:

  1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2 Setting the name-value pair argument `Learners` to 'linear' or a linear
classification model template returned by `templateLinear`

To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the ECOC
model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the
argument name and `Value` is the corresponding value. `Name` must appear inside quotes.
You can specify several name and value pair arguments in any order as
`Name1,Value1,...,NameN,ValueN`.

**BinaryLoss — Binary learner loss function**

- 'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of
'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where `y_j` is a class
  label for a particular binary learner (in the set {1,1,0}), `s_j` is the score for observation
  `j`, and `g(y_j,s_j)` is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th><code>g(y_j,s_j)</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/\log(2)$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1] \text{ or } (-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y Js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>max(0,1 - $y-js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y Js_j)]/\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also,
the software calculates the mean binary loss for each class.
• For a custom binary loss function, e.g., `customFunction`, specify its function handle 
  `'BinaryLoss','@customFunction'`.

`customFunction` should have this form

```matlab
bLoss = customFunction(M,s)
```

where:

• `M` is the `K`-by-`L` coding matrix stored in `Mdl.CodingMatrix`.
• `s` is the 1-by-`L` row vector of classification scores.
• `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
• `K` is the number of classes.
• `L` is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are linear classification models using:

• SVM, then `BinaryLoss` is 'hinge'
• Logistic regression, then `BinaryLoss` is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

**Folds — Fold indices to use for classification-score prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers
Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

Mode — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns classification edges averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns classification edges for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

Options — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options',statset('UseParallel',1).

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbosity controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.
Example: 'Verbose',1
Data Types: single | double

Output Arguments

**e — Cross-validated classification edges**
numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-3124, returned as a numeric scalar, vector, or matrix.

Let \( L \) be the number of regularization strengths in the cross-validated models (that is, \( L \) is \( \text{numel}(\text{CVMdl.Trained{1}.BinaryLearners{1}.Lambda}) \)) and \( F \) be the number of folds (stored in \( \text{CVMdl.KFold} \)).

- If \( \text{Mode} \) is 'average', then \( e \) is a 1-by-\( L \) vector. \( e(j) \) is the average classification edge over all folds of the cross-validated model that uses regularization strength \( j \).
- Otherwise, \( e \) is a \( F \)-by-\( L \) matrix. \( e(i,j) \) is the classification edge for fold \( i \) of the cross-validated model that uses regularization strength \( j \).

Examples

**Estimate k-Fold Cross-Validation Edge**

Load the NLP data set.

```matlab
load nlpdata
```

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in \( Y \) that are not 'simulink', 'dsp', or 'comm'.

```matlab
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```
CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

\[ e = \text{kfoldEdge(CVMdl)} \]

\[ e = 0.7232 \]

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in kfoldEdge.

**Feature Selection Using k-fold Edges**

One way to perform feature selection is to compare k-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 32-3118, and orient the predictor data so that observations correspond to columns.

\[ \text{load nlpdata} \]
\[ Y(~(\text{ismember}(Y,\{\text{simulink}',\text{dsp}',\text{comm}'\}))) = '\text{others}'; \]
\[ X = X'; \]

Create these two data sets:

- fullX contains all predictors.
- partX contains a 1/2 of the predictors chosen at random.

\[ \text{rng(1); % For reproducibility} \]
\[ p = \text{size}(X,1); % Number of predictors} \]
\[ \text{halfPredIdx = randsample}(p,\text{ceil}(0.5*p)); \]
\[ \text{fullX} = X; \]
\[ \text{partX} = X(\text{halfPredIdx},:); \]

Create a linear classification model template that specifies to optimize the objective function using SpaRSA.

\[ t = \text{templateLinear('Solver','sparsa');} \]
Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```matlab
CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

CVMdl and PCVMdl are `ClassificationPartitionedLinearECOC` models.

Estimate the $k$-fold edge for each classifier.

```matlab
fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.3090
partEdge = kfoldEdge(PCVMdl)
partEdge = 0.2617
```

Based on the $k$-fold edges, the classifier that uses all of the predictors is the better model.

**Find Good Lasso Penalty Using $k$-fold Edge**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare $k$-fold edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using $k$-fold Edges” on page 32-3119.

```matlab
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 8 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^1$.

```matlab
Lambda = logspace(-8,1,8);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, optimize the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to $1e-8$. 

```matlab
Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

 rng(10); % For reproducibility
 CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)

 CVMdl is a ClassificationPartitionedLinearECOC model.

 Estimate the edges for each fold and regularization strength.

eFolds = kfoldEdge(CVMdl,'Mode','individual')

 eFolds is a 5-by-8 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in Lambda. You can use eFolds to identify ill-performing folds, that is, unusually low edges.

 Estimate the average edge over all folds for each regularization strength.

e = kfoldEdge(CVMdl)

 Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

 figure;
 plot(log10(Lambda),log10(e),'-o')
 [~, maxEIdx] = max(e);
 maxLambda = Lambda(maxEIdx);
Several values of \texttt{Lambda} yield similarly high edges. Greater regularization strength values lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

\texttt{LambdaFinal = Lambda(4);}
Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength $\text{LambdaFinal}$.

```matlab
    t = templateLinear('Learner','logistic','Solver','sparsa',...
                      'Regularization','lasso','Lambda',LambdaFinal,'GradientTolerance',1e-8);
    MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

---

**Definitions**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,
Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>

<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j (2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.
Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2016a
kfoldEdge

Classification edge for observations not used for training

Syntax

E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)

Description

E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification model obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

obj

Object of class ClassificationPartitionedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
folds
Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.

Default: 1:obj.KFold

mode
Character vector or string scalar representing the meaning of the output edge:

- 'average' — edge is a scalar value, the average over all folds.
- 'individual' — edge is a vector of length obj.KFold with one element per fold.

Default: 'average'

Output Arguments

E
The average classification margin. E is a scalar or vector, depending on the setting of the mode name-value pair.

Examples

Estimate the k-fold Edge of a Classifier

Compute the k-fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

load fisheriris

Train a classification tree classifier.

tree = fitctree(meas,species);

Cross validate the classifier using 10-fold cross validation.

cvtree = crossval(tree);
Compute the $k$-fold edge.

```matlab
e = kfoldEdge(cvtree)
e = 0.8578
```

### Definitions

#### Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

#### Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix $X$. A high value of margin indicates a more reliable prediction than a low value.

#### Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-7.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')

Prune the tree:

treel = prune(tree,'Level',1);
view(treel,'Mode','Graph')
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85 = .06 for true, and about .8/.85 = .94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
 [~, score] = predict(tree1, X(1:10));
 [score X(1:10,:)]
```
Indeed, every value of \( X \) (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of \( X \) have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in \( X \) in the range \((.95,1)\) instead of the expected 5 observations.

kfoldfun

Package: classreg.learning.partition

Cross-validate function using cross-validated ECOC model

Syntax

vals = kfoldfun(CVMdl,fun)

Description

vals = kfoldfun(CVMdl,fun) cross-validates the function fun by applying fun to the data stored in the cross-validated ECOC model CVMdl. You must pass fun as a function handle.

Examples

Estimate Classification Error Using Custom Loss Function

Train a multiclass ECOC classifier, and then cross-validate the model using a custom k-fold loss function.

Load Fisher’s iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);

CVMdl is a ClassificationPartitionedECOC model. By default, the software
implements 10-fold cross-validation.

Compute the classification error (proportion of misclassified observations) for the
validation-fold observations.

L = kfoldLoss(CVMdl)

L = 0.0400

Examine the result when the cost of misclassifying a flower as versicolor is 10 and the
cost of any other error is 1. Write a function named noversicolor that assigns a cost of
1 for general misclassification and a cost of 10 for misclassifying a flower as
versicolor.

If you use the live script file for this example, the noversicolor function is already
included at the end of the file. Otherwise, you need to create this function at the end of
your .m file or add it as a file on the MATLAB path.

Compute the mean misclassification error with the noversicolor cost.

foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)

ans = 0.0667

This code creates the function noversicolor.

```matlab
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
% noversicolor: Example custom cross-validation function that assigns a cost of
% 10 for misclassifying versicolor irises and a cost of 1 for misclassifying
% the other irises. This example function requires the fisheriris data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = single(cost/numel(Ytest)); % Average error
end
```
Input Arguments

**CVMdl — Cross-validated ECOC model**

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model.

**fun — Cross-validated function**

function handle

Cross-validated function, specified as a function handle. `fun` has this syntax:

```
vals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- **CMP** is a compact model stored in one element of the `CVMdl.Trained` property.
- **Xtrain** is the training matrix of predictor values.
- **Ytrain** is the training array of response values.
- **Wtrain** is the set of training weights for observations.
- **Xtest** and **Ytest** are the validation data, with associated weights **Wtest**.
- The returned value **testvals** must have the same size across all folds.

Data Types: `function_handle`

Output Arguments

**vals — Cross-validation results**

numeric matrix

Cross-validation results, returned as a numeric matrix. `vals` corresponds to the arrays of the `testvals` output, concatenated vertically over all the folds. For example, if `testvals` from every fold is a numeric vector of length `n`, `kfoldfun` returns a KFold-by-`n` numeric matrix with one row per fold.

Introduced in R2014b
kfoldfun

Cross validate function

Syntax

vals = kfoldfun(CVMdl,fun)

Description

vals = kfoldfun(CVMdl,fun) cross validates the function fun by applying fun to the data stored in the cross-validated model CVMdl. You must pass fun as a function handle.

Input Arguments

CVMdl — Cross-validated model
ClassificationPartitionedECOC model | ClassificationPartitionedEnsemble model | ClassificationPartitionedModel model

Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

fun — Cross-validated function
function handle

Cross-validated function, specified as a function handle. fun has the syntax
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

- CMP is a compact model stored in one element of the CVMdl.Trained property.
- Xtrain is the training matrix of predictor values.
- Ytrain is the training array of response values.
- Wtrain are the training weights for observations.
• Xtest and Ytest are the test data, with associated weights Wtest.
• The returned value testvals needs the same size across all folds.

Data Types: function_handle

Output Arguments

crossval  
vals — Cross-validation results
numeric matrix

Cross-validation results, returned as an numeric matrix. vals is the arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

Data Types: double

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom k-fold loss function.

Load Fisher’s iris data set.

load fisheriris

Train a classification tree classifier.

Mdl = fitctree(meas,species);

Mdl is a ClassificationTree model.

Cross validate Mdl using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

rng(1); % For reproducibility
CVMdl = crossval(Mdl);
L = kfoldLoss(CVMdl)
Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as versicolor, and save it on your MATLAB path.

```matlab
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
    %noversicolor Example custom cross-validation function
    % Attributes a cost of 10 for misclassifying versicolor irises, and 1 for the other irises. This example function requires the |fisheriris| data set.
    Ypredict = predict(CMP,Xtest);
    misclassified = not(strcmp(Ypredict,Ytest)); % Different result
    classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
    cost = sum(misclassified) + ...
           9*sum(misclassified & classifiedAsVersicolor); % Total differences
    averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```matlab
mean(kfoldfun(CVMdl,@noversicolor))
```

```matlab
ans =
```

```matlab
0.2267
```

**See Also**

- `ClassificationPartitionedECOC` | `ClassificationPartitionedModel` |
- `crossval` | `crossval` | `kfoldEdge` | `kfoldLoss` | `kfoldMargin` | `kfoldPredict`
kfoldfun

Cross validate function

Syntax

vals = kfoldfun(obj,fun)

Description

vals = kfoldfun(obj,fun) cross validates the function fun by applying fun to the
data stored in the cross-validated model obj. You must pass fun as a function handle.

Input Arguments

obj

Object of class RegressionPartitionedModel or
RegressionPartitionedEnsemble. Create obj with fitrtree or fitrensemble
along with one of the cross-validation options: 'CrossVal', 'KFold', 'Holdout',
'Leaveout', or 'CVPartition'. Alternatively, create obj from a regression tree or
regression ensemble with crossval.

fun

A function handle for a cross-validation function. fun has the syntax
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

- CMP is a compact model stored in one element of the obj.Trained property.
- Xtrain is the training matrix of predictor values.
- Ytrain is the training array of response values.
- Wtrain is the training array of response values.
- Wtrain are the training weights for observations.
- Xtest and Ytest are the test data, with associated weights Wtest.
• The returned value testvals must have the same size across all folds.

Output Arguments

vals

The arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see kfoldLoss):

load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictornames',{'length' 'width'},...
    'responsename','price');
cv = crossval(t);
L = kfoldLoss(cv)

L =
    1.5489e+007

Examine the result of simple averaging of responses instead of using predictions:

f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
    mean(kfoldfun(cv,f))

ans =
    6.3497e+007

RegressionPartitionedEnsemble | RegressionPartitionedModel | crossval | fitrtree | kfoldLoss | kfoldPredict
**kfoldLoss**

**Package:** classreg.learning.partition

Classification loss for cross-validated ECOC model

**Syntax**

```latex
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

**Description**

```latex
loss = kfoldLoss(CVMdl) returns the classification loss obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) CVMdl. For every fold, kfoldLoss computes the classification loss for validation-fold observations using a model trained on training-fold observations. CVMdl.X contains both sets of observations.

loss = kfoldLoss(CVMdl,Name,Value) returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.
```

**Examples**

**Determine k-Fold Cross-Validation Loss**

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```latex
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```
Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```matlab
T = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the average classification error.

```matlab
L = kfoldLoss(CVMdl)
```

```matlab
L = 0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in `kfoldLoss`.

**Display Individual Losses for Each Cross-Validation Fold**

The classification loss is a measure of classifier quality. To determine which folds perform poorly, display the losses for each fold.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across all folds and the losses for each fold.
loss = kfoldLoss(CVMdl)
loss = 0.0333
losses = kfoldLoss(CVMdl,'Mode','individual')
losses = 8×1
    0.0556
    0.0526
    0.1579
    0
    0
    0
    0
    0
The third fold misclassifies a much higher percentage of observations than any other fold.

Return the average classification loss for the folds that perform well by specifying the 'Folds' name-value pair argument.
newloss = kfoldLoss(CVMdl,'Folds',[1:2 4:8])
newloss = 0.0153
The total classification loss decreases by approximately half its original size.
Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to kfoldLoss.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y)  % Class order

classOrder = 3x1 categorical array
  setosa
  versicolor
  virginica

rng(1) % For reproducibility

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the
predictors using an SVM template, and specify the class order.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

CVMdl is a ClassificationPartitionedECOC model. By default, the software
implements 10-fold cross-validation. You can specify a different number of folds using the
'KFold' name-value pair argument.

Create a custom function that takes the minimal loss for each observation, then averages
the minimal losses for all observations. S corresponds to the NegLoss output of
kfoldPredict.

lossfun = @(~,S,~,~)mean(min(-S,[],2));

Compute the cross-validated custom loss.

kfoldLoss(CVMdl,'LossFun',lossfun)
ans = 0.0101

The average minimal binary loss for the validation-fold observations is 0.0101.

Input Arguments

CVMdl — Cross-validated ECOC model
ClassificationPartitionedECOC model
Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

**BinaryLoss — Binary learner loss function**

This table contains names and descriptions of the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\text{max}(0,1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/[2\log(2)]$</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
<td>Score Domain</td>
<td>( g(y_j, s_j) )</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------</td>
<td>--------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>[0,1]</td>
<td>([1 - y_j(2s_j - 1)]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

\[
\text{bLoss} = \text{customFunction}(\text{M}, \text{s})
\]

where:

- \( \text{M} \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( \text{s} \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

- SVMs or either linear or kernel classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default value for `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.
Example: 'BinaryLoss','binodeviance'
Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

**Folds — Fold indices for prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]
Data Types: single | double

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3150.
- Or, specify your own function using function handle notation.

Assume that n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature lossvalue = lossfun(C,S,W,Cost), where:

- The output argument lossvalue is a scalar.
- You specify the function name (lossfun).
• C is an \( n \times K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set every element of row \( p \) to 0.

• \( S \) is an \( n \times K \) numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMdl.ClassNames. The input \( S \) resembles the output argument NegLoss of kfoldPredict.

• \( W \) is an \( n \times 1 \) numeric vector of observation weights. If you pass \( W \), the software normalizes its elements to sum to 1.

• \( \text{Cost} \) is a \( K \times K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

Data Types: char | string | function_handle

**Mode — Aggregation level for output**

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length ( k ) containing one value per fold, where ( k ) is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

**Options — Estimation options**

[] (default) | structure array returned by statset
Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:
- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', 1).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**loss — Classification loss**

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k-by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

**Definitions**

**Classification Error**

The classification error is a binary classification error measure that has the form...
where:

- \( w_j \) is the weight for observation \( j \). The software renormalizes the weights to sum to 1.
- \( e_j = 1 \) if the predicted class of observation \( j \) differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,
\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j, s_j)\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j, s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>(\frac{\log[1 + \exp(-2y_js_j)]}{2\log(2)})</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty, \infty))</td>
<td>(\exp(-y_js_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty, \infty))</td>
<td>(\frac{1 - \text{sign}(y_js_j)}{2})</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty, \infty))</td>
<td>(\max(0, 1 - y_js_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty, \infty))</td>
<td>(\frac{1 - y_js_j}{2})</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty, \infty))</td>
<td>(\frac{\log[1 + \exp(-y_js_j)]}{2\log(2)})</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>(\frac{1 - y_j(2s_j - 1)^2}{2})</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**References**

**Extended Capabilities**

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

**kfoldLoss**

Classification loss for observations not used for training

**Syntax**

\[
L = \text{kfoldLoss}(\text{ens})
\]

\[
L = \text{kfoldLoss}(\text{ens},\text{Name},\text{Value})
\]

**Description**

\[L = \text{kfoldLoss}(\text{ens})\] returns loss obtained by cross-validated classification model \(\text{ens}\). For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

\[L = \text{kfoldLoss}(\text{ens},\text{Name},\text{Value})\] calculates loss with additional options specified by one or more \text{Name,Value} pair arguments. You can specify several name-value pair arguments in any order as \text{Name1,Value1,...,NameN,ValueN}.

**Input Arguments**

\text{ens}

Object of class \text{ClassificationPartitionedEnsemble}. Create \text{ens} with \text{fitcensemble} along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create \text{ens} from a classification ensemble with \text{crossval}.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \text{Name,Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \text{Name1,Value1,...,NameN,ValueN}.
folds

Indices of folds ranging from 1 to ens.KFold. Use only these folds for predictions.

Default: 1:ens.KFold

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'Mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

  ```matlab
  ens.ScoreTransform = 'doublelogit';
  ```

- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.
Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(\text{ens}.\text{ClassNames}) \), \( \text{ens} \) is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \( \text{ens}.\text{ClassNames} \).

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( \text{ens}.\text{ClassNames} \). \( S \) is a matrix of classification scores, similar to the output of \( \text{predict} \).
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.
- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@\( \text{lossfun} \).

For more details on loss functions, see “Classification Loss” on page 32-3159.

**Default:** 'classiferror'

**mode**

A character vector or string scalar for determining the output of \( \text{kfoldLoss} \):

- 'average' — \( L \) is a scalar, the loss averaged over all folds.
- 'individual' — \( L \) is a vector of length \( \text{ens}.\text{KFold} \), where each entry is the loss for a fold.
- 'cumulative' — \( L \) is a vector in which element \( J \) is obtained by using learners \( 1:J \) from the input list of learners.
Default: 'average'

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

load ionosphere

Train a classification ensemble of 100 decision trees using AdaBoostM1. Specify tree stumps as the weak learners.

t = templateTree('MaxNumSplits',1);
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);

Cross-validate the ensemble using 10-fold cross-validation.

cvens = crossval(ens);

Estimate the cross-validated classification error.

L = kfoldLoss(cvens)

L = 0.0655
Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).
  - \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):
  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_2^* = [0 \ 0 \ 1 \ 0]' \). The order of the classes corresponds to the order in the ClassNames property of the input model.
  - \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,
Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>

crossval | kfoldEdge | kfoldMargin | kfoldPredict | kfoldfun
**kfoldLoss**

**Package:** classreg.learning.partition

Classification loss for cross-validated kernel classification model

**Syntax**

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

**Description**

`loss = kfoldLoss(CVMdl)` returns the classification loss on page 32-3169 obtained by the cross-validated, binary kernel model (ClassificationPartitionedKernel) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations.

By default, `kfoldLoss` returns the classification error.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, or aggregation level.

**Examples**

**Estimate k-Fold Cross-Validation Classification Error**

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```matlab
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```matlab
CVMdl = fitckernel(X,Y,'Crossval','on')
```
CVMdl =
classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

    loss = kfoldLoss(CVMdl)

    loss = 0.0940

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Specify Custom Classification Loss

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

    load ionosphere

Cross-validate a binary kernel classification model using the data.

    CVMdl = fitckernel(X,Y,'Crossval','on')

    CVMdl =
        classreg.learning.partition.ClassificationPartitionedKernel
        CrossValidatedModel: 'Kernel'
CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Create an anonymous function that measures linear loss, that is,

$$ L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}. $$

$w_j$ is the weight for observation $j$, $y_j$ is the response $j$ (-1 for the negative class and 1 otherwise), and $f_j$ is the raw classification score of observation $j$.

```matlab
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

Estimate the cross-validated classification loss using the linear loss function.

```matlab
loss = kfoldLoss(CVMdl,'LossFun',linearloss)
```

loss = -0.7792

### Input Arguments

- **CVMdl** — Cross-validated, binary kernel classification model
  ClassificationPartitionedKernel model object
Cross-validated, binary kernel classification model, specified as a ClassificationPartitionedKernel model object. You can create a ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldLoss applies the same data used to cross-validate the kernel classification model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldLoss(CVMdl,'Folds',[1 3 5]) specifies to use only the first, third, and fifth folds to calculate the classification loss.

**Folds — Fold indices for prediction**
1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

**LossFun — Loss function**
'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binominal deviance</td>
</tr>
</tbody>
</table>

32-3166
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see kfoldPredict).

- Specify your own function by using function handle notation.

Assume that n is the number of observations in X, and K is the number of distinct classes (numel(CVMdl.ClassNames), where CVMdl is the input model). Your function must have this signature:

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

- The output argument lossvalue is a scalar.
- You specify the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct C by setting \( C(p,q) = 1 \), if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in CVMdl.ClassNames. S is a matrix of classification scores, similar to the output of kfoldPredict.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes the weights to sum to 1.
- Cost is a K-by-K numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.
Example: 'LossFun', @lossfun

Data Types: char | string | function_handle

**Mode — Aggregation level for output**

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>

</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length ( k ) containing one value per fold, where ( k ) is the number of folds.</td>
</tr>
</tbody>
</table>

Example: 'Mode', 'individual'

**Output Arguments**

**loss — Classification loss**

numeric scalar | numeric column vector

Classification loss on page 32-3169, returned as a numeric scalar or numeric column vector.

If `Mode` is 'average', then `loss` is the average classification loss over all folds. Otherwise, `loss` is a \( k \)-by-1 numeric column vector containing the classification loss for each fold, where \( k \) is the number of folds.
Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- \( f(X_j) \) is the raw classification score for the transformed observation (row) \( j \) of the predictor data \( X \) using feature expansion.
- \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute to the average loss.
- The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

This table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

This figure compares the loss functions (except minimal cost) for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 

kfoldLoss
See Also
ClassificationPartitionedKernel | fitckernel

Introduced in R2018b
kfoldLoss

**Package:** classreg.learning.partition

Classification loss for cross-validated kernel ECOC model

**Syntax**

```matlab
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

**Description**

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `kfoldLoss` applies the same data used to create `CVMdl` (see `fitcecoc`).

By default, `kfoldLoss` returns the classification error on page 32-3180.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Classification Error**

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```
Cross-validate an ECOC model composed of kernel binary learners.

\[
\text{CVMdl} = \text{fitcecoc}(X, Y, '\text{Learners}', '\text{kernel}', '\text{CrossVal}', '\text{on}')
\]

\[
\text{CVMdl} =
\begin{align*}
\text{classreg.learning.partition.ClassificationPartitionedKernelECOC} \\
\text{CrossValidatedModel: 'KernelECOC'} \\
\text{ResponseName: 'Y'} \\
\text{NumObservations: 150} \\
\text{Kfold: 10} \\
\text{Partition: [1x1 cvpartition]} \\
\text{ClassNames: {'setosa' 'versicolor' 'virginica'}} \\
\text{ScoreTransform: 'none'}
\end{align*}
\]

\text{CVMdl} \text{ is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'Kfold' name-value pair argument instead of 'Crossval'.}

Estimate the cross-validated classification loss. By default, the software computes the classification error.

\[
\text{loss} = \text{kfoldLoss(CVMdl)}
\]

\[
\text{loss} = 0.0333
\]

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair 'Mode', 'individual' in kfoldLoss.

**Determine Model Quality Using Custom Cross-Validation Loss**

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to kfoldLoss.

Load Fisher's iris data set. \(X\) contains flower measurements, and \(Y\) contains the names of flower species.
load fisheriris
X = meas;
Y = species;

Cross-validate an ECOC model composed of kernel binary learners.

rng(1) \% For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. S corresponds to the NegLoss output of kfoldPredict.

lossfun = @(~,S,~,~)mean(min(-S,[],2));

Compute the cross-validated custom loss.

kfoldLoss(CVMdl,'LossFun',lossfun)

ans = 0.0199

The average minimal binary loss for the validation-fold observations is about 0.02.
Input Arguments

**CVMdl — Cross-validated kernel ECOC model**

ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners'– Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',1:3)` specifies to use only the first, second, and third folds to calculate the classification loss.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/\sqrt{2\log(2)}$</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
<td>Score Domain</td>
<td>$g(y_j, s_j)$</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------------</td>
<td>--------------</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0, 1]$ or $(-\infty, \infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>$\max(0, 1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>$\log[1 + \exp(-y_j s_j)]/2\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0, 1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction has this form:

\[
bLoss = \text{customFunction}(M,s)\]

where:

- $M$ is the $K$-by-$L$ coding matrix stored in Mdl.CodingMatrix.
- $s$ is the 1-by-$L$ row vector of classification scores.
- $bLoss$ is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$ is the number of classes.
- $L$ is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then BinaryLoss is 'hinge'. If all binary learners are kernel classification models using logistic regression, then BinaryLoss is 'quadratic'.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3181.

Example: 'Decoding','lossbased'

**Folds — Fold indices for prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3180.
- Or, specify your own function using function handle notation.

Assume that $n$ is the number of observations in the training data (CVMdl.NumObservations) and $K$ is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature lossvalue = lossfun(C,S,W,Cost), where:

- The output argument lossvalue is a scalar.
- You specify the function name (lossfun).
- C is an $n$-by-$K$ logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct C by setting $C(p,q) = 1$ if observation $p$ is in class $q$, for each row. Set every element of row $p$ to 0.
• \( S \) is an \( n \)-by-\( K \) numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in \texttt{CVMdl.ClassNames}. The input \( S \) resembles the output argument \texttt{NegLoss} of \texttt{kfoldPredict}.

• \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes its elements to sum to 1.

• \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using \texttt{'LossFun'},@\texttt{lossfun}.

Data Types: \texttt{char} | \texttt{string} | \texttt{function_handle}

**Mode — Aggregation level for output**

\texttt{'average'} (default) | \texttt{'individual'}

Aggregation level for the output, specified as the comma-separated pair consisting of \texttt{'Mode'} and \texttt{'average'} or \texttt{'individual'}.

This table describes the values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>The output is a scalar average over all folds.</td>
</tr>
<tr>
<td>'individual'</td>
<td>The output is a vector of length ( k ) containing one value per fold, where ( k ) is the number of folds.</td>
</tr>
</tbody>
</table>

Example: \texttt{'Mode','individual'}

**Options — Estimation options**

\texttt{[]} (default) | \texttt{structure array returned by statset}

Estimation options, specified as the comma-separated pair consisting of \texttt{'Options'} and a structure array returned by \texttt{statset}.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel',1).

**Verbose — Verbosity level**

θ (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and θ or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is θ, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**loss — Classification loss**

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k-by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

**Definitions**

**Classification Error**

The classification error is a binary classification error measure that has the form

\[
L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j}
\]
where:

- \( w_j \) is the weight for observation \( j \). The software renormalizes the weights to sum to 1.
- \( e_j = 1 \) if the predicted class of observation \( j \) differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]
Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set \{-1,1,0\}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/2\log(2)$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/2\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b
kfoldLoss

Classification loss for observations not used in training

Syntax

L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)

Description

$L = \text{kfoldLoss}($CVMdl$)$ returns the cross-validated classification losses on page 32-3193 obtained by the cross-validated, binary, linear classification model $CVMdl$. That is, for every fold, $\text{kfoldLoss}$ estimates the classification loss for observations that it holds out when it trains using all other observations.

$L$ contains a classification loss for each regularization strength in the linear classification models that compose $CVMdl$.

$L = \text{kfoldLoss}($CVMdl$,$Name$,$Value$)$ uses additional options specified by one or more $Name$, $Value$ pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

Input Arguments

$CVMdl$ — Cross-validated, binary, linear classification model
ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model object using fitclinear and specifying any one of the cross-validation, name-value pair arguments, for example, $\text{CrossVal}$.

To obtain estimates, kfoldLoss applies the same data used to cross-validate the linear classification model ($X$ and $Y$).
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Folds — Fold indices to use for classification-score prediction**

1:CVMdl.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

**LossFun — Loss function**

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

32-3185
'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see predict).

- Specify your own function using function handle notation.

Let \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(Mdl.\text{ClassNames}) \), \( Mdl \) is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \( Mdl.\text{ClassNames} \).

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( Mdl.\text{ClassNames} \). \( S \) is a matrix of classification scores, similar to the output of \( \text{predict} \).

- \( W \) is an \( n \)-by-\( 1 \) numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@\( \text{lossfun} \).

Data Types: char | string | function_handle

**Mode — Loss aggregation level**

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

32-3186
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns losses averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns losses for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode','individual'

**Output Arguments**

L — Cross-validated classification losses  
numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-3193, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LossFun.

Let R be the number of regularizations strengths is the cross-validated models (stored in numel(CVMdl.Trained{1}.Lambda)) and F be the number of folds (stored in CVMdl.KFold).

- If Mode is 'average', then L is a 1-by-R vector. L(j) is the average classification loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, L is an F-by-R matrix. L(i,j) is the classification loss for fold i of the cross-validated model that uses regularization strength j.

To estimate L, kfoldLoss uses the data that created CVMdl (see X and Y).

**Examples**

**Estimate k-Fold Cross-Validation Classification Error**

Load the NLP data set.

```matlab
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.
The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

\[ Y_{\text{stats}} = Y == '\text{stats}' \]

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

\[
\text{rng}(1); \quad \% \text{For reproducibility} \\
\text{CVMdl} = \text{fitclinear}(X,Y_{\text{stats}},'\text{CrossVal}','on');
\]

CVMdl is a ClassificationPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

\[
\text{ce} = \text{kfoldLoss}(\text{CVMdl})
\]

\[
\text{ce} = 7.6017e^{-04}
\]

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode','individual' in kfoldLoss.

**Specify Custom Classification Loss**

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Classification Error” on page 32-3187, and transpose the predictor data.

\[
\text{load nldata} \\
\text{Y_{stats}} = Y == '\text{stats}'; \\
\text{X} = X';
\]

Cross-validate a binary, linear classification model using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

\[
\text{rng}(1); \quad \% \text{For reproducibility} \\
\text{CVMdl} = \text{fitclinear}(X,Y_{\text{stats}},'\text{Solver}','\text{sparsa}','\text{KFold}',5,...
\]
'ObservationsIn', 'columns');
CMdl = CVMdl.Trained{1};

CVMdl is a ClassificationPartitionedLinear model. It contains the property
Trained, which is a 5-by-1 cell array holding a ClassificationLinear models that the
software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

\[
L = \frac{\sum_{j} -w_{j}y_{j}f_{j}}{\sum_{j}w_{j}}.
\]

\(w_{j}\) is the weight for observation \(j\), \(y_{j}\) is response \(j\) (-1 for the negative class, and 1
otherwise), and \(f_{j}\) is the raw classification score of observation \(j\). Custom loss functions
must be written in a particular form. For rules on writing a custom loss function, see the
LossFun name-value pair argument. Because the function does not use classification
cost, use ~ to have kfoldLoss ignore its position.

\[
\text{linearloss} = @(C,S,W,~)\text{sum}(-W.*\text{sum}(S.*C,2))/\text{sum}(W);
\]

Estimate the average cross-validated classification loss using the linear loss function.
Also, obtain the loss for each fold.

\[
\text{ce} = \text{kfoldLoss(CVMdl, 'LossFun', linearloss)}
\]

\[
\text{ce} = -8.0982
\]

\[
\text{ceFold} = \text{kfoldLoss(CVMdl, 'LossFun', linearloss, 'Mode', 'individual')}
\]

\[
\text{ceFold} = 5\times1
\]

\[
\begin{array}{c}
-8.3165 \\
-8.7633 \\
-7.4342 \\
-8.0423 \\
-7.9347
\end{array}
\]
Find Good Lasso Penalty Using k-fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3188.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{0.5}$.

```matlab
Lambda = logspace(-6,-0.5,11);
```

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

Extract a trained linear classification model.

```matlab
Mdl1 = CVMdl.Trained{1}
```
Mdl1 = ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023×11 double]
    Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.0071 0.0251 0.0891 0.3162]
    Learner: 'logistic'

Properties, Methods

Mdl1 is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

ce = kfoldLoss(CVMdl);

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta==0);

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'\text{log}_{10} \text{ classification error}')
Choose the indexes of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

```matlab
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```matlab
MdlFinal = selectModels(Mdl,idxFinal);
```
MdlFinal is a ClassificationLinear model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to predict.

**Definitions**

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - $y^*_j$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y^*_2 = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  - $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - $m_j = y^*_j f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
• The weight for observation $j$ is $w_j$. The software Normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>$L = \sum_{j=1}^{n} w_j \log\left{1 + \exp\left[-2m_j\right]\right}.$</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>$L = \sum_{j=1}^{n} w_j \exp(-m_j).$</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>$L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}. $ It is the weighted fraction of misclassified observations where $\hat{y}_j$ is the class label corresponding to the class with the maximal posterior probability. $I{x}$ is the indicator function.</td>
</tr>
<tr>
<td>Hinge loss</td>
<td>'hinge'</td>
<td>$L = \sum_{j=1}^{n} w_j \max{0,1 - m_j}. $</td>
</tr>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>$L = \sum_{j=1}^{n} w_j \log\left(1 + \exp(-m_j)\right).$</td>
</tr>
</tbody>
</table>
Loss Function | Value of LossFun | Equation |
--- | --- | ---
Minimal cost | 'mincost' | Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1,\ldots,n$.

1. Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:

$$\gamma_j = f(X_j)C.$$ 

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the Cost property.

2. For observation $j$, predict the class label corresponding to the minimum expected classification cost:

$$\hat{y}_j = \min_{j=1,\ldots,K} (\gamma_j).$$

3. Using $C$, identify the cost incurred ($c_j$) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^{n} w_j c_j.$$ 

Quadratic loss | 'quadratic' | $L = \sum_{j=1}^{n} w_j \left(1-m_j\right)^2$. 

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through [0,1].

Introduced in R2016a
kfoldLoss

Classification loss for observations not used in training

Syntax

L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)

Description

L = kfoldLoss(CVMdl) returns the cross-validated classification error on page 32-3197 rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models CVMdl. That is, for every fold, kfoldLoss estimates the classification error rate for observations that it holds out when it trains using all other observations. kfoldLoss applies the same data used create CVMdl (see fitcecoc).

L contains a classification loss for each regularization strength in the linear classification models that compose CVMdl.

L = kfoldLoss(CVMdl,Name,Value) uses additional options specified by one or more Name,Value pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models
ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model object using fitcecoc and by:

1 Specifying any one of the cross-validation, name-value pair arguments, for example, CrossVal
Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`.

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the ECOC model (`X` and `Y`).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**BinaryLoss — Binary learner loss function**

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where `y_j` is a class label for a particular binary learner (in the set `-1,1,0`), `s_j` is the score for observation `j`, and `g(y_j,s_j)` is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th><code>g(y_j,s_j)</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'binodeviance'</code></td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/\ [2\log(2)]$</td>
</tr>
<tr>
<td><code>'exponential'</code></td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td><code>'hamming'</code></td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>

<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td><code>'logit'</code></td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_j s_j)]/\ [2\log(2)]$</td>
</tr>
<tr>
<td><code>'quadratic'</code></td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j (2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when `y_j = 0`. Also, the software calculates the mean binary loss for each class.
For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is 'hinge'
- Logistic regression, then `BinaryLoss` is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: `char` | `string` | `function_handle`

**Decoding** — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

**Folds** — Fold indices to use for classification-score prediction

1:CVMdl.KFold (default) | numeric vector of positive integers
Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMdl.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or 'classiferror'.

You can:

- Specify the built-in function 'classiferror', then the loss function is the classification error on page 32-3209.
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature lossvalue = lossfun(C,S,W,Cost), where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct C by setting $C(p,q) = 1$ if observation p is in class q, for each row. Set every element of row p to 0.

- S is an n-by-K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMdl.ClassNames. S resembles the output argument NegLoss of kfoldPredict.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes its elements to sum to 1.
Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) - eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

Data Types: function_handle | char | string

Mode — Loss aggregation level
'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Returns losses averaged over all folds</td>
</tr>
<tr>
<td>'individual'</td>
<td>Returns losses for each fold</td>
</tr>
</tbody>
</table>

Example: 'Mode', 'individual'

Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', 1).

Verbose — Verbosity level
0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbosity controls the number of diagnostic messages that the software displays in the Command Window.

If Verbosity is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1
Data Types: single | double

Output Arguments

**L — Cross-validated classification losses**
numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-3209, returned as a numeric scalar, vector, or matrix. The interpretation of **L** depends on **LossFun**.

Let **R** be the number of regularizations strengths is the cross-validated models (CVMdl.Trained{1}.BinaryLearners{1}.Lambda) and **F** be the number of folds (stored in CVMdl.KFold).

- If **Mode** is 'average', then **L** is a 1-by-**R** vector. **L(j)** is the average classification loss over all folds of the cross-validated model that uses regularization strength **j**.
- Otherwise, **L** is a **F**-by-**R** matrix. **L(i,j)** is the classification loss for fold **i** of the cross-validated model that uses regularization strength **j**.

Examples

**Estimate k-Fold Cross-Validation Classification Error**

Load the NLP data set.

```matlab
load nlpdata
```

**X** is a sparse matrix of predictor data, and **Y** is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

**CVMdl** is a *ClassificationPartitionedLinearECOC* model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.
ce = kfoldLoss(CVMdl)

ce = 0.0958

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

load nlpdata
X = X';

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

t = templateLinear('Solver','sparsa');

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}

CMdl1 =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]
CVMdl is a ClassificationPartitionedLinearECOC model. It contains the property Trained, which is a 5-by-1 cell array holding a CompactClassificationECOC models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (C), observation weights (W), and classification cost (Cost), use ~ to have kfoldLoss ignore its their positions.

\[
\text{lossfun} = @(~,S,~,~)\text{mean}(\text{min}(-S,[],2));
\]

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

\[
\text{ce} = \text{kfoldLoss}(\text{CVMdl},'\text{LossFun}',\text{lossfun})
\]

\[
\text{ce} = 0.0243
\]

\[
\text{ceFold} = \text{kfoldLoss}(\text{CVMdl},'\text{LossFun}',\text{lossfun},'\text{Mode}','\text{individual}')
\]

\[
\text{ceFold} = 5\times1
\]

\[
\begin{array}{c}
0.0244 \\
0.0255 \\
0.0248 \\
0.0240 \\
0.0226
\end{array}
\]

**Find Good Lasso Penalty Using Cross-Validation**

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

\[
\text{load nlpdata}
\]

\[
\text{X} \text{ is a sparse matrix of predictor data, and } \text{Y} \text{ is a categorical vector of class labels.}
\]
For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

\[ Y(~(\text{ismember}(Y,\{'simulink','dsp','comm'\}))) = \text{'others'}; \]

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-7}$ through $10^{-2}$.

\[ \text{Lambda} = \text{logspace}(-7,-2,11); \]

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in \text{Lambda}, train using SpaRSA, and lower the tolerance on the gradient of the objective function to $1e-8$.

\[ \text{t} = \text{templateLinear('Learner','logistic','Solver','sparsa',...\text{'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8});} \]

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

\[ \text{X} = \text{X}'; \]
\[ \text{rng}(10); \quad \% \text{For reproducibility} \]
\[ \text{CVMdl} = \text{fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);} \]

\text{CVMdl} is a \text{ClassificationPartitionedLinearECOC} model.

Dissect \text{CVMdl}, and each model within it.

\[ \text{numECOCModels} = \text{numel(CVMdl.Trained)} \]
\[ \text{numECOCModels} = 5 \]

\[ \text{ECOCMdl1} = \text{CVMdl.Trained{1}} \]

\text{ECOCMdl1} =
\[
\text{classreg.learning.classif.CompactClassificationECOC}
\quad \text{ResponseName: 'Y'}
\quad \text{ClassNames: [comm dsp simulink others]}
\quad \text{ScoreTransform: 'none'}
\quad \text{BinaryLearners: {6x1 cell}}
\quad \text{CodingMatrix: [4x6 double]}
\]
Properties, Methods

numCLModels = numel(ECOCMdl1.BinaryLearners)
numCLModels = 6
CLMdl1 = ECOCMdl1.BinaryLearners{1}

CLMdl1 = ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [-1 1]
  ScoreTransform: 'logit'
  Beta: [34023×11 double]
  Bias: [-0.3125 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596]
  Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04 3.1623e-04 1.0000e-03 0.0032 0.0100]
  Learner: 'logistic'

Because fitcecoc implements 5-fold cross-validation, CVMdl contains a 5-by-1 cell array of CompactClassificationECOC models that the software trains on each fold. The BinaryLearners property of each CompactClassificationECOC model contains the ClassificationLinear models. The number of ClassificationLinear models within each compact ECOC model depends on the number of distinct labels and coding design. Because Lambda is a sequence of regularization strengths, you can think of CLMdl1 as 11 models, one for each regularization strength in Lambda.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

ce = kfoldLoss(CVMdl);
figure;
plot(log10(Lambda),log10(ce))
 [~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```matlab
t = templateLinear('Learner','logistic','Solver','sparsa',...    'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`. 
Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.
\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.
<table>

</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Classification Error**

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j}$$

where:

- $w_j$ is the weight for observation $j$. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation $j$ differs from its true class, and $0$ otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2016a
kfoldLoss

Classification loss for observations not used for training

Syntax

L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)

Description

L = kfoldLoss(obj) returns loss obtained by cross-validated classification model obj. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

L = kfoldLoss(obj,Name,Value) calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

obj

Object of class ClassificationPartitionedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

folds

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.
**Default:** 1:obj.KFold

**lossfun**

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. All models use posterior probabilities as classification scores by default except SVM models. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior',true when you cross-validate the model using fitcsvm.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (numel(obj.ClassNames), obj is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
• C is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \texttt{obj.ClassNames}.

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

• \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \texttt{obj.ClassNames}. \( S \) is a matrix of classification scores, similar to the output of \texttt{predict}.

• \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

• \texttt{Cost} is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \texttt{Cost} = \texttt{ones}(K) - \texttt{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@\texttt{lossfun}.

For more details on loss functions, see “Classification Loss” on page 32-3215.

**Default:** 'classiferror'

**mode**

A character vector or string scalar for determining the output of \texttt{kfoldLoss}:

• 'average' — \( L \) is a scalar, the loss averaged over all folds.
• 'individual' — \( L \) is a vector of length \texttt{obj.KFold}, where each entry is the loss for a fold.

**Default:** 'average'

**Output Arguments**

\( L \)

Loss, by default the fraction of misclassified data. \( L \) can be a vector, and can mean different things, depending on the name-value pair settings.
Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.
load ionosphere

Grow a classification tree.
tree = fitctree(X,Y);

Cross-validate the classification tree using 10-fold cross-validation.
cvtree = crossval(tree);

Estimate the cross-validated classification error.
L = kfoldLoss(cvtree)
L = 0.1111

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
• \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).

• \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.

• For algorithms that support multiclass classification (that is, \( K \geq 3 \)):

• \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_j^* = [0 0 1 0] \). The order of the classes corresponds to the order in the \texttt{ClassNames} property of the input model.

• \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the \texttt{ClassNames} property of the input model.

• \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.

• The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Topics
“Examine Quality of KNN Classifier” on page 18-37
**kfoldLoss**

Cross-validation loss of partitioned regression ensemble

**Syntax**

\[ L = \text{kfoldLoss}(\text{cvens}) \]

\[ L = \text{kfoldLoss}(\text{cvens}, \text{Name,Value}) \]

**Description**

\[ L = \text{kfoldLoss}(\text{cvens}) \] returns the cross-validation loss of \( \text{cvens} \).

\[ L = \text{kfoldLoss}(\text{cvens}, \text{Name,Value}) \] returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Input Arguments**

\text{cvens}

Object of class RegressionPartitionedEnsemble. Create \text{obj} with \text{fitrensemble} along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvsample'. Alternatively, create \text{obj} from a regression ensemble with \text{crossval}.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \text{Name,Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.
folds
Indices of folds ranging from 1 to cvens.KFold. Use only these folds for predictions.

**Default:** 1:cvens.KFold

lossfun
Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, loss calls it as

\[ \text{fun}(Y,Yfit,W) \]

where \( Y, Yfit, \) and \( W \) are numeric vectors of the same length.

- \( Y \) is the observed response.
- \( Yfit \) is the predicted response.
- \( W \) is the observation weights.

The returned value \( \text{fun}(Y,Yfit,W) \) should be a scalar.

**Default:** 'mse'

mode
Method for computing cross-validation loss.

- 'average' — \( L \) is a scalar value, the average loss over all folds.
- 'individual' — \( L \) is a vector with one element per fold.
- 'cumulative' — \( L \) is a vector with a length of minimum number of observations used for training in each fold. Each element in the vector \( L \) is obtained by taking the average of loss across all folds.

**Default:** 'average'
Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find Cross-Validation Loss for Regression Ensemble

Find the cross-validation loss for a regression ensemble of the carsmall data.

Load the carsmall data set and select displacement, horsepower, and vehicle weight as predictors.

load carsmall
X = [Displacement Horsepower Weight];

Train an ensemble of regression trees.

rens = fitrensemble(X,MPG);

Create a cross-validated ensemble from rens and find the k-fold cross-validation loss.

rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
L = 28.7077

See Also
RegressionPartitionedEnsemble | kfoldPredict | loss
**kfoldLoss**

Regression loss for observations not used in training

**Syntax**

\[ L = \text{kfoldLoss}(\text{CVMdl}) \]

\[ L = \text{kfoldLoss}(\text{CVMdl},\text{Name},\text{Value}) \]

**Description**

Description

\[ L = \text{kfoldLoss}(\text{CVMdl}) \] returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model \( \text{CVMdl} \). That is, for every fold, \( \text{kfoldLoss} \) estimates the regression loss for observations that it holds out when it trains using all other observations.

\( L \) contains a regression loss for each regularization strength in the linear regression models that compose \( \text{CVMdl} \).

\[ L = \text{kfoldLoss}(\text{CVMdl},\text{Name},\text{Value}) \] uses additional options specified by one or more \( \text{Name},\text{Value} \) pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

**Input Arguments**

**CVMdl — Cross-validated, linear regression model**

RegressionPartitionedLinear model object

Cross-validated, linear regression model, specified as a RegressionPartitionedLinear model object. You can create a RegressionPartitionedLinear model using \text{fitrlinear} and specifying any of the one of the cross-validation, name-value pair arguments, for example, CrossVal.
To obtain estimates, kfoldLoss applies the same data used to cross-validate the linear regression model \((X\ and\ Y)\).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Folds — Fold indices to use for response prediction**

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: 'Folds',[1 4 10]

Data Types: `single` | `double`

**LossFun — Loss function**

'`mse`' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, \(f(x) = x\beta + b\).

  - \(\beta\) is a vector of \(p\) coefficients.
  - \(x\) is an observation from \(p\) predictor variables.
  - \(b\) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'epsiloninsensitive'</td>
<td>Epsilon-insensitive loss:</td>
</tr>
<tr>
<td></td>
<td>[\ell[y, f(x)] = \max[0,</td>
</tr>
</tbody>
</table>
**Value** | **Description**
--- | ---
'mse' | \[\ell[y, f(x)] = (y - f(x))^2\]

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let \( n \) be the number of observations in \( X \). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(Y, \text{Yhat}, W)
\]

where:
- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( Y \) is an \( n \)-dimensional vector of observed responses. \( \text{kfoldLoss} \) passes the input argument \( Y \) in for \( Y \).
- \( \text{Yhat} \) is an \( n \)-dimensional vector of predicted responses, which is similar to the output of \( \text{predict} \).
- \( W \) is an \( n \)-by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @\( \text{lossfun} \).

Data Types: char | string | function_handle

**Mode — Loss aggregation level**

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

**Value** | **Description**
--- | ---
'average' | Returns losses averaged over all folds
'individual' | Returns losses for each fold

Example: 'Mode','individual'
Output Arguments

**L — Cross-validated regression losses**
numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of **L** depends on **LossFun**.

Let **R** be the number of regularizations strengths is the cross-validated models (stored in \texttt{numel(CVMdl.Trained{1}.Lambda)}) and **F** be the number of folds (stored in \texttt{CVMdl.KFold}).

- If **Mode** is 'average', then **L** is a 1-by-**R** vector. **L(j)** is the average regression loss over all folds of the cross-validated model that uses regularization strength **j**.
- Otherwise, **L** is an **F**-by-**R** matrix. **L(i,j)** is the regression loss for fold **i** of the cross-validated model that uses regularization strength **j**.

To estimate **L**, \texttt{kfoldLoss} uses the data that created \texttt{CVMdl} (see \texttt{X} and \texttt{Y}).

### Examples

**Estimate k-Fold Mean Squared Error**

Simulate 10000 observations from this model

\[
y = x_{100} + 2x_{200} + e.
\]

- **X** = \{\{x_{1},...,x_{100}\}\} is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- **e** is random normal error with mean 0 and standard deviation 0.3.

\texttt{rng(1) \% For reproducibility}
\texttt{n = 1e4;}
\texttt{d = 1e3;}
\texttt{nz = 0.1;}
\texttt{X = sprandn(n,d,nz);}
\texttt{Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);}
Cross-validate a linear regression model using SVM learners.

```matlab
rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');
```

*CVMdl* is a *RegressionPartitionedLinear* model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the test-sample MSEs.

```matlab
mse = kfoldLoss(CVMdl)
```

```
mse = 0.1735
```

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair 'Mode','individual' in *kfoldLoss*.

**Specify Custom Regression Loss**

Simulate data as in “Estimate k-Fold Mean Squared Error” on page 32-3226.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Cross-validate a linear regression model using 10-fold cross-validation. Optimize the objective function using SpaRSA.

```matlab
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',...
                   'Solver','sparsa');
```

*CVMdl* is a *RegressionPartitionedLinear* model. It contains the property *Trained*, which is a 10-by-1 cell array holding *RegressionLinear* models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,
where

\[
L = \frac{1}{\sum w_j} \sum_{j=1}^{n} w_j \ell_j,
\]

where

\[
\ell_j = \begin{cases} 
0.5\hat{e}_j^2; & |\hat{e}_j| \leq 1 \\
|\hat{e}_j| - 0.5; & |\hat{e}_j| > 1
\end{cases}
\]

\(\hat{e}_j\) is the residual for observation \(j\). Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

\[
\text{huberloss} = @(Y,Yhat,W)\text{sum}(W.*((0.5*(abs(Y-Yhat)<=1).*((Y-Yhat).^2) + ... 
((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/\text{sum}(W);
\]

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

\[
\text{mseAve} = \text{kfoldLoss}(CVMdl,'LossFun',\text{huberloss})
\]

\[
\text{mseAve} = -0.4447
\]

\[
\text{mseFold} = \text{kfoldLoss}(CVMdl,'LossFun',\text{huberloss},'\text{Mode}','\text{individual}')
\]

\[
\text{mseFold} = 10\times1
\]

-0.4454
-0.4473
-0.4452
-0.4469
-0.4434
-0.4427
-0.4471
-0.4430
-0.4438
-0.4426
Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \( 10^{-5} \) through \( 10^{-1} \).

```matlab
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```matlab
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```matlab
numCLModels = numel(CVMdl.Trained)
numCLModels = 5
```

`CVMdl` is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, `CVMdl` contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.
Md11 = CVMdl.Trained{1}

Md11 =
    RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
        Beta: [1000x15 double]
        Bias: [1x15 double]
        Lambda: [1x15 double]
        Learner: 'leastsquares'

Properties, Methods

Md11 is a RegressionLinear model object. fitrlinear constructed Md11 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Md11 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

mse = kfoldLoss(CVMdl);

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

Md1 = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, \( \text{Lambda}(10) \)).

\[ \text{idxFinal} = 10; \]

Extract the model with corresponding to the minimal MSE.

\[ \text{MdlFinal} = \text{selectModels}(\text{Mdl}, \text{idxFinal}) \]

\[ \text{MdlFinal} = \text{RegressionLinear} \]
\[ \text{ResponseName}: 'Y' \]
\[ \text{ResponseTransform}: 'none' \]
\[ \text{Beta}: [1000x1 \text{ double}] \]
Bias: -0.0050
Lambda: 0.0037
Learner: 'leastsquares'

Properties, Methods

idxNZCoeff = find(MdlFinal.Beta~=0)
idxNZCoeff = 2x1
    100
    200

EstCoeff = Mdl.Beta(idxNZCoeff)
EstCoeff = 2x1
    1.0051
    1.9965

MdlFinal is a RegressionLinear model with one regularization strength. The nonzero coefficients EstCoeff are close to the coefficients that simulated the data.

RegressionLinear | RegressionPartitionedLinear | kfoldPredict | loss

Introduced in R2016a
**kfoldLoss**

Cross-validation loss of partitioned regression model

**Syntax**

\[
L = \text{kfoldLoss}(\text{cvmodel})
\]

\[
L = \text{kfoldLoss}(\text{cvmodel},\text{Name},\text{Value})
\]

**Description**

\[
L = \text{kfoldLoss}(\text{cvmodel}) \text{ returns the cross-validation loss of } \text{cvmodel}.
\]

\[
L = \text{kfoldLoss}(\text{cvmodel},\text{Name},\text{Value}) \text{ returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.}
\]

**Input Arguments**

**cvmodel**

Object of class RegressionPartitionedModel. Create obj with fitrtree along with one of the cross-validation options: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Alternatively, create obj from a regression tree with crossval.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**folds**

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.
**Default**: `1:obj.KFold`

**lossfun**

Function handle for loss function or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

`fun(Y,Yfit,W)`

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default**: `'mse'`

**mode**

One of the following:

- `'average'` — `L` is the average loss over all folds.
- `'individual'` — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

**Default**: `'average'`

**Output Arguments**

**L**

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is `'individual'`, `L` is a vector of the losses. If `mode` is `'average'`, `L` is the average loss.
Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')

L =
 44.9635
 11.8525
 18.2046
  9.2965
 29.4329
 54.8659
 24.6446
  8.2085
 19.7593
 16.7394

Alternatives

You can avoid constructing a cross-validated tree model by calling cvLoss instead of kfoldLoss. The cross-validated tree can save time if you are going to examine it more than once.

fitrtree | kfoldPredict | loss
kfoldMargin

**Package:** classreg.learning.partition

Classification margins for cross-validated ECOC model

**Syntax**

```matlab
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

**Description**

`margin = kfoldMargin(CVMdl)` returns classification margins obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldMargin` computes classification margins for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```
Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the margins for validation-fold observations. Display the distribution of the margins using a boxplot.

```matlab
margin = kfoldMargin(CVMdl);
boxplot(margin)
title('Distribution of Margins')
```
Select ECOC Model Features by Comparing Cross-Validation Margins

One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. Specify the predictor data \( X \), the response data \( Y \), and the order of the classes in \( Y \).

```matlab
load fisheriris
X = meas;
```
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Define the following two data sets.

- fullX contains all the predictors.
- partX contains the petal dimensions.

fullX = X;
partX = X(:,3:4);

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
              'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
                 'ClassNames',classOrder);

CVMdl and PCVMdl are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross-validation.

Estimate the margins for each classifier. Use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Distributions of Margins')
The margin distributions are approximately the same.

**Input Arguments**

**CVMdl** — Cross-validated ECOC model
ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`. 
• Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldMargin(CVMdl,'Verbose',1)` specifies to display diagnostic messages in the Command Window.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

• This table contains names and descriptions of the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set {-1,1,0}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty, \infty)$</td>
<td>[\log[1 + \exp(-2y_j s_j)]/\ [2\log(2)]]</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>[\exp(-y_j s_j)/2]</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty, \infty)$</td>
<td>[1 - \text{sign}(y_j s_j)/2]</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>[\max(0,1 - y_j s_j)/2]</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>[(1 - y_j s_j)/2]</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>[\log[1 + \exp(-y_j s_j)]/\ [2\log(2)]]</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>[1 - y_j(2s_j - 1)]^2/2]</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.
• For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss', @customFunction.

customFunction has this form:

\[ bLoss = customFunction(M,s) \]

where:

• \( M \) is the \( K \)-by-\( L \) coding matrix stored in Mdl.CodingMatrix.
• \( s \) is the 1-by-\( L \) row vector of classification scores.
• \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
• \( K \) is the number of classes.
• \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

• SVMs or either linear or kernel classification models of SVM learners, then BinaryLoss is 'hinge'
• Ensembles trained by AdaboostM1 or GentleBoost, then BinaryLoss is 'exponential'
• Ensembles trained by LogitBoost, then BinaryLoss is 'binodeviance'
• Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior', 1 in fitcecoc), then BinaryLoss is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'
Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding', 'lossbased'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel', 1).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**margin — Classification margins**

numeric vector

Classification margins on page 32-3244, returned as a numeric vector. **margin** is an n-by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (size(CVMdl.X, 1)).
Definitions

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \text{argmin}_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,
\[
\hat{k} = \arg\min_k \frac{1}{L} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).
\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j, s_j)\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j, s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((-\infty, \infty))</td>
<td>(\log[1 + \exp(-2y_j s_j)]/\left[2\log(2)\right])</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((-\infty, \infty))</td>
<td>(\exp(-y_j s_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((-\infty, \infty))</td>
<td>([1 - \text{sign}(y_j s_j)]/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((-\infty, \infty))</td>
<td>(\max(0,1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((-\infty, \infty))</td>
<td>((1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((-\infty, \infty))</td>
<td>(\log[1 + \exp(-y_j s_j)]/\left[2\log(2)\right])</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>([1 - y_j(2s_j - 1)]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

References

**Extended Capabilities**

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Classification margins for cross-validated kernel classification model

**Syntax**

```
margin = kfoldMargin(CVMdl)
```

**Description**

```
margin = kfoldMargin(CVMdl) returns the classification margins on page 32-3253 obtained by the cross-validated, binary kernel model (ClassificationPartitionedKernel) CVMdl. For every fold, kfoldMargin computes the classification margins for validation-fold observations using a model trained on training-fold observations.
```

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled as either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
```
KFold: 10
Partition: [1x1 cvpartition]
ClassNames: {'b'  'g'}
ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the classification margins for validation-fold observations.

m = kfoldMargin(CVMdl);
size(m)
ans = 1×2
    351     1

m is a 351-by-1 vector. m(j) is the classification margin for observation j.

Plot the k-fold margins using a boxplot.

boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
Feature Selection Using \( k \)-Fold Margins

Perform feature selection by comparing \( k \)-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load the \texttt{ionosphere} data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

\texttt{load ionosphere}

Randomly choose 10\% of the predictor variables.
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses 10% of the predictors.

CVMdl = fitckernel(X,Y,'CrossVal','on');
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');

CVMdl and PCVMdl are ClassificationPartitionedKernel models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold margins for each classifier.

fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

Plot the distribution of the margin sets using box plots.

boxplot([fullMargins partMargins], ...  
    'Labels',{'All Predictors','10% of the Predictors'});
title('Distribution of Margins')
The quartiles of the PCVMdl margin distribution are situated higher than the quartiles of the CVMdl margin distribution, indicating that the PCVMdl model is the better classifier.

**Input Arguments**

**CVMdl** — Cross-validated, binary kernel classification model
ClassificationPartitionedKernel model object

Cross-validated, binary kernel classification model, specified as a ClassificationPartitionedKernel model object. You can create a
ClassificationPartitionedKernel model by using fitckernel and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldMargin applies the same data used to cross-validate the kernel classification model (X and Y).

Output Arguments

margin — Classification margins
numeric vector

Classification margins on page 32-3253, returned as a numeric vector. margin is an n-by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (size(CVMdl.Y,1)).

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. f(x) is the positive-class classification score for the observation x. The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.
**Classification Score**

For kernel classification models, the raw classification score for classifying the observation $x$, a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$  

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- $\beta$ is the estimated column vector of coefficients.
- $b$ is the estimated scalar bias.

The raw classification score for classifying $x$ into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

ClassificationPartitionedKernel | fitckernel

**Introduced in R2018b**
**kfoldMargin**

**Package:** classreg.learning.partition

Classification margins for cross-validated kernel ECOC model

**Syntax**

```matlab
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

**Description**

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 32-3262 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the classification margins for validation-fold observations.

m = kfoldMargin(CVMdl);
size(m)

ans = 1x2

150   1

m is a 150-by-1 vector. m(j) is the classification margin for observation j.

Plot the k-fold margins using a boxplot.

boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
Feature Selection Using k-Fold Margins

Perform feature selection by comparing k-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```
Randomly choose half of the predictor variables.

```matlab
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```matlab
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

CVMdl and PCVMdl are ClassificationPartitionedKernelECOC models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k-fold margins for each classifier.

```matlab
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);
```

Plot the distribution of the margin sets using box plots.

```matlab
boxplot([fullMargins partMargins], ... 'Labels',{'All Predictors','Half of the Predictors'});
title('Distribution of Margins')
```
The PCVMdl margin distribution is similar to the CVMdl margin distribution.

**Input Arguments**

**CVMdl** — Cross-validated kernel ECOC model
`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:
• 'Learners' – Set the value to 'kernel', a template object returned by 
templateKernel, or a cell array of such template objects.
• One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 
'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the 
argument name and Value is the corresponding value. Name must appear inside quotes. 
You can specify several name and value pair arguments in any order as 
Name1, Value1, ..., NameN, ValueN.

Example: kfoldMargin(CVMdl,'Verbose',1) specifies 
to display diagnostic messages 
in the Command Window.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 
'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 
'BinaryLoss' and a built-in loss function name or function handle.

• This table contains names and descriptions of the built-in functions, where \( y_j \) is a class 
label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation 
\( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>

</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the 
software calculates the mean binary loss for each class.
For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction.'

`customFunction` has this form:

\[ bLoss = customFunction(M,s) \]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

`'lossweighted'`(default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3263.

Example: `'Decoding','lossbased'`

**Options — Estimation options**

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:
• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel', 1).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**margin — Classification margins**

numeric vector

Classification margins on page 32-3262, returned as a numeric vector. **margin** is an \( n \)-by-1 vector, where each row is the margin of the corresponding observation and \( n \) is the number of observations (\( \text{size(CVMdl.Y,1)} \)).

**Definitions**

**Classification Margin**

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.
Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg \min_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj},s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg \min_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj},s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.
<table>

</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b
kfoldMargin

Classification margins for observations not used in training

Syntax

\[ m = \text{kfoldMargin(CVMdl)} \]

Description

\[ m = \text{kfoldMargin(CVMdl)} \] returns the cross-validated classification margins on page 32-3274 obtained by the cross-validated, binary, linear classification model \( CVMdl \). That is, for every fold, \( \text{kfoldMargin} \) estimates the classification margins for observations that it holds out when it trains using all other observations.

\( m \) contains classification margins for each regularization strength in the linear classification models that comprise \( CVMdl \).

Input Arguments

\( CVMdl \) — Cross-validated, binary, linear classification model
\text{ClassificationPartitionedLinear} model object

Cross-validated, binary, linear classification model, specified as a \text{ClassificationPartitionedLinear} model object. You can create a \text{ClassificationPartitionedLinear} model using \text{fitclinear} and specifying any one of the cross-validation, name-value pair arguments, for example, \text{CrossVal}.

To obtain estimates, \( \text{kfoldMargin} \) applies the same data used to cross-validate the linear classification model (\( X \) and \( Y \)).
Output Arguments

m — Cross-validated classification margins
numeric vector | numeric matrix

Cross-validated classification margins on page 32-3274, returned as a numeric vector or matrix.

m is \( n\)-by-\( L \), where \( n \) is the number of observations in the data that created CVMdl (see \( X \) and \( Y \)) and \( L \) is the number of regularization strengths in CVMdl (that is, numel(CVMdl.Trained{1}.Lambda)).

\( m(i,j) \) is the cross-validated classification margin of observation \( i \) using the linear classification model that has regularization strength \( \text{CVMdl.Trained{1}.Lambda}(j) \).

Data Types: single | double

Examples

Estimate k-Fold Cross-Validation Margins

Load the NLP data set.

load nlpdata

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

\[ Y_{\text{stats}} = Y == '\text{stats}' \; \]

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

\[ \text{rng}(1); \% \text{For reproducibility} \]
\[ \text{CVMdl} = \text{fitclinear}(X,Y_{\text{stats}},'\text{CrossVal}','\text{on}'); \]
CVMdl is a ClassificationPartitionedLinear model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the cross-validated margins.

```matlab
m = kfoldMargin(CVMdl);
size(m)
```

ans = 1×2

31572 1

`m` is a 31572-by-1 vector. `m(j)` is the average of the out-of-fold margins for observation `j`.

Plot the `k`-fold margins using box plots.

```matlab
figure;
boxplot(m);
h = gca;
h.YLim = [-5 30];
title('Distribution of Cross-Validated Margins')
```
Feature Selection Using $k$-fold Margins

One way to perform feature selection is to compare $k$-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate $k$-Fold Cross-Validation Margins” on page 32-3267.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```
Create these two data sets:

- **fullX** contains all predictors.
- **partX** contains 1/2 of the predictors chosen at random.

```matlab
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```matlab
CVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

*CVMdl* and *PCVMdl* are `ClassificationPartitionedLinear` models.

Estimate the $k$-fold margins for each classifier. Plot the distribution of the $k$-fold margins sets using box plots.

```matlab
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',...%
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```
The distributions of the margins of the two classifiers are similar.

**Find Good Lasso Penalty Using k-fold Margins**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k-fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Margins” on page 32-3267.
load nlpdata
Ystats = Y == 'stats';
X = X';

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^1$.

Lambda = logspace(-8,1,11);

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedLinear model. Because fitclinear implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models that the software trains on each fold.

Estimate the $k$-fold margins for each regularization strength.

m = kfoldMargin(CVMdl);
size(m)

ans =
    31572         11
$m$ is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the $k$-fold margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```matlab
figure;
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```
Several values of Lambda yield k-fold margin distributions that are compacted near 10000^1. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the k-fold margin distributions start decreasing.

LambdaFinal = Lambda(5);

Train a linear classification model using the entire data set and specify the desired regularization strength.

MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);

To estimate labels for new observations, pass MdlFinal and the new data to predict.

**Definitions**

**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. f(x) is the positive-class classification score for the observation x. The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.
**Classification Score**

For linear classification models, the raw classification score for classifying the observation $x$, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$  

For the model with regularization strength $j$, $\beta_j$ is the estimated column vector of coefficients (the model property `Beta(:,j)` and $b_j$ is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying $x$ into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationLinear` | `ClassificationPartitionedLinear` | `kfoldEdge` | `kfoldPredict` | `margin`

**Introduced in R2016a**
**kfoldMargin**

Classification margins for observations not used in training

**Syntax**

```matlab
m = kfoldMargin(CVMdl)
```

```matlab
m = kfoldMargin(CVMdl,Name,Value)
```

**Description**

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 32-3288 obtained by `CVMdl`, which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

`m = kfoldMargin(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme or verbosity level.

**Input Arguments**

`CVMdl` — Cross-validated, ECOC model composed of linear classification models
`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model object using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2 Setting the name-value pair argument Learners to 'linear' or a linear classification model template returned by templateLinear

To obtain estimates, kfoldMargin applies the same data used to cross-validate the ECOC model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>

<td>( [1 - y_j (2s_j - 1)]^2/2 )</td>
</tr>
</tbody>
</table>

The software normalizes the binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.
For a custom binary loss function, e.g., customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction should have this form

\[
bLoss = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \( Mdl.CodingMatrix \).
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are linear classification models using:

- SVM, then BinaryLoss is 'hinge'
- Logistic regression, then BinaryLoss is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.
To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', 1).

**Verbose** — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**m** — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins on page 32-3288, returned as a numeric vector or matrix.

m is n-by-L, where n is the number of observations in X and L is the number of regularization strengths in Mdl (that is, numel(Mdl.Lambda)).

m(i, j) is the cross-validated classification margin of observation i using the ECOC model, composed of linear classification models, that has regularization strength Mdl.Lambda(j).

**Examples**

**Estimate k-Fold Cross-Validation Margins**

Load the NLP data set.
load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';

Cross-validate a multiclass, linear classification model.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the \( k \)-fold margins.

\[
m = \text{kfoldMargin}(\text{CVMdl});
\]

\[
\text{size}(m)
\]

ans = 1x2

31572     1

\( m \) is a 31572-by-1 vector. \( m(j) \) is the average of the out-of-fold margins for observation \( j \).

Plot the \( k \)-fold margins using box plots.

figure;
boxplot(m);
h = gca;
h.YLim = [-5 5];
title('Distribution of Cross-Validated Margins')
Feature Selection Using \( k \)-fold Margins

One way to perform feature selection is to compare \( k \)-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate \( k \)-Fold Cross-Validation Margins” on page 32-3279, and orient the predictor data so that observations correspond to columns.
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';

Create these two data sets:

- **fullX** contains all predictors.
- **partX** contains 1/2 of the predictors chosen at random.

rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

t = templateLinear('Solver','sparsa');

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
                 'ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
                 'ObservationsIn','columns');

CVMdl and PCVMdl are ClassificationPartitionedLinearECOC models.

Estimate the k-fold margins for each classifier. Plot the distribution of the k-fold margins sets using box plots.

fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',... 
        {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')
The distributions of the \( k \)-fold margins of the two classifiers are similar.

**Find Good Lasso Penalty Using \( k \)-fold Margins**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of \( k \)-fold margins.

Load the NLP data set. Preprocess the data as in “Feature Selection Using \( k \)-fold Margins” on page 32-3281.
load nlpdata
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';

Create a set of 11 logarithmically-spaced regularization strengths from \( 10^{-8} \) through \( 10^1 \).

\[ \text{Lambda} = \text{logspace}(-8,1,11); \]

Create a linear classification model template that specifies using logistic regression with a lasso penalty, using each of the regularization strengths, optimizing the objective function using SpaRSA, and reducing the tolerance on the gradient of the objective function to \( 1e-8 \).

\[ t = \text{templateLinear}('\text{Learner}','\text{logistic}', '\text{Solver}', '\text{sparsa}',... '\text{Regularization}','\text{lasso}', '\text{Lambda}', \text{Lambda}, '\text{GradientTolerance}', 1e-8); \]

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

\[ \text{rng}(10); \% \text{For reproducibility} \]
\[ \text{CVMdl} = \text{fitcecoc}(X,Y,'\text{Learners}',t,'\text{ObservationsIn}','\text{columns}','\text{KFold}',5) \]

\[ \text{CVMdl} = \]
\[ \text{classreg.learning.partition.ClassificationPartitionedLinearECOC} \]
\[ \text{CrossValidatedModel: 'Linear'} \]
\[ \text{ResponseName: 'Y'} \]
\[ \text{NumObservations: 31572} \]
\[ \text{KFold: 5} \]
\[ \text{Partition: [1x1 cvpartition]} \]
\[ \text{ClassNames: [comm dsp simulink others]} \]
\[ \text{ScoreTransform: 'none'} \]

Properties, Methods

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the \( k \)-fold margins for each regularization strength. The scores for logistic regression are in \([0,1]\). Apply the quadratic binary loss.

\[ m = \text{kfoldMargin(CVMdl,'\text{BinaryLoss}','\text{quadratic}');} \]
\[ \text{size(m)} \]
m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k-fold margins for each regularization strength.

```matlab
figure;
boxplot(m)
ylabel('Cross-validated margins')
xlabel('Lambda indices')
```

Several values of Lambda yield similarly high margin distribution centers with low spreads. Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier.
Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

\[
\text{LambdaFinal} = \text{Lambda}(5);
\]

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength LambdaFinal.

\[
t = \text{templateLinear('Learner','logistic','Solver','sparsa',...}
\quad \text{'Regularization','lasso',\text{Lambda},\text{Lambda}(5),\text{GradientTolerance},1e-8);}
MdlFinal = \text{fitcecoc}(X,Y,'Learners',t,'ObservationsIn','columns');
\]

To estimate labels for new observations, pass MdlFinal and the new data to predict.

**Definitions**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k, j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).
\]
In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j) / \sum_{j=1}^{L} m_{kj}.
\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j,s_j)\).

<table>

</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.
Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

References

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2016a
kfoldMargin

Classification margins for observations not used for training

Syntax

M = kfoldMargin(obj)

Description

M = kfoldMargin(obj) returns classification margins obtained by cross-validated classification model obj. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

obj

A partitioned classification model of type ClassificationPartitionedModel or ClassificationPartitionedEnsemble.

Output Arguments

M

The classification margin.

Examples

Estimate the k-fold Margins of a Classifier

Find the k-fold margins for an ensemble that classifies the ionosphere data.
Load the `ionosphere` data set.

```matlab
load ionosphere
```

Create a template tree stump.

```matlab
t = templateTree('MaxNumSplits',1);
```

Train a classification ensemble of decision trees. Specify `t` as the weak learner.

```matlab
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross validate the classifier using 10-fold cross validation.

```matlab
cvens = crossval(Mdl);
```

Compute the k-fold margins. Display summary statistics for the margins.

```matlab
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'});
```

<table>
<thead>
<tr>
<th></th>
<th>Min</th>
<th>Mean</th>
<th>Max</th>

</thead>
<tbody>
<tr>
<td></td>
<td>-11.312</td>
<td>7.3236</td>
<td>23.517</td>
</tr>
</tbody>
</table>

**Definitions**

**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.
Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-7.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- **AdaBoostM1** scores range from $-\infty$ to $\infty$.
- **Bag** scores range from $0$ to $1$.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```
Prune the tree:

treel = prune(tree,'Level',1);
view(treel,'Mode','Graph')
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
[~,score] = predict(tree1,X(1:10));
[(score X(1:10,:))]
```
Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95,1) instead of the expected 5 observations.

ClassificationPartitionedModel | crossval | kfoldEdge | kfoldLoss | kfoldPredict | kfoldfun
kfoldPredict

Package: classreg.learning.partition

Classify observations in cross-validated ECOC model

Syntax

label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(__)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)

Description

label = kfoldPredict(CVMdl) returns class labels predicted by the cross-validated ECOC model (ClassificationPartitionedECOC) CVMdl. For every fold, kfoldPredict predicts class labels for observations that it holds out during training. CVMdl.X contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

label = kfoldPredict(CVMdl,Name,Value) returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

[label,NegLoss,PBScore] = kfoldPredict(__) additionally returns negated values of the average binary loss per class (NegLoss) for validation-fold observations and positive-class scores (PBScore) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is sparserandom or denserandom), then PBScore is empty ([]).
[label,NegLoss,PBScore,Posterior] = kfoldPredict(___) additionally returns posterior class probability estimates for validation-fold observations (Posterior).

To obtain posterior class probabilities, you must set 'FitPosterior',1 when training the cross-validated ECOC model using fitcecoc. Otherwise, kfoldPredict throws an error.

### Examples

#### Predict k-Fold Cross-Validation Labels

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order:

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Predict the validation-fold labels. Print a random subset of true and predicted labels.

```matlab
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
'VariableNames',{'TrueLabels','PredictedLabels'})
```

ans=10×2 table
     TrueLabels    PredictedLabels
           {'setosa'     }    {'setosa'     }
         {'versicolor' }    {'versicolor'}
         {'virginica'  }    {'virginica' }
         {'setosa'     }    {'versicolor'}
         {'setosa'     }    {'versicolor'}
         {'setosa'     }    {'virginica' }
         {'setosa'     }    {'setosa'     }
         {'versicolor' }    {'versicolor'}
         {'versicolor' }    {'versicolor'}
         {'virginica'  }    {'virginica' }

32-3297
CVMdl correctly labels the validation-fold observations with indices idx.

**Predict Cross-Validation Labels Using Custom Binary Loss Function**

Load Fisher's iris data set. Specify the predictor data \( X \), the response data \( Y \), and the order of the classes in \( Y \).

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder);  % Number of classes
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is \((-\infty, \infty)\). Create a custom binary loss function that:
• Maps the coding design matrix \( (M) \) and positive-class classification scores \( (s) \) for each learner to the binary loss for each observation
• Uses linear loss
• Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Alternatively, you can specify an anonymous binary loss function. In this case, create a function handle \( (\text{customBL}) \) to an anonymous binary loss function.

\[
\text{customBL} = @(M,s)\frac{\text{nanmedian}(1 - \text{bsxfun}(@\times,M,s),2)}{2};
\]

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 validation-fold observations.

\[
\text{[label,NegLoss]} = \text{kfoldPredict}(\text{CVMdl},\text{''BinaryLoss'',''}\text{customBL});
\]

\[
\text{idx} = \text{randsample}(\text{numel(label)},10);
\]

\[
\text{classOrder} = 3\times1 \text{ categorical array}
\]

\[
\begin{align*}
\text{setosa} \\
\text{versicolor} \\
\text{virginica}
\end{align*}
\]

\[
\text{table}(\text{Y(idx),label(idx),NegLoss(idx,:)},\text{''VariableNames'',''}\text{''TrueLabel'',''}\text{''PredictedLabel'',''}\text{''NegLoss''})
\]

\[
\begin{array}{ccc}
\text{TrueLabel} & \text{PredictedLabel} & \text{NegLoss} \\
\hline
\text{setosa} & \text{versicolor} & 0.37141 \\
\text{versicolor} & \text{versicolor} & -1.2167 \\
\text{setosa} & \text{versicolor} & 0.23927 \\
\text{virginica} & \text{virginica} & -1.9154 \\
\text{versicolor} & \text{versicolor} & -1.3746 \\
\text{setosa} & \text{versicolor} & 0.20061 \\
\text{virginica} & \text{versicolor} & -1.4928 \\
\text{virginica} & \text{virginica} & -1.7669 \\
\text{setosa} & \text{versicolor} & 0.19999 \\
\text{setosa} & \text{versicolor} & 0.16108 \\
\end{array}
\]

\[
\text{32-3299}
\]
The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

**Estimate Cross-Validation Posterior Probabilities**

Load Fisher's iris data set. Use the petal dimensions as the predictor data X. Specify the response data Y and the order of the classes in Y.

```matlab
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```matlab
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
t
```

t is an SVM template. Most of its properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train and cross-validate an ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (returned by `kfoldPredict`) using the 'FitPosterior' name-value pair argument. Specify the class order.

```matlab
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...  'ClassNames',classOrder);
CVMdl
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities. Use 10 random initial values for the Kullback-Leibler algorithm.

```matlab
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
Posterior
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all the binary learners compute posterior probabilities, the binary loss function is quadratic.

Display a random set of results.
idx = randsample(size(X,1),10);
CVMdl.ClassNames
ans = 3x1 categorical array
    setosa
    versicolor
    virginica

table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
ans=10×3 table
    TrueLabel     PredLabel                   Posterior
    __________    __________    ______________________________________
    versicolor    versicolor     0.0086394       0.98243     0.0089291
    versicolor    virginica     2.2197e-14       0.12447       0.87553
    setosa        setosa             0.999    0.00022837    0.00076884
    versicolor    versicolor    2.2194e-14       0.98916      0.010839
    virginica     virginica       0.012318      0.012925       0.97468
    virginica     virginica      0.0015571     0.0015638       0.99688
    virginica     virginica      0.0042895     0.0043556       0.99135
    setosa        setosa             0.999    0.00028329    0.00071382
    virginica     virginica      0.0094721     0.0098231        0.9807
    setosa        setosa             0.999    0.00013562    0.00086192

The columns of Posterior correspond to the class order of CVMdl.ClassNames.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the arrhythmia data set. Examine the response data Y.

load arrhythmia
Y = categorical(Y);
tabulate(Y)

    Value    Count    Percent
        1       245    54.20%
Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

\[
t = \text{templateEnsemble}('\text{GentleBoost}', 50, '\text{Tree}');
\]

\[t\] is a template object. Most of the options are empty ([]). The software uses default values for all empty options during training.

Because the response variable contains many classes, specify a sparse random coding design.

\[
\text{rng}(1); \quad \% \text{For reproducibility}
\]
\[
\text{Coding} = \text{designecoc}(K, '\text{sparserandom}');
\]

Train and cross-validate an ECOC model using parallel computing. Fit posterior probabilities (returned by \text{kfoldPredict}).

\[
\text{pool} = \text{parpool}; \quad \% \text{Invokes workers}
\]

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

\[
\text{options} = \text{statset}('\text{UseParallel}', 1);
\]
\[
\text{CVMdl} = \text{fitcecoc}(X, Y, '\text{Learner}', t, '\text{Options}', options, '\text{Coding}', Coding, ...
\quad '\text{FitPosterior}', 1, '\text{CrossVal}', 'on');
\]

Warning: One or more folds do not contain points from all the groups.
CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

The pool invokes six workers, although the number of workers might vary among systems. Because some classes have low relative frequency, one or more folds most likely do not contain observations from all classes.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of validation-fold observations.

```matlab
[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),
    'VariableNames',{'OOFSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

<table>

</tbody>
</table>

**Input Arguments**

**CVMdl — Cross-validated ECOC model**

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model in two ways:
• Pass a trained ECOC model (ClassificationECOC) to crossval.
• Train an ECOC model using fitcecoc and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: kfoldPredict(CVMdl,'PosteriorMethod','qp') specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

• This table contains names and descriptions of the built-in functions, where yj is a class label for a particular binary learner (in the set {–1,1,0}), sj is the score for observation j, and g(yj,sj) is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>g(yj,sj)</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>(–∞,∞)</td>
<td>[\log[1 + \exp(-2y_j s_j)]/2\log(2)]</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>(–∞,∞)</td>
<td>[\exp(-y_j s_j)/2]</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>[0,1] or (–∞,∞)</td>
<td>[(1 - \text{sign}(y_j s_j))/2]</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>(–∞,∞)</td>
<td>[\max(0,1 - y_j s_j)/2]</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>(–∞,∞)</td>
<td>[1 - y_j s_j]/2</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>(–∞,∞)</td>
<td>[\log[1 + \exp(-y_j s_j)]/2\log(2)]</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>[0,1]</td>
<td>[(1 - y_j (2s_j - 1))^2/2]</td>
</tr>
</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, customFunction, specify its function handle 'BinaryLoss',@customFunction.

customFunction has this form:

```
bLoss = customFunction(M,s)
```

where:

- $M$ is the $K$-by-$L$ coding matrix stored in Mdl.CodingMatrix.
- $s$ is the 1-by-$L$ row vector of classification scores.
- $bLoss$ is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$ is the number of classes.
- $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

- SVMs or either linear or kernel classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by AdaboostM1 or GentleBoost, then `BinaryLoss` is 'exponential'
- Ensembles trained by LogitBoost, then `BinaryLoss` is 'binodeviance'
- Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior',1 in fitcecoc), then `BinaryLoss` is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle
Decoding — Decoding scheme
'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

NumKLInitializations — Number of random initial values
0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod','kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4988.

Example: 'NumKLInitializations',5

Data Types: single | double

Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options',statset('UseParallel',1).

PosteriorMethod — Posterior probability estimation method
'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

32-3306
• If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4988.
• If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-4990.
• If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: 'PosteriorMethod','qp'

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: `single` | `double`

**Output Arguments**

**label — Predicted class labels**

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type and number of rows as `CVMdl.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).
NegLoss — Negated average binary losses
numeric matrix

Negated average binary losses, returned as a numeric matrix. NegLoss is an \( n \)-by-\( K \) matrix, where \( n \) is the number of observations (\( \text{size(CVMdl.X,1)} \)) and \( K \) is the number of unique classes (\( \text{size(CVMdl.ClassNames,1)} \)).

PBScore — Positive-class scores
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. PBScore is an \( n \)-by-\( L \) matrix, where \( n \) is the number of observations (\( \text{size(CVMdl.X,1)} \)) and \( L \) is the number of binary learners (\( \text{size(CVMdl.CodingMatrix,2)} \)).

If the coding matrix varies across folds (that is, the coding scheme is sparserandom or denserandom), then PBScore is empty (\([]\)).

Posterior — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. Posterior is an \( n \)-by-\( K \) matrix, where \( n \) is the number of observations (\( \text{size(CVMdl.X,1)} \)) and \( K \) is the number of unique classes (\( \text{size(CVMdl.ClassNames,1)} \)).

You must set 'FitPosterior', 1 when training the cross-validated ECOC model using fitcecoc in order to request Posterior. Otherwise, the software throws an error.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-22, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L \left| m_{kj} \right| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-22, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^L \left| m_{kj} \right| g(m_{kj}, s_j)}{\sum_{j=1}^L \left| m_{kj} \right|}.$$

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>

<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/2\log(2)$</td>
</tr>
</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

### Algorithms

- The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:
  - \( m_{kj} \) is the element \((k,j)\) of the coding design matrix \( M \).
  - \( I \) is the indicator function.
  - \( \hat{p}_k \) is the class posterior probability estimate for class \( k \) of an observation, \( k = 1,...,K \).
  - \( r_j \) is the positive-class posterior probability for binary learner \( j \). That is, \( r_j \) is the probability that binary learner \( j \) classifies an observation into the positive class, given the training data.

### Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

\[
\Delta(r, \hat{r}) = \sum_{j=1}^{L} w_j \left[ r_j \log \frac{r_j}{\hat{r}_j} + (1-r_j) \log \frac{1-r_j}{1-\hat{r}_j} \right],
\]

where \( w_j = \sum_{S_j} w^*_i \) is the weight for binary learner \( j \).
• \( S_j \) is the set of observation indices on which binary learner \( j \) is trained.

• \( w^*_i \) is the weight of observation \( i \).

The software minimizes the divergence iteratively. The first step is to choose initial values \( \hat{p}^{(0)}_k; k = 1,...,K \) for the class posterior probabilities.

• If you do not specify 'NumKLIterations', then the software uses both sets of deterministic initial values described next, and uses the one that minimizes \( \Delta \).

• \( \hat{p}^{(0)}_k = 1 / K; k = 1,...,K \).

• \( \hat{p}^{(0)}_k; k = 1,...,K \) is the solution of the system

\[
M_{01} \hat{p}^{(0)} = r,
\]

where \( M_{01} \) is \( M \) with all \( m_{kj} = -1 \) replaced with 0, and \( r \) is a vector of positive-class posterior probabilities returned by the \( L \) binary learners [Dietterich et al.] on page 18-222. The software uses \texttt{lsqnonneg} to solve the system.

• If you specify 'NumKLIterations', \( c \), where \( c \) is a natural number, then the software does the following to choose \( \hat{p}^{(0)}_k; k = 1,...,K \), and uses the one that minimizes \( \Delta \).

• The software chooses both sets of deterministic initial values as described previously.

• The software randomly generates \( c \) vectors of length \( K \) using \texttt{rand}, and then normalizes each vector to sum to 1.

At iteration \( t \), the software completes these steps:

1. Compute

\[
\hat{p}^{(t)}_j = \frac{\sum_{k=1}^{K} \hat{p}^{(t)}_k I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}^{(t)}_k I(m_{kj} = +1 \cup m_{kj} = -1)}.
\]
2 Estimate the next class posterior probability using

\[
\hat{p}_k^{(t+1)} = \frac{\sum_{j=1}^{L} w_j \left[ r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1) \right]}{\sum_{j=1}^{L} w_j \left[ \hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1) \right]}.
\]

3 Normalize \( \hat{p}_k^{(t+1)} \); \( k = 1, \ldots, K \) so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-222 and [Zadrozny] on page 18-224.

**Posterior Estimation Using Quadratic Programming**

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1 Estimate the positive-class posterior probabilities, \( r_j \), for binary learners \( j = 1, \ldots, L \).

2 Using the relationship between \( r_j \) and \( \hat{p}_k \) [Wu et al.] on page 18-224, minimize

\[
\sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = +1) \right]^2
\]

with respect to \( \hat{p}_k \) and the restrictions

\[
0 \leq \hat{p}_k \leq 1
\]

\[
\sum_k \hat{p}_k = 1.
\]

The software performs minimization using `quadprog`.

Introduced in R2014b
**kfoldPredict**

**Package:** classreg.learning.partition

Classify observations in cross-validated kernel classification model

**Syntax**

```matlab
label = kfoldPredict(CVMdl)
[label,score] = kfoldPredict(CVMdl)
```

**Description**

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations.

`[label,score] = kfoldPredict(CVMdl)` also returns classification scores on page 32-3320 for both classes.

**Examples**

**Classify Observations Using Cross-Validation**

Classify observations using a cross-validated, binary kernel classifier, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```matlab
load ionosphere
```

Cross-validate a binary kernel classification model using the data.
rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on')

CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernel 
    CrossValidatedModel: 'Kernel' 
    ResponseName: 'Y' 
    NumObservations: 351 
    KFold: 10 
    Partition: [1x1 cvpartition] 
    ClassNames: {'b' 'g'} 
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Classify the observations that fitckernel does not use in training the folds.

label = kfoldPredict(CVMdl);

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

C = confusionmat(Y,label,'Order',{'b','g'})

C = 2x2

    119     7
    32    193

The CVMdl model misclassifies 32 good ('g') radar returns as being bad ('b') and misclassifies 7 bad radar returns as being good.

Estimate k-Fold Cross-Validation Posterior Class Probabilities

Estimate posterior class probabilities using a cross-validated, binary kernel classifier, and determine the quality of the model by plotting a receiver operating characteristic (ROC)
curve. Cross-validated kernel classification models return posterior probabilities for logistic regression learners only.

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

load ionosphere

Cross-validate a binary kernel classification model using the data. Specify the class order, and fit logistic regression learners.

rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on', ... 'ClassNames',{'b','g'},'Learner','logistic')

CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'

Properties, Methods

CVMdl is a ClassificationPartitionedKernel model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Predict the posterior class probabilities for the observations that fitckernel does not use in training the folds.

 [~,posterior] = kfoldPredict(CVMdl);

The output posterior is a matrix with two columns and n rows, where n is the number of observations. Column i contains posterior probabilities of CVMdl.ClassNames(i) given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.
[fpr,tpr,~,auc] = perfcurve(Y,posterior(:,2),CVMdl.ClassNames(2));

auc

auc = 0.9441

The AUC is close to 1, which indicates that the model predicts labels well.

Plot an ROC curve.

plot(fpr,tpr)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
Input Arguments

CVMdl — Cross-validated, binary kernel classification model
ClassificationPartitionedKernel model object

Cross-validated, binary kernel classification model, specified as a
ClassificationPartitionedKernel model object. You can create a
ClassificationPartitionedKernel model by using fitckernel and specifying any
one of the cross-validation name-value pair arguments.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the
kernel classification model (X and Y).

Output Arguments

label — Predicted class labels
categorical array | character array | logical matrix | numeric matrix | cell array of
class labels
character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric
matrix, or cell array of character vectors.

label has \( n \) rows, where \( n \) is the number of observations in \( X \), and has the same data
type as the observed class labels (\( Y \)) used to train \( CVMdl \). (The software treats string
arrays as cell arrays of character vectors.)

kfoldPredict classifies observations into the class yielding the highest score.

score — Classification scores
numeric array

Classification scores on page 32-3320, returned as an \( n \)-by-2 numeric array, where \( n \) is
the number of observations in \( X \). score\((i,j)\) is the score for classifying observation \( i \)
into class \( j \). The order of the classes is stored in \( CVMdl.ClassNames \).

If \( CVMdl.Trained{1}.Learner \) is 'logistic', then classification scores are posterior
probabilities.
Definitions

Classification Score

For kernel classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by

\[
f(x) = T(x)\beta + b.
\]

- \( T(\cdot) \) is a transformation of an observation for feature expansion.
- \( \beta \) is the estimated column vector of coefficients.
- \( b \) is the estimated scalar bias.

The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

ClassificationPartitionedKernel | fitckernel

Introduced in R2018b
kfoldPredict

**Package:** classreg.learning.partition

Classify observations in cross-validated kernel ECOC model

**Syntax**

```matlab
label = kfoldPredict(CVMdl)
labeled = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(__)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(__)
```

**Description**

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations. `kfoldPredict` applies the same data used to create `CVMdl` (see `fitcecoc`).

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(__)` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty ([]).
[label,NegLoss,PBScore,Posterior] = kfoldPredict(___) additionally returns posterior class probability estimates for validation-fold observations (Posterior).

To obtain posterior class probabilities, the kernel classification binary learners must be logistic regression models. Otherwise, kfoldPredict throws an error.

Examples

Classify Observations Using Cross-Validation

Classify observations using a cross-validated, multiclass kernel ECOC classifier, and display the confusion matrix for the resulting classification.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

load fisheriris
X = meas;
Y = species;

Cross-validate an ECOC model composed of kernel binary learners.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
CVMdl = 
    classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
    ResponseName: 'Y'
    NumObservations: 150
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

Properties, Methods
CVMdl is a ClassificationPartitionedKernelECOC model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Classify the observations that fitcecoc does not use in training the folds.

```matlab
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```matlab
C = confusionmat(Y,label,'Order',{'setosa','versicolor','virginica'})
```

```
C = 3×3
50 0 0
0 46 4
0 1 49
```

The CVMdl model misclassifies four 'versicolor' irises as 'virginica' irises and misclassifies one 'virginica' iris as a 'versicolor' iris.

### Predict Cross-Validation Labels Using Custom Binary Loss

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```matlab
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model of kernel classification models using 5-fold cross-validation.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','KFold',5)
```

```
CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernelECOC
        CrossValidatedModel: 'KernelECOC'
        ResponseName: 'Y'
```

32-3323
NumObservations: 150
KFold: 5
Partition: [1x1 cvpartition]
ClassNames: {'setosa' 'versicolor' 'virginica'}
ScoreTransform: 'none'

CVMdl is a ClassificationPartitionedKernelECOC model. It contains the property
Trained, which is a 5-by-1 cell array of CompactClassificationECOC models.

By default, the kernel classification models that compose the
CompactClassificationECOC models use SVMs. SVM scores are signed distances
from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create
a custom binary loss function that:

- Maps the coding design matrix ($M$) and positive-class classification scores ($s$) for each
  learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the
MATLAB® path. Or, you can specify an anonymous binary loss function. In this case,
create a function handle (customBL) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the
median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
```

```matlab
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
    'VariableNames',{{'True'};'Predicted'};...
    unique(CVMdl.ClassNames))
```

```
ans=10×5 table
     True          Predicted       setosa     versicolor    virginica
   _______    ____________    ________    __________    _________
32       Predicted       setosa     versicolor    virginica
```
The cross-validated model correctly predicts the labels for 9 of the 10 random observations.

**Estimate k-Fold Cross-Validation Posterior Class Probabilities**

Estimate posterior class probabilities using a cross-validated, multiclass kernel ECOC classification model. Kernel classification models return posterior probabilities for logistic regression learners only.

Load Fisher's iris data set. \(X\) contains flower measurements, and \(Y\) contains the names of flower species.

```plaintext
load fisheriris
X = meas;
Y = species;
```

Create a kernel template for the binary kernel classification models. Specify to fit logistic regression learners.

```plaintext
t = templateKernel('Learner','logistic')
t =
Fit template for classification Kernel.
```

```
BetaTolerance: []
BlockSize: []
BoxConstraint: []
Epsilon: []
NumExpansionDimensions: []
GradientTolerance: []
```
t is a kernel template. Most of its properties are empty. When training an ECOC classifier using the template, the software sets the applicable properties to their default values.

Cross-validate an ECOC model using the kernel template.

```matlab
rng('default'); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on')
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities.

```matlab
[label,~,~,Posterior] = kfoldPredict(CVMdl);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is quadratic.
Display the posterior probabilities for 10 randomly selected observations.

idx = randsample(size(X,1),10);
CVMdl.ClassNames

ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})

ans=10×3 table
    TrueLabel       PredLabel                 Posterior
    ____________    ____________    ________________________________
    'setosa'        'setosa'         0.68216     0.18546     0.13238
    'virginica'     'virginica'       0.1581     0.14405     0.69785
    'virginica'     'virginica'     0.071807    0.093291      0.8349
    'setosa'        'setosa'         0.74918     0.11434     0.13648
    'versicolor'    'versicolor'     0.09375     0.67149     0.23476
    'versicolor'    'versicolor'    0.036202     0.85544     0.10836
    'versicolor'    'versicolor'      0.2252     0.50473     0.27007
    'virginica'     'virginica'     0.061562     0.11086     0.82758
    'setosa'        'setosa'         0.42448     0.21181     0.36371
    'virginica'     'virginica'     0.082705      0.1428      0.7745

The columns of Posterior correspond to the class order of CVMdl.ClassNames.

Input Arguments

CVMdl — Cross-validated kernel ECOC model
ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:
• 'Learners' – Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
• One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldPredict(CVMdl,'PosteriorMethod','qp') specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>
<tr>

</tbody>
</table>
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss','@customFunction`.

  `customFunction` has this form:

  \[
  bLoss = customFunction(M,s)
  \]

  where:

  - \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
  - \( s \) is the 1-by-\( L \) row vector of classification scores.
  - \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - \( K \) is the number of classes.
  - \( L \) is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3332.

Example: `'Decoding','lossbased'`

**NumKLInitializations — Number of random initial values**

\( 0 \) (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer scalar.
If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod','kl' (the default), then the software ignores the value of NumKLIInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3334.

Example: 'NumKLIInitializations',5

Data Types: single | double

Options — Estimation options

| [] (default) | structure array returned by statset |

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel',1).

PosteriorMethod — Posterior probability estimation method

| 'kl' (default) | 'qp' |

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If PosteriorMethod is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3334.
- If PosteriorMethod is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-3336.
- If you do not request the fourth output argument (Posterior), then the software ignores the value of PosteriorMethod.

Example: 'PosteriorMethod','qp'

Verbose — Verbosity level

| 0 (default) | 1 |
Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

**Output Arguments**

`label — Predicted class labels`  
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type and number of rows as `CVMdl.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss — Negated average binary losses`  
numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n-by-K matrix, where n is the number of observations (size(CVMdl.Y,1)) and K is the number of unique classes (size(CVMdl.ClassNames,1)).

`PBScore — Positive-class scores`  
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n-by-L matrix, where n is the number of observations (size(CVMdl.Y,1)) and L is the number of binary learners (size(CVMdl.CodingMatrix,2)).

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty ([]).
**Posterior — Posterior class probabilities**

numeric matrix

Posterior class probabilities, returned as a numeric matrix. **Posterior** is an \( n \)-by-\( K \) matrix, where \( n \) is the number of observations (\( \text{size}(\text{CVMdl}.Y,1) \)) and \( K \) is the number of unique classes (\( \text{size}(\text{CVMdl}.\text{ClassNames},1) \)).

To return posterior probabilities, each kernel classification binary learner must have its **Learner** property set to 'logistic'. Otherwise, the software throws an error.

**Definitions**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^{L} m_{kj} g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,
\[\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.\]

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \(y_j\) is a class label for a particular binary learner (in the set \{-1,1,0\}), \(s_j\) is the score for observation \(j\), and \(g(y_j, s_j)\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>(g(y_j, s_j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>((\infty, \infty))</td>
<td>(\log[1 + \exp(-2y_j s_j)]/\left[2\log(2)\right])</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>((\infty, \infty))</td>
<td>(\exp(-y_j s_j)/2)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>([0,1]) or ((\infty, \infty))</td>
<td>([1 - \text{sign}(y_j s_j)]/2)</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>((\infty, \infty))</td>
<td>(\max(0,1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>((\infty, \infty))</td>
<td>((1 - y_j s_j)/2)</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>((\infty, \infty))</td>
<td>(\log[1 + \exp(-y_j s_j)]/\left[2\log(2)\right])</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>([0,1])</td>
<td>([1 - y_j (2s_j - 1)]^2/2)</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \(y_j = 0\), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Algorithms**

- The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:
• \( m_{kj} \) is the element \((k,j)\) of the coding design matrix \( M \).
• \( I \) is the indicator function.
• \( \hat{\hat{p}}_k \) is the class posterior probability estimate for class \( k \) of an observation, \( k = 1,\ldots,K \).
• \( r_j \) is the positive-class posterior probability for binary learner \( j \). That is, \( r_j \) is the probability that binary learner \( j \) classifies an observation into the positive class, given the training data.

**Posterior Estimation Using Kullback-Leibler Divergence**

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

\[
\Delta(r, r) = \sum_{j=1}^{L} w_j \left[ r_j \log \frac{r_j}{1-r_j} + (1-r_j) \log \frac{1-r_j}{r_j} \right],
\]

where \( w_j = \sum_{S_j} w_i^* \) is the weight for binary learner \( j \).
• \( S_j \) is the set of observation indices on which binary learner \( j \) is trained.
• \( w_i^* \) is the weight of observation \( i \).

The software minimizes the divergence iteratively. The first step is to choose initial values \( \hat{\hat{p}}_k^{(0)}; k = 1,\ldots,K \) for the class posterior probabilities.
• If you do not specify 'NumKLLIterations', then the software uses both sets of deterministic initial values described next, and uses the one that minimizes \( \Delta \).
  • \( \hat{\hat{p}}_k^{(0)} = 1/K; k = 1,\ldots,K \).
  • \( \hat{\hat{p}}_k^{(0)}; k = 1,\ldots,K \) is the solution of the system

\[ M_{01} \hat{\hat{p}}^{(0)} = r, \]
where $M_{01}$ is $M$ with all $m_{kj} = -1$ replaced with 0, and $r$ is a vector of positive-class posterior probabilities returned by the $L$ binary learners [Dietterich et al.] on page 18-222. The software uses lsqnonneg to solve the system.

- If you specify 'NumKLIterations', $c$, where $c$ is a natural number, then the software does the following to choose $\hat{p}_k^{(0)}$, $k = 1, \ldots, K$, and uses the one that minimizes $\Delta$.

  - The software chooses both sets of deterministic initial values as described previously.
  - The software randomly generates $c$ vectors of length $K$ using rand, and then normalizes each vector to sum to 1.

At iteration $t$, the software completes these steps:

1. Compute

   $$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = 1) + \sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = -1)}.$$

2. Estimate the next class posterior probability using

   $$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j [r_j I(m_{kj} = 1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^{L} \hat{r}_j^{(t)} I(m_{kj} = 1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)}.$$

3. Normalize $\hat{p}_k^{(t+1)}$, $k = 1, \ldots, K$ so that they sum to 1.

4. Check for convergence.

For more details, see [Hastie et al.] on page 18-222 and [Zadrozny] on page 18-224.
Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1. Estimate the positive-class posterior probabilities, $r_j$, for binary learners $j = 1, \ldots, L$.

2. Using the relationship between $r_j$ and $\hat{p}_k$ [Wu et al.] on page 18-224, minimize

$$
\sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = +1) \right]^2
$$

with respect to $\hat{p}_k$ and the restrictions

$$
0 \leq \hat{p}_k \leq 1
$$

$$
\sum_k \hat{p}_k = 1.
$$

The software performs minimization using quadprog.

**Introduced in R2018b**
**kfoldPredict**

Predict labels for observations not used for training

**Syntax**

Label = kfoldPredict(CVMdl)
[Label,Score] = kfoldPredict(CVMdl)

**Description**

Label = kfoldPredict(CVMdl) returns cross-validated class labels predicted by the cross-validated, binary, linear classification model CVMdl. That is, for every fold, kfoldPredict predicts class labels for observations that it holds out when it trains using all other observations.

Label contains predicted class labels for each regularization strength in the linear classification models that compose CVMdl.

[Label,Score] = kfoldPredict(CVMdl) also returns cross-validated classification scores on page 32-3348 for both classes. Score contains classification scores for each regularization strength in CVMdl.

**Input Arguments**

**CVMdl — Cross-validated, binary, linear classification model**
ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model object using fitclinear and specifying any one of the cross-validation, name-value pair arguments, for example, CrossVal.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the linear classification model (X and Y).
Output Arguments

Label — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, Label is an n-by-L array of the same data type as the observed class labels (see Y) used to create CVMdl. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in the predictor data (see X) and L is the number of regularization strengths in CVMdl.Trained{1}.Lambda. That is, Label(i,j) is the predicted class label for observation i using the linear classification model that has regularization strength CVMdl.Trained{1}.Lambda(j).

If Y is a character array and L > 1, then Label is a cell array of class labels.

Score — Cross-validated classification scores

numeric array

Cross-validated classification scores on page 32-3348, returned as an n-by-2-by-L numeric array. n is the number of observations in the predictor data that created CVMdl (see X) and L is the number of regularization strengths in CVMdl.Trained{1}.Lambda. Score(i,k,j) is the score for classifying observation i into class k using the linear classification model that has regularization strength CVMdl.Trained{1}.Lambda(j). CVMdl.ClassNames stores the order of the classes.

If CVMdl.Trained{1}.Learner is 'logistic', then classification scores are posterior probabilities.

Examples

Predict k-fold Cross-Validation Labels

Load the NLP data set.

load nlpdata
\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

\[ Y_{\text{stats}} = Y == '\text{stats}' \; \]

Cross-validate a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

\[
\text{rng}(1); \; \% \text{For reproducibility}
\]
\[
\text{CVMdl} = \text{fitclinear}(X,Y_{\text{stats}},'\text{CrossVal}','on');
\]
\[
\text{Mdl1} = \text{CVMdl.Trained}{1}
\]

\[
\text{Mdl1} = \begin{array}{c}
\text{ClassificationLinear} \\
\text{ResponseName: 'Y'} \\
\text{ClassNames: [0 1]} \\
\text{ScoreTransform: 'none'} \\
\text{Beta: [34023x1 double]} \\
\text{Bias: -1.0008} \\
\text{Lambda: 3.5193e-05} \\
\text{Learner: 'svm'}
\end{array}
\]

\[
\text{CVMdl}\;\text{is a}\;\text{ClassificationPartitionedLinear}\;\text{model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.}
\]

Predict labels for the observations that \text{fitclinear} did not use in training the folds.

\[
\text{label} = \text{kfoldPredict(CVMdl)};
\]

Because there is one regularization strength in \text{Mdl1}, \text{label} is a column vector of predictions containing as many rows as observations in \( X \).

Construct a confusion matrix.

\[
\text{ConfusionTrain} = \text{confusionmat(Ystats,label)}
\]
ConfusionTrain = 2×2

<table>
<thead>
<tr>
<th></th>
<th>30009</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>1539</td>
<td></td>
</tr>
</tbody>
</table>

The model misclassifies 15 'stats' documentation pages as being outside of the Statistics and Machine Learning Toolbox documentation, and misclassifies nine pages as 'stats' pages.

**Estimate k-fold Cross-Validation Posterior Class Probabilities**

Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict k-fold Cross-Validation Labels” on page 32-3339. Transpose the predictor data matrix.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate binary, linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to 1e-8.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...%
    'Regularization','lasso','GradientTolerance',1e-8);
```

Predict the posterior class probabilities for observations not used to train each fold.

```matlab
 [~,posterior] = kfoldPredict(CVMdl);
 CVMdl.ClassNames
```

```matlab
ans = 2x1 logical array

0
1
```
Because there is one regularization strength in `CVMdl`, `posterior` is a matrix with 2 columns and rows equal to the number of observations. Column `i` contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Ystats,posterior(:,2),CVMdl.ClassNames(2));
auc
```

```
auc = 0.9990
```

The AUC is 0.9990, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```
The ROC curve indicates that the model classifies almost perfectly.

**Find Good Lasso Penalty Using Cross-Validated AUC**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare cross-validated AUC values.

Load the NLP data set. Preprocess the data as in “Estimate k-fold Cross-Validation Posterior Class Probabilities” on page 32-3341.
load nlpdata
Ystats = Y == 'stats';
X = X';

There are 9471 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

Lambda = logspace(-6,-0.5,11);

Cross-validate a binary, linear classification models that use each of the regularization strengths and 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...'
   KFold',5,'Learner','logistic','Solver','sparsa',...'
   'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl = 
   classreg.learning.partition.ClassificationPartitionedLinear
   CrossValidatedModel: 'Linear'
   ResponseName: 'Y'
   NumObservations: 31572
   KFold: 5
   Partition: [1x1 cvpartition]
   ClassNames: [0 1]
   ScoreTransform: 'none'

Properties, Methods

Mdl1 = CVMdl.Trained{1}

Mdl1 = 
   ClassificationLinear
   ResponseName: 'Y'
   ClassNames: [0 1]
   ScoreTransform: 'logit'
   Beta: [34023×11 double]
   Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 2.0316e-03 7.0642e-03 2.4744e-02 8.6048e-02 3.1220e-01]
Mdl1 is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Predict the cross-validated labels and posterior class probabilities.

[label,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames;
[n,K,L] = size(posterior)

n = 31572
K = 2
L = 11

posterior(3,1,5)
ans = 1.0000

label is a 31572-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. posterior is a 31572-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, posterior(3,1,5) indicates that the posterior probability that the first class (label 0) is assigned to observation 3 by the model that uses Lambda(5) as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

auc = 1:numel(Lambda);   % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(Ystats,posterior(:,2,j),CVMdl.ClassNames(2));
end

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',... 
    'Learner','logistic','Solver','sparsa','Regularization','lasso',... 
    'Lambda',Lambda,'GradientTolerance',1e-8); 
numNZCoeff = sum(Mdl.Beta~=0);

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure; 
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),... 
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o'; 
hL2.Marker = 'o'; 
ylabel(h(1),'
log_{10} AUC')
ylabel(h(2),'
log_{10} nonzero-coefficient frequency')
xlabel('
log_{10} Lambda')
title('Cross-Validated Statistics')
hold off
Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between $10^{-3}$ to $10^{-1}$ should suffice.

```matlab
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```matlab
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`. 
Definitions

Classification Score

For linear classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by

\[
f_j(x) = x\beta_j + b_j.
\]

For the model with regularization strength \( j \), \( \beta_j \) is the estimated column vector of coefficients (the model property \( \text{Beta}(:,j) \)) and \( b_j \) is the estimated, scalar bias (the model property \( \text{Bias}(j) \)).

The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see \( \text{ScoreTransform} \)).

Introduced in R2016a
kfoldPredict

Predict labels for observations not used for training

Syntax

Label = kfoldPredict(CVMdl)
Label = kfoldPredict(CVMdl,Name,Value)
[Label,NegLoss,PBScore] = kfoldPredict(__)
[Label,NegLoss,PBScore,Posterior] = kfoldPredict(__)

Description

Label = kfoldPredict(CVMdl) returns class labels predicted by the cross-validated ECOC model composed of linear classification models CVMdl. That is, for every fold, kfoldPredict predicts class labels for observations that it holds out when it trains using all other observations. kfoldPredict applies the same data used create CVMdl (see fitcecoc).

Also, Label contains class labels for each regularization strength in the linear classification models that compose CVMdl.

Label = kfoldPredict(CVMdl,Name,Value) returns predicted class labels with additional options specified by one or more Name,Value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

[Label,NegLoss,PBScore] = kfoldPredict(__) additionally returns, for held-out observations and each regularization strength:

- Negated values of the average binary loss per class (NegLoss).
- Positive-class scores (PBScore) for each binary learner.

[Label,NegLoss,PBScore,Posterior] = kfoldPredict(__) additionally returns posterior class probability estimates for held-out observations and for each regularization strength. To return posterior probabilities, the linear classification model learners must be logistic regression models.
**Input Arguments**

**CVMdl** — Cross-validated, ECOC model composed of linear classification models
ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using fitcecoc and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to 'linear' or a linear classification model template returned by `templateLinear`

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the ECOC model (X and Y).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**BinaryLoss** — Binary learner loss function

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>g(yj,sj)</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>(-∞,∞)</td>
<td>log[1 + exp(-2yjsj)]/[2log(2)]</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>(-∞,∞)</td>
<td>exp(-yjsj)/2</td>
</tr>
</tbody>
</table>

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where yj is a class label for a particular binary learner (in the set {-1,1,0}), sj is the score for observation j, and g(yj,sj) is the binary loss formula.
The software normalizes the binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction.`

`customFunction` should have this form

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is 'hinge'
- Logistic regression, then `BinaryLoss` is 'quadratic'

Example: 'BinaryLoss','binodeviance'

Data Types: `char` | `string` | `function_handle`
Decoding — Decoding scheme
'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

NumKLInitializations — Number of random initial values
0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

To use this option, you must:

• Return the fourth output argument (Posterior).
• The linear classification models that compose the ECOC models must use logistic regression learners (that is, CVMdl.Trained{1}.BinaryLearners{1}.Learner must be 'logistic').
• PosteriorMethod must be 'kl'.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4988.

Example: 'NumKLInitializations',5

Data Types: single | double

Options — Estimation options
[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options',statset('UseParallel',1).
PosteriorMethod — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- To use this option, you must return the fourth output argument (Posterior) and the linear classification models that compose the ECOC models must use logistic regression learners (that is, CVMdl.Trained{1}.BinaryLearners{1}.Learner must be 'logistic').
- If PosteriorMethod is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-4988.
- If PosteriorMethod is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-4990.

Example: 'PosteriorMethod','qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

Label — Cross-validated, predicted class labels
categorical array | character array | logical matrix | numeric matrix | cell array of character vectors
Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, Label is an $n$-by-$L$ array of the same data type as the observed class labels (Y) used to create CVMdl. (The software treats string arrays as cell arrays of character vectors.) $n$ is the number of observations in the predictor data ($X$) and $L$ is the number of regularization strengths in the linear classification models that compose the cross-validated ECOC model. That is, Label($i,j$) is the predicted class label for observation $i$ using the ECOC model of linear classification models that has regularization strength CVMdl.Trained{1}.BinaryLearners{1}.Lambda($j$).

If $Y$ is a character array and $L > 1$, then Label is a cell array of class labels.

The software assigns the predicted label corresponding to the class with the largest, negated, average binary loss (NegLoss), or, equivalently, the smallest average binary loss.

**NegLoss — Cross-validated, negated, average binary losses**

numeric array

Cross-validated, negated, average binary losses, returned as an $n$-by-$K$-by-$L$ numeric matrix or array. $K$ is the number of distinct classes in the training data and columns correspond to the classes in CVMdl.ClassNames. For $n$ and $L$, see Label. NegLoss($i,k,j$) is the negated, average binary loss for classifying observation $i$ into class $k$ using the linear classification model that has regularization strength CVMdl.Trained{1}.BinaryLoss{1}.Lambda($j$).

**PBScore — Cross-validated, positive-class scores**

numeric array

Cross-validated, positive-class scores, returned as an $n$-by-$B$-by-$L$ numeric array. $B$ is the number of binary learners in the cross-validated ECOC model and columns correspond to the binary learners in CVMdl.Trained{1}.BinaryLearners. For $n$ and $L$, see Label. PBScore($i,b,j$) is the positive-class score of binary learner $b$ for classifying observation $i$ into its positive class, using the linear classification model that has regularization strength CVMdl.Trained{1}.BinaryLearners{1}.Lambda($j$).

If the coding matrix varies across folds (that is, if the coding scheme is sparserandom or denserandom), then PBScore is empty ([]).

**Posterior — Cross-validated posterior class probabilities**

numeric array
Cross-validated posterior class probabilities, returned as an \( n \)-by-\( K \)-by-\( L \) numeric array. For dimension definitions, see \texttt{NegLoss}. \texttt{Posterior}(i,k,j) is the posterior probability for classifying observation \( i \) into class \( k \) using the linear classification model that has regularization strength \texttt{CVMdl.Trained{1}.BinaryLearners{1}.Lambda}(j).

To return posterior probabilities, \texttt{CVMdl.Trained{1}.BinaryLearner{1}.Learner} must be 'logistic'.

**Examples**

**Predict \( k \)-fold Cross-Validation Labels**

Load the NLP data set.

```matlab
load nlpdata
```

\( X \) is a sparse matrix of predictor data, and \( Y \) is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```matlab
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

\texttt{CVMdl} is a \texttt{ClassificationPartitionedLinearECOC} model. By default, the software implements 10-fold cross validation.

Predict labels for the observations that \texttt{fitcecoc} did not use in training the folds.

```matlab
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in \texttt{CVMdl}, \texttt{label} is a column vector of predictions containing as many rows as observations in \texttt{X}.

Construct a confusion matrix.

```matlab
ConfusionTrain = confusionmat(Y,label)
```

\texttt{ConfusionTrain} = 13\( \times \)13

Rows correspond to the true class and columns to the predicted class. The dimensions correspond to the order in CVMdl.ClassNames.

Specify Custom Binary Loss

Load the NLP data set. Transpose the predictor data.

load nlpdata
X = X';

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

t = templateLinear('Solver','sparsa');

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns.

rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}

CMdl1 =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]

Properties, Methods

CVMdl is a ClassificationPartitionedLinearECOC model. It contains the property Trained, which is a 5-by-1 cell array holding a CompactClassificationECOC models that the software trained using the training set of each fold.

By default, the linear classification models that compose the ECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is \((-\infty, \infty)\). Create a custom binary loss function that:

- Maps the coding design matrix \((M)\) and positive-class classification scores \((s)\) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...  
    NegLoss(idx,4),'VariableNames',{{'True'};{'Predicted'};...  
    categories(CVMdl.ClassNames))

ans=10×6 table
True      Predicted      comm         dsp       simulink    others
________    _________    _________    ________    ________    _______

dsp         dsp          -0.7387     -0.11534    -0.88466     0.2613
others      others      -0.1251     -0.8749    -0.99766     0.14517
dsp         dsp          2.5867      6.4187     -3.5867    -4.4165
others      others      -0.02535     -1.2287    -0.97464     0.19747
others      others      -2.6725     -0.56708    -0.51092     2.7453
others      others      -1.1605     -0.88321    -0.11679     0.43504
others      others      -1.9511     -1.3175     0.24735     0.95111
simulink    others      -7.848       -5.8203     4.8203      6.8457

The software predicts the label based on the maximum negated loss.

**Estimate Posterior Class Probabilities**

ECOC models composed of linear classification models return posterior probabilities for logistic regression learners only. This example requires the Parallel Computing Toolbox™ and the Optimization Toolbox™.

Load the NLP data set and preprocess the data as in “Specify Custom Binary Loss” on page 32-3356.

load nlpdata
X = X';
Y(~ismember(Y,{'simulink','dsp','comm'}))) = 'others';
Create a set of 5 logarithmically-spaced regularization strengths from $10^{-5}$ through $10^{-0.5}$.

$$\text{Lambda} = \logspace(-6,-0.5,5);$$

Create a linear classification model template that specifies optimizing the objective function using SpaRSA and to use logistic regression learners.

$$\text{t} = \text{templateLinear('Solver','sparsa','Learner','logistic','Lambda',\text{Lambda});}$$

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns, and to use parallel computing.

```matlab
rng(1); % For reproducibility
Options = statset('UseParallel',true);
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns',... 'Options',Options);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

Predict the cross-validated posterior class probabilities. Specify to use parallel computing and to estimate posterior probabilities using quadratic programming.

```matlab
[label,~,~,Posterior] = kfoldPredict(CVMdl,'Options',Options,... 'PosteriorMethod','qp');
size(label)
label(3,4)
size(Posterior)
Posterior(3,:,4)
```

```matlab
ans =
     31572      5
```

```matlab
ans =
categorical
     others
```
Because there are five regularization strengths:

- **label** is a 31572-by-5 categorical array. `label(3,4)` is the predicted, cross-validated label for observation 3 using the model trained with regularization strength `Lambda(4)`.
- **Posterior** is a 31572-by-4-by-5 matrix. `Posterior(3,:,4)` is the vector of all estimated, posterior class probabilities for observation 3 using the model trained with regularization strength `Lambda(4)`. The order of the second dimension corresponds to `CVMdl.ClassNames`.

Display a random sample of cross-validated labels and posterior probabilities for the model trained using `Lambda(4)`.

```matlab
idx = randsample(size(label,1),10);
table(Y(idx),label(idx,4),Posterior(idx,1,4),Posterior(idx,2,4),...
    Posterior(idx,3,4),Posterior(idx,4,4),...
    'VariableNames',[['True';'Predicted';categories(CVMdl.ClassNames)])
```

```plaintext
ans =

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

• $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
• $s_j$ is the score of binary learner $j$ for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$
Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1, 1, 0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).

</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \), and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Algorithms**

- The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:
  - \( m_{kj} \) is the element \((k, j)\) of the coding design matrix \( M \).
  - \( I \) is the indicator function.
  - \( \hat{p}_k \) is the class posterior probability estimate for class \( k \) of an observation, \( k = 1, ..., K \).
• \( r_j \) is the positive-class posterior probability for binary learner \( j \). That is, \( r_j \) is the probability that binary learner \( j \) classifies an observation into the positive class, given the training data.

**Posterior Estimation Using Kullback-Leibler Divergence**

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

\[
\Delta(r, \hat{r}) = \sum_{j=1}^{L} w_j \left[ r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],
\]

where \( w_j = \sum_{S_j} w_i^* \) is the weight for binary learner \( j \).

- \( S_j \) is the set of observation indices on which binary learner \( j \) is trained.
- \( w_i^* \) is the weight of observation \( i \).

The software minimizes the divergence iteratively. The first step is to choose initial values \( \hat{p}^{(0)}_k; \ k = 1, \ldots, K \) for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software uses both sets of deterministic initial values described next, and uses the one that minimizes \( \Delta \).

  - \( \hat{p}^{(0)}_k = 1 / K; \ k = 1, \ldots, K \).
  - \( \hat{p}^{(0)}_k; \ k = 1, \ldots, K \) is the solution of the system

\[
M_{01} \hat{p}^{(0)} = r,
\]

where \( M_{01} \) is \( M \) with all \( m_{kj} = -1 \) replaced with 0, and \( r \) is a vector of positive-class posterior probabilities returned by the \( L \) binary learners [Dietterich et al.] on page 18-222. The software uses \texttt{lsqnonneg} to solve the system.
• If you specify 'NumKLIterations', c, where c is a natural number, then the software does the following to choose \( \hat{p}_k^{(0)}; \ k = 1, ..., K \), and uses the one that minimizes \( \Delta \).

• The software chooses both sets of deterministic initial values as described previously.

• The software randomly generates c vectors of length K using \texttt{rand}, and then normalizes each vector to sum to 1.

At iteration \( t \), the software completes these steps:

1. Compute

\[
\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.
\]

2. Estimate the next class posterior probability using

\[
\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[ r_j I(m_{kj} = +1) + (1-r_j) I(m_{kj} = -1) \right]}{\sum_{j=1}^{L} w_j \left[ \hat{r}_j^{(t)} I(m_{kj} = +1) + (1-\hat{r}_j^{(t)}) I(m_{kj} = -1) \right]}.
\]

3. Normalize \( \hat{p}_k^{(t+1)}; \ k = 1, ..., K \) so that they sum to 1.

4. Check for convergence.

For more details, see [Hastie et al.] on page 18-222 and [Zadrozny] on page 18-224.

**Posterior Estimation Using Quadratic Programming**

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:
Estimate the positive-class posterior probabilities, $r_j$, for binary learners $j = 1, \ldots, L$.

Using the relationship between $r_j$ and $\hat{p}_k$ [Wu et al.] on page 18-224, minimize

$$\sum_{j=1}^{L} \left[ -r_j \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to $\hat{p}_k$ and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$ 

The software performs minimization using `quadprog`.

## Extended Capabilities

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to true.

Set the `'UseParallel'` field of the options structure to true using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options', statset('UseParallel',true)

For more information, see the `'Options'` name-value pair argument.

Introduced in R2016a
**kfoldPredict**

Predict response for observations not used for training

**Syntax**

`label = kfoldPredict(obj)`  
`[label,score] = kfoldPredict(obj)`  
`[label,score,cost] = kfoldPredict(obj)`

**Description**

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label,score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label,score,cost] = kfoldPredict(obj)` returns misclassification costs.

**Input Arguments**

`obj`

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

**Output Arguments**

`label`

Vector of class labels of the same type as the response data used in training `obj`. (The software treats string arrays as cell arrays of character vectors.) Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`. 
score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in obj.X, and K is the number of classes (in obj.ClassNames). score(i,j) represents the confidence that row i of obj.X is of class j. For details, see “Definitions” on page 32-3370.

cost

Numeric matrix of misclassification costs of size N-by-K. cost(i,j) is the average misclassification cost of predicting that row i of obj.X is of class j.

Examples

Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

load fisheriris

Train an ensemble of classification trees using AdaBoostM2. Specify tree stumps as the weak learners.

rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);

Cross validate the trained ensemble using 10-fold cross validation.

CVMdl = crossval(Mdl);

Estimate cross-validation predicted labels and scores.

[elabel,escore] = kfoldPredict(CVMdl);

Display the maximum and minimum scores of each class.

max(escore)

ans = 1x3
9.3862  8.9871  10.1866

\text{min}(\text{escore})
\text{ans} = 1\times3

\begin{align*}
0.0017 & & 3.8359 & & 0.8981
\end{align*}

\section*{Definitions}

\subsection*{Cost (discriminant analysis)}

The average misclassification cost is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 20-8.

\subsection*{Score}

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-7.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- \texttt{AdaBoostM1} scores range from $-\infty$ to $\infty$.
- \texttt{Bag} scores range from 0 to 1.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.
For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:
[-,score] = predict(tree1,X(1:10));
[(score X(1:10,:))]

ans = 10×3

0.9059   0.0941   0.8147
0.9059   0.0941   0.9058
0       1.0000   0.1270
0.9059   0.0941   0.9134
0.9059   0.0941   0.6324
0       1.0000   0.0975
0.9059   0.0941   0.2785
0.9059   0.0941   0.5469
0.9059   0.0941   0.9575
0.9059   0.0941   0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95,1) instead of the expected 5 observations.

**kfoldPredict**

Predict responses for observations not used for training

**Syntax**

\[ YHat = \text{kfoldPredict}(CVMdl) \]

**Description**

\[ YHat = \text{kfoldPredict}(CVMdl) \] returns cross-validated predicted responses by the cross-validated linear regression model \( CVMdl \). That is, for every fold, \( \text{kfoldPredict} \) predicts responses for observations that it holds out when it trains using all other observations.

\( YHat \) contains predicted responses for each regularization strength in the linear regression models that compose \( CVMdl \).

**Input Arguments**

- \( CVMdl \) — Cross-validated, linear regression model
  - \( \text{RegressionPartitionedLinear} \) model object

Cross-validated, linear regression model, specified as a \( \text{RegressionPartitionedLinear} \) model object. You can create a \( \text{RegressionPartitionedLinear} \) model using \( \text{fitrlinear} \) and specifying any of the one of the cross-validation, name-value pair arguments, for example, \( \text{CrossVal} \).

To obtain estimates, \( \text{kfoldPredict} \) applies the same data used to cross-validate the linear regression model (\( X \) and \( Y \)).
Output Arguments

**YHat — Cross-validated predicted responses**

numeric array

Cross-validated predicted responses, returned as an \(n\)-by-\(L\) numeric array. \(n\) is the number of observations in the predictor data that created \(CVMdl\) (see \(X\)) and \(L\) is the number of regularization strengths in \(CVMdl.Trained\{1\}.Lambda\). \(YHat(i,j)\) is the predicted response for observation \(i\) using the linear regression model that has regularization strength \(CVMdl.Trained\{1\}.Lambda(j)\).

The predicted response using the model with regularization strength \(j\) is \(\hat{y}_j = x\beta_j + b_j\).

- \(x\) is an observation from the predictor data matrix \(X\), and is row vector.
- \(\beta_j\) is the estimated column vector of coefficients. The software stores this vector in \(Mdl.Beta(:,j)\).
- \(b_j\) is the estimated, scalar bias, which the software stores in \(Mdl.Bias(j)\).

Examples

Predict Cross-Validated Responses

Simulate 10000 observations from this model

\[
y = x_{100} + 2x_{200} + e.
\]

- \(X = x_1, \ldots, x_{1000}\) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \(e\) is random normal error with mean 0 and standard deviation 0.3.

```plaintext
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
.nz = 0.1;
```

32-3375
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Cross-validate a linear regression model.

CVMdl = fitrlinear(X,Y,'CrossVal','on')

CVMdl =
    classreg.learning.partition.RegressionPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 10000
    KFold: 10
    Partition: [1x1 cvpartition]
    ResponseTransform: 'none'

Properties, Methods

Mdl1 = CVMdl.Trained{1}

Mdl1 =
    RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
    Bias: 0.0107
    Lambda: 1.1111e-04
    Learner: 'svm'

Properties, Methods

By default, fitrlinear implements 10-fold cross-validation. CVMdl is a
RegressionPartitionedLinear model. It contains the property Trained, which is a
10-by-1 cell array holding 10 RegressionLinear models that the software trained using
the training set.

Predict responses for observations that fitrlinear did not use in training the folds.

yHat = kfoldPredict(CVMdl);

Because there is one regularization strength in Mdl, yHat is a numeric vector.
Predict for Models Containing Several Regularization Strengths

Simulate 10000 observations as in “Predict Cross-Validated Responses” on page 32-3375.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Create a set of 15 logarithmically-spaced regularization strengths from $10^{-5}$ through $10^{-1}$.

Lambda = logspace(-5,-1,15);

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Specify using least squares with a lasso penalty and optimizing the objective function using SpaRSA.

X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
                 'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

CVMdl is a RegressionPartitionedLinear model. Its Trained property contains a 5-by-1 cell array of trained RegressionLinear models, each one holds out a different fold during training. Because fitrlinear trained using 15 regularization strengths, you can think of each RegressionLinear model as 15 models.

Predict cross-validated responses.

YHat = kfoldPredict(CVMdl);
size(YHat)

ans = 1x2
     10000     15

YHat(2,:)
ans = 1×15
   -1.7338  -1.7332  -1.7319  -1.7299  -1.7266  -1.7239  -1.7135  -1.7210  -1.7324  -1.7063  -1.6397  -1.5112  -1.2631  -0.7841  -0.0096

YHat is a 10000-by-15 matrix. YHat(2,:) is the cross-validated response for observation 2 using the model regularized with all 15 regularization values.

RegressionLinear | RegressionPartitionedLinear | fitrlinear | predict

Introduced in R2016a
**kfoldPredict**

Predict response for observations not used for training

**Syntax**

```plaintext
yfit = kfoldPredict(obj)
```

**Description**

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

**Input Arguments**

`obj`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitrensemble` along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

**Output Arguments**

`yfit`

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

**Examples**

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)

L =
    26.5271

yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )

ans =
    26.5271

See Also
fitrtree | kfoldLoss
**kmeans**

*k*-means clustering

**Syntax**

```plaintext
idx = kmeans(X,k)
dx = kmeans(X,k,Name,Value)
[idx,C] = kmeans(__)
[idx,C,sumd] = kmeans(__)
[idx,C,sumd,D] = kmeans(__)
```

**Description**

`idx = kmeans(X,k)` performs *k*-means clustering on page 32-3397 to partition the observations of the $n$-by-$p$ data matrix $X$ into $k$ clusters, and returns an $n$-by-1 vector ($idx$) containing cluster indices of each observation. Rows of $X$ correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance metric and the *k*-means++ algorithm on page 32-3397 for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans(__)` returns the $k$ cluster centroid locations in the $k$-by-$p$ matrix $C$.

`[idx,C,sumd] = kmeans(__)` returns the within-cluster sums of point-to-centroid distances in the $k$-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmeans(__)` returns distances from each point to every centroid in the $n$-by-$k$ matrix $D$. 
Examples

Train a k-Means Clustering Algorithm

Cluster data using k-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify \( k = 3 \) clusters.

```matlab
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

\texttt{kmeans} uses the \textit{k}-means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the 'Replicates' name-value pair argument.

\texttt{idx} is a vector of predicted cluster indices corresponding to the observations in \( X \). \texttt{C} is a 3-by-2 matrix containing the final centroid locations.
Use \texttt{kmeans} to compute the distance from each centroid to points on a grid. To do this, pass the centroids (C) and points on a grid to \texttt{kmeans}, and implement one iteration of the algorithm.

\begin{verbatim}
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot
idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);
\end{verbatim}

\texttt{kmeans} displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

\begin{verbatim}
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
         [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'.');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','SouthEast');
hold off;
\end{verbatim}
Partition Data into Two Clusters

Randomly generate the sample data.

rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
    randn(100,2)*0.5-ones(100,2)];

figure;
plot(X(:,1),X(:,2),'.');
title 'Randomly Generated Data';
There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```matlab
opts = statset('Display','final');
[idx,C] = kmeans(X,2,'Distance','cityblock',
    'Replicates',5,'Options',opts);
```

Replicate 1, 3 iterations, total sum of distances = 201.533.
Replicate 2, 5 iterations, total sum of distances = 201.533.
Replicate 3, 3 iterations, total sum of distances = 201.533.
Replicate 4, 3 iterations, total sum of distances = 201.533.
Replicate 5, 2 iterations, total sum of distances = 201.533.
Best total sum of distances = 201.533

By default, the software initializes the replicates separately using $k$-means++.

Plot the clusters and the cluster centroids.

```matlab
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(C(:,1),C(:,2),'kx',...
     'MarkerSize',15,'LineWidth',3)
legend('Cluster 1','Cluster 2','Centroids',... 
       'Location','NW')
title 'Cluster Assignments and Centroids'
hold off
```
You can determine how well separated the clusters are by passing idx to silhouette.

**Cluster Data Using Parallel Computing**

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox™ license and you set the options for parallel computing, then kmeans runs each clustering task (or replicate) in parallel. And, if Replicates > 1, then parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.
Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
Mdl = gmdistribution(Mu,Sigma); % Define the Gaussian mixture distribution

rng(1); % For reproducibility
X = random(Mdl,10000);

Mdl is a 30-dimensional gmdistribution model with 20 components. X is a 10000-by-30 matrix of data generated from Mdl.

Specify the options for parallel computing.

stream = RandStream('mlfg6331_64'); % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);

The input argument 'mlfg6331_64' of RandStream specifies to use the multiplicative lagged Fibonacci generator algorithm. options is a structure array with fields that specify options for controlling estimation.

Cluster the data using k-means clustering. Specify that there are k = 20 clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);

Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.
Replicate 5, 72 iterations, total sum of distances = 7.73161e+06.
Replicate 1, 64 iterations, total sum of distances = 7.72988e+06.
Replicate 3, 68 iterations, total sum of distances = 7.72576e+06.
Replicate 4, 84 iterations, total sum of distances = 7.72696e+06.
Replicate 6, 82 iterations, total sum of distances = 7.73006e+06.
Replicate 7, 40 iterations, total sum of distances = 7.73451e+06.
Replicate 2, 194 iterations, total sum of distances = 7.72953e+06.
Replicate 9, 105 iterations, total sum of distances = 7.72064e+06.
Replicate 10, 125 iterations, total sum of distances = 7.72816e+06.
Best total sum of distances = 7.72064e+06.

toc % Terminate stopwatch timer
Elapsed time is 61.915955 seconds.

The Command Window indicates that six workers are available. The number of workers might vary on your system. The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

### Input Arguments

**X** — Data
numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

If X is a numeric vector, then kmeans treats it as an n-by-1 data matrix, regardless of its orientation.

Data Types: single | double

**k** — Number of clusters
positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','cosine','Replicates',10,'Options',statset('UseParallel',1) specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

**Display** — Level of output to display

'off' (default) | 'final' | 'iter'
Level of output to display in the Command Window, specified as the comma-separated pair consisting of 'Display' and one of the following options:

- 'final' — Displays results of the final iteration
- 'iter' — Displays results of each iteration
- 'off' — Displays nothing

Example: 'Display','final'

**Distance — Distance metric**

'sqeuclidean' (default) | 'cityblock' | 'cosine' | 'correlation' | 'hamming'

Distance metric, in p-dimensional space, used for minimization, specified as the comma-separated pair consisting of 'Distance' and 'sqeuclidean', 'cityblock', 'cosine', 'correlation', or 'hamming'.

*kmeans* computes centroid clusters differently for the different, supported distance metrics. This table summarizes the available distance metrics. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sqeuclidean'</td>
<td>Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.</td>
<td>( d(x,c) = (x - c)(x - c)' )</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>Sum of absolute differences, i.e., the L1 distance. Each centroid is the component-wise median of the points in that cluster.</td>
<td>( d(x,c) = \sum_{j=1}^{p}</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.</td>
<td>( d(x,c) = 1 - \frac{x'c'}{\sqrt{(x'x')(c'c')}} )</td>
</tr>
<tr>
<td>Distance Metric</td>
<td>Description</td>
<td>Formula</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.</td>
<td></td>
</tr>
</tbody>
</table>

\[
d(x, c) = 1 - \frac{(x - \bar{x})(c - \bar{c})'}{\sqrt{(x - \bar{x})(x - \bar{x})'}\sqrt{(c - \bar{c})(c - \bar{c})'}}
\]

where

- \( \bar{x} = \frac{1}{p} \left( \sum_{j=1}^{p} x_j \right) \bar{1}_p \)
- \( \bar{c} = \frac{1}{p} \left( \sum_{j=1}^{p} c_j \right) \bar{1}_p \)
- \( \bar{1}_p \) is a row vector of \( p \) ones.

| 'hamming'       | This metric is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster. | 

\[
d(x, y) = \frac{1}{p} \sum_{j=1}^{p} I\{x_j \neq y_j\}
\]

where \( I \) is the indicator function.

Example: 'Distance','cityblock'

**EmptyAction — Action to take if cluster loses all member observations**

'singleton' (default) | 'error' | 'drop'

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of 'EmptyAction' and one of the following options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'error'</td>
<td>Treat an empty cluster as an error.</td>
</tr>
</tbody>
</table>
### Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'drop'</td>
<td>Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.</td>
</tr>
<tr>
<td>'singleton'</td>
<td>Create a new cluster consisting of the one point furthest from its centroid (default).</td>
</tr>
</tbody>
</table>

Example: 'EmptyAction','error'

### MaxIter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter',1000

Data Types: double | single

### OnlinePhase — Online update flag

'off' (default) | 'on'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'off' or 'on'.

If OnlinePhase is on, then kmeans performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase','on'

### Options — Options for controlling iterative algorithm for minimizing fitting criteria

[] (default) | structure array returned by statset

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. These options require Parallel Computing Toolbox.

This table summarizes the available options.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Streams'</td>
<td>A RandStream object or cell array of such objects. If you do not specify Streams, kmeans uses the default stream or streams. If you specify Streams, use a single object except when:</td>
</tr>
</tbody>
</table>
|               | • You have an open parallel pool  
|               | • UseParallel is true.  
|               | • UseSubstreams is false.  
|               | In that case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then Streams must supply a single random number stream. |
| 'UseParallel' | • If true and Replicates > 1, then kmeans implements k-means algorithm on each replicate in parallel.  
|               | • If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is false, meaning serial computation. |
| 'UseSubstreams'| Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. |

To ensure more predictable results, use parpool and explicitly create a parallel pool before invoking kmeans and setting 'Options', statset('UseParallel',1).

Example: 'Options', statset('UseParallel',1)

Data Types: struct

**Replicates — Number of times to repeat clustering using new initial cluster centroid positions**
1 (default) | positive integer
Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of 'Replicates' and an integer. kmeans returns the solution with the lowest sumd.

You can set 'Replicates' implicitly by supplying a 3-D array as the value for the 'Start' name-value pair argument.

Example: 'Replicates',5

Data Types: double | single

**Start — Method for choosing initial cluster centroid positions**

'plus' (default) | 'cluster' | 'sample' | 'uniform' | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or seeds), specified as the comma-separated pair consisting of 'Start' and 'cluster', 'plus', 'sample', 'uniform', a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cluster'</td>
<td>Perform a preliminary clustering phase on a random 10% subsample of X. This preliminary phase is itself initialized using 'sample'.</td>
</tr>
<tr>
<td>'plus' (default)</td>
<td>Select k seeds by implementing the k-means++ algorithm on page 32-3397 for cluster center initialization.</td>

<tr>
<td>numeric array</td>
<td>k-by-p-r array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page <em>j</em> contains the set of seeds for replicate <em>j</em>. The software infers the number of replicates (specified by the 'Replicates' name-value pair argument) from the size of the third dimension.</td>
</tr>
</tbody>
</table>

Example: 'Start','sample'

Data Types: char | string | double | single

**Note** The software treats NaNs as missing data, and removes any row of X containing at least one NaN. Removing rows of X reduces the sample size.

### Output Arguments

**idx — Cluster indices**

numeric column vector

Cluster indices, returned as a numeric column vector. *idx* has as many rows as *X*, and each row indicates the cluster assignment of the corresponding observation.

**C — Cluster centroid locations**

numeric matrix

Cluster centroid locations, returned as a numeric matrix. *C* is a k-by-*p* matrix, where row *j* is the centroid of cluster *j*.

**sumd — Within-cluster sums of point-to-centroid distances**

numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. *sumd* is a k-by-1 vector, where element *j* is the sum of point-to-centroid distances within cluster *j*. 
**D — Distances from each point to every centroid**

numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. \( D \) is an \( n \)-by-\( k \) matrix, where element \((j,m)\) is the distance from observation \( j \) to centroid \( m \).

**Definitions**

**k-Means Clustering**

k-means clustering, or Lloyd’s algorithm [2], is an iterative, data-partitioning algorithm that assigns \( n \) observations to exactly one of \( k \) clusters defined by centroids, where \( k \) is chosen before the algorithm starts.

The algorithm proceeds as follows:

1. Choose \( k \) initial cluster centers (centroid). For example, choose \( k \) observations at random (by using `'Start','sample'`) or use the \( k \)-means ++ algorithm on page 32-3397 for cluster center initialization (the default).
2. Compute point-to-cluster-centroid distances of all observations to each centroid.
3. There are two ways to proceed (specified by `OnlinePhase`):
   - Batch update — Assign each observation to the cluster with the closest centroid.
   - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

   For more details, see “Algorithms” on page 32-3399.
4. Compute the average of the observations in each cluster to obtain \( k \) new centroid locations.
5. Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

**k-means++ Algorithm**

The \( k \)-means++ algorithm uses an heuristic to find centroid seeds for \( k \)-means clustering. According to Arthur and Vassilvitskii [1], \( k \)-means++ improves the running time of Lloyd’s algorithm, and the quality of the final solution.
The \( k \)-means++ algorithm chooses seeds as follows, assuming the number of clusters is \( k \).

1. Select an observation uniformly at random from the data set, \( X \). The chosen observation is the first centroid, and is denoted \( c_1 \).

2. Compute distances from each observation to \( c_1 \). Denote the distance between \( c_j \) and the observation \( m \) as \( d(x_m, c_j) \).

3. Select the next centroid, \( c_2 \) at random from \( X \) with probability

\[
\frac{d^2(x_m, c_1)}{\sum_{j=1}^{n} d^2(x_j, c_1)}.
\]

4. To choose center \( j \):
   
   a. Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.
   
   b. For \( m = 1, \ldots, n \) and \( p = 1, \ldots, j - 1 \), select centroid \( j \) at random from \( X \) with probability

\[
\frac{d^2(x_m, c_p)}{\sum_{\{h : x_h \in C_p\}} d^2(x_h, c_p)}.
\]

   where \( C_p \) is the set of all observations closest to centroid \( c_p \) and \( x_m \) belongs to \( C_p \).

   That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5. Repeat step 4 until \( k \) centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that \( k \)-means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd’s algorithm.
Algorithms

- **kmeans** uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all \( k \) clusters.

  1. This first phase uses batch updates, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.

  2. This second phase uses online updates, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

- If \( \text{Replicates} = r > 1 \) and \( \text{Start} \) is \text{plus} (the default), then the software selects \( r \) possibly different sets of seeds according to the \( k \)-means++ algorithm on page 32-3397.

- If you enable the \text{UseParallel} option in \text{Options} and \( \text{Replicates} > 1 \), then each worker selects seeds and clusters in parallel.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

Only random sample initialization is supported. Supported syntaxes:

- `idx = kmeans(X,k)` performs classic k-means clustering.
- `[idx,C] = kmeans(X,k)` also returns the k cluster centroid locations.
- `[idx,C,sumd] = kmeans(X,k)` additionally returns the k within-cluster sums of point-to-centroid distances.
- `[___] = kmeans(___,Name,Value)` specifies additional name-value pair options using any of the other syntaxes. Valid options are:

  - `'Start'` — Method used to choose the initial cluster centroid positions. Value can be:
    - `'plus'` (default) — Select k observations from X using a variant of the kmeans ++ algorithm adapted for tall data.
    - `'sample'` — Select k observations from X at random.
    - Numeric matrix — A k-by-p matrix to explicitly specify starting locations.
  - `'Options'` — An options structure created using the `statset` function. For tall arrays, `kmeans` uses the fields listed here and ignores all other fields in the options structure:
    - `'Display'` — Level of display. Choices are 'iter' (default), 'off', and 'final'.
    - `'MaxIter'` — Maximum number of iterations. Default is 100.
    - `'TolFun'` — Convergency tolerance for the within-cluster sums of point-to-centroid distances. Default is $1e^{-4}$. This option field only works with tall arrays.

For more information, see “Tall Arrays” (MATLAB).
C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• If the Start method uses random selections, the initial centroid cluster positions
  might not match MATLAB.
• If the number of rows in \( X \) is fixed, code generation does not remove rows of \( X \) that
  contain a NaN.
• The cluster centroid locations in \( C \) can have a different order than in MATLAB. In this
  case, the cluster indices in \( \text{idx} \) have corresponding differences.
• If you provide Display, its value must be 'off'.
• If you provide Streams, it must be empty and UseSubstreams must be false.
• When you set the UseParallel option to true:
  • Some computations can execute in parallel even when Replicates is 1. For large
    data sets, when Replicates is 1, consider setting the UseParallel option to
    true.
  • \textit{kmeans} uses \texttt{parfor} to create loops that run in parallel on supported shared-
    memory multicore platforms. Loops that run in parallel can be faster than loops
    that run on a single thread. If your compiler does not support the Open
    Multiprocessing (OpenMP) application interface or you disable OpenMP library,
    MATLAB Coder treats the \texttt{parfor}-loops as \texttt{for}-loops. To find supported compilers,
    see \url{https://www.mathworks.com/support/compilers/current_release/}.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel
Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using \texttt{statset} and specify
the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

32-3401
GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a
**kmedoids**

_k-medoids clustering_

**Syntax**

```plaintext
idx = kmedoids(X,k)
idx = kmedoids(X,k,Name,Value)
[idx,C] = kmedoids(___)
[idx,C,sumd] = kmedoids(___)
[idx,C,sumd,D] = kmedoids(___)
[idx,C,sumd,D,midx] = kmedoids(___)
[idx,C,sumd,D,midx,info] = kmedoids(__)
```

**Description**

`idx = kmedoids(X,k)` performs “k-medoids Clustering” on page 32-3419 to partition the observations of the n-by-p matrix X into k clusters, and returns an n-by-1 vector `idx` containing cluster indices of each observation. Rows of X correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance metric and the _k-means++_ algorithm on page 32-3397 for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[idx,C] = kmedoids(__)` returns the k cluster medoid locations in the k-by-p matrix C.

`[idx,C,sumd] = kmedoids(__)` returns the within-cluster sums of point-to-medoid distances in the k-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmedoids(__)` returns distances from each point to every medoid in the n-by-k matrix D.

`[idx,C,sumd,D,midx] = kmedoids(__)` returns the indices `midx` such that C = X(midx,:). `midx` is a k-by-1 vector.
[idx,C,sumd,D,info] = kmedoids(__) returns a structure info with information about the options used by the algorithm when executed.

**Examples**

**Group Data into Two Clusters**

Randomly generate data.

```matlab
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```
Group data into two clusters using kmedoids. Use the cityblock distance metric.

```matlab
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

<table>
<thead>
<tr>
<th>rep</th>
<th>iter</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>209.856</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>209.856</td>
</tr>
</tbody>
</table>

Best total sum of distances = 209.856

info is a struct that contains information about how the algorithm was executed. For example, bestReplicate field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is pam in this case.
info

info = struct with fields:
    algorithm: 'pam'
    start: 'plus'
    distance: 'cityblock'
    iterations: 2
    bestReplicate: 1

Plot the clusters and the cluster medoids.

figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',7)

Cluster Categorical Data Using k-Medoids

This example uses "Mushroom" data set [3][4][5][6][7] from the UCI machine learning archive [7], described in http://archive.ics.uci.edu/ml/datasets/Mushroom. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of 'b' for bell-shaped cap and 'c' for conical. Mushroom color is also categorized with features of 'n' for brown, and 'p' for pink. The data set also includes a classification for each mushroom of either edible or poisonous.
Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used $k$-means clustering algorithm cannot be meaningfully applied to this data set. $k$-medoids is a related algorithm that partitions data into $k$ distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing $k$-medoids to be used for a broader range of problems than $k$-means.

Using $k$-medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set from the UCI database and saved it in your current directory as a text file named agaricus-lepiota.txt. There is no column headers in the data, so readtable uses the default variable names.

```matlab
clear all
data = readtable('agaricus-lepiota.txt','ReadVariableNames',false);
```

Display the first 5 mushrooms with their first few features.

```matlab
data(1:5,1:10)
```

```matlab
ans =

</tr>
</tbody>
</table>
```

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.
labels = data(:,1);
labels = categorical(labels{:,:});
data(:,1) = [];

Store the names of predictors (features), which are described in http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names.

VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...
    'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...
    'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...
    'stalk_surface_below_ring' 'stalk_color_above_ring' ...
    'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....
    'ring_type' 'spore_print_color' 'population' 'habitat'};

Set the variable names.

data.Properties.VariableNames = VarNames;

There are a total of 2480 missing values denoted as '?'.

sum(char(data{:,:}) == '?')

ans = 2480

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (stalk_root). Remove the column from the table.

data(:,11) = [];

kmedoids only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

cats = categorical(data{:,:});
data = double(cats);

kmedoids can use any distance metric supported by pdist2 to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

v1 = [1 0 2 1];
v2 = [1 1 2 1];

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function pdist2 to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value .2857 means that 6 of the 21 features of the mushroom differ.

pdist2(data(1,:), data(2,:), 'hamming')

ans =

    0.2857

In this example, you’re clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The kmedoids function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the 'replicates' parameter. When 'replicates' is set to a value, n, greater than 1, the k-medoids algorithm is run n times, and the best result is returned.

To run kmedoids to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

rng('default'); % For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data, 2, 'distance', 'hamming', 'replicates', 3);

Let’s assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the confusionmat function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label information from the IDX variable. IDX contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

predLabels = labels; % Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); % Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); % Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)

confMatrix =
    4176     32
     816  3100

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))

accuracy =
    0.8956

precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))

precision =
    0.8365

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

**Input Arguments**

- **X — Data**
  numeric matrix

  Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

- **k — Number of medoids**
  positive integer
Number of medoids in the data, specified as a positive integer.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','euclidean','Replicates', 3,'Options',statset('UseParallel',1) specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

**Algorithm — Algorithm to find medoids**

'pam' | 'small' | 'clara' | 'large'

Algorithm to find medoids, specified as the comma-separated pair consisting of 'Algorithm' and 'pam', 'small', 'clara', or 'large'. The default algorithm depends on the number of rows of X.

- If the number of rows of X is less than 3000, 'pam' is the default algorithm.
- If the number of rows is between 3000 and 10000, 'small' is the default algorithm.
- For all other cases, 'large' is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.
<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'pam'     | Partitioning Around Medoids (PAM) is the classical algorithm for solving the \( k \)-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the 'Start' name-value pair argument.  

The algorithm proceeds as follows.  

1 Build-step: Each of \( k \) clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.  

2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.  

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.  

The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.  

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'small'   | Use an algorithm similar to the k-means algorithm to find \( k \) medoids. This option employs a variant of the Lloyd’s iterations based on [2]. The algorithm proceeds as follows.  
1. For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid.  
2. Update the cluster membership for each data point to reflect the new medoid.  
The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the clara or large algorithms, but it may not be the best choice for very large data. |
| 'clara'   | Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling. The algorithm proceeds as follows.  
1. Select a subset of the data and apply the PAM algorithm to the subset.  
2. Assign points of the full data set to clusters by picking the closest medoid.  
The algorithm repeats these steps until the medoids do not change, or other termination criteria are met.  
For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples \( s \) rows from \( X \) (specified by 'NumSamples' name-value pair argument) to perform clustering on. By default, \( 40+2*\text{k} \) samples are selected. |
Algorithm | Description
--- | ---
'large' | This is similar to the small scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, 'PercentNeighbors', controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of r replicates (specified by 'Replicates' name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality.

Example: 'Algorithm','pam'

**OnlinePhase** — Flag to perform PAM-like online update phase

'on' (default) | 'off'

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of 'OnlinePhase' and 'on' or 'off'.

If it is on, then kmedoids performs a PAM-like update to the medoids after the Lloyd iterations in the small and large algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: OnlinePhase,'off'

**Distance** — Distance metric

'squeenclidean'(default) | 'euclidean' | 'seuclidean' | 'cityblock' | 'minkowski' | 'chebychev' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | custom distance function
Distance metric, in p-dimensional space, specified as the comma-separate pair consisting of 'Distance' and 'euclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'mahalanobis', 'cosine', 'correlation', 'spearman', 'hamming', 'jaccard', or a custom distance function.

kmedoids minimizes the sum of medoid to cluster member distances. See pdist for the definition of each distance metric. kmedoids supports all distance metrics supported by pdist.

Example: 'Distance', 'hamming'

Options — Options to control iterative algorithm to minimize fitting criteria

[] (default) | structure array returned by statset

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. This table summarizes these options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display</td>
<td>Level of display output. Choices are 'off' (default) and 'iter'.</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of iterations allowed. The default is 100.</td>
</tr>
<tr>
<td>UseParallel</td>
<td>If true, compute in parallel. If Parallel Computing Toolbox is not available, then computation occurs in serial mode. The default is false, meaning serial computation.</td>
</tr>
<tr>
<td>UseSubstreams</td>
<td>Set to true to compute in parallel in a reproducible fashion. The default is false. To compute reproducibly, you must also set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
<tr>
<td>Streams</td>
<td>A RandStream object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see “Speed Up Statistical Computations” or enter help parallelstats at the command line.</td>
</tr>
</tbody>
</table>

Example: 'Options', statset('Display', 'off')

Replicates — Number of times to repeat clustering using new initial cluster medoid positions

positive integer

32-3416
Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For pam and small, the default is 1. For clara, the default is 5. For large, the default is 3.

Example: 'Replicates',4

NumSamples — Number of samples to take from data when executing clara algorithm

40+2*k (default) | positive integer

Number of samples to take from the data when executing the clara algorithm, specified as a positive integer. The default number of samples is calculated as 40+2*k.

Example: 'NumSamples',160

PercentNeighbors — Percent of data set to examine using large algorithm

0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the large algorithm, specified as a positive number.

The program examines percentneighbors*size(X,1) number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: 'PercentNeighbors',0.01

Start — Method for choosing initial cluster medoid positions

'plus' (default) | 'sample' | 'cluster' | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of 'Start' and 'plus', 'sample', 'cluster', or a matrix. This table summarizes the available methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'plus' (default)</td>
<td>Select k observations from X according to the k-means++ algorithm on page 32-3397 for cluster center initialization.</td>
</tr>
</tbody>
</table>
### Method Descriptions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sample'</td>
<td>Select $k$ observations from $X$ at random.</td>
</tr>
<tr>
<td>'cluster'</td>
<td>Perform preliminary clustering phase on a random subsample (10%) of $X$. This preliminary phase is itself initialized using sample, that is, the observations are selected at random.</td>
</tr>
</tbody>
</table>

**matrix**

A custom $k$-by-$p$ matrix of starting locations. In this case, you can pass in [] for the $k$ input argument, and kmedoids infers $k$ from the first dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array’s third dimension.

**Example:** 'Start','sample'

**Data Types:** char | string | single | double

### Output Arguments

**idx — Medoid indices**

numeric column vector

Medoid indices, returned as a numeric column vector. idx has as many rows as $X$, and each row indicates the medoid assignment of the corresponding observation.

**C — Cluster medoid locations**

numeric matrix

Cluster medoid locations, returned as a numeric matrix. C is a $k$-by-$p$ matrix, where row $j$ is the medoid of cluster $j$.

**sumd — Within-cluster sums of point-to-medoid distances**

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. sumd is a $k$-by1 vector, where element $j$ is the sum of point-to-medoid distances within cluster $j$. 
**D — Distances from each point to every medoid**
numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. **D** is an *n*-by-*k* matrix, where element \((j,m)\) is the distance from observation \(j\) to medoid \(m\).

**midx — Index to X**
column vector

Index to **X**, returned as a column vector of indices. **midx** is a *k*-by-1 vector and the indices satisfy \(C = X(midx,:)\).

**info — Algorithm information**
struct

Algorithm information, returned as a struct. **info** contains options used by the function when executed such as *k*-medoid clustering algorithm (**algorithm**), method used to choose initial cluster medoid positions (**start**), distance metric (**distance**), number of iterations taken in the best replicate (**iterations**) and the replicate number of the returned results (**bestReplicate**).

**Definitions**

**k-medoids Clustering**

*k*-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to *k*-means, and the goal of both methods is to divide a set of measurements or observations into *k* subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement’s cluster. In the *k*-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the *k*-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The *k*-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between *k*-medoids and *k*-means.
where the centroids returned by \( k \)-means may not be within the data set. Hence \( k \)-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

1. **Build-step**: Each of \( k \) clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.

2. **Swap-step**: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the \( k \)-means++ algorithm on page 32-3397 for cluster medoid initialization and the squared Euclidean metric to determine distances.

**References**

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel', true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2014b
knnsearch

Find k-nearest neighbors using object

Syntax

Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch(__)

Description

Idx = knnsearch(Mdl,Y) searches for the nearest neighbor (i.e., the closest point, row, or observation) in Mdl.X to each point (i.e., row or observation) in the query data Y using an exhaustive search or a Kd-tree. knnsearch returns Idx, which is a column vector of the indices in Mdl.X representing the nearest neighbors.

Idx = knnsearch(Mdl,Y,Name,Value) returns the indices of the closest points in Mdl.X to Y with additional options specified by one or more Name,Value pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in Mdl.Distance. You can also specify which action to take if the closest distances are tied.

[Idx,D] = knnsearch(__) additionally returns the matrix D using any of the input arguments in the previous syntaxes. D contains the distances between each observation in Y that correspond to the closest observations in Mdl.X. The function arranges the columns of D in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using Kd-tree and Exhaustive Search

knnsearch accepts ExhaustiveSearcher or KDTreeSearcher model objects to search the training data for the nearest neighbors to the query data. An
ExhaustiveSearcher model invokes the exhaustive searcher algorithm, and a KDTreeSearcher model defines a Kd-tree, which knnsearch uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

```matlab
clear; % For reproducibility
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:);                % Query data
```

The variable `meas` contains 4 predictors.

Grow a default four-dimensional Kd-tree.

```matlab
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =  
    KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [145x4 double]
```

`MdlKDT` is a KDTreeSearcher model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```matlab
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =  
    ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [145x4 double]
```
MdlKDT is an ExhaustiveSearcher model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a Kd-tree or prepare an exhaustive nearest neighbor searcher using createns.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is 1.

IdxKDT = knnsearch(MdlKDT,Y);
IdxES = knnsearch(MdlES,Y);
[IdxKDT IdxES]

ans = 5×2
17 17
 6  6
 1  1
 89 89
124 124

In this case, the results of the search are the same.

**Search for Nearest Neighbors of Query Data Using Minkowski Distance**

Grow a Kd-tree nearest neighbor searcher object by using the createns function. Pass the object and query data to the knnsearch function to find k-nearest neighbors.

Load Fisher's iris data set.

load fisheriris

Remove five irises randomly from the predictor data to use as a query set.

rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

\[ \text{Mdl} = \text{createns}(X,'\text{Distance}','\text{minkowski}') \]

\[ \text{Mdl} = \text{KDTreeSearcher with properties:} \]

\[
\begin{array}{l}
\text{BucketSize: 50} \\
\text{Distance: 'minkowski'} \\
\text{DistParameter: 2} \\
\text{X: [145x4 double]} \\
\end{array}
\]

Because \( X \) has four columns and the distance metric is Minkowski, \text{createns} creates a \text{KDTreeSearcher} model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (\text{Mdl}.X) that are the two nearest neighbors of each point in the query data (\( Q \)).

\[ \text{IdxNN} = \text{knnsearch(Mdl,Q,'K',2)} \]

\[ \text{IdxNN} = 5\times2 \]

\[
\begin{array}{ll}
17 & 4 \\
6 & 2 \\
1 & 12 \\
89 & 66 \\
124 & 100 \\
\end{array}
\]

Each row of \text{IdxNN} corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of \( Q(3,:) \) is \( X(12,:) \).

**Include Ties in Nearest Neighbor Search**

Load Fisher's iris data set.

\text{load fisheriris}
Remove five irises randomly from the predictor data to use as a query set.

```matlab
rng(4); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```matlab
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are the seven nearest neighbors of each point in the query data (`Y`).

```matlab
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);
```

`Idx` and `D` are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in `Idx`.

```matlab
cellfun('length',Idx)
an = 5×1
   8
   7
   7
   7
   7
```

Because cell 1 contains a vector with length greater than $k = 7$, query observation 1 (`Y(1,:)`) is equally close to at least two observations in `X`.

Display the indices of the nearest neighbors to `Y(1,:)` and their distances.

```matlab
nn5 = Idx{1}
nn5 = 1×8
```
nn5d = D{1}
nn5d = 1×8

0.1414  0.2646  0.2828  0.3000  0.3464  0.3742  0.3873  0.3873

Training observations 88 and 95 are 0.3873 cm away from query observation 1.

**Compare k-Nearest Neighbors Using Different Distance Metrics**

Train two KDTreeSearcher models using different distance metrics, and compare k-nearest neighbors of query data for the two models.

Load Fisher's iris data set. Consider the petal measurements as predictors.

```matlab
load fisheriris
X = meas(:,3:4); % Predictors
Y = species; % Response
```

Train a KDTreeSearcher model object by using the predictors. Specify the Minkowski distance with exponent 5.

```matlab
KDTreeMdl = KDTreeSearcher(X,'Distance','minkowski','P',5)
```

Find the 10 nearest neighbors from X to a query point (newpoint), first using Minkowski then Chebychev distance metrics. The query point must have the same column dimension as the data used to train the model.

```matlab
newpoint = [5 1.45];
[IdxMk,DMk] = knnsearch(KDTreeMdl,newpoint,'k',10);
[IdxCb,DCb] = knnsearch(KDTreeMdl,newpoint,'k',10,'Distance','chebychev');
```
IdxMk and IdxCb are 1-by-10 matrices containing the row indices of X corresponding to the nearest neighbors to newpoint using Minkowski and Chebychev distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

Plot the training data, query point, and nearest neighbors.

```matlab
figure;
gscatter(X(:,1),X(:,2),Y);
title('Fisher''s Iris Data -- Nearest Neighbors');
xlabel('Petal length (cm)');
ylabel('Petal width (cm)');
hold on
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,'LineWidth',2);   % Query point
plot(X(IdxMk,1),X(IdxMk,2),'o','Color',[.5 .5 .5],'MarkerSize',10); % Minkowski nearest neighbors
plot(X(IdxCb,1),X(IdxCb,2),'p','Color',[.5 .5 .5],'MarkerSize',10); % Chebychev nearest neighbors
legend('setosa','versicolor','virginica','query point','minkowski','chebychev','Location','Best');
```
Zoom in on the points of interest.

```matlab
h = gca; % Get current axis handle.
h.XLim = [4.5 5.5];
h.YLim = [1 2];
axis square;
```
Several observations are equal, which is why only eight nearest neighbors are identified in the plot.

Input Arguments

Md1 — Nearest neighbor searcher
ExhaustiveSearcher model object | KDTreeSearcher model object

Nearest neighbor searcher, specified as an ExhaustiveSearcher or KDTreeSearcher model object, respectively.
If \( Mdl \) is an \texttt{ExhaustiveSearcher} model, then \texttt{knnsearch} searches for nearest neighbors using an exhaustive search. Otherwise, \texttt{knnsearch} uses the grown Kd-tree to search for nearest neighbors.

**Y — Query data**
numeric matrix

Query data, specified as a numeric matrix.

\( Y \) is an \( m \)-by-\( K \) matrix. Rows of \( Y \) correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). \( Y \) must have the same number of columns as the training data stored in \( Mdl.X \).

Data Types: \texttt{single} | \texttt{double}

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: \texttt{'K',2,'Distance','minkowski'} specifies to find the two nearest neighbors of \( Mdl.X \) to each point in \( Y \) and to use the Minkowski distance metric.

**For Both Nearest Neighbor Searchers**

**Distance — Distance metric**

\( Mdl.Distance \) (default) | \texttt{'cityblock'} | \texttt{'euclidean'} | \texttt{'mahalanobis'} | \texttt{'minkowski'} | \texttt{'seuclidean'} | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of \texttt{'Distance'} and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, \texttt{knnsearch} supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
</tbody>
</table>

If Mdl is an ExhaustiveSearcher model object, then knnsearch also supports these distance metrics.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as row vectors).</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the 'Scale' name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>
If `Mdl` is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). The custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ).`
- Take as arguments:
  - A 1-by-`K` vector `ZI` containing a single row from `Mdl.X` or `Y`, where `K` is the number of columns of `Mdl.X`.
  - An `m`-by-`K` matrix `ZJ` containing multiple rows of `Mdl.X` or `Y`, where `m` is a positive integer.
- Return an `m`-by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-16.

Example: 'Distance','minkowski'

**IncludeTies — Flag to include all nearest neighbors**

`false (0) (default) | true (1)`

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of `'IncludeTies'` and `false (0)` or `true (1)`.

If `IncludeTies` is true, then:

- `knnsearch` includes all nearest neighbors whose distances are equal to the `k`th smallest distance in the output arguments, where `k` is the number of searched nearest neighbors specified by the 'K' name-value pair argument.
- `Idx` and `D` are `m`-by-1 cell arrays such that each cell contains a vector of at least `k` indices and distances, respectively. Each vector in `D` contains arranged distances in ascending order. Each row in `Idx` contains the indices of the nearest neighbors corresponding to these smallest distances in `D`.

If `IncludeTies` is false, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: 'IncludeTies',true

**K — Number of nearest neighbors**

1 (default) | positive integer
Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of 'K' and a positive integer.

Example: 'K',2

Data Types: single | double

**P — Exponent for Minkowski distance metric**

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

**For Exhaustive Nearest Neighbor Searchers**

**Cov — Covariance matrix for Mahalanobis distance metric**

nancov(Mdl.X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. Cov is a K-by-K matrix, where K is the number of columns of Mdl.X. If you specify Cov and do not specify 'Distance','mahalanobis', then knnsearch returns an error message.

Example: 'Cov',eye(3)

Data Types: single | double

**Scale — Scale parameter value for standardized Euclidean distance metric**

nanstd(Mdl.X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length K, where K is the number of columns of Mdl.X.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance','seuclidean', then knnsearch returns an error message.

Example: 'Scale',quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)

Data Types: single | double
If you specify 'Distance', 'Cov', 'P', or 'Scale', then Mdl.Distance and Mdl.DistParameter do not change value.

### Output Arguments

**Idx — Training data indices of nearest neighbors**  
numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then Idx is an m-by-k numeric matrix, where m is the number of rows in Y and k is the number of searched nearest neighbors specified by the 'K' name-value pair argument. Idx(j,l) indicates that Mdl.X(Idx(j,l),:) is the observation with the lth smallest distance to the query observation Y(j,:).
- If you specify 'IncludeTies', true, then Idx is an m-by-1 cell array such that cell j (Idx{j}) contains a vector of at least k indices of the closest observations in Mdl.X to the query observation Y(j,:). The function arranges the elements of the vectors in ascending order by distance.

**D — Distances of nearest neighbors**  
numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then D is an m-by-k numeric matrix, where m is the number of rows in Y and k is the number of searched nearest neighbors specified by the 'K' name-value pair argument. D(j,l) is the distance between Mdl.X(Idx(j,l),:) and the query observation Y(j,:) with respect to the distance metric, and it represents the lth smallest distance.
- If you specify 'IncludeTies', true, then D is an m-by-1 cell array such that cell j (D{j}) contains a vector of at least k distances of the closest observations in Mdl.X to the query observation Y(j,:). The function arranges the elements of the vectors in ascending order by distance.
**Tips**

knnsearch finds the \( k \) (positive integer) points in \( Mdl.X \) that are \( k \)-nearest for each \( Y \) point. In contrast, rangesearch finds all the points in \( Mdl.X \) that are within distance \( r \) (positive scalar) of each \( Y \) point.

**Alternative Functionality**

- knnsearch is an object function that requires an ExhaustiveSearcher or a KDTreeSearcher model object and query data. Under equivalent conditions, the knnsearch object function returns the same results as the knnsearch function when you specify the name-value pair argument 'NSMethod','exhaustive' or 'NSMethod','kdtree', respectively.
- For \( k \)-nearest neighbors classification, see fitcknn and ClassificationKNN.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- This table contains notes about arguments of knnsearch.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Notes and Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mdl</td>
<td>There are two ways to use Mdl in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.</td>
</tr>
<tr>
<td></td>
<td>• Use <code>saveCompactModel</code>, <code>loadCompactModel</code>, and <code>codegen</code> to generate code for the <code>knnsearch</code> function. Save a trained model by using <code>saveCompactModel</code> and define an entry-point function that loads the saved model by using <code>loadCompactModel</code> and calls the <code>knnsearch</code> function. Then use <code>codegen</code> to generate code for the entry-point function.</td>
</tr>
<tr>
<td></td>
<td>• Include <code>coder.Constant(Mdl)</code> in the <code>-args</code> value of <code>codegen</code>.</td>
</tr>
<tr>
<td>'Distance'</td>
<td>• Cannot be a custom distance function.</td>
</tr>
<tr>
<td></td>
<td>• Must be a compile-time constant; its value cannot change in the generated code.</td>
</tr>
<tr>
<td>'IncludeTies'</td>
<td>Must be a compile-time constant; its value cannot change in the generated code.</td>
</tr>
<tr>
<td>Name-value pair arguments</td>
<td>Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include <code>{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}</code> in the <code>-args</code> value of <code>codegen</code>.</td>
</tr>
<tr>
<td>Idx</td>
<td>When you specify 'IncludeTies' as true, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.</td>
</tr>
</tbody>
</table>

- For code generation, `knnsearch` uses `parfor` (by default) to create loops that run in parallel on supported shared-memory multicore platforms. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, specify the `EnableOpenMP` property of the `codegen` configuration object as `false`. For details, see `coder.CodeConfig`. 

32-3437

Topics
“k-Nearest Neighbor Search and Radius Search” on page 18-19
“Distance Metrics” on page 18-16

Introduced in R2010a
**knnsearch**

Find $k$-nearest neighbors using data

**Syntax**

Idx = knnsearch(X,Y)
Idx = knnsearch(X,Y,Name,Value)
[Idx,D] = knnsearch(__)

**Description**

Idx = knnsearch(X,Y) finds the nearest neighbor in X for each query point in Y and returns the indices of the nearest neighbors in Idx, a column vector. Idx has the same number of rows as Y.

Idx = knnsearch(X,Y,Name,Value) returns Idx with additional options specified using one or more name-value pair arguments. For example, you can specify the number of nearest neighbors to search for and the distance metric used in the search.

[Idx,D] = knnsearch(__) additionally returns the matrix D, using any of the input arguments in the previous syntaxes. D contains the distances between each observation in Y and the corresponding closest observations in X.

**Examples**

Find Nearest Neighbors

Find the patients in the hospital data set that most closely resemble the patients in Y, according to age and weight.

Load the hospital data set.
load hospital;
X = [hospital.Age hospital.Weight];
Y = [20 162; 30 169; 40 168; 50 170; 60 171];   % New patients

Perform a knnsearch between X and Y to find indices of nearest neighbors.

Idx = knnsearch(X,Y);

Find the patients in X closest in age and weight to those in Y.

X(Idx,:)

ans = 5×2

25   171
25   171
39   164
49   170
50   172

Find k-Nearest Neighbors Using Different Distance Metrics

Find the 10 nearest neighbors in X to each point in Y, first using the Minkowski distance metric and then using the Chebychev distance metric.

Load Fisher's iris data set.

load fisheriris
X = meas(:,3:4);    % Measurements of original flowers
Y = [5 1.45;6 2;2.75 .75];  % New flower data

Perform a knnsearch between X and the query points Y using Minkowski and Chebychev distance metrics.

[mIdx,mD] = knnsearch(X,Y,'K',10,'Distance','minkowski','P',5);
[cIdx,cD] = knnsearch(X,Y,'K',10,'Distance','chebychev');

Visualize the results of the two nearest neighbor searches. Plot the training data. Plot the query points with the marker X. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.
gscatter(X(:,1),X(:,2),species)
line(Y(:,1),Y(:,2),"Marker","x","Color","k",...
   'Markersize',10,'Linewidth',2,'Linestyle','none')
line(X(mIdx,1),X(mIdx,2),"Color",[.5 .5 .5],"Marker","o",...
   'Linestyle','none','Markersize',10)
line(X(cIdx,1),X(cIdx,2),"Color",[.5 .5 .5],"Marker","p",...
   'Linestyle','none','Markersize',10)
legend('setosa','versicolor','virginica','query point',...
    'minkowski','chebychev','Location','best')
Input Arguments

X — Input data
numeric matrix

Input data, specified as a numeric matrix. Rows of X correspond to observations, and columns correspond to variables.

Data Types: single | double

Y — Query points
numeric matrix

Query points, specified as a numeric matrix. Rows of Y correspond to observations, and columns correspond to variables. Y must have the same number of columns as X.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as
Name1,Value1,...,NameN,ValueN.

Example: knnsearch(X,Y,'K',
10,'IncludeTies',true,'Distance','cityblock') searches for 10 nearest neighbors, including ties and using the city block distance.

K — Number of nearest neighbors
1 (default) | positive integer

Number of nearest neighbors to find in X for each point in Y, specified as the comma-separated pair consisting of 'K' and a positive integer.

Example: 'K',10

Data Types: single | double

IncludeTies — Flag to include all nearest neighbors
false (0) (default) | true (1)
Flag to include all nearest neighbors that have the same distance from query points, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If 'IncludeTies' is false, then knnsearch chooses the observation with the smallest index among the observations that have the same distance from a query point.

If 'IncludeTies' is true, then:

- knnsearch includes all nearest neighbors whose distances are equal to the \(k\)th smallest distance in the output arguments. To specify \(k\), use the 'K' name-value pair argument.
- \(\text{Idx}\) and \(\text{D}\) are \(m\)-by-1 cell arrays such that each cell contains a vector of at least \(k\) indices and distances, respectively. Each vector in \(\text{D}\) contains distances arranged in ascending order. Each row in \(\text{Idx}\) contains the indices of the nearest neighbors corresponding to the smallest distances in \(\text{D}\).

Example: 'IncludeTies',true

**NSMethod — Nearest neighbor search method**

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and one of these values.

- 'kdtree' — Creates and uses a Kd-tree to find nearest neighbors. 'kdtree' is the default value when the number of columns in \(X\) is less than or equal to 10, \(X\) is not sparse, and the distance metric is 'euclidean', 'cityblock', 'chebychev', or 'minkowski'. Otherwise, the default value is 'exhaustive'.

  The value 'kdtree' is valid only when the distance metric is one of the four metrics noted above.

- 'exhaustive' — Uses the exhaustive search algorithm by computing the distance values from all the points in \(X\) to each point in \(Y\).

Example: 'NSMethod','exhaustive'

**Distance — Distance metric**

'eucilidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | function handle | ...
Distance metric `knnsearch` uses, specified as the comma-separated pair consisting of 'Distance' and one of the values in this table or a function handle.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix Y is scaled by dividing by the corresponding element of the standard deviation computed from X. To specify another scaling, use the 'Scale' name-value pair argument.</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of non-zero coordinates that differ.</td>
</tr>
</tbody>
</table>

You can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form function `D2 = distfun(ZI,ZJ)`.
- Take as arguments:
  - A 1-by-`n` vector `ZI` containing a single row from `X` or from the query points `Y`.
  - An `m_2`-by-`n` matrix `ZJ` containing multiple rows of `X` or `Y`.
- Return an `m_2`-by-1 vector of distances `D2`, whose `j`th element is the distance between the observations `ZI` and `ZJ(j,:)`.  

32-3444
For more information, see “Distance Metrics” on page 18-16.

Example: 'Distance','chebychev'

**P — Exponent for Minkowski distance metric**
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',4

Data Types: single | double

**Cov — Covariance matrix for Mahalanobis distance metric**
nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. This argument is valid only when 'Distance' is 'mahalanobis'.

Example: 'Cov',eye(4)

Data Types: single | double

**Scale — Scale parameter value for standardized Euclidean distance metric**
nanstd(X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. 'Scale' has length equal to the number of columns in X. When knnsearch computes the standardized Euclidean distance, each coordinate of X is scaled by the corresponding element of 'Scale', as is each query point. This argument is valid only when 'Distance' is 'seuclidean'.

Example: 'Scale',quantile(X,0.75) - quantile(X,0.25)

Data Types: single | double

**BucketSize — Maximum number of data points in leaf node of Kd-tree**
50 (default) | positive integer

Maximum number of data points in the leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer. This argument is valid only when NSMethod is 'kdtree'.

32-3445
Output Arguments

**Idx — Input data indices of nearest neighbors**
numeric matrix | cell array of numeric vectors

Input data indices of the nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (false by default), then `Idx` is an `m`-by-`k` numeric matrix, where `m` is the number of rows in `Y` and `k` is the number of searched nearest neighbors. `Idx(j,i)` indicates that `X(Idx(j,i),:)` is the observation with the `i`th smallest distance to the query point `Y(j,:)`.

- If you specify `'IncludeTies'`, `true`, then `Idx` is an `m`-by-`1` cell array such that cell `j` (`Idx{j}`) contains a vector of at least `k` indices of the closest observations in `X` to the query point `Y(j,:)`. The `knnsearch` function arranges the elements of the vectors in ascending order by distance.

**D — Distances of nearest neighbors**
numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query points, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (false by default), then `D` is an `m`-by-`k` numeric matrix, where `m` is the number of rows in `Y` and `k` is the number of searched nearest neighbors. `D(j,i)` is the distance between `X(Idx(j,i),:)` and `Y(j,:)` with respect to the distance metric, and it represents the `i`th smallest distance.

- If you specify `'IncludeTies'`, `true`, then `D` is an `m`-by-`1` cell array such that cell `j` (`D{j}`) contains a vector of at least `k` distances of the closest observations in `X` to the query point `Y(j,:)`. The `knnsearch` function arranges the elements of the vectors in ascending order by distance.
Tips

• For a fixed positive integer \( k \), \texttt{knnsearch} finds the \( k \) points in \( X \) that are the nearest to each point in \( Y \). To find all points in \( X \) within a fixed distance of each point in \( Y \), use \texttt{rangesearch}.
• \texttt{knnsearch} does not save a search object. To create a search object, use \texttt{creatsens}.

Algorithms

For information on a specific search algorithm, see “Distance Metrics” on page 18-16.

Alternative Functionality

If you set the \texttt{knnsearch} function's 'NSMethod' name-value pair argument to the appropriate value ('exhaustive' for an exhaustive search algorithm or 'kdtree' for a Kd-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the \texttt{knnsearch} object function. Unlike the \texttt{knnsearch} function, the \texttt{knnsearch} object function requires an \texttt{ExhaustiveSearcher} or a \texttt{KDTreeSearcher} model object.

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• For code generation, the default value of the 'NSMethod' name-value pair argument is 'exhaustive' when the number of columns in X is greater than 7.
• The value of the 'Distance' name-value pair argument must be a compile-time constant and cannot be a custom distance function.
• The value of the 'IncludeTies' name-value pair argument must be a compile-time constant.
• Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include
  \{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0\} in the -args value of codegen.
• When you specify 'IncludeTies' as true, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
• For code generation, knnsearch uses parfor (by default) to create loops that run in parallel on supported shared-memory multicore platforms. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the parfor-loops as for-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, specify the EnableOpenMP property of the codegen configuration object as false. For details, see coder.CodeConfig.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The 'IncludeTies' and 'NSMethod' Name arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced in R2010a**
kruskalwallis

Kruskal-Wallis test

Syntax

\[ p = \text{kruskalwallis}(x) \]
\[ p = \text{kruskalwallis}(x,\text{group}) \]
\[ p = \text{kruskalwallis}(x,\text{group},\text{displayopt}) \]
\[ [p,tbl,stats] = \text{kruskalwallis}(\_\_\_) \]

Description

\[ p = \text{kruskalwallis}(x) \] returns the \( p \)-value for the null hypothesis that the data in each column of the matrix \( x \) comes from the same distribution, using a Kruskal-Wallis test on page 32-3458. The alternative hypothesis is that not all samples come from the same distribution. \text{kruskalwallis} also returns an ANOVA table and a box plot.

\[ p = \text{kruskalwallis}(x,\text{group}) \] returns the \( p \)-value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable \( \text{group} \) comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

\[ p = \text{kruskalwallis}(x,\text{group},\text{displayopt}) \] returns the \( p \)-value of the test and lets you display or suppress the ANOVA table and box plot.

\[ [p,tbl,stats] = \text{kruskalwallis}(\_\_\_) \] also returns the ANOVA table as the cell array \( tbl \) and the structure \( stats \) containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has \( \text{mu} = 0 \) and \( \text{sigma} = 1 \), and the second distribution has \( \text{mu} = 2 \) and \( \text{sigma} = 1 \).
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);

Create a matrix of sample data by generating random numbers from these two distributions.

rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];

The first two columns of x contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in x comes from the same distribution.

p = kruskalwallis(x)
### Kruskal-Wallis ANOVA Table

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Chi-sq</th>
<th>Prob&gt;Chi-sq</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns</td>
<td>7631.1</td>
<td>2</td>
<td>3815.55</td>
<td>25.02</td>
<td>3.68957e-06</td>
</tr>
<tr>
<td>Error</td>
<td>10363.9</td>
<td>57</td>
<td>181.82</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>17995</td>
<td>59</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The returned value of $p$ indicates that kruskalwallis rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in $x$.

**Conduct Followup Tests for Unequal Medians**

Create two different normal probability distribution objects. The first distribution has $\mu = 0$ and $\sigma = 1$. The second distribution has $\mu = 2$ and $\sigma = 1$. 
pd1 = makedist('Normal');
pd2 = makedist('Normal', 'mu', 2, 'sigma', 1);

Create a matrix of sample data by generating random numbers from these two distributions.

rng('default'); % for reproducibility
x = [random(pd1, 20, 2), random(pd2, 20, 1)];

The first two columns of x contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in x comes from the same distribution. Suppress the output displays, and generate the structure stats to use in further testing.

[p, tbl, stats] = kruskalwallis(x, [], 'off')

p = 3.6896e-06

tbl = 4x6 cell array
  Columns 1 through 5
    {'Source'}    {'SS'       }    {'df'}    {'MS'      }    {'Chi-sq'  }
    {'Columns'}    {[7.6311e+03]}    {[ 2]}    {[3.8155e+03]}    {[ 25.0200]}
    {'Error' }    {[1.0364e+04]}    {[57]}    {[  181.8228]}    {0x0 double}
    {'Total' }    {[ 17995]}    {[59]}    {0x0 double  }    {0x0 double  }

  Column 6
    {'Prob>Chi-sq'}
    {[ 3.6896e-06]}
    {0x0 double  }
    {0x0 double  }

stats = struct with fields:
  gnames: [3x1 char]
  n: [20 20 20]
  source: 'kruskalwallis'
  meanranks: [26.7500 18.9500 45.8000]
  sumt: 0

The returned value of p indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure stats to perform additional followup testing.
The cell array tbl contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

c = multcompare(stats)

Note: Intervals can be used for testing but are not simultaneous confidence intervals.
The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

**Test for the Same Distribution Across Groups**

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, indicating the type of metal alloy from which the corresponding beam is made.

```matlab
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 77 78 82 79];

alloy = {'st','st','st','st','st','st','st','st',...
        'al1','al1','al1','al1','al1','al1',...
        'al2','al2','al2','al2','al2','al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```matlab
p = kruskalwallis(strength,alloy,'off')
p = 0.0018
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

**Input Arguments**

- `x` — Sample data
  
  vector | matrix

  Sample data for the hypothesis test, specified as a vector or an `m-by-n` matrix. If `x` is an `m-by-n` matrix, each of the `n` columns represents an independent sample containing `m` mutually independent observations.
Data Types: single | double

**group — Grouping variable**

numeric vector | logical vector | character array | string array | cell array of character vectors

Grouping variable, specified as a numeric or logical vector, a character or string array, or a cell array of character vectors.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty value, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.
- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

Example:

```{red,'
blue',
green',
'blue',
'red',
'blue',
'green',
'green',
'red'}
```

Data Types: single | double | logical | char | string | cell

**displayopt — Display option**

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: 'off'
## Output Arguments

**p — p-value**  
scalar value in the range [0,1]  

$p$-value of the test, returned as a scalar value in the range [0,1]. $p$ is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of $p$ cast doubt on the validity of the null hypothesis.

**tbl — ANOVA table**  

cell array  

ANOVA table of test results, returned as a cell array. `tbl` includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`, as well as column and row labels.

**stats — Test data**  

structure  

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with `stats` as the input value.

## Definitions

### Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in `x` to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The $F$-statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the $p$-value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and
that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

Introduced before R2006a
ksdensity

Kernel smoothing function estimate for univariate and bivariate data

Syntax

[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(___,Name,Value)
[f,xi,bw] = ksdensity(___)

ksdensity(___)
ksdensity(ax,___)

Description

[f,xi] = ksdensity(x) returns a probability density estimate, f, for the sample data in the vector or two-column matrix x. The estimate is based on a normal kernel function, and is evaluated at equally-spaced points, xi, that cover the range of the data in x. ksdensity estimates the density at 100 points for univariate data, or 900 points for bivariate data.

ksdensity works best with continuously distributed samples.

[f,xi] = ksdensity(x,pts) specifies points (pts) to evaluate f. Here, xi and pts contain identical values.

[f,xi] = ksdensity(___,Name,Value) uses additional options specified by one or more name-value pair arguments in addition to any of the input arguments in the previous syntaxes. For example, you can define the function type ksdensity evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

[f,xi,bw] = ksdensity(___) also returns the bandwidth of the kernel smoothing window, bw. The default bandwidth is the optimal for normal densities.

ksdensity(___) plots the kernel smoothing function estimate.
ksdensity(ax,___) plots the results using axes with the handle, ax, instead of the current axes returned by gca.

Examples

Estimate Density

Generate a sample data set from a mixture of two normal distributions.

rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];

Plot the estimated density.

[f,xi] = ksdensity(x);
figure
plot(xi,f);
The density estimate shows the bimodality of the sample.

**Estimate Density with Boundary Correction**

Generate a nonnegative sample data set from the half-normal distribution.

```matlab
rng('default') % For reproducibility
pd = makedist('HalfNormal','mu',0,'sigma',1);
x = random(pd,100,1);
```

Estimate pdfs with two different boundary correction methods, log transformation and reflection, by using the 'BoundaryCorrection' name-value pair argument.
pts = linspace(0,5,1000); % points to evaluate the estimator
[f1,xi1] = ksdensity(x,pts,'Support','positive');
[f2,xi2] = ksdensity(x,pts,'Support','positive','BoundaryCorrection','reflection');

Plot the two estimated pdfs.

plot(xi1,f1,xi2,f2)
lgd = legend('log','reflection');
title(lgd, 'Boundary Correction Method')
xl = xlim;
xlim([xl(1)-0.25 xl(2)])

ksdensity uses a boundary correction method when you specify either positive or bounded support. The default boundary correction method is log transformation. When
ksdensity transforms the support back, it introduces the $1/x$ term in the kernel density estimator. Therefore, the estimate has a peak near $x = 0$. On the other hand, the reflection method does not cause undesirable peaks near the boundary.

**Estimate Cumulative Distribution Function at Specified Values**

Load the sample data.

```matlab
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```matlab
pts = (min(hospital.Weight):2:max(hospital.Weight));
figure()
ecdf(hospital.Weight)
hold on
[f,xi,bw] = ksdensity(hospital.Weight,pts,'Support','positive', ...
    'Function','cdf');
plot(xi,f,'-g','LineWidth',2)
legend('empirical cdf','kernel-bw:default','Location','northwest')
xlabel('Patient weights')
ylabel('Estimated cdf')
```
ksdensity seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

bw

bw = 0.1070

Plot the cumulative distribution function estimate using a smaller bandwidth.

[f,xi] = ksdensity(hospital.Weight,pts,'Support','positive',... 'Function','cdf','Bandwidth',0.05);
The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

**Plot Estimated Cumulative Density Function for Given Number of Points**

Load the sample data.
load hospital

Plot the estimated cdf evaluated at 50 equally spaced points.

figure()
ksdensity(hospital.Weight,'Support','positive','Function','cdf',... 
'NumPoints',50)
xlabel('Patient weights')
ylabel('Estimated cdf')
Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

```matlab
rng('default') % For reproducibility
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```matlab
T = 10;
cens = (x>T);
```

Compute and plot the estimated density function.

```matlab
figure
ksdensity(x,'Support','positive','Censoring',cens);
```
Compute and plot the survivor function.

```matlab
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','survivor');
```
Compute and plot the cumulative hazard function.

```matlab
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','cumhazard');
```
**Estimate Inverse Cumulative Distribution Function for Specified Probability Values**

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```matlab
rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'Function','icdf');
```
Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];

Return the bandwidth of the smoothing window for the probability density estimate.

[f,xi,bw] = ksdensity(x);
bw
bw = 1.5141

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```matlab
figure
plot(xi,f);
xlabel('xi')
ylabel('f')
hold on
```

Plot the density using an increased bandwidth value.
[f,xi] = ksdensity(x,'Bandwidth',1.8);
plot(xi,f,'--r','LineWidth',1.5)

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

[f,xi] = ksdensity(x,'Bandwidth',0.8);
plot(xi,f,'-.k','LineWidth',1.5)
legend('bw = default','bw = 1.8','bw = 0.8')
hold off
A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

**Plot Kernel Density Estimate of Bivariate Data**

Create a two-column vector of points at which to evaluate the density.

```matlab
gridx1 = -0.25:.05:1.25;
gridx2 = 0:.1:15;
[x1,x2] = meshgrid(gridx1, gridx2);
x1 = x1(:);
```
x2 = x2(:);
x = [x1 x2];

Generate a 30-by-2 matrix containing random numbers from a mixture of bivariate normal distributions.

rng('default')  % For reproducibility
x = [0+.5*rand(20,1) 5+2.5*rand(20,1);
    .75+.25*rand(10,1) 8.75+1.25*rand(10,1)];

Plot the estimated density of the sample data.
figure
ksdensity(x,xi);
Input Arguments

x — Sample data
column vector | two-column matrix

Sample data for which ksdensity returns f values, specified as a column vector or two-column matrix. Use a column vector for univariate data, and a two-column matrix for bivariate data.

Example: [f,xi] = ksdensity(x)
Data Types: single | double

pts — Points to evaluate f
vector | two-column matrix

Points to evaluate f at, specified as a vector or two-column matrix. For univariate data, pts can be a row or column vector. The returned output f has the same dimensions as pts.

Example: pts = (0:1:25); ksdensity(x,pts);
Data Types: single | double

ax — Axes handle
handle

Axes handle for the figure ksdensity plots to, specified as a handle.

For example, if h is a handle for a figure, then ksdensity can plot to that figure as follows.

Example: ksdensity(h,x)

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Censoring',cens,'Kernel','triangle','NumPoints',20,'Function','cdf' specifies that ksdensity estimates the cdf by evaluating at 20 points.
equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector cens.

**Bandwidth — Bandwidth of the kernel smoothing window**

optimal value for normal densities (default) | scalar value | two-element vector

The bandwidth of the kernel-smoothing window, which is a function of the number of points in x, specified as the comma-separated pair consisting of 'Bandwidth' and a scalar value. If the sample data is bivariate, Bandwidth can also be a two-element vector. The default is optimal for estimating normal densities [1], but you might want to choose a larger or smaller value to smooth more or less.

If you specify 'BoundaryCorrection' as 'log'(default) and 'Support' as either 'positive' or a vector [L U], ksdensity converts bounded data to be unbounded by using log transformation. The value of 'Bandwidth' is on the scale of the transformed values.

Example: 'Bandwidth',0.8

Data Types: single | double

**BoundaryCorrection — Boundary correction method**

'log' (default) | 'reflection'

Boundary correction method, specified as the comma-separated pair consisting of 'BoundaryCorrection' and 'log' or 'reflection'.

---

32-3478
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'log'</td>
<td>ksdensity converts bounded data ( x ) to be unbounded by one of the following transformations. Then, it transforms back to the original bounded scale after density estimation.</td>
</tr>
<tr>
<td></td>
<td>- For univariate data, if you specify 'Support','positive', then ksdensity applies ( \log(x) ).</td>
</tr>
<tr>
<td></td>
<td>- For univariate data, if you specify 'Support',[( L ) ( U )], where ( L ) and ( U ) are numeric scalars and ( L &lt; U ), then ksdensity applies ( \log((x-L)/(U-x)) ).</td>
</tr>
<tr>
<td></td>
<td>- For bivariate data, ksdensity transforms each column of ( x ) in the same way with the univariate data.</td>
</tr>
<tr>
<td></td>
<td>The value of 'Bandwidth' and the ( bw ) output are on the scale of the transformed values.</td>
</tr>
<tr>
<td>'reflection'</td>
<td>ksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 32-3484.</td>
</tr>
</tbody>
</table>

ksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection','reflection'

**Censoring — Logical vector**

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as the comma-separated pair consisting of 'Censoring' and a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring. This name-value pair is only valid for univariate data.

Example: 'Censoring',censdata

Data Types: logical

**Function — Function to estimate**

'pdf' (default)| 'cdf' | 'icdf' | 'survivor' | 'cumhazard'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.
<table>
<thead>
<tr>
<th><strong>Value</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>'pdf'</td>
<td>Probability density function.</td>
</tr>
<tr>
<td>'cdf'</td>
<td>Cumulative distribution function.</td>
</tr>
<tr>
<td>'icdf'</td>
<td>Inverse cumulative distribution function. <code>ksdensity</code> computes the estimated inverse cdf of the values in <code>x</code>, and evaluates it at the probability values specified in <code>pi</code>. This value is valid only for univariate data.</td>
</tr>
<tr>
<td>'survivor'</td>
<td>Survivor function.</td>
</tr>
<tr>
<td>'cumhazard'</td>
<td>Cumulative hazard function. This value is valid only for univariate data.</td>
</tr>
</tbody>
</table>

Example: 'Function','icdf'

**Kernel — Type of kernel smoother**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'

You can also specify a custom kernel function as a function handle (for example, `@normpdf`) or as either a character vector or string scalar (for example, 'normpdf'). This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'Function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'Function' is 'icdf' returns an error.

For bivariate data, `ksdensity` applies the same kernel to each dimension.
Example: 'Kernel', 'box'

**NumPoints — Number of equally spaced points**

100 (default) | scalar value

Number of equally spaced points in \( xi \), specified as the comma-separated pair consisting of 'NumPoints' and a scalar value. This name-value pair is only valid for univariate data.

For example, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: 'NumPoints', 80

Data Types: single | double

**Support — Support for the density**

'unbounded' (default) | 'positive' | two-element vector, [L U] | two-by-two matrix, [L1 L2 ; U1 U2]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'unbounded'</td>
<td>Default. Allow the density to extend over the whole real line.</td>
</tr>
<tr>
<td>'positive'</td>
<td>Restrict the density to positive values.</td>
</tr>
<tr>
<td>Two-element vector, [L U]</td>
<td>Give the finite lower and upper bounds for the support of the density. This option is only valid for univariate sample data.</td>
</tr>
<tr>
<td>Two-by-two matrix, [L1 L2 ; U1 U2]</td>
<td>Give the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. This option is only valid for bivariate sample data.</td>
</tr>
</tbody>
</table>

For bivariate data, 'Support' can be a combination of positive, unbounded, or bounded variables specified as [0 -Inf ; Inf Inf] or [0 L ; Inf U].

Example: 'Support', 'positive'

Example: 'Support', [0 10]

Data Types: single | double | char | string

**PlotFcn — Function used to create kernel density plot**

'surf' (default) | 'contour' | 'plot3' | 'surfc'

32-3481
Function used to create kernel density plot, specified as the comma-separated pair consisting of 'PlotFcn' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'surf'</td>
<td>3-D shaded surface plot, created using surf</td>
</tr>
<tr>
<td>'contour'</td>
<td>Contour plot, created using contour</td>
</tr>
<tr>
<td>'plot3'</td>
<td>3-D line plot, created using plot3</td>
</tr>
<tr>
<td>'surfc'</td>
<td>Contour plot under a 3-D shaded surface plot, created using surfc</td>
</tr>
</tbody>
</table>

This name-value pair is only valid for bivariate sample data.

Example: 'PlotFcn','contour'

**Weights** — Weights for sample data
type: vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length size(x,1), where x is the sample data.

Example: 'Weights',xw

Data Types: single | double

**Output Arguments**

**f** — Estimated function values
type: vector

Estimated function values, returned as a vector of the same dimension as xi or pts.

**xi** — Evaluation points
type: 100 equally spaced points | 900 equally spaced points | vector

Evaluation points at which ksdensity calculates f, returned as a vector. For univariate data, the default is 100 equally-spaced points that cover the range of data in x. For bivariate data, the default is 900 equally-spaced points created using meshgrid from 30 equally-spaced points in each dimension.

**bw** — Bandwidth of smoothing window
type: scalar value
Bandwidth of smoothing window, returned as a scalar value.

If you specify 'BoundaryCorrection' as 'log'(default) and 'Support' as either 'positive' or a vector [L U], ksdensity converts bounded data to be unbounded by using log transformation. The value of bw is on the scale of the transformed values.

Definitions

Kernel Distribution

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

The kernel density estimator is the estimated pdf of a random variable. For any real values of $x$, the kernel density estimator's formula is given by

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^{n} K\left(\frac{x - x_i}{h}\right),$$

where $x_1, x_2, ..., x_n$ are random samples from an unknown distribution, $n$ is the sample size, $K(\cdot)$ is the kernel smoothing function, and $h$ is the bandwidth.

The kernel estimator for the cumulative distribution function (cdf), for any real values of $x$, is given by

$$\hat{F}_h(x) = \int_{-\infty}^{x} \hat{f}_h(t)dt = \frac{1}{n} \sum_{i=1}^{n} G\left(\frac{x - x_i}{h}\right),$$

where $G(x) = \int_{-\infty}^{x} K(t)dt$.

For more details, see “Kernel Distribution” on page B-81.
Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify 'BoundaryCorrection','reflection', ksdensity uses the reflection method. This method augments bounded data by adding reflected data near the boundaries, and estimates the pdf. Then, ksdensity returns the estimated pdf corresponding to the original support with proper normalization, so that the estimated pdf's integral over the original support is equal to one.

If you additionally specify 'Support',[L U], then ksdensity finds the kernel estimator as follows.

- If 'Function' is 'pdf', then the kernel density estimator is

\[
\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^{n} \left[ K\left( \frac{x-x_i^-}{h} \right) + K\left( \frac{x-x_i^+}{h} \right) \right]
\]

for \( L \leq x \leq U \),

where \( x_i^- = 2L - x_i \), \( x_i^+ = 2U - x_i \), and \( x_i \) is the \( i \)th sample data.

- If 'Function' is 'cdf', then the kernel estimator for cdf is

\[
\hat{F}_h(x) = \frac{1}{n} \sum_{i=1}^{n} \left[ G\left( \frac{x-x_i^-}{h} \right) + G\left( \frac{x-x_i^+}{h} \right) \right] - \frac{1}{n} \sum_{i=1}^{n} \left[ G\left( \frac{L-x_i^-}{h} \right) + G\left( \frac{L-x_i^+}{h} \right) \right]
\]

for \( L \leq x \leq U \).

- To obtain a kernel estimator for an inverse cdf, a survivor function, or a cumulative hazard function (when 'Function' is 'icdf', 'survivor', or 'cumhazard'), ksdensity uses both \( \hat{f}_h(x) \) and \( \hat{F}_h(x) \).

If you additionally specify 'Support' as 'positive' or [0 inf], then ksdensity finds the kernel estimator by replacing [L U] with [0 inf] in the above equations.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• Some options that require extra passes or sorting of the input data are not supported:
  • 'BoundaryCorrection'
  • 'Censoring'
  • 'Support' (support is always unbounded).
• Uses standard deviation (instead of median absolute deviation) to compute the bandwidth.

For more information, see “Tall Arrays” (MATLAB).

ktest

One-sample Kolmogorov-Smirnov test

Syntax

h = ktest(x)
h = ktest(x,Name,Value)
[h,p] = ktest(___)
[h,p,ksstat,cv] = ktest(___)  

Description

h = ktest(x) returns a test decision for the null hypothesis that the data in vector x comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test on page 32-3496. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

h = ktest(x,Name,Value) returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

[h,p] = ktest(__) also returns the p-value p of the hypothesis test, using any of the input arguments from the previous syntaxes.

[h,p,ksstat,cv] = ktest(__) also returns the value of the test statistic ksstat and the approximate critical value cv of the test.

Examples
Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the examgrades data set. Create a vector containing the first column of the exam grade data.

```matlab
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

```matlab
x = (test1-75)/10;
h = kstest(x)
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```matlab
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```
The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

**Specify the Hypothesized Distribution Using a Two-Column Matrix**

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

```matlab
load examgrades;
x = grades(:,1);
```
Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector \( x \). Column 2 contains cdf values evaluated at each value in \( x \) for a hypothesized Student’s \( t \) distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

\[
\text{test}_\text{cdf} = [x, \text{cdf('tlocationscale',}x, 75, 10, 1)];
\]

Test if the data are from the hypothesized distribution.

\[
h = \text{kstest}(x, 'CDF', \text{test}_\text{cdf})
\]

\[
h = \text{logical}
\]

\[
1
\]

The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis at the default 5% significance level.

**Specify the Hypothesized Distribution Using a Probability Distribution Object**

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

\[
\text{load examgrades;}
\]

\[
x = \text{grades}(:,1);
\]

Create a probability distribution object to test if the data comes from a Student’s \( t \) distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

\[
\text{test}_\text{cdf} = \text{makedist('tlocationscale',}'\mu',75,'\sigma',10,'\nu',1);
\]

Test the null hypothesis that the data comes from the hypothesized distribution.

\[
h = \text{kstest}(x, 'CDF', \text{test}_\text{cdf})
\]

\[
h = \text{logical}
\]

\[
1
\]
The returned value of \( h = 1 \) indicates that \texttt{kstest} rejects the null hypothesis at the default 5% significance level.

**Test the Hypothesis at Different Significance Levels**

Load the sample data. Create a vector containing the first column of the students’ exam grades.

```matlab
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student’s \( t \) distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```matlab
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```matlab
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
h = logical
    1
p = 0.0021
```

The returned value of \( h = 1 \) indicates that \texttt{kstest} rejects the null hypothesis at the 1% significance level.

**Conduct a One-Sided Hypothesis Test**

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```matlab
load stockreturns;
x = stocks(:,3);
```
Test the null hypothesis that the data comes from a standard normal distribution, against
the alternative hypothesis that the population cdf of the data is larger than the standard
normal cdf.

\[ [h,p,k,c] = kstest(x,'Tail','larger') \]

\[ h = \text{logical} \]
\[ 1 \]

\[ p = 5.0854e-05 \]
\[ k = 0.2197 \]
\[ c = 0.1207 \]

The returned value of \( h = 1 \) indicates that \text{kstest} rejects the null hypothesis in favor of
the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

\[ [f,x\_values] = \text{ecdf}(x); \]
\[ J = \text{plot}(x\_values,f); \]
\[ \text{hold on}; \]
\[ K = \text{plot}(x\_values,\text{normcdf}(x\_values),'r--'); \]
\[ \text{set}(J,'\text{LineWidth'},2); \]
\[ \text{set}(K,'\text{LineWidth'},2); \]
\[ \text{legend}([J\ K],'\text{Empirical CDF}', '\text{Standard Normal CDF}', '\text{Location'}, '\text{SE}'); \]
The plot shows the difference between the empirical cdf of the data vector \( x \) and the cdf of the standard normal distribution.

**Input Arguments**

\( x \) — Sample data vector

Sample data, specified as a vector.

Data Types: single | double
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Tail', 'larger', 'Alpha', 0.01 specifies a test using the alternative hypothesis that the cdf of the population from which the sample data is drawn is greater than the cdf of the hypothesized distribution, conducted at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: single | double

**CDF — cdf of hypothesized continuous distribution**

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of 'CDF' and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible x values, and column 2 contains the corresponding hypothesized cumulative distribution function values \( G(x) \). The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector \( x \). If there are values in \( x \) not found in column 1 of CDF, kstest approximates \( G(x) \) by interpolation. All values in \( x \) must lie in the interval between the smallest and largest values in the first column of CDF. By default, kstest tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test on page 32-3496 is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test \( x \) against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use lillietest instead.

Data Types: single | double

**Tail — Type of alternative hypothesis**

'unequal' (default) | 'larger' | 'smaller'
Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'unequal' Test the alternative hypothesis that the cdf of the population from which x is drawn is not equal to the cdf of the hypothesized distribution.

'larger' Test the alternative hypothesis that the cdf of the population from which x is drawn is greater than the cdf of the hypothesized distribution.

'smaller' Test the alternative hypothesis that the cdf of the population from which x is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector x tend to be larger than expected from the hypothesized distribution, the empirical distribution function of x tends to be smaller, and vice versa.

Example: 'Tail','larger'

Output Arguments

h — Hypothesis test result
1 | 0
Hypothesis test result, returned as a logical value.

• If h = 1, this indicates the rejection of the null hypothesis at the Alpha significance level.
• If h = 0, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ksstat — Test statistic
nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.
**cv — Critical value**
nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

**Definitions**

**One-Sample Kolmogorov-Smirnov Test**

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from \( x \) and the hypothesized cdf:

\[
D^* = \max_x \left| \hat{F}(x) - G(x) \right|
\]

where \( \hat{F}(x) \) is the empirical cdf and \( G(x) \) is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from \( x \) exceeds the hypothesized cdf:

\[
D^* = \max_x \left( \hat{F}(x) - G(x) \right)
\]

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from \( x \):

\[
D^* = \max_x \left( G(x) - \hat{F}(x) \right)
\]
kstest computes the critical value cv using an approximate formula or by interpolation in a table. The formula and table cover the range $0.01 \leq \alpha \leq 0.2$ for two-sided tests and $0.005 \leq \alpha \leq 0.1$ for one-sided tests. cv is returned as NaN if alpha is outside this range.

**Algorithms**

kstest decides to reject the null hypothesis by comparing the p-value p with the significance level Alpha, not by comparing the test statistic ksstat with the critical value cv. Since cv is approximate, comparing ksstat with cv occasionally leads to a different conclusion than comparing p with Alpha.

Introduced before R2006a
kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(__)
[h,p,ks2stat] = kstest2(__)

Description

h = kstest2(x1,x2) returns a test decision for the null hypothesis that the data in vectors x1 and x2 are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test on page 32-3502. The alternative hypothesis is that x1 and x2 are from different continuous distributions. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

h = kstest2(x1,x2,Name,Value) returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

[h,p] = kstest2(__) also returns the asymptotic $p$-value p, using any of the input arguments from the previous syntaxes.

[h,p,ks2stat] = kstest2(__) also returns the test statistic ks2stat.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.
rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);

Test the null hypothesis that data in vectors x1 and x2 comes from populations with the same distribution.

h = kstest2(x1,x2)

h = logical
  1

The returned value of h = 1 indicates that ktest rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);

Test the null hypothesis that data vectors x1 and x2 are from populations with the same distribution at the 1% significance level.

[h,p] = kstest2(x1,x2,'Alpha',0.01)

h = logical
  0

p = 0.0317

The returned value of h = 0 indicates that ktest does not reject the null hypothesis at the 1% significance level.
**One-Sided Hypothesis Test**

Generate sample data from two different Weibull distributions.

```matlab
rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```matlab
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h = logical
   1
p = 0.0158
k = 0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

**Input Arguments**

**x1 — Sample data vector**

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

**x2 — Sample data vector**

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.
Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Tail', 'larger', 'Alpha', 0.01 specifies a test using the alternative hypothesis that the empirical cdf of x1 is larger than the empirical cdf of x2, conducted at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: single | double

**Tail — Type of alternative hypothesis**

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'unequal' Test the alternative hypothesis that the empirical cdf of x1 is unequal to the empirical cdf of x2.
- 'larger' Test the alternative hypothesis that the empirical cdf of x1 is larger than the empirical cdf of x2.
- 'smaller' Test the alternative hypothesis that the empirical cdf of x1 is smaller than the empirical cdf of x2.

If the data values in x1 tend to be larger than those in x2, the empirical distribution function of x1 tends to be smaller than that of x2, and vice versa.

Example: 'Tail', 'larger'

32-3501
Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.
- If $h = 1$, this indicates the rejection of the null hypothesis at the $\alpha$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $\alpha$ significance level.

p — Asymptotic $p$-value

scalar value in the range (0,1)

Asymptotic $p$-value of the test, returned as a scalar value in the range (0,1). $p$ is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic $p$-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes $n_1$ and $n_2$, such that $(n_1*n_2)/(n_1 + n_2) \geq 4$.

ks2stat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

Definitions

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of $x$ in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x \left( |F_1(x) - F_2(x)| \right),$$
where \( \hat{F}_1(x) \) is the proportion of \( x_1 \) values less than or equal to \( x \) and \( \hat{F}_2(x) \) is the proportion of \( x_2 \) values less than or equal to \( x \).

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

\[
D^* = \max_x (F_1(x) - F_2(x)).
\]

**Algorithms**

In `kstest2`, the decision to reject the null hypothesis is based on comparing the \( p \)-value \( p \) with the significance level \( \text{Alpha} \), not by comparing the test statistic \( \text{ks2stat} \) with a critical value.

`adtest` | `ktest` | `lillietest`

**Introduced before R2006a**
kurtosis

Kurtosis

Syntax

\[
\text{k} = \text{kurtosis}(\text{X}) \\
\text{k} = \text{kurtosis}(\text{X,flag}) \\
\text{k} = \text{kurtosis}(\text{X,flag,'all'}) \\
\text{k} = \text{kurtosis}(\text{X,flag,dim}) \\
\text{k} = \text{kurtosis}(\text{X,flag,vecdim})
\]

Description

\(
\text{k} = \text{kurtosis}(\text{X}) \) returns the sample kurtosis of \( \text{X} \). For vectors, \text{kurtosis(x)} is the kurtosis of the elements in the vector \( x \). For matrices \text{kurtosis(X)} returns the sample kurtosis for each column of \( X \). For N-dimensional arrays, \text{kurtosis} operates along the first nonsingleton dimension of \( X \).

\( \text{k} = \text{kurtosis}(\text{X,flag}) \) specifies whether to correct for bias (\text{flag is 0}) or not (\text{flag is 1}, the default). When \( X \) represents a sample from a population, the kurtosis of \( X \) is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set \text{flag to 0} to correct for this systematic bias.

\( \text{k} = \text{kurtosis}(\text{X,flag,'all'}) \) returns the kurtosis of all elements of \( X \).

\( \text{k} = \text{kurtosis}(\text{X,flag,dim}) \) takes the kurtosis along the operating dimension \( \text{dim} \) of \( X \).

\( \text{k} = \text{kurtosis}(\text{X,flag,vecdim}) \) returns the kurtosis over the dimensions specified in the vector \text{vecdim}. Each element of \text{vecdim} represents a dimension of the input array \( X \). The output \( k \) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \( X \) and \( k \). For example, if \( X \) is a 2-by-3-by-4 array, then \text{kurtosis(X,1,[1 2])} returns a 1-by-1-by-4 array. Each element of the output array is the biased kurtosis of the elements on the corresponding page of \( X \).
Examples

Find Kurtosis of Matrix

Set the random seed for reproducibility of the results.

rng('default')

Generate a matrix with 5 rows and 4 columns.

\[X = \text{randn}(5,4)\]

\[
X = \begin{bmatrix}
0.5377 & -1.3077 & -1.3499 & -0.2050 \\
1.8339 & -0.4336 & 3.0349 & -0.1241 \\
-2.2588 & 0.3426 & 0.7254 & 1.4897 \\
0.8622 & 3.5784 & -0.0631 & 1.4090 \\
0.3188 & 2.7694 & 0.7147 & 1.4172 \\
\end{bmatrix}
\]

Find the sample kurtosis of \(X\).

\[k = \text{kurtosis}(X)\]

\[
k = \begin{bmatrix}
2.7067 & 1.4069 & 2.3783 & 1.1759 \\
\end{bmatrix}
\]

\(k\) is a row vector containing the sample kurtosis of each column in \(X\).

Find Kurtosis Along Vector of Dimensions

Find the kurtosis over multiple dimensions by using the 'all' and 'vecdim' input arguments.

Set the random seed for reproducibility of the results.

rng('default')
Create a 4-by-3-by-2 array of random numbers.

\[
X = \text{randn([4 3 2])}
\]

\[
X = \\
X(:,:,1) = \\
\begin{bmatrix}
0.5377 & 0.3188 & 3.5784 \\
1.8339 & -1.3077 & 2.7694 \\
-2.2588 & -0.4336 & -1.3499 \\
0.8622 & 0.3426 & 3.0349 \\
\end{bmatrix}
\]

\[
X(:,:,2) = \\
\begin{bmatrix}
0.7254 & -0.1241 & 0.6715 \\
-0.0631 & 1.4897 & -1.2075 \\
0.7147 & 1.4090 & 0.7172 \\
-0.2050 & 1.4172 & 1.6302 \\
\end{bmatrix}
\]

Find the biased kurtosis of \(X\).

\[
kall = \text{kurtosis}(X,1,\text{'all'})
\]

\[
kall = 2.8029
\]

\(kall\) is the biased kurtosis of the entire sample \(X\).

Find the biased kurtosis of each page of \(X\) by specifying the first and second dimensions.

\[
kpage = \text{kurtosis}(X,1,[1 2])
\]

\[
kpage = \\
kpage(:,:,1) = \\
\begin{bmatrix}
1.9345 \\
\end{bmatrix}
\]

\[
kpage(:,:,2) = \\
\begin{bmatrix}
2.5877 \\
\end{bmatrix}
\]

For example, \(kpage(1,1,2)\) is the biased kurtosis of the elements in \(X(:,:,2)\).
Find the biased kurtosis of the elements in each \( X(i,:,:) \) slice by specifying the second and third dimensions.

\[
krow = \text{kurtosis}(X,1,[2\ 3])
\]

\[
krow = 4\times1
\]

\[
3.8457 \\
1.4306 \\
1.7094 \\
2.3378
\]

For example, \( krow(3) \) is the biased kurtosis of the elements in \( X(3,:,:) \).

**Tips**

- \text{kurtosis} treats NaNs as missing values and removes them.

**Algorithms**

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

\[
k = \frac{E((x - \mu)^4)}{\sigma^4}
\]

where \( \mu \) is the mean of \( x \), \( \sigma \) is the standard deviation of \( x \), and \( E(t) \) represents the expected value of the quantity \( t \). \text{kurtosis} computes a sample version of this population value.

**Note** Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The \text{kurtosis} function does not use this convention.
When you set \texttt{flag} to 1, the following equation applies:

\[
    k_1 = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^4 \left( \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2 \right)^2
\]

When you set \texttt{flag} to 0, the following equation applies:

\[
    k_0 = \frac{n-1}{(n-2)(n-3)} ((n+1)k_1 - 3(n-1)) + 3
\]

This bias-corrected formula requires that \( X \) contain at least four elements.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- The following syntaxes are not supported.
  - \( k = \text{kurtosis}(X,\text{flag},'all') \)
  - \( k = \text{kurtosis}(X,\text{flag},\text{vecdim}) \)

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
• k = kurtosis(X,flag,'all')
• k = kurtosis(X,flag,vecdim)

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • k = kurtosis(X,flag,'all')
  • k = kurtosis(X,flag,vecdim)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

mean | moment | skewness | std | var

**Introduced before R2006a**
lasso

Lasso or elastic net regularization for linear models

Syntax

B = lasso(X,y)
B = lasso(X,y,Name,Value)
[B,FitInfo] = lasso(__)

Description

B = lasso(X,y) returns fitted least-squares regression coefficients for linear models of the predictor data X and the response y. Each column of B corresponds to a particular regularization coefficient in Lambda. By default, lasso performs lasso regularization using a geometric sequence of Lambda values.

B = lasso(X,y,Name,Value) fits regularized regressions with additional options specified by one or more name-value pair arguments. For example, 'Alpha', 0.5 sets elastic net as the regularization method, with the parameter Alpha equal to 0.5.

[B,FitInfo] = lasso(__) also returns the structure FitInfo, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using lasso.

Create a matrix X of 100 five-dimensional normal variables. Create a response vector y from just two components of X, and add a small amount of noise.
rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise

Construct the default lasso fit.
B = lasso(X,y);

Find the coefficient vector for the 25th Lambda value in B.
B(:,25)
ans = 5x1
     0
    1.6093
     0
   -2.5865
     0

lasso identifies and removes the redundant predictors.

Remove Redundant Predictors by Using Cross-Validated Fits

Construct a data set with redundant predictors and identify those predictors by using cross-validated lasso.

Create a matrix X of 100 five-dimensional normal variables. Create a response vector y from two components of X, and add a small amount of noise.

rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise

Construct the lasso fit by using 10-fold cross-validation with labeled predictor variables.
[B,FitInfo] = lasso(X,y,'CV',10,'PredictorNames',{'x1','x2','x3','x4','x5'});

Display the variables in the model that corresponds to the minimum cross-validated mean squared error (MSE).
idxLambdaMinMSE = FitInfo.IndexMinMSE;
minMSEModelPredictors = FitInfo.PredictorNames(B(:,idxLambdaMinMSE)~=0)

minMSEModelPredictors = 1x2 cell array
    {'x2'}    {'x4'}

Display the variables in the sparsest model within one standard error of the minimum MSE.

idxLambda1SE = FitInfo.Index1SE;
sparseModelPredictors = FitInfo.PredictorNames(B(:,idxLambda1SE)~=0)

sparseModelPredictors = 1x2 cell array
    {'x2'}    {'x4'}

In this example, lasso identifies the same predictors for the two models and removes the redundant predictors.

**Lasso Plot with Cross-Validated Fits**

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

load acetylene

Create a design matrix with interactions and no constant term.

X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = [];
    % No constant term

Construct the lasso fit using 10-fold cross-validation. Include the FitInfo output so you can plot the result.

rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);

Plot the cross-validated fits.
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

**Predict Values Using Elastic Net Regularization**

Predict students' exam scores using `lasso` and the elastic net method.

Load the `examgrades` data set.
load examgrades
X = grades(:,1:4);
y = grades(:,5);

Split the data into training and test sets.

n = length(y);
c = cvpartition(n,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = y(idxTrain);
XTest = X(idxTest,:);
yTest = y(idxTest);

Find the coefficients of a regularized linear regression model using 10-fold cross-validation and the elastic net method with Alpha = 0.75. Use the largest Lambda value such that the mean squared error (MSE) is within one standard error of the minimum MSE.

[B,FitInfo] = lasso(XTrain,yTrain,'Alpha',0.75,'CV',10);
idxLambda1SE = FitInfo.Index1SE;
coef = B(:,idxLambda1SE);
coef0 = FitInfo.Intercept(idxLambda1SE);

Predict exam scores for the test data. Compare the predicted values to the actual exam grades using a reference line.

yhat = XTest*coef + coef0;
hold on
scatter(yTest,yhat)
plot(yTest,yTest)
xlabel('Actual Exam Grades')
ylabel('Predicted Exam Grades')
hold off
**Input Arguments**

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: `single` | `double`

**y — Response data**
numeric vector
Response data, specified as a numeric vector. \( y \) has length \( n \), where \( n \) is the number of rows of \( X \). The response \( y(i) \) corresponds to the \( i \)th row of \( X \).

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name, Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as

```
Name1,Value1,...,NameN,ValueN.
```

Example: `lasso(X,y,'Alpha',0.75,'CV',10)` performs elastic net regularization with 10-fold cross-validation. The `'Alpha',0.75` name-value pair argument sets the parameter used in the elastic net optimization.

**AbsTol — Absolute error tolerance**

1e–4 (default) | positive scalar

Absolute error tolerance used to determine the convergence of the “ADMM Algorithm” on page 32-3524, specified as the comma-separated pair consisting of `'AbsTol'` and a positive scalar. The algorithm converges when successive estimates of the coefficient vector differ by an amount less than `AbsTol`.

**Note** This option applies only when you use `lasso` on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Example: `'AbsTol',1e–3`

Data Types: single | double

**Alpha — Weight of lasso versus ridge optimization**

1 (default) | positive scalar

Weight of lasso (\( L^1 \)) versus ridge (\( L^2 \)) optimization, specified as the comma-separated pair consisting of `'Alpha'` and a positive scalar value in the interval \((0,1]\). The value `Alpha = 1` represents lasso regression, `Alpha` close to 0 approaches ridge regression on page 11-135, and other values represent elastic net optimization. See “Elastic Net” on page 32-3523.

Example: `'Alpha',0.5`
Data Types: single | double

**B0 — Initial values for x-coefficients in ADMM Algorithm**

vector of zeros (default) | numeric vector

Initial values for x-coefficients in “ADMM Algorithm” on page 32-3524, specified as the comma-separated pair consisting of 'B0' and a numeric vector.

**Note** This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types: single | double

**CV — Cross-validation specification for estimating mean squared error**

'resubstitution' (default) | positive integer scalar | cvpartition object

Cross-validation specification for estimating the mean squared error (MSE), specified as the comma-separated pair consisting of 'CV' and one of the following:

- 'resubstitution' — lasso uses X and y to fit the model and to estimate the MSE without cross-validation.
- Positive scalar integer K — lasso uses K-fold cross-validation.
- cvpartition object cvp — lasso uses the cross-validation method expressed in cvp. You cannot use a 'leaveout' partition with lasso.

Example: 'CV',3

**DFmax — Maximum number of nonzero coefficients**

Inf (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of 'DFmax' and a positive integer scalar. lasso returns results only for Lambda values that satisfy this criterion.

Example: 'DFmax',5

Data Types: single | double

**Lambda — Regularization coefficients**

nonnegative vector
Regularization coefficients, specified as the comma-separated pair consisting of 'Lambda' and a vector of nonnegative values. See “Lasso” on page 32-3523.

- If you do not supply Lambda, then lasso calculates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, then lasso ignores LambdaRatio and NumLambda.
- If Standardize is true, then Lambda is the set of values used to fit the models with the X data standardized to have zero mean and a variance of one.

The default is a geometric sequence of NumLambda values, with only the largest value able to produce B = 0.

Example: 'Lambda',linspace(0,1)
Data Types: single | double

**LambdaRatio — Ratio of smallest to largest Lambda values**

1e–4 (default) | positive scalar

Ratio of the smallest to the largest Lambda values when you do not supply Lambda, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set LambdaRatio = 0, then lasso generates a default sequence of Lambda values and replaces the smallest one with 0.

Example: 'LambdaRatio',1e–2
Data Types: single | double

**MaxIter — Maximum number of iterations allowed**

positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.

If the algorithm executes MaxIter iterations before reaching the convergence tolerance RelTol, then the function stops iterating and returns a warning message.

The function can return more than one warning when NumLambda is greater than 1.

Default values are 1e5 for standard data and 1e4 for tall arrays.
Example: 'MaxIter',1e3
Data Types: single | double

**MCReps — Number of Monte Carlo repetitions for cross-validation**
1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCReps' and a positive integer scalar.

- If `CV` is 'resubstitution' or a `cvpartition` of type 'resubstitution', then `MCReps` must be 1.
- If `CV` is a `cvpartition` of type 'holdout', then `MCReps` must be greater than 1.

Example: 'MCReps',5
Data Types: single | double

**NumLambda — Number of Lambda values**
100 (default) | positive integer scalar

Number of Lambda values `lasso` uses when you do not supply `Lambda`, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `y`.

Example: 'NumLambda',50
Data Types: single | double

**Options — Option to cross-validate in parallel and specify random streams**

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of 'Options' and a structure. This option requires Parallel Computing Toolbox.

Create the `Options` structure with `statset`. The option fields are:

- **UseParallel** — Set to true to compute in parallel. The default is false.
- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. The default is false.
- **Streams** — A RandStream object or cell array consisting of one such object. If you do not specify Streams, then lasso uses the default stream.

  Example: 'Options', statset('UseParallel', true)

  Data Types: struct

**PredictorNames** — Names of predictor variables

{} (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in X, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors.

Example: 'PredictorNames', {'x1', 'x2', 'x3', 'x4'}

Data Types: string | cell

**RelTol** — Convergence threshold for coordinate descent algorithm

1e-4 (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of 'RelTol' and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the $L^2$ norm by a relative amount less than RelTol.

Example: 'RelTol', 5e-3

Data Types: single | double

**Rho** — Augmented Lagrangian parameter

positive scalar

Augmented Lagrangian parameter $\rho$ for the “ADMM Algorithm” on page 32-3524, specified as the comma-separated pair consisting of 'Rho' and a positive scalar. The default is automatic selection.

**Note** This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Example: 'Rho', 2

Data Types: single | double
**Standardize** — Flag for standardizing predictor data before fitting models

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of 'Standardize' and either true or false. If Standardize is true, then the X data is scaled to have zero mean and a variance of one. Standardize affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

X and y are always centered.

Example: 'Standardize',false

Data Types: logical

**U0** — Initial value of scaled dual variable

vector of zeros (default) | numeric vector

Initial value of the scaled dual variable u in the “ADMM Algorithm” on page 32-3524, specified as the comma-separated pair consisting of 'U0' and a numeric vector.

**Note** This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types: single | double

**Weights** — Observation weights

1/n*ones(n,1) (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. Weights has length n, where n is the number of rows of X. The lasso function scales Weights to sum to 1.

Data Types: single | double

**Output Arguments**

**B** — Fitted coefficients

numeric matrix
Fitted coefficients, returned as a numeric matrix. \( B \) is a \( p \)-by-\( L \) matrix, where \( p \) is the number of predictors (columns) in \( X \), and \( L \) is the number of \( \text{Lambda} \) values. You can specify the number of \( \text{Lambda} \) values using the \text{NumLambda} name-value pair argument.

The coefficient corresponding to the intercept term is a field in \text{FitInfo}.

Data Types: \text{single} | \text{double}

\textbf{FitInfo — Fit information of models structure}

Fit information of the linear models, returned as a structure with the fields described in this table.

<table>
<thead>
<tr>
<th>Field in \text{FitInfo}</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intercept</td>
<td>Intercept term ( \beta_0 ) for each linear model, a 1-by-( L ) vector</td>

Definitions

Lasso

For a given value of $\lambda$, a nonnegative parameter, lasso solves the problem

$$
\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^{N} (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^{p} |\beta_j| \right).
$$

- $N$ is the number of observations.
- $y_i$ is the response at observation $i$.
- $x_i$ is data, a vector of length $p$ at observation $i$.
- $\lambda$ is a nonnegative regularization parameter corresponding to one value of $\text{Lambda}$.
- The parameters $\beta_0$ and $\beta$ are a scalar and a vector of length $p$, respectively.

As $\lambda$ increases, the number of nonzero components of $\beta$ decreases.

The lasso problem involves the $L^1$ norm of $\beta$, as contrasted with the elastic net algorithm.

Elastic Net

For $\alpha$ strictly between 0 and 1, and nonnegative $\lambda$, elastic net solves the problem

$$
\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^{N} (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),
$$

where

$$
P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^{p} \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).
$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of $\alpha$, the penalty term $P_\alpha(\beta)$ interpolates between the $L^1$ norm of $\beta$ and the squared $L^2$ norm of $\beta$. As $\alpha$ shrinks toward 0, elastic net approaches ridge regression.
Algorithms

ADMM Algorithm

When operating on tall arrays, \texttt{lasso} uses an algorithm based on the Alternating Direction Method of Multipliers (ADMM) [5]. The notation used here is the same as in the reference paper. This method solves problems of the form

\[ \text{Minimize } l(x) + g(z) \]

Subject to \( Ax + Bz = c \)

Using this notation, the lasso regression problem is

\[ \text{Minimize } l(x) + g(z) = \frac{1}{2} \|Ax - b\|_2^2 + \lambda \|z\|_1 \]

Subject to \( x - z = 0 \)

Because the loss function \( l(x) = \frac{1}{2} \|Ax - b\|_2^2 \) is quadratic, the iterative updates performed by the algorithm amount to solving a linear system of equations with a single coefficient matrix but several right-hand sides. The updates performed by the algorithm during each iteration are

\[
x^{k+1} = (A^T A + \rho I)^{-1} \left( A^T b + \rho \left( z^k - u^k \right) \right)
\]

\[
z^{k+1} = S_{\lambda/\rho} \left( x^{k+1} + u^k \right)
\]

\[
u^{k+1} = u^k + x^{k+1} - z^{k+1}
\]

\( A \) is the dataset (a tall array), \( x \) contains the coefficients, \( \rho \) is the penalty parameter (augmented Lagrangian parameter), \( b \) is the response (a tall array), and \( S \) is the soft thresholding operator.
lasso solves the linear system using Cholesky factorization because the coefficient matrix $A^T A + \rho I$ is symmetric and positive definite. Because $\rho$ does not change between iterations, the Cholesky factorization is cached between iterations.

Even though $A$ and $b$ are tall arrays, they appear only in the terms $A^T A$ and $A^T b$. The results of these two matrix multiplications are small enough to fit in memory, so they are precomputed and the iterative updates between iterations are performed entirely within memory.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• With tall arrays, lasso uses an algorithm based on ADMM (Alternating Direction Method of Multipliers).
• No elastic net support. The 'Alpha' parameter is always 1.
• No cross-validation ('CV' parameter) support, which includes the related parameter 'MCReps'.
• The output FitInfo does not contain the additional fields 'SE', 'LambdaMinMSE', 'Lambda1SE', 'IndexMinMSE', and 'Index1SE'.
• The 'Options' parameter is not supported because it does not contain options that apply to the ADMM algorithm. You can tune the ADMM algorithm using name-value pair arguments.
• Supported name-value pair arguments are:
  • 'Lambda'
  • 'LambdaRatio'
  • 'NumLambda'
  • 'Standardize'
  • 'PredictorNames'
  • 'RelTol'
  • 'Weights'
• Additional name-value pair arguments to control the ADMM algorithm are:
  • 'Rho' — Augmented Lagrangian parameter, \( \rho \). The default value is automatic selection.
  • 'AbsTol' — Absolute tolerance used to determine convergence. The default value is \( 1e-4 \).
  • 'MaxIter' — Maximum number of iterations. The default value is \( 1e4 \).
• 'B0' — Initial values for the coefficients x. The default value is a vector of zeros.
• 'U0' — Initial values of the scaled dual variable u. The default value is a vector of zeros.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

“Lasso and Elastic Net” on page 11-140

**Introduced in R2011b**
lassoglm

Lasso or elastic net regularization for generalized linear models

Syntax

B = lassoglm(X,y)
B = lassoglm(X,y,distr)
B = lassoglm(X,y,distr,Name,Value)
[B,FitInfo] = lassoglm(__)

Description

B = lassoglm(X,y) returns penalized, maximum-likelihood fitted coefficients for generalized linear models of the predictor data X and the response y, where the values in y are assumed to have a normal probability distribution. Each column of B corresponds to a particular regularization coefficient in Lambda. By default, lassoglm performs lasso regularization using a geometric sequence of Lambda values.

B = lassoglm(X,y,distr) performs lasso regularization to fit the models using the probability distribution distr for y.

B = lassoglm(X,y,distr,Name,Value) fits regularized generalized linear regressions with additional options specified by one or more name-value pair arguments. For example, 'Alpha', 0.5 sets elastic net as the regularization method, with the parameter Alpha equal to 0.5.

[B,FitInfo] = lassoglm(__) also returns the structure FitInfo, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples
Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using `lassoglm`.

Create a random matrix `X` with 100 observations and 10 predictors. Create the normally distributed response `y` using only four of the predictors and a small amount of noise.

```matlab
rng default
X = randn(100,10);
weights = [0.6;0.5;0.7;0.4];
y = X(:,[2 4 5 7])*weights + randn(100,1)*0.1; % Small added noise
```

Perform lasso regularization.

```matlab
B = lassoglm(X,y);
```

Find the coefficient vector for the 75th Lambda value in `B`.

```matlab
B(:,75)
```

```matlab
ans = 10×1
       0
    0.5431
       0
    0.3944
    0.6173
       0
    0.3473
       0
       0
       0
```

`lassoglm` identifies and removes the redundant predictors.

Cross-Validated Lasso Regularization of Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors by using `lassoglm`. 
Create data with 20 predictors. Create a Poisson response variable using only three of the predictors plus a constant.

```matlab
rng default % For reproducibility
X = randn(100,20);
weights = [.4;.2;.3];
mu = exp(X(:,[5 10 15])*weights + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```matlab
[B,FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

```matlab
lassoPlot(B,FitInfo,'plottype','CV');
legend('show') % Show legend
```
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```matlab
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
mincoefs = find(B(:,idxLambdaMinDeviance))
```

```
mincoefs = 7×1
3 5 6
```
idxLambda1SE = FitInfo.Index1SE;
min1coefs = find(B(:,idxLambda1SE))

min1coefs = 3x1

5
10
15

The coefficients from the minimum-plus-one standard error point are exactly those coefficients used to create the data.

**Predict Values Using Lasso Regularization**

Predict whether students got a B or above on their last exam by using `lassoglm`.

Load the `examgrades` data set. Convert the last exam grades to a logical vector, where 1 represents a grade of 80 or above and 0 represents a grade below 80.

```matlab
load examgrades
X = grades(:,1:4);
y = grades(:,5);
yBinom = (y>=80);
```

Partition the data into training and test sets.

```matlab
rng default    % Set the seed for reproducibility
c = cvpartition(yBinom,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = yBinom(idxTrain);
XTest = X(idxTest,:);
yTest = yBinom(idxTest);
```
Perform lasso regularization for generalized linear model regression with 3-fold cross-validation on the training data. Assume the values in $y$ are binomially distributed. Choose model coefficients corresponding to the Lambda with minimum expected deviance.

```matlab
[B,FitInfo] = lassoglm(XTrain,yTrain,'binomial','CV',3);
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
B0 = FitInfo.Intercept(idxLambdaMinDeviance);
coef = [B0; B(:,idxLambdaMinDeviance)]
```

```
coef = 5×1
-21.1911
 0.0235
 0.0670
 0.0693
 0.0949
```

Predict exam grades for the test data using the model coefficients found in the previous step. Specify the link function for a binomial response using 'logit'. Convert the prediction values to a logical vector.

```matlab
yhat = glmval(coef,XTest,'logit');
yhatBinom = (yhat>=0.5);
```

Determine the accuracy of the predictions using a confusion matrix.

```matlab
[c,order] = confusionmat(yTest,yhatBinom)
```

```
c = 2×2
 29 1
 4 2
```

```
order = 2x1 logical array
0
 1
```

The function correctly predicts 31 exam grades. However, the function incorrectly predicts that 1 student receives a B or above and 4 students receive a grade below a B.
Input Arguments

\( X \) — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: single | double

\( y \) — Response data

numeric vector | logical vector | categorical array | numeric matrix

Response data, specified as a numeric vector, logical vector, categorical array, or two-column numeric matrix.

- When \( \text{distr} \) is not 'binomial', \( y \) is a numeric vector or categorical array of length \( n \), where \( n \) is the number of rows in \( X \). The response \( y(i) \) corresponds to row \( i \) in \( X \).
- When \( \text{distr} \) is 'binomial', \( y \) is one of the following:
  - Numeric vector of length \( n \), where each entry represents success (1) or failure (0)
  - Logical vector of length \( n \), where each entry represents success or failure
  - Categorical array of length \( n \), where each entry represents success or failure
  - Two-column numeric matrix, where the first column contains the number of successes for each observation and the second column contains the total number of trials

Data Types: single | double | logical | categorical

\( \text{distr} \) — Distribution of response data

'normal' | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of response data, specified as one of the following:

- 'normal'
- 'binomial'
- 'poisson'
- 'gamma'
- 'inverse gaussian'
lassoglm uses the default link function on page 32-3542 corresponding to distr. Specify another link function using the Link name-value pair argument.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: lassoglm(X,y,'poisson','Alpha',0.5) performs elastic net regularization assuming that the response values are Poisson distributed. The 'Alpha', 0.5 name-value pair argument sets the parameter used in the elastic net optimization.

**Alpha — Weight of lasso versus ridge optimization**

1 (default) | positive scalar

Weight of lasso \((L^1)\) versus ridge \((L^2)\) optimization, specified as the comma-separated pair consisting of 'Alpha' and a positive scalar value in the interval \((0, 1]\). The value \(\text{Alpha} = 1\) represents lasso regression, \(\text{Alpha}\) close to 0 approaches ridge regression, and other values represent elastic net optimization. See “Elastic Net” on page 32-3543.

Example: 'Alpha',0.75

Data Types: single | double

**CV — Cross-validation specification for estimating deviance**

'resubstitution' (default) | positive integer scalar | cvpartition object

Cross-validation specification for estimating the deviance, specified as the comma-separated pair consisting of 'CV' and one of the following:

- 'resubstitution' — lassoglm uses X and y to fit the model and to estimate the deviance without cross-validation.
- Positive scalar integer K — lassoglm uses K-fold cross-validation.
- cvpartition object cp — lassoglm uses the cross-validation method expressed in cp. You cannot use a 'leaveout' partition with lassoglm.

Example: 'CV',10

**DFmax — Maximum number of nonzero coefficients**

Inf (default) | positive integer scalar
Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of 'DFmax' and a positive integer scalar. `lassoglm` returns results only for Lambda values that satisfy this criterion.

Example: 'DFmax',25

Data Types: single | double

**Lambda — Regularization coefficients**

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of 'Lambda' and a vector of nonnegative values. See “Lasso” on page 32-3542.

- If you do not supply Lambda, then `lassoglm` estimates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, then `lassoglm` ignores LambdaRatio and NumLambda.
- If Standardize is true, then Lambda is the set of values used to fit the models with the X data standardized to have zero mean and a variance of one.

The default is a geometric sequence of NumLambda values, with only the largest value able to produce B = 0.

Data Types: single | double

**LambdaRatio — Ratio of smallest to largest Lambda values**

1e–4 (default) | positive scalar

Ratio of the smallest to the largest Lambda values when you do not supply Lambda, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set LambdaRatio = 0, then `lassoglm` generates a default sequence of Lambda values and replaces the smallest one with 0.

Example: 'LambdaRatio',1e–2

Data Types: single | double

**Link — Mapping between mean of response and linear predictor**

'comploglog' | 'identity' | 'log' | 'logit' | 'loglog' | ...
Mapping between the mean $\mu$ of the response and the linear predictor $Xb$, specified as the comma-separated pair consisting of 'Link' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'comploglog'</td>
<td>$\log(-\log((1 - \mu))) = Xb$</td>

<td>$\log(\mu/(1 - \mu)) = Xb$</td>
</tr>
<tr>
<td>'loglog'</td>
<td>$\log(-\log(\mu)) = Xb$</td>
</tr>
<tr>
<td>'probit'</td>
<td>$\Phi^{-1}(\mu) = Xb$, where $\Phi$ is the normal (Gaussian) cumulative distribution function</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>$\mu^{-1} = Xb$</td>
</tr>
<tr>
<td>$p$ (a number)</td>
<td>$\mu^p = Xb$</td>
</tr>
</tbody>
</table>

A cell array of the form `{FL FD FI}`, containing three function handles created using `@`, which define the link (FL), the derivative of the link (FD), and the inverse link (FI). Or, a structure of function handles with the field `Link` containing FL, the field `Derivative` containing FD, and the field `Inverse` containing FI. User-specified link function (see “Custom Link Function” on page 12-16)

Example: 'Link','probit'

Data Types: char | string | single | double | cell

**MaxIter** — Maximum number of iterations allowed

1e4 (default) | positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.
If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than 1.

Example: 'MaxIter',1e3
Data Types: single | double

**MCReps — Number of Monte Carlo repetitions for cross-validation**

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCReps' and a positive integer scalar.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', then MCReps must be 1.
- If CV is a cvpartition of type 'holdout', then MCReps must be greater than 1.

Example: 'MCReps',2
Data Types: single | double

**NumLambda — Number of Lambda values**

100 (default) | positive integer scalar

Number of Lambda values `lassoglm` uses when you do not supply `Lambda`, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. `lassoglm` can return fewer than NumLambda fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors X).

Example: 'NumLambda',150
Data Types: single | double

**Offset — Additional predictor variable**

text

Additional predictor variable, specified as the comma-separated pair consisting of 'Offset' and a numeric vector with the same number of rows as X. The `lassoglm` function keeps the coefficient value of Offset fixed at 1.0.

Data Types: single | double
Options — Option to cross-validate in parallel and specify random streams
structure

Option to cross-validate in parallel and specify the random streams, specified as the
comma-separated pair consisting of 'Options' and a structure. This option requires
Parallel Computing Toolbox.

Create the Options structure with statset. The option fields are:

• UseParallel — Set to true to compute in parallel. The default is false.
• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. For
reproducibility, set Streams to a type allowing substreams: 'mlfg6331_64' or
'mrg32k3a'. The default is false.
• Streams — A RandStream object or cell array consisting of one such object. If you do
not specify Streams, then lassoglm uses the default stream.

Example: 'Options', statset('UseParallel', true)

Data Types: struct

PredictorNames — Names of predictor variables

{} (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in X, specified as the
c comma-separated pair consisting of 'PredictorNames' and a string array or cell array
of character vectors.

Example: 'PredictorNames', {'Height', 'Weight', 'Age'}

Data Types: string | cell

RelTol — Convergence threshold for coordinate descent algorithm

1e–4 (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-
separated pair consisting of 'RelTol' and a positive scalar. The algorithm terminates
when successive estimates of the coefficient vector differ in the $L^2$ norm by a relative
amount less than RelTol.

Example: 'RelTol', 2e–3

Data Types: single | double
Standardize — Flag for standardizing predictor data before fitting models
true (default) | false

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of 'Standardize' and either true or false. If Standardize is true, then the X data is scaled to have zero mean and a variance of one. Standardize affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

Example: 'Standardize',false
Data Types: logical

Weights — Observation weights
1/n*ones(n,1) (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. Weights has length n, where n is the number of rows of X. At least two values must be positive.

Data Types: single | double

Output Arguments

B — Fitted coefficients
numeric matrix

Fitted coefficients, returned as a numeric matrix. B is a p-by-L matrix, where p is the number of predictors (columns) in X, and L is the number of Lambda values. You can specify the number of Lambda values using the NumLambda name-value pair argument.

The coefficient corresponding to the intercept term is a field in FitInfo.

Data Types: single | double

FitInfo — Fit information of models
structure

Fit information of the generalized linear models, returned as a structure with the fields described in this table.
<table>
<thead>
<tr>
<th><strong>Field in FitInfo</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Intercept</td>
<td>Intercept term $\beta_0$ for each linear model, a 1-by-$L$ vector</td>

Link Function

A link function $f(\mu)$ maps a distribution with mean $\mu$ to a linear model with data $X$ and coefficient vector $b$ using the formula

$$f(\mu) = Xb.$$ 

You can find the formulas for the link functions in the Link name-value pair argument description. This table lists the link functions that are typically used for each distribution.

Lasso

For a nonnegative value of $\lambda$, `lassoglm` solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance} (\beta_0, \beta) + \lambda \sum_{j=1}^{p} |\beta_j| \right).$$

- The function Deviance in this equation is the deviance of the model fit to the responses using the intercept $\beta_0$ and the predictor coefficients $\beta$. The formula for Deviance depends on the distr parameter you supply to `lassoglm`. Minimizing the $\lambda$-penalized deviance is equivalent to maximizing the $\lambda$-penalized loglikelihood.
- $N$ is the number of observations.
- $\lambda$ is a nonnegative regularization parameter corresponding to one value of Lambda.
The parameters \( \beta_0 \) and \( \beta \) are a scalar and a vector of length \( p \), respectively. As \( \lambda \) increases, the number of nonzero components of \( \beta \) decreases.

The lasso problem involves the \( L^1 \) norm of \( \beta \), as contrasted with the elastic net algorithm.

**Elastic Net**

For \( \alpha \) strictly between 0 and 1, and nonnegative \( \lambda \), elastic net solves the problem

\[
\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),
\]

where

\[
P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^{p} \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).
\]

Elastic net is the same as lasso when \( \alpha = 1 \). For other values of \( \alpha \), the penalty term \( P_\alpha(\beta) \) interpolates between the \( L^1 \) norm of \( \beta \) and the squared \( L^2 \) norm of \( \beta \). As \( \alpha \) shrinks toward 0, elastic net approaches ridge regression.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

lassoPlot

Trace plot of lasso fit

Syntax

lassoPlot(B)
lassoPlot(B,FitInfo)
lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(___)

Description

lassoPlot(B) creates a trace plot of the values in B against the $L^1$ norm of B.

lassoPlot(B,FitInfo) creates a plot with type depending on the data type of FitInfo and the value, if any, of the PlotType name-value pair.

lassoPlot(B,FitInfo,Name,Value) creates a plot with additional options specified by one or more Name,Value pair arguments.

[ax,figh] = lassoPlot(___), for any previous input syntax, returns a handle ax to the plot axis, and a handle figh to the figure window.

Input Arguments

B

Coefficients of a sequence of regression fits, as returned from the lasso or lassoglm functions. B is a p-by-NLambda matrix, where p is the number of predictors, and each column of B is a set of coefficients lasso calculates using one Lambda penalty value.

FitInfo

Information controlling the plot:
- **FitInfo** is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.

- **FitInfo** is a vector — `lassoPlot` forms the x-axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Parent**

Axis in which to draw the plot.

**Default:** New plot

**PlotType**

Plot type when you specify a `FitInfo` vector or structure:

<table>
<thead>
<tr>
<th>PlotType</th>
<th>Plot</th>
</tr>
</thead>
<tbody>
<tr>
<td>'L1'</td>
<td><code>lassoPlot</code> creates the x-axis from the $L^1$ norm of the coefficients in <code>B</code>. The x-axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code>.</td>
</tr>
<tr>
<td>'Lambda'</td>
<td>When you choose this value, <code>FitInfo</code> must be a structure. <code>lassoPlot</code> creates the x-axis from the Lambda field of <code>FitInfo</code>. The x-axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code>.</td>
</tr>
<tr>
<td>PlotType</td>
<td>Plot</td>
</tr>
<tr>
<td>----------</td>
<td>------</td>
</tr>
</tbody>
</table>
| 'CV'     | - For each Lambda, `lassoPlot` plots an estimate of the mean squared prediction error on new data for the model fitted by `lasso` with that value of Lambda.  
- `lassoPlot` plots error bars for the estimates.  

If you include a cross-validated `FitInfo` structure, `lassoPlot` also indicates two specific `Lambda` values with green and blue dashed lines.  
- A green, dashed line indicates the value of `Lambda` with a minimum cross-validated mean squared error (MSE).  
- A blue, dashed line indicates the greatest `Lambda` that is within one standard error of the minimum MSE. This `Lambda` value makes the sparsest model with relatively low MSE.  

To display the label for each plot in the legend of the figure, type `legend('show')` in the Command Window.  

**Default:** 'L1'  

**PredictorNames**  
String array or cell array of character vectors to label each coefficient of `B`. If the length of `PredictorNames` is less than the number of rows of `B`, the remaining labels are padded with default values.  

`lassoPlot` uses `PredictorNames` in `FitInfo` only if:  
- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.  
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.  
- You include `FitInfo` in your `lassoPlot` call.  

For an example, see “Lasso Plot with Default Plot Type” on page 32-3548.
Default: \{'B1', 'B2', \ldots\}\n
**XScale**

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

Default: 'linear', except 'log' for the 'CV' plot type

**Output Arguments**

**ax**

Handle to the axis of the plot (see “Axes Appearance” (MATLAB)).

**figh**

Handle to the figure window (see “Special Object Identifiers” (MATLAB)).

**Examples**

**Lasso Plot with Default Plot Type**

Load the sample data

```matlab
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```matlab
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = [] ; % No constant term
```

The `x2fx` function returns the quadratic model in the order of a constant term, linear terms and interaction terms: constant term, x1, x2, x3, x1.*x2, x1.*x3, and x2.*x3.  

Fit a regularized model of the data using `lasso`.

```matlab
B = lasso(D,y);
```
Plot the lasso fits with labeled coefficients by using the `PredictorNames` name-value pair.

```matlab
lassoPlot(B,'PredictorNames',{'x1','x2','x3','x1.*x2','x1.*x3','x2.*x3'});
legend('show','Location','NorthWest') % Show legend
```

Each line represents a trace of the values in B for a single predictor variable: `x1`, `x2`, `x3`, `x1.*x2`, `x1.*x3`, and `x2.*x3`.

Display a data tip for the trace plot. A data tip appears when you hover over a data tip.
A data tip displays these lines of information: the name of the selected coefficient with a fitted value, the L1 norm of a set of coefficients including the selected coefficient, and the index of the corresponding Lambda.

**Lasso Plot with Lambda Plot Type**

Load the sample data.

```matlab
load acetylene
```

Prepare the data for lasso fit with interactions.
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term

Fit a regularized model of the data with lasso.

[B,FitInfo] = lasso(D,y);

Plot the fits with the Lambda plot type and logarithmic scaling.

lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');

**Lasso Plot with Cross-Validated Fits**

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```matlab
load acetylene
```

Create a design matrix with interactions and no constant term.

```matlab
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = [] ; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the `FitInfo` output so you can plot the result.

```matlab
rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```matlab
lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
```
The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Introduced in R2011b
**le**

**Class:** qrandstream

Less than or equal relation for handles

**Syntax**

\[ \text{h1} \leq \text{h2} \]

**Description**

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

\[ \text{h1} \leq \text{h2} \] performs element-wise comparisons between handle arrays \( \text{h1} \) and \( \text{h2} \). \( \text{h1} \) and \( \text{h2} \) must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise \( \leq \) result.

If one of \( \text{h1} \) or \( \text{h2} \) is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

\[ \text{tf} = \text{le}(\text{h1}, \text{h2}) \] stores the result in a logical array of the same dimensions.

Leap property

Class: qrandset

Interval between points

Description

Number of points to leap over and omit for each point taken from the sequence. The Leap property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default Leap value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the Leap values with care; many Leap values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

Choosing Leap Values for Halton Sets

A known rule for choosing Leap values for Halton sets is to set it to \((P-1)\) where \(P\) is a prime number that has not been used to generate one of the dimensions, i.e. for a \(k\)-dimensional point set \(P\) would be the \((k+1)th\) or greater prime.

Examples

Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.
P = haltonset(5);
P(1:5,:)

% Set a leap of 1. The point set now includes every other point from the sequence.
P.Leap = 1;
P(1:5,:)
```

learnerCoderConfigurer

Create coder configurer of machine learning model

After training a machine learning model, create a coder configurer for the model by using learnerCoderConfigurer. Use the object functions and properties of the configurer to specify code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use learnerCoderConfigurer for the highlighted step.

![Code generation workflow flowchart](image)

Syntax

```matlab
configurer = learnerCoderConfigurer(Mdl,X)
configurer = learnerCoderConfigurer(Mdl,X,Name,Value)
```

Description

`configurer = learnerCoderConfigurer(Mdl,X)` returns the coder configurer configurer for the machine learning model `Mdl`. Specify the predictor data `X` for the `predict` function of `Mdl`.

`configurer = learnerCoderConfigurer(Mdl,X,Name,Value)` returns a coder configurer with additional options specified by one or more name-value pair arguments.
For example, you can specify the number of output arguments in the predict function, the file name of generated C/C++ code, and the verbosity level of the coder configurer.

## Examples

### Generate Code Using Coder Configurer

Train a machine learning model and then generate code for the predict and update functions of the model by using a coder configurer.

Load the carsmall data set and train a support vector machine (SVM) regression model.

```matlab
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a RegressionSVM object.

Create a coder configurer for the RegressionSVM model by using learnerCoderConfigurer. Specify the predictor data `X`. The learnerCoderConfigurer function uses the input `X` to configure the coder attributes of the predict function input.

```matlab
configurer = learnerCoderConfigurer(Mdl,X)
```

```matlab
configurer =
    RegressionSVMCoderConfigurer with properties:

    Update Inputs:
        Alpha: [1×1 LearnerCoderInput]
        SupportVectors: [1×1 LearnerCoderInput]
        Scale: [1×1 LearnerCoderInput]
        Bias: [1×1 LearnerCoderInput]

    Predict Inputs:
        X: [1×1 LearnerCoderInput]

    Code Generation Parameters:
        NumOutputs: 1
        OutputFileName: 'RegressionSVMModel'
```
**Properties, Methods**

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the `RegressionSVM` model with default settings.

`generateCode(configurer)`

These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates these files for code generation.

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of the `RegressionSVM` model (Mdl), respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions and the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files.

```matlab
type predict.m % Display contents of predict.m

function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB,  19-Jul-2018 13:17:23
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```matlab
type update.m % Display contents of update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB,  19-Jul-2018 13:17:23
initialize('update',varargin{:});
end
```
type initialize.m % Display contents of initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 19-Jul-2018 13:17:23
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        % SupportVectors
        % Scale
        % Bias

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
end

**Update Model Parameters in Generated Code**

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.
**Train Model**

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```matlab
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

**Create Coder Configurer**

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```matlab
configurer = learnerCoderConfigurer(Mdl,X(1:50,:),'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

**Specify Coder Attributes of Parameters**

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```matlab
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.
The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. X contains 34 predictors, so the value of the SizeVector attribute must be 34 and the value of the VariableDimensions attribute must be false.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of SupportVectors so that you can update the support vectors in the generated code.

```matlab
cifigurer.SupportVectors.SizeVector = [250 34];
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constraints.

cifigurer.SupportVectors.VariableDimensions = [true false];
VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration constraints.
```

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

**Generate Code**

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the predict and update functions of the ClassificationSVM model with default settings.

```matlab
generateCode(configurer)
```

These files do not exist in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates these files for code generation.

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the predict and update functions of the ClassificationSVM model (Mdl), respectively. Then `generateCode` creates a
MEX function named `ClassificationSVMModel` for the two entry-point functions in the codegen\mex\ClassificationSVMModel folder and copies the MEX function to the current folder.

**Verify Generated Code**

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
ans = logical
    1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
ans =
         0×1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance $1\times10^{-8}$.

**Retrain Model and Update Parameters in Generated Code**

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```
Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```matlab
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```matlab
ClassificationSVMModel('update',params)
```

### Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```matlab
labels = predict(retrainedMdl,X);
label_mex = ClassificationSVMModel('predict',X);
isequal(labels,label_mex)
```

```matlab
ans = logical
   1
```

```matlab
find(abs(score-score_mex) > 1e-8)
```

```matlab
ans =
     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

### Input Arguments

**Mdl — Machine learning model**

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in this table of supported models.
<table>
<thead>
<tr>
<th>Model</th>

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

**X — Predictor data**

numeric matrix

Predictor data for the `predict` function of `Mdl`, specified as an `n`-by-`p` numeric matrix, where `n` is the number of observations and `p` is the number of predictor variables.

The `predict` function of a machine learning model predicts labels for classification and responses for regression for given predictor data. After creating the coder configurer `configurer`, you can use the `generateCode` function to generate C/C++ code for the `predict` function of `Mdl`. The generated code accepts predictor data that has the same size and data type of `X`. You can specify whether each dimension has a variable size or fixed size after creating `configurer`.

For example, if you want to generate C/C++ code that predicts labels using 100 observations with three predictor variables, then specify `X` as `zeros(100,3)`. The `learnerCoderConfigurer` function uses only the size and data type of `X`, not its values. Therefore, `X` can be predictor data or a MATLAB expression that represents the set of values with a certain data type. The output `configurer` stores the size and data type of `X` in the `X` property of `configurer`. You can modify the size and data type of `X` after creating `configurer`. For example, change the number of observations to 200 and the data type to `single`.

```matlab
configurer.X.SizeVector = [200 3];
configurer.X.DataType = 'single';
```

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify `X` as `zeros(100,3)` and change the `VariableDimensions` property.

```matlab
configurer.X.VariableDimensions = [1 0];
```
[1 0] indicates that the first dimension of $X$ (number of observations) has a variable size and the second dimension of $X$ (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as Inf.

`configurer.X.SizeVector = [Inf 3];`

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2,'OutputFileName','myModel')` sets the number of outputs in `predict` to 2 and specifies the file name 'myModel' for the generated C/C++ code.

**NumOutputs — Number of outputs in predict**

1 (default) | positive integer

Number of output arguments in the `predict` function of the machine learning model `Mdl`, specified as the comma-separated pair consisting of 'NumOutputs' and a positive integer. This table describes the number and type of outputs for the `predict` function of different models.

<table>
<thead>
<tr>
<th>Model</th>
<th><code>predict</code> function of Model</th>
<th>Number of Outputs</th>
<th>Outputs</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVM classification</td>
<td><code>predict</code></td>
<td>1</td>
<td>Predicted class labels</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
<td>Predicted class labels and scores (or posterior probabilities)</td>
</tr>
<tr>
<td>SVM regression</td>
<td><code>predict</code></td>
<td>1</td>
<td>Predicted responses</td>
</tr>
</tbody>
</table>

For example, if you specify 'NumOutputs',1 for an SVM classification model, then `predict` returns predicted class labels in the generated C/C++ code.
After creating the coder configurer `configurer`, you can modify the number of outputs by using dot notation.

```matlab
configurer.NumOutputs = 2;
```

The `'NumOutputs'` name-value pair argument is equivalent to the `-nargout` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` of a coder configurer generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively—and generates C/C++ code for the two entry-point functions. The specified value for `'NumOutputs'` corresponds to the number of output arguments in `predict.m`.

Example: `'NumOutputs',2`

Data Types: `single` | `double`

**OutputFileName — File name of generated C/C++ code**

`Mdl` object name plus `'Model'` (default) | character vector | string scalar

File name of the generated C/C++ code, specified as the comma-separated pair consisting of `'OutputFileName'` and a character vector or string scalar.

The object function `generateCode` of a coder configurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

The default file name is the object name of `Mdl` followed by `'Model'`. For example, if `Mdl` is a `CompactClassificationSVM` or `ClassificationSVM` object, then the default name is `'ClassificationSVMModel'`.

After creating the coder configurer `configurer`, you can modify the file name by using dot notation.

```matlab
configurer.OutputFileName = 'myModel';
```

Example: `'OutputFileName','myModel'`

Data Types: `char` | `string`
Verbose — Verbosity level
true (logical 1) (default) | false (logical 0)

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either true (logical 1) or false (logical 0). The verbosity level controls the display of notification messages at the command line for the coder configurer configurer.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true (logical 1)</td>
<td>The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.</td>
</tr>
<tr>
<td>false (logical 0)</td>
<td>The software does not display notification messages.</td>
</tr>
</tbody>
</table>

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using the coder configurer configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating configurer, you can modify the verbosity level by using dot notation.

```matlab
configurer.Verbose = false;
```

Example: 'Verbose',false

Data Types: logical

Output Arguments

configurer — Coder configurer
coder configurer object

Coder configurer of a machine learning model, returned as one of the coder configurer objects in this table.
Use the object functions and properties of a coder configurer object to configure code generation options and to generate C/C++ code for the predict and update functions of the machine learning model.

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-90

*Introduced in R2018b*
length

Class: dataset

Length of dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

n = length(A)

Description

n = length(A) returns the number of observations in the dataset A. length is equivalent to size(A,1).

See Also

size
length

Class: qrandset

Length of point set

Syntax

length(p)

Description

length(p) returns the number of points in the point set p. It is equivalent to size(p, 1).

See Also

qrandset | size
levelcounts

Element counts by level of a nominal or ordinal array

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

```matlab
C = levelcounts(A)
C = levelcounts(A,dim)
```

**Description**

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array `A` equal to each possible level in `A`.

- If `A` is a vector, then `C` is a vector containing as many elements as the number of levels in `A`.
- If `A` is a matrix, then `C` is a matrix of column counts.
- If `A` is an `N`-dimensional array, then `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

**Examples**

**Count Observations in Each Level**

Create a nominal array from data in a cell array.

```matlab
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...{'blue','green','red'});
```
colors = 3x3 nominal array
    red    blue    green
    green   red    blue
    blue   red    green

Count the number of observations of each level in each column.
levelcounts(colors)
ans = 3x3
     1   1   1
     1   0   2
     1   2   0

Count the number of observations of each level in each row.
levelcounts(colors,2)
ans = 3x3
     1   1   1
     1   1   1
     1   1   1

Alternatively, you can use summary to display the counts with their labels. The default is to count elements in each column.
summary(colors)

    blue    green    red
     1       1       1
     1       0       2
     1       2       0

You can also count elements in each row.
summary(colors,2)

    blue    green    red
     1       1       1
     1       1       1
     1       1       1
Input Arguments

A — Nominal or ordinal array
nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

dim — Dimension along which to count
positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is 1, then levelcounts counts along each column, while if the dimension is 2, then levelcounts counts along each row.

Data Types: double | single

nominal | ordinal | summary

Introduced in R2007a
leverage

Leverage

Syntax

\[ h = \text{leverage}(\text{data}) \]
\[ h = \text{leverage}(\text{data}, model) \]

Description

\( h = \text{leverage}(\text{data}) \) finds the leverage of each row (point) in the matrix \( \text{data} \) for a linear additive regression model.

\( h = \text{leverage}(\text{data}, model) \) finds the leverage on a regression, using a specified model type, where \( model \) can be one of the following:

- 'linear' - includes constant and linear terms
- 'interaction' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to \( 2p/n \) where \( n \) is the number of observations and \( p \) is the number of parameters in the model. For the Hald data set this value is 0.7692.

load hald
\[ h = \max(\text{leverage}(\text{ingredients}, \text{'linear'})) \]
\[ h =
\]
\[ 0.7004 \]
Since $0.7004 < 0.7692$, there are no high leverage points using this rule.

**Algorithms**

\[
[Q,R] = \text{qr}(x2fx(data,'model'),0);
\]

\[
\text{leverage} = (\text{sum}(Q'\cdot Q))'
\]

**References**

regstats

*Introduced before R2006a*
**lhsdesign**

Latin hypercube sample

**Syntax**

\[ X = \text{lhsdesign}(n,p) \]
\[ X = \text{lhsdesign}(...,\text{'smooth'},\text{'off'}) \]
\[ X = \text{lhsdesign}(...,\text{'criterion'},\text{criterion}) \]
\[ X = \text{lhsdesign}(...,\text{'iterations'},k) \]

**Description**

\[ X = \text{lhsdesign}(n,p) \] returns an \( n \)-by-\( p \) matrix, \( X \), containing a latin hypercube sample of \( n \) values on each of \( p \) variables. For each column of \( X \), the \( n \) values are randomly distributed with one from each interval \((0, 1/n), (1/n, 2/n), \ldots, (1-1/n, 1)\), and they are randomly permuted.

\[ X = \text{lhsdesign}(...,\text{'smooth'},\text{'off'}) \] produces points at the midpoints of the above intervals: \( 0.5/n, 1.5/n, \ldots, 1-0.5/n \). The default is 'on'.

\[ X = \text{lhsdesign}(...,\text{'criterion'},\text{criterion}) \] iteratively generates latin hypercube samples to find the best one according to \textit{criterion}, which can be 'none', 'maximin', or 'correlation'.

<table>
<thead>
<tr>
<th><strong>Criterion</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>No iteration.</td>
</tr>
<tr>
<td>'maximin'</td>
<td>Maximize minimum distance between points. This is the default.</td>
</tr>
<tr>
<td>'correlation'</td>
<td>Reduce correlation.</td>
</tr>
</tbody>
</table>

\[ X = \text{lhsdesign}(...,\text{'iterations'},k) \] iterates up to \( k \) times in an attempt to improve the design according to the specified criterion. The default is \( k = 5 \).

haltonset | lhsnorm | sobolset | unifrnd

Introduced before R2006a
**lhsnorm**

Latin hypercube sample from normal distribution

**Syntax**

```matlab
X = lhsnorm(mu, sigma, n)
X = lhsnorm(mu, sigma, n, flag)
[X, Z] = lhsnorm(...)```

**Description**

`X = lhsnorm(mu, sigma, n)` returns an `n`-by-`p` matrix, `X`, containing a latin hypercube sample of size `n` from a `p`-dimensional multivariate normal distribution with mean vector, `mu`, and covariance matrix, `sigma`.

`X` is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu, sigma, n, flag)` controls the amount of smoothing in the sample. If `flag` is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values \(G(0.5/n), G(1.5/n), \ldots, G(1-0.5/n)\), where \(G\) is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of \(0.5/n\) you use a value having a uniform distribution on the interval \((0/n, 1/n)\).

`[X, Z] = lhsnorm(...)` also returns `Z`, the original multivariate normal sample before the marginals are adjusted to obtain `X`.

**References**

lhsdesign | mvnrnd

Introduced before R2006a
lillietest

Lilliefors test

Syntax

h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest(__)
[h,p,kstat,critval] = lillietest(__)

Description

h = lillietest(x) returns a test decision for the null hypothesis that the data in vector x comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

h = lillietest(x,Name,Value) returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the p-value using a Monte Carlo approximation.

[h,p] = lillietest(__) also returns the p-value p, using any of the input arguments from the previous syntaxes.

[h,p,kstat,critval] = lillietest(__) also returns the test statistic kstat and the critical value critval for the test.

Examples

Test for Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.
load 'carbig'
[h,p,k,c] = lillietest(MPG)

Warning: P is less than the smallest tabulated value, returning 0.001.

h = 1
p = 1.0000e-03
k = 0.0789
c = 0.0451

The test statistic k is greater than the critical value c, so lillietest returns a result of h = 1 to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned P-value is less the smallest value in the table of precomputed values. To find a more accurate P-value, use MCTol to run a Monte Carlo approximation. See “Determine the p-value Using Monte Carlo Approximation” on page 32-3586.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

load 'examgrades'
x = grades(:,1);

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

[h,p] = lillietest(x,'Alpha',0.01)

h = 0
p = 0.0348

The returned value of h = 0 indicates that lillietest does not reject the null hypothesis at the 1% significance level.
Test for Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```matlab
load carbig
h = lillietest(MPG,'Distribution','exponential')
```

```matlab
h = 1
```

The returned value of \( h = 1 \) indicates that \texttt{lillietest} rejects the null hypothesis at the default 5\% significance level.

Test for Weibull Distribution

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (\texttt{wblplot}).

Generate samples from a Weibull distribution.

```matlab
rng('default')
data1 = wblrnd(0.5,2,[500,1]);
```

Perform the Lilliefors test by using the \texttt{lillietest}. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```matlab
h1 = lillietest(log(data1),'Distribution','extreme value')
```

```matlab
h1 = 0
```

The returned value of \( h1 = 0 \) indicates that \texttt{lillietest} fails to reject the null hypothesis at the default 5\% significance level. Confirm the test decision using a Weibull probability plot.

```matlab
wblplot(data1)
```
The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.

\[
data2 = \text{lognrnd}(5,2,[500,1]);\]

Perform the Lilliefors test.

\[
h2 = \text{lillietest}(\log(data2),'Distribution','\text{'extreme value'}')\]

\[
h2 = 1\]

The returned value of \( h2 = 1 \) indicates that \text{lillietest} rejects the null hypothesis at the default 5\% significance level. Confirm the test decision using a Weibull probability plot.
wblplot(data2)

The plot indicates that the data does not follow a Weibull distribution.

**Determine the p-value Using Monte Carlo Approximation**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the $p$-value using a Monte Carlo approximation with a maximum Monte Carlo standard error of $1e^{-4}$. 
load carbig
[h,p] = lillietest(MPG,'MCTol',1e-4)

h = 1
p = 8.3333e-06

The returned value of \( h = 1 \) indicates that \texttt{lillietest} rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

**Input Arguments**

\( x \) — Sample data
vector

Sample data, specified as a vector.
Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: \texttt{'Distribution','exponential','Alpha',0.01} tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of \texttt{'Alpha'} and a scalar value in the range (0,1).

- If \texttt{MCTol} is not used, \texttt{Alpha} must be in the range [0.001,0.50].
- If \texttt{MCTol} is used, \texttt{Alpha} must be in the range (0,1).

Example: \texttt{'Alpha',0.01}
Data Types: single | double

**Distribution — Distribution family**

'normal' (default) | 'exponential' | 'extreme value'

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of 'Distr' and one of the following.

- 'normal' Normal distribution
- 'exponential' Exponential distribution
- 'extreme value' Extreme value distribution

- To test \( x \) for a lognormal distribution, test if \( \log(x) \) has a normal distribution.
- To test \( x \) for a Weibull distribution, test if \( \log(x) \) has an extreme value distribution.

Example: 'Distribution','exponential'

**MCTol — Maximum Monte Carlo standard error**

scalar value in the range (0,1)

Maximum Monte Carlo standard error on page 32-3590 for \( p \), the \( p \)-value of the test, specified as the comma-separated pair consisting of 'MCTol' and a scalar value in the range (0,1).

Example: 'MCTol',0.001

Data Types: single | double

**Output Arguments**

**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as 1 or 0.

- If \( h = 1 \), this indicates the rejection of the null hypothesis at the \( \alpha \) significance level.
- If \( h = 0 \), this indicates a failure to reject the null hypothesis at the \( \alpha \) significance level.
**p — p-value**

Scalar value in the range (0,1)

The p-value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

- If `MCTol` is not used, p is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when p is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If `MCTol` is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate p-value, and p is returned as a scalar value in the range (0,1).

**kstat — Test statistic**

Nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

**critval — Critical value**

Nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

## Definitions

### Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

\[ D^* = \max_x |F(x) - G(x)|, \]
where \( \hat{F}(x) \) is the empirical cdf of the sample data and \( G(x) \) is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

\texttt{lillietest} can be used to test whether the data vector \( x \) has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test \( x \) for a lognormal distribution, test if \( \log(x) \) has a normal distribution.
- To test \( x \) for a Weibull distribution, test if \( \log(x) \) has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

**Monte Carlo Standard Error**

The Monte Carlo standard error is the error due to simulating the \( p \)-value.

The Monte Carlo standard error is calculated as:

\[
SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{mcreps}},
\]

where \( \hat{p} \) is the estimated \( p \)-value of the hypothesis test, and \( mcreps \) is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, \( mcreps \), is determined such that the Monte Carlo standard error for \( \hat{p} \) less than the value specified for \( MCTol \).

**Algorithms**

To compute the critical value for the hypothesis test, \texttt{lillietest} interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by \texttt{lillietest} is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate \( p \)-value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the \( MCTol \) input argument can be used to run a Monte Carlo simulation to calculate the \( p \)-value more exactly.
When the computed value of the test statistic is greater than the critical value, \texttt{lillietest} rejects the null hypothesis at significance level $\text{Alpha}$.

\texttt{lillietest} treats NaN values in $x$ as missing values and ignores them.

**Introduced before R2006a**
**LinearModel class**

**Superclasses:**

Linear regression model class

**Description**

An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

**Construction**

```plaintext
mdl = fitlm(tbl) or mdl = fitlm(X,y) create a linear model of a table or dataset array tbl, or of the responses y to a data matrix X. For details, see fitlm.

mdl = stepwiselm(tbl) or mdl = stepwiselm(X,y) create a linear model of a table or dataset array tbl, or of the responses y to a data matrix X, with unimportant predictors excluded. For details, see stepwiselm.
```

**Input Arguments**

`tbl` — Input data
table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a `formula`, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-57). The response must be numeric or logical.
To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

**X — Predictor variables**

matrix

Predictor variables, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables. Each column of \( X \) represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in \( X \).

Data Types: `single` | `double` | `logical`

**y — Response variable**

vector

Response variable, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations. Each entry in \( y \) is the response for the corresponding row of \( X \).

Data Types: `single` | `double` | `logical`

### Properties

**CoefficientCovariance — Covariance matrix of coefficient estimates**

numeric matrix

Covariance matrix of coefficient estimates, specified as a \( p \)-by-\( p \) matrix of numeric values. \( p \) is the number of coefficients in the fitted model.

**CoefficientNames — Coefficient names**

cell array of character vectors

Coefficient names, specified as a cell array of character vectors containing a label for each coefficient.

**Coefficients — Coefficient values**

table
Coefficient values, specified as a table. **Coefficients** has one row for each coefficient and the following columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — $t$ statistic for a test that the coefficient is zero
- **pValue** — $p$-value for the $t$ statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```matlab
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

**DFE** — **Degrees of freedom for error**

**positive integer value**

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer value.

**Diagnostics** — **Diagnostic values**

**table**

Diagnostic values, specified as a table with the same number of rows as the input data (tbl or X). **Diagnostics** contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. **Diagnostics** contains the following fields.
<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
<th>Utility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leverage</td>
<td>Diagonal elements of HatMatrix</td>
<td>Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. An observation with Leverage larger than 2*P/N can be regarded as having high leverage.</td>
</tr>
<tr>
<td>CooksDistance</td>
<td>Cook's measure of scaled change in fitted values</td>
<td>CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.</td>
</tr>
<tr>
<td>Dffits</td>
<td>Delete-1 scaled differences in fitted values vs. observation number</td>
<td>Dffits is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than 2*sqrt(P/N) may be considered influential.</td>
</tr>
<tr>
<td>S2_i</td>
<td>Delete-1 variance vs. observation number</td>
<td>S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the MSE property.</td>
</tr>
<tr>
<td>CovRatio</td>
<td>Delete-1 ratio of determinant of covariance vs. observation number</td>
<td>CovRatio is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than 1+3<em>P/N or smaller than 1-3</em>P/N indicate influential points.</td>
</tr>
<tr>
<td>Dfbetas</td>
<td>Delete-1 scaled differences in covariance estimates vs. observation number</td>
<td>Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than 3/sqrt(N) in absolute value indicate that the observation has a large influence on the corresponding coefficient.</td>
</tr>
<tr>
<td>Field</td>
<td>Meaning</td>
<td>Utility</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HatMatrix</td>
<td>Projection matrix to compute fitted from observed responses</td>
<td>HatMatrix is an N-by-N matrix such that Fitted = HatMatrix*Y, where Y is the response vector and Fitted is the vector of fitted response values.</td>
</tr>
</tbody>
</table>

Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

**Fitted — Fitted response values based on input data**
vector of numeric values

Fitted (predicted) response values based on input data, specified as an n-by-1 vector of numeric values. n is the number of observations in the input data. Use predict to compute predictions for other predictor values, or to compute confidence bounds on Fitted.

**Formula — Model information**
LinearFormula object | NonLinearFormula object

Model information, specified as a LinearFormula object or NonLinearFormula object. If you fit a linear or generalized linear regression model, then Formula is a LinearFormula object. If you fit a nonlinear regression model, then Formula is a NonLinearFormula object.

**LogLikelihood — Log likelihood**
numeric value

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

**ModelCriterion — Criterion for model comparison**
structure

Criterion for model comparison, specified as a structure with the following fields:
• **AIC** — Akaike information criterion. AIC = \(-2*\log L + 2*m\), where \(\log L\) is the loglikelihood and \(m\) is the number of estimated parameters.

• **AICc** — Akaike information criterion corrected for the sample size. AICc = AIC + \((2*m*(m+1))/(n–m–1)\), where \(n\) is the number of observations.

• **BIC** — Bayesian information criterion. BIC = \(-2*\log L + m*\log(n)\).

• **CAIC** — Consistent Akaike information criterion. CAIC = \(-2*\log L + m*(\log(n) +1)\).

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model \(mdl\), the AIC value \(aic\) is:

\[aic = mdl.ModelCriterion.AIC\]

**MSE** — **Mean squared error**

numeric value

Mean squared error (residuals), specified as a numeric value. Mean square error is calculated as \(MSE = SSE / DFE\), where \(MSE\) is the mean square error, \(SSE\) is the sum of squared errors, and \(DFE\) is the degrees of freedom.

**NumCoefficients** — **Number of model coefficients**

positive integer

Number of model coefficients, specified as a positive integer. \(\text{NumCoefficients}\) includes coefficients that are set to zero when the model terms are rank deficient.

**NumEstimatedCoefficients** — **Number of estimated coefficients**

positive integer

Number of estimated coefficients in the model, specified as a positive integer. \(\text{NumEstimatedCoefficients}\) does not include coefficients that are set to zero when the model terms are rank deficient. \(\text{NumEstimatedCoefficients}\) is the degrees of freedom for regression.
NumObservations — Number of observations
positive integer

Number of observations the fitting function used in fitting, specified as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the Exclude name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables
positive integer

Number of predictor variables used to fit the model, specified as a positive integer.

NumVariables — Number of variables
positive integer

Number of variables in the input data, specified as a positive integer. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo — Observation information
table

Observation information, specified as a n-by-4 table, where n is equal to the number of rows of input data. The four columns of ObservationInfo contain the following:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>Observation weights. Default is all 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>Logical value, 1 indicates an observation that you excluded from the fit with the Exclude name-value pair.</td>
</tr>
<tr>
<td>Missing</td>
<td>Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.</td>
</tr>
<tr>
<td>Subset</td>
<td>Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.</td>
</tr>
</tbody>
</table>

ObservationNames — Observation names
cell array of character vectors

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.
• If the fit is based on a table or dataset containing observation names, ObservationNames uses those names.
• Otherwise, ObservationNames is an empty cell array

**PredictorNames — Names of predictors used to fit the model**
cell array of character vectors

Names of predictors used to fit the model, specified as a cell array of character vectors.

**Residuals — Residuals for fitted model**
table

Residuals for fitted model, specified as a table that contains one row for each observation and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw</td>
<td>Observed minus fitted values.</td>
</tr>
<tr>
<td>Pearson</td>
<td>Raw residuals divided by RMSE.</td>
</tr>
<tr>
<td>Standardized</td>
<td>Raw residuals divided by their estimated standard deviation.</td>
</tr>
<tr>
<td>Studentized</td>
<td>Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i.</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model mdl, the ordinary raw residual vector r is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain NaN values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain NaN values, with the following exceptions:

• raw contains the difference between the observed and predicted values.
• standardized is the residual, standardized in the usual way.
• studentized matches the standardized values because this residual is not used in the estimate of the residual standard deviation.
**ResponseName — Response variable name**

character vector

Response variable name, specified as a character vector.

**RMSE — Root mean squared error**

numeric value

Root mean squared error (residuals), specified as a numeric value. The root mean squared error (RMSE) is equal to $RMSE = \sqrt{MSE}$, where $MSE$ is the mean squared error.

**Robust — Robust fit information**

structure

Robust fit information, specified as a structure with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WgtFun</td>
<td>Robust weighting function, such as 'bisquare' (see robustfit)</td>
</tr>
<tr>
<td>Tune</td>
<td>Value specified for tuning parameter (can be [])</td>
</tr>
<tr>
<td>Weights</td>
<td>Vector of weights used in final iteration of robust fit. This field is empty for compacted CompactLinearModel models.</td>
</tr>
</tbody>
</table>

This structure is empty unless fitlm constructed the model using robust regression.

**Rsquared — R-squared value for the model**

structure

R-squared value for the model, specified as a structure.

For a linear or nonlinear model, Rsquared is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, Rsquared is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
• LLR — Log-likelihood ratio
• Deviance — Deviance
• AdjGeneralized — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = \frac{SSR}{SST} = 1 - \frac{SSE}{SST}.$$  

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

$$r2 = mdl.Rsquared.Adjusted$$

**SSE — Sum of squared errors**

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$  

**SSR — Regression sum of squares**

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$  

**SST — Total sum of squares**

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector y from mean(y).

The Pythagorean theorem implies

$$SST = SSE + SSR.$$  

32-3601
Steps — Stepwise fitting information

structure

Stepwise fitting information, specified as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Formula representing the starting model</td>
</tr>
<tr>
<td>Lower</td>
<td>Formula representing the lower bound model, these terms that must remain in the model</td>
</tr>
<tr>
<td>Upper</td>
<td>Formula representing the upper bound model, model cannot contain more terms than Upper</td>
</tr>
<tr>
<td>Criterion</td>
<td>Criterion used for the stepwise algorithm, such as 'sse'</td>
</tr>
<tr>
<td>PEnter</td>
<td>Value of the parameter, such as 0.05</td>
</tr>
<tr>
<td>PRemove</td>
<td>Value of the parameter, such as 0.10</td>
</tr>
<tr>
<td>History</td>
<td>Table representing the steps taken in the fit</td>
</tr>
</tbody>
</table>

The History table has one row for each step including the initial fit, and the following variables (columns).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Action taken during this step, one of:</td>
</tr>
<tr>
<td></td>
<td>• 'Start' — First step</td>
</tr>
<tr>
<td></td>
<td>• 'Add' — A term is added</td>
</tr>
<tr>
<td></td>
<td>• 'Remove' — A term is removed</td>
</tr>
<tr>
<td>TermName</td>
<td>• 'Start' step: The starting model specification</td>
</tr>
<tr>
<td></td>
<td>• 'Add' or 'Remove' steps: The term moved in that step</td>
</tr>
<tr>
<td>Terms</td>
<td>Terms matrix (see modelspec of fitlm)</td>
</tr>
<tr>
<td>DF</td>
<td>Regression degrees of freedom after this step</td>
</tr>
<tr>
<td>delDF</td>
<td>Change in regression degrees of freedom from previous step (negative for steps that remove a term)</td>
</tr>
<tr>
<td>Deviance</td>
<td>Deviance (residual sum of squares) at that step</td>
</tr>
<tr>
<td>FStat</td>
<td>$F$ statistic that led to this step</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>PValue</td>
<td>p-value of the $F$ statistic</td>
</tr>
</tbody>
</table>

The structure is empty unless you use `stepwiselm` or `stepwiseglm` to fit the model.

### VariableInfo — Information about input variables

**table**

Information about input variables contained in `Variables`, specified as a table with one row for each model term and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Character vector giving variable class, such as 'double'</td>
</tr>
<tr>
<td>Range</td>
<td>Cell array giving variable range:</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector $[\text{min}, \text{max}]$, the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Cell array of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Logical vector, where <code>true</code> indicates the variable is in the model</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Logical vector, where <code>true</code> indicates a categorical variable</td>
</tr>
</tbody>
</table>

### VariableNames — Names of variables used in fit

**cell array of character vectors**

Names of variables used in fit, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

### Variables — Data used to fit the model

**table**

Data used to fit the model, specified as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix $X$ and response vector $y$. 
Methods

addTerms  Add terms to linear regression model
compact  Compact linear regression model
dwtest  Durbin-Watson test of linear model
fit  Create linear regression model
plot  Scatter plot or added variable plot of linear model
plotAdded  Added variable plot or leverage plot for linear model
plotAdjustedResponse  Adjusted response plot for linear regression model
plotDiagnostics  Plot diagnostics of linear regression model
plotResiduals  Plot residuals of linear regression model
removeTerms  Remove terms from linear model
step  Improve linear regression model by adding or removing terms
stepwise  Create linear regression model by stepwise regression

Inherited Methods

anova  Analysis of variance for linear model
coefCI  Confidence intervals of coefficient estimates of linear model
coefTest  Linear hypothesis test on linear regression model coefficients
disp  Display linear regression model
feval  Evaluate linear regression model prediction
plotEffects  Plot main effects of each predictor in linear regression model
plotInteraction  Plot interaction effects of two predictors in linear regression model
plotSlice  Plot of slices through fitted linear regression surface
predict  Predict response of linear regression model
random  Simulate responses for linear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).
Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```matlab
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a default linear model to the data.

```matlab
mdl = fitlm(X,y)
```

```matlab
dmdl =
Linear regression model:
  y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
     Estimate        SE         tStat       pValue
    ________    _______    ________    ________
(Intercept)      62.405     70.071      0.8906     0.39913
x1               1.5511    0.74477      2.0827    0.070822
x2              0.51017    0.72379     0.70486      0.5009
x3              0.10191    0.75471     0.13503     0.89592
x4             -0.14406    0.70905    -0.20317     0.84407
```

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the `carsmall` data.
load carsmall

Construct a table containing continuous predictor variable Weight, categorical predictor variable Year, and response variable MPG.

```matlab
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
```

Create a fitted model of MPG as a function of Year, Weight, and Weight^2. You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight^2. The `fitlm` function includes Weight automatically.

```matlab
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```matlab
mdl = 
Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2

Estimated Coefficients:
               Estimate      SE       tStat       pValue
    __________    ______    _______    __________
    (Intercept)    54.206    4.7117    11.505    2.6648e-19
    Weight         -0.016404    0.0031249    -5.2493    1.0283e-06
    Year_76          2.0887    0.71491     2.9215    0.0044137
    Year_82          8.1864    0.81531    10.041    2.6364e-16
    Weight^2    1.5573e-06    4.9454e-07      3.149    0.0022303

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885,  Adjusted R-Squared 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

The `fitlm` function creates two dummy (indicator) variables for the categorical variate, Year. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

\[
\hat{\text{MPG}} = 54.206 - 0.016404\text{Weight} + 2.0887\text{Year}_{76} + 8.1864\text{Year}_{82} + 1.5573 \cdot 10^{-06}\text{Weight}^2.
\]
Fit a Robust Linear Regression Model

Fit a linear regression model using a robust fitting method.

Load the sample data.

```matlab
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```matlab
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```matlab
mdl =
Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                          Estimate    SE         tStat     pValue
     __________________    ________    ________    ________
     (Intercept)           60.09      75.818     0.79256    0.4509
     x1                   1.5753      0.80585    1.9548     0.086346
     x2                   0.5322      0.78315    0.67957    0.51596
     x3                  -0.13346    0.8166    0.16343    0.87424
     x4                   -0.12052    0.7672    -0.15709    0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,    Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

Definitions

Hat Matrix

The hat matrix $H$ is defined in terms of the data matrix $X$: 
\[ H = X(X^T X)^{-1} X^T. \]

The diagonal elements \( h_{ii} \) satisfy

\[
0 \leq h_{ii} \leq 1 \\
\sum_{i=1}^{n} h_{ii} = p,
\]

where \( n \) is the number of observations (rows of \( X \)), and \( p \) is the number of coefficients in the regression model.

**Leverage**

The leverage of observation \( i \) is the value of the \( i \)th diagonal term, \( h_{ii} \), of the hat matrix \( H \). Because the sum of the leverage values is \( p \) (the number of coefficients in the regression model), an observation \( i \) can be considered to be an outlier if its leverage substantially exceeds \( p/n \), where \( n \) is the number of observations.

**Cook’s Distance**

Cook’s distance is the scaled change in fitted values. Each element in \( \text{CooksDistance} \) is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook’s distance, \( D_i \), of observation \( i \) is

\[
D_i = \frac{\sum_{j=1}^{n} (\hat{y}_j - \hat{y}_{j(i)})^2}{p \cdot \text{MSE}},
\]

where

- \( \hat{y}_j \) is the \( j \)th fitted response value.
- \( \hat{y}_{j(i)} \) is the \( j \)th fitted response value, where the fit does not include observation \( i \).
- \( \text{MSE} \) is the mean squared error.
- \( p \) is the number of coefficients in the regression model.

Cook’s distance is algebraically equivalent to the following expression:
\[ D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right), \]

where \( r_i \) is the \( i \)th residual, and \( h_{ii} \) is the \( i \)th leverage value.

CooksDistance is an \( n \)-by-1 column vector in the Diagnostics table of the LinearModel object.

**Algorithms**

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is robustfit.

**Alternatives**

To remove redundant predictors in linear regression using lasso or elastic net, use the lasso function.

To regularize a regression with correlated terms using ridge regression, use the ridge or lasso functions.

To regularize a regression with correlated terms using partial least squares, use the plsregress function.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The predict and random functions support code generation.
- When you fit a model by using fitlm or stepwiselm, you cannot supply training data in a table that contains at least one categorical predictor, and you cannot use the
'CategoricalVars' name-value pair argument. Code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, preprocess the categorical data by using dummyvar before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

“Linear Regression” on page 11-11

Introduced in R2012a
LinearMixedModel class

Linear mixed-effects model class

Description

A LinearMixedModel object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl,formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G).

Input Arguments

- `tbl` — Input data
  table | dataset array
  Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.
  Data Types: `table`

- `formula` — Formula for model specification
  character vector or string scalar of the form `y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'
Formula for model specification, specified as a character vector or string scalar of the form \('y \sim \text{fixed} + (\text{random1}|\text{grouping1}) + \ldots + (\text{randomR}|\text{groupingR})'\). For a full description, see “Formula” on page 32-3628.

Example: \('y \sim \text{treatment} + (1|\text{block})'\)

**X — Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of *X* corresponds to one observation, and each column of *X* corresponds to one variable.

Data Types: `single` | `double`

**y — Response values**

*n*-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

**Z — Random-effects design**

*n*-by-*q* matrix | cell array of *R* *n*-by-*q(r)* matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then *Z* must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then *Z* must be a cell array of length *R*. Each cell of *Z* contains an *n*-by-*q(r)* design matrix \(Z\{r\}\), *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, \(q(r)\) is the number of random effects term in the *r*th random effects design matrix, \(Z\{r\}\).

Data Types: `single` | `double` | `cell`

**G — Grouping variable or variables**

*n*-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.

- If there is one random-effects term, then *G* must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.
G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then G must be a cell array of length $R$. Each cell of G contains a grouping variable $G\{r\}, \ r = 1, 2, ..., R,$ with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: categorical | logical | single | double | char | string | cell

Properties

**Coefficients — Fixed-effects coefficient estimates**

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the term.</td>
</tr>
<tr>
<td>Estimate</td>
<td>Estimated value of the coefficient.</td>
</tr>
<tr>
<td>SE</td>
<td>Standard error of the coefficient.</td>
</tr>
<tr>
<td>tStat</td>
<td>$t$-statistics for testing the null hypothesis that the coefficient is equal to zero.</td>
</tr>
<tr>
<td>DF</td>
<td>Degrees of freedom for the $t$-test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. Coefficients always uses the 'Residual' method for 'DFMethod'.</td>
</tr>
<tr>
<td>pValue</td>
<td>$p$-value for the $t$-test.</td>
</tr>
<tr>
<td>Lower</td>
<td>Lower limit of the confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.</td>
</tr>
<tr>
<td>Upper</td>
<td>Upper limit of confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.</td>
</tr>
</tbody>
</table>
You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the coefCI and coefTest methods.

**CoefficientCovariance** — Covariance of the estimated fixed-effects coefficients

*p-by-*p* matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a *p*-by-*p* matrix, where *p* is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the covarianceParameters method.

Data Types: double

**CoefficientNames** — Names of the fixed-effects coefficients

1-by-*p* cell array of character vectors

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by-*p* cell array of character vectors.

Data Types: cell

**DFE** — Residual degrees of freedom

Positive integer value

Residual degrees of freedom, stored as a positive integer value. \( DFE = n - p \), where *n* is the number of observations, and *p* is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the fixedEffects and randomEffects methods.

Data Types: double

**FitMethod** — Method used to fit the linear mixed-effects model

ML | REML

Method used to fit the linear mixed-effects model, stored as either of the following.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

Data Types: char
**Formula — Specification of the fixed- and random-effects terms, and grouping variables**

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 32-3628.

**LogLikelihood — Maximized log or restricted log likelihood**

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: double

**ModelCriterion — Model criterion**

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIC</td>
<td>Akaike Information Criterion</td>
</tr>
<tr>
<td>BIC</td>
<td>Bayesian Information Criterion</td>
</tr>
<tr>
<td>Loglikelihood</td>
<td>Log likelihood value of the model</td>
</tr>
<tr>
<td>Deviance</td>
<td>–2 times the log likelihood of the model</td>
</tr>
</tbody>
</table>

If \( n \) is the number of observations used in fitting the model, and \( p \) is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - \( n \), when the fitting method is maximum likelihood (ML)
  - \( n - p \), when the fitting method is restricted maximum likelihood (REML)

**MSE — ML or REML estimate**

positive scalar value
ML or REML estimate, based on the fitting method used for estimating $\sigma^2$, stored as a positive scalar value. $\sigma^2$ is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: double

**NumCoefficients — Number of fixed-effects coefficients**
positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumEstimatedCoefficients — Number of estimated fixed-effects coefficients**
positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumObservations — Number of observations**
positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

Data Types: double

**NumPredictors — Number of predictors**
positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: double

**NumVariables — Total number of variables**
positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.
• If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.

• If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

**ObservationInfo — Information about the observations**

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

- **Weights**
  - The value of the weighted variable for that observation. Default value is 1.

- **Excluded**
  - `true`, if the observation was excluded from the fit using the `Exclude` name-value pair argument, `false`, otherwise. 1 stands for `true` and 0 stands for `false`.

- **Missing**
  - `true`, if the observation was excluded from the fit because any response or predictor value is missing, `false`, otherwise.

  Missing values include `NaN` for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the `<undefined>` value for categorical arrays.

- **Subset**
  - `true`, if the observation was used in the fit, `false`, if it was not used because it is missing or excluded.

Data Types: `table`

**ObservationNames — Names of observations**

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.
• If the data is in a table or dataset array, \( \text{tbl} \), containing observation names, \( \text{ObservationNames} \) has those names.

• If the data is provided in matrices, or a table or dataset array without observation names, then \( \text{ObservationNames} \) is an empty cell array.

Data Types: cell

**PredictorNames — Names of predictors**

cell array of character vectors

Names of the variables that you use as predictors in the fit, stored as a cell array of character vectors that has the same length as \( \text{NumPredictors} \).

Data Types: cell

**ResponseName — Names of response variable**

character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: char

**R squared — Proportion of variability in the response explained by the fitted model**

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. \( \text{R squared} \) has two fields.

**Ordinary**

R-squared value, stored as a scalar value in a structure. \( \text{R squared}.\text{Ordinary} = 1 - \frac{\text{SSE}}{\text{SST}} \)

**Adjusted**

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

\[
\text{R squared}.\text{Adjusted} = 1 - \left( \frac{\text{SSE}}{\text{SST}} \right) \left( \frac{\text{DFT}}{\text{DFE}} \right),
\]

where \( \text{DFE} = n - p \), \( \text{DFT} = n - 1 \), and \( n \) is the total number of observations, \( p \) is the number of fixed-effects coefficients.
Data Types: struct

**SSE — Error sum of squares**  
positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

\[
SSE = \sum ((y - F)^2), \quad \text{where} \quad y \text{ is the response vector, and } F \text{ is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.}
\]

Data Types: double

**SSR — Regression sum of squares**  
positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

\[
SSR = \sum ((F - \text{mean}(F))^2), \quad \text{where} \quad F \text{ is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.}
\]

Data Types: double

**SST — Total sum of squares**  
positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

\[
SST = \sum ((y - \text{mean}(y))^2) = SSR + SSE, \quad \text{where} \quad y \text{ is the response vector.}
\]

Data Types: double

**Variables — Variables**  
table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

32-3619
• If the fit is based on matrix input, then Variables is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: table

**VariableInfo — Information about the variables**

`table`

Information about the variables used in the fit, stored as a table.

VariableInfo has one row for each variable and contains the following four columns.

- **Class**
  - Class of the variable ('double', 'cell', 'nominal', and so on).

- **Range**
  - Value range of the variable.
  - For a numerical variable, it is a two-element vector of the form `[min, max]`.
  - For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.

- **InModel**
  - true, if the variable is a predictor in the fitted model.
  - false, if the variable is not in the fitted model.

- **IsCategorical**
  - true, if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the fit method.
  - false, if it is a continuous predictor.

Data Types: table

**VariableNames — Names of the variables**

`cell array of character vectors`

Names of the variables used in the fit, stored as a cell array of character vectors.
• If sample data is in a table or dataset array tbl, VariableNames contains the names of the variables in tbl.
• If sample data is in matrix format, then VariableInfo includes variable names you supply while fitting the model. If you do not supply the variable names, then VariableInfo contains the default names.

Data Types: cell

**Methods**

- **anova** Analysis of variance for linear mixed-effects model
- **coefCI** Confidence intervals for coefficients of linear mixed-effects model
- **coefTest** Hypothesis test on fixed and random effects of linear mixed-effects model
- **compare** Compare linear mixed-effects models
- **covarianceParameters** Extract covariance parameters of linear mixed-effects model
- **designMatrix** Fixed- and random-effects design matrices
- **disp** Display linear mixed-effects model
- **fit** Fit linear mixed-effects model using tables
- **fitmatrix** Fit linear mixed-effects model using design matrices
- **fitted** Fitted responses from a linear mixed-effects model
- **fixedEffects** Estimates of fixed effects and related statistics
- **plotResiduals** Plot residuals of linear mixed-effects model
- **predict** Predict response of linear mixed-effects model
- **random** Generate random responses from fitted linear mixed-effects model
- **randomEffects** Estimates of random effects and related statistics
- **residuals** Residuals of fitted linear mixed-effects model
- **response** Response vector of the linear mixed-effects model
Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable, FluRate, the nominal variable, Region, that shows which region each estimate is from, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...'
    IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Because region is a nominal variable, fitlme takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, I[MidAtl] is the dummy variable representing the region MidAtl. For details, see “Dummy Indicator Variables” on page 2-60.

The corresponding model is

\[ y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + e_{im}, \quad m = 1, 2, \ldots, 52, \]
where $y_{im}$ is the observation $i$ for level $m$ of grouping variable Date, $\beta_j$, $j = 0, 1, ..., 8$, are the fixed-effects coefficients, $b_{0m}$ is the random effect for level $m$ of the grouping variable Date, and $\epsilon_{im}$ is the observation error for observation $i$. The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\epsilon_{im} \sim N(0, \sigma^2)$.

lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')

lme = 
Linear mixed-effects model fit by ML

Model information:
  Number of observations             468
  Fixed effects coefficients           9
  Random effects coefficients         52
  Covariance parameters                2

Formula:
  FluRate ~ 1 + Region + (1 | Date)

Model fit statistics:
  AIC       BIC       LogLikelihood    Deviance
  318.71    364.35    -148.36          296.71

Fixed effects coefficients (95% CIs):
  Name          Estimate    SE          tStat      DF
  '(Intercept)'                1.2233    0.096678     12.654    459
  'Region_MidAtl'            0.010192    0.052221    0.19518    459
  'Region_ENCentral'         0.051923    0.052221     0.9943    459
  'Region_WNCentral'         0.23687    0.052221     4.5359    459
  'Region_SAtl'              0.075481    0.052221     1.4454    459
  'Region_ESCentral'         0.33917    0.052221      6.495    459
  'Region_WSCentral'          0.069    0.052221     1.3213    459
  'Region_Mtn'               0.046673    0.052221    0.89377    459
  'Region_Pac'               -0.16013    0.052221    -3.0665    459

  pValue        Lower        Upper
  1.085e-31       1.0334       1.4133
  0.84534    -0.092429      0.11281
  0.3206    -0.050698      0.15454
The $p$-values $7.3324e-06$ and $2.1623e-10$ respectively show that the fixed effects of the flu rates in regions WNCentral and ESEntral are significantly different relative to the flu rates in region NE.

The confidence limits for the standard deviation of the random-effects term, $\sigma_b$, do not include 0 ($0.5297$, $0.78368$), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region WNCentral in week 10/9/2005 is

$$\hat{y}_{\text{WNCentral, 10/9/2005}} = \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005}$$

$$= 1.2233 + 0.23687 - 0.1718$$

$$= 1.28837.$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat = 1.2884

You can simply display the fitted value using the fitted method.

F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans = 1.2884

Compute the fitted marginal response for region WNCentral in week 10/9/2005.

F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans = 1.4602

**Linear Mixed-Effects Model with a Random Slope**

Load the sample data.

load carbig

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

\[
MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + e_{im}, \quad m = 1, 2, 3,
\]

with the random-effects terms having the following prior distributions:

\[
b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),
\]

where \( m \) represents the model year.
First, prepare the design matrices for fitting the linear mixed-effects model.

\[
X = [\text{ones}(406,1) \text{ Acceleration Horsepower}];
\]
\[
Z = [\text{ones}(406,1) \text{ Acceleration}];
\]
\[
\text{Model Year} = \text{nominal} (\text{Model Year});
\]
\[
G = \text{Model Year};
\]

Now, fit the model using \text{fitlmematrix} with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

\[
\text{lme} = \text{fitlmematrix}(X,\text{MPG},Z,G,'\text{FixedEffectPredictors}',\ldots
\{\text{'Intercept'},\text{'Acceleration'},\text{'Horsepower'}\},'	ext{RandomEffectPredictors}',\ldots
\{\{\text{'Intercept'},\text{'Acceleration'}\}\},'\text{RandomEffectGroups}',\{\text{'Model Year'}\},\ldots
'\text{FitMethod}','\text{REML}')
\]

\[
lme =
\]
Linear mixed-effects model fit by REML

Model information:
- Number of observations: 392
- Fixed effects coefficients: 3
- Random effects coefficients: 26
- Covariance parameters: 4

Formula:
Linear Mixed Formula with 4 predictors.

Model fit statistics:
- AIC: 2202.9
- BIC: 2230.7
- LogLikelihood: -1094.5
- Deviance: 2188.9

Fixed effects coefficients (95% CIs):

<table>
<thead>
<tr>
<th>Name</th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>DF</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Intercept'</td>
<td>50.064</td>
<td>2.3176</td>
<td>21.602</td>
<td>389</td>
<td>1.4185e-68</td>
</tr>
<tr>
<td>'Acceleration'</td>
<td>-0.57897</td>
<td>0.13843</td>
<td>-4.1825</td>
<td>389</td>
<td>3.5654e-05</td>
</tr>
<tr>
<td>'Horsepower'</td>
<td>-0.16958</td>
<td>0.0073242</td>
<td>-23.153</td>

</tbody>
</table>

Lower       Upper
-45.507     54.62
-0.85112    -0.30681
-0.18398    -0.15518

Random effects covariance parameters (95% CIs):
Group: Model Year (13 Levels)
The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (Lower and Upper). The \( p \)-values for (pValue) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```markdown
lme.CoefficientCovariance
ans = 3x3

5.3711  -0.2809  -0.0126
-0.2809   0.0192   0.0005
-0.0126   0.0005   0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is \( \sqrt{5.3711} \).

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is \(-0.2809\) and the correlation between acceleration and horsepower is 0.0005.
Display the coefficient of determination for the model.

\texttt{lme.Rsquared}

\texttt{ans = struct with fields:}
  Ordinary: 0.7826
  Adjusted: 0.7815

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

\section*{Definitions}

\subsection*{Formula}

In general, a formula for model specification is a character vector or string scalar of the form \texttt{\'y ~ terms\}'. For the linear mixed-effects models, this formula is in the form \texttt{\'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)\'}, where \texttt{fixed} and \texttt{random} contain the fixed-effects and the random-effects terms.

Suppose a table \texttt{tbl} contains the following:

- A response variable, \texttt{y}
- Predictor variables, \texttt{Xj}, which can be continuous or grouping variables
- Grouping variables, \texttt{g1}, \texttt{g2}, ..., \texttt{gR},

where the grouping variables in \texttt{Xj} and \texttt{gR} can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form \texttt{\'y ~ fixed + (random1|g1) + ... + (randomR|gR)\'} , the term \texttt{fixed} corresponds to a specification of the fixed-effects design matrix \texttt{X}, \texttt{random1} is a specification of the random-effects design matrix \texttt{Z1} corresponding to grouping variable \texttt{g1}, and similarly \texttt{randomR} is a specification of the random-effects design matrix \texttt{ZR} corresponding to grouping variable \texttt{gR}. You can express the \texttt{fixed} and \texttt{random} terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>
<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (X1</td>
<td>g1)'</td>
</tr>
</tbody>
</table>
### Formula

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1) + (1</td>

linhyptest

Linear hypothesis test

Syntax

\[ p = \text{linhyptest}(\beta, \text{COVB}, c, H, dfe) \]
\[ [p, t, r] = \text{linhyptest}(...) \]

Description

\[ p = \text{linhyptest}(\beta, \text{COVB}, c, H, dfe) \] returns the \( p \) value \( p \) of a hypothesis test on a vector of parameters. \( \beta \) is a vector of \( k \) parameter estimates. \( \text{COVB} \) is the \( k \)-by-\( k \) estimated covariance matrix of the parameter estimates. \( c \) and \( H \) specify the null hypothesis in the form \( H^*b = c \), where \( b \) is the vector of unknown parameters estimated by \( \beta \). \( dfe \) is the degrees of freedom for the \( \text{COVB} \) estimate, or \( \text{Inf} \) if \( \text{COVB} \) is known rather than estimated.

\( \beta \) is required. The remaining arguments have default values:

- \( \text{COVB} = \text{eye}(k) \)
- \( c = \text{zeros}(k,1) \)
- \( H = \text{eye}(K) \)
- \( dfe = \text{Inf} \)

If \( H \) is omitted, \( c \) must have \( k \) elements and it specifies the null hypothesis values for the entire parameter vector.

\textbf{Note} The following functions return outputs suitable for use as the \( \text{COVB} \) input argument to \text{linhyptest}: \text{nlinfit}, \text{coxphfit}, \text{glmfit}, \text{mnrfit}, \text{regstats}, \text{robustfit}. \text{nlinfit} returns \( \text{COVB} \) directly; the other functions return \( \text{COVB} \) in \text{stats.covb}.

\[ [p, t, r] = \text{linhyptest}(...) \] also returns the test statistic \( t \) and the rank \( r \) of the hypothesis matrix \( H \). If \( dfe \) is \( \text{Inf} \) or is not given, \( t*r \) is a chi-square statistic with \( r \)
degrees of freedom. If dfe is specified as a finite value, t is an F statistic with r and dfe degrees of freedom.

linhyptest performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as regstats or glmfit. For linear regression, the p-values are exact. For other procedures, the p-values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

**Examples**

Fit a multiple linear model to the data in hald.mat:

```matlab
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
   62.4054
   1.5511
   0.5102
   0.1019
  -0.1441
```

Perform an F-test that the last two coefficients are both 0:

```matlab
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhyptest(beta,SIGMA,c,H,dfe)
p =
  0.4668
F =
  0.8391
```

*Introduced in R2007a*
linkage

Agglomerative hierarchical cluster tree

Syntax

Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(X,method,pdist_inputs)
Z = linkage(y)
Z = linkage(y,method)

Description

Z = linkage(X) returns a matrix Z that encodes a tree containing hierarchical clusters of the rows of the input data matrix X.

Z = linkage(X,method) creates the tree using the specified method, which describes how to measure the distance between clusters. For more information, see “Linkages” on page 32-3643.

Z = linkage(X,method,metric) performs clustering by passing metric to the pdist function, which computes the distance between the rows of X.

Z = linkage(X,method,metric,'savememory',value) uses a memory-saving algorithm when value is 'on', and uses the standard algorithm when value is 'off'.

Z = linkage(X,method,pdist_inputs) passes pdist_inputs to the pdist function, which computes the distance between the rows of X. The pdist_inputs argument consists of the 'seuclidean', 'minkowski', or 'mahalanobis' metric and an additional distance metric option.
\[ Z = \text{linkage}(y) \] uses a vector representation \( y \) of a distance matrix. \( y \) is either computed by \texttt{pdist} or is a more general dissimilarity matrix conforming to the output format of \texttt{pdist}.

\[ Z = \text{linkage}(y, \text{method}) \] creates the tree using the specified \texttt{method}, which describes how to measure the distance between clusters.

**Examples**

**Cluster Data and Plot Result**

Randomly generate sample data with 20,000 observations.

```matlab
rng('default') % For reproducibility
X = rand(20000,3);

Create a hierarchical cluster tree using Ward's linkage. In this case, 'savememory' is set to 'on' by default. In general, choose the best value for 'savememory' based on the dimensions of \( X \) and the available memory.

\[ Z = \text{linkage}(X, 'ward'); \]

Cluster data into four groups and plot the result.

```matlab
c = \text{cluster}(Z, 'Maxclust', 4);
scatter3(X(:,1), X(:,2), X(:,3), 10, c)```
**Compare Cluster Assignments to Classes**

Compare cluster assignments of flowers to their species classification.

Load the sample data.

```markdown
load fisheriris
```

Compute three clusters of the Fisher iris data using the 'average' method and the 'chebychev' metric.

```markdown
```
\[ Z = \text{linkage}(\text{meas}, 'average', 'chebychev'); \]
\[ c = \text{cluster}(Z, 'maxclust', 3); \]

Create a dendrogram plot of \( Z \). To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

\[ \text{cutoff} = \text{median}([Z(\text{end}-2,3) \ Z(\text{end}-1,3)]); \]
\[ \text{dendrogram}(Z, 'ColorThreshold', \text{cutoff}) \]

Display the last two rows of \( Z \) to see how the three clusters are combined into one. \( \text{linkage} \) combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of 1.7583. \( \text{linkage} \) then combines the 296th (green) cluster with the 298th cluster.

\[ \text{lastTwo} = Z(\text{end}-1:\text{end},:) \]
lastTwo = 2×3

293.0000  297.0000   1.7583
296.0000  298.0000   3.4445

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

crosstab(c,species)

ans = 3×3

0    0    10
0   50    40
50    0    0

Observe Clustering Step in Hierarchical Tree

Load the examgrades data set.

load examgrades

Create a hierarchical tree using linkage. Use the 'single' method and the Minkowski metric with an exponent of 3.

Z = linkage(grades,'single',{'minkowski',3});

Observe the 25th clustering step.

Z(25,:)

ans = 1×3

86.0000  137.0000   4.5307

linkage combines the 86th observation and the 137th cluster to form a cluster of index 120 + 25 = 145, where 120 is the total number of observations in grades and 25 is the row number in Z. The shortest distance between the 86th observation and any of the points in the 137th cluster is 4.5307.
Cluster Data Using Dissimilarity Matrix

Create an agglomerative hierarchical cluster tree using a dissimilarity matrix.

Take a dissimilarity matrix $X$ and convert it to a vector form that `linkage` accepts by using `squareform`.

```matlab
X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0];
y = squareform(X);
```

Create a cluster tree using `linkage` with the 'complete' method of calculating the distance between clusters. The first two columns of $Z$ show how `linkage` combines clusters. The third column of $Z$ gives the distance between clusters.

```matlab
Z = linkage(y,'complete')
Z = 3×3
     1     2     1     
     3     5     4     
     4     6     6
```

Create a dendrogram plot of $Z$. The x-axis corresponds to the leaf nodes of the tree, and the y-axis corresponds to the linkage distances between clusters.

```matlab
dendrogram(Z)
```
Input Arguments

**X — Input data**
numeric matrix

Input data, specified as a numeric matrix with two or more rows. The rows represent observations, and the columns represent categories or dimensions.

Data Types: `single` | `double`

**method — Algorithm for computing distance between clusters**

'single' (default) | 'average' | 'centroid' | 'complete' | ...
Algorithm for computing the distance between clusters, specified as one of the values in this table.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'average'</td>
<td>Unweighted average distance (UPGMA)</td>
</tr>
<tr>
<td>'centroid'</td>
<td>Centroid distance (UPGMC), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'complete'</td>
<td>Farthest distance</td>
</tr>
<tr>
<td>'median'</td>
<td>Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'single'</td>
<td>Shortest distance</td>
</tr>
<tr>
<td>'ward'</td>
<td>Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only</td>
</tr>
<tr>
<td>'weighted'</td>
<td>Weighted average distance (WPGMA)</td>
</tr>
</tbody>
</table>

For more information on these methods, see “Linkages” on page 32-3643.

**metric — Distance metric**

'euclidean'(default) | 'squaredeuclidean' | 'seuclidean' | 'mahalanobis' | function handle |
|---------------------|-------------------|--------------|--------------|----------------|

Distance metric, specified as any metric accepted by the pdist function. These metrics are described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance (default).</td>
</tr>
<tr>
<td>'squaredeuclidean'</td>
<td>Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, ( S = \text{nanstd}(X) ). Use DistParameter to specify another value for ( S ).</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance using the sample covariance of ( X, C = \text{nancov}(X) ). Use DistParameter to specify another value for ( C ), where the matrix ( C ) is symmetric and positive definite.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. Use DistParameter to specify a different exponent P, where P is a positive scalar value of the exponent.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between points (treated as vectors).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample correlation between points (treated as sequences of values).</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman’s rank correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>@distfun</td>
<td>Custom distance function handle. A distance function has the form:</td>
</tr>
<tr>
<td></td>
<td>function D2 = distfun(ZI,ZJ)</td>
</tr>
<tr>
<td></td>
<td>% calculation of distance</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td></td>
<td>where</td>
</tr>
<tr>
<td></td>
<td>• ZI is a 1-by-n vector containing a single observation.</td>
</tr>
<tr>
<td></td>
<td>• ZJ is an m2-by-n matrix containing multiple observations.</td>
</tr>
<tr>
<td></td>
<td>distfun must accept a matrix ZJ with an arbitrary number of observations.</td>
</tr>
<tr>
<td></td>
<td>• D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).</td>
</tr>
<tr>
<td></td>
<td>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</td>
</tr>
</tbody>
</table>

For more information, see “Distance Metrics” on page 32-4703.
Use `pdist_inputs` instead of `metric` to specify the additional input argument `DistParameter` of `pdist` for 'seuclidean', 'minkowski', or 'mahalanobis'.

Data Types: `char` | `string` | `function_handle`

**pdist_inputs — Distance metric and distance metric option**

cell array

Distance metric and distance metric option, specified as a cell array of the comma-separated pair consisting of the two input arguments `Distance` and `DistParameter` of the function `pdist`. This argument is valid only for specifying 'seuclidean', 'minkowski', or 'mahalanobis'.

Example: `{'minkowski',5}`

Data Types: `cell`

**value — Flag for 'savememory' option**

'on' | 'off'

Flag for the 'savememory' option, specified as either 'on' or 'off'. The 'on' setting causes `linkage` to construct clusters without computing the distance matrix. The 'on' setting is available only when `method` is 'centroid', 'median', or 'ward' and `metric` is 'euclidean'.

When `value` is 'on', the `linkage` run time is proportional to the number of dimensions (number of columns of `X`). When `value` is 'off', the `linkage` memory requirement is proportional to $N^2$, where $N$ is the number of observations. The best (least-time) setting to use for `value` depends on the problem dimensions, number of observations, and available memory. The default `value` setting is a rough approximation of an optimal setting.

The default is 'on' when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix. Otherwise, the default is 'off'.

Example: `{'savememory', 'on'}`

**y — Distances**

numeric vector

Distances, specified as a numeric vector with the same format as the output of the `pdist` function:

- A row vector of length $m(m - 1)/2$, corresponding to pairs of observations in a matrix with $m$ rows
Distances arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m – 1))
y can be a more general dissimilarity matrix conforming to the output format of pdist.

Data Types: single | double

Output Arguments

Z — Agglomerative hierarchical cluster tree
numeric matrix

Agglomerative hierarchical cluster tree, returned as a numeric matrix. Z is an (m – 1)-by-3
matrix, where m is the number of observations in the original data. Columns 1 and 2 of Z
contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered
from 1 to m. Leaf nodes are the singleton clusters from which all higher clusters are built.
Each newly formed cluster, corresponding to row Z(I,:), is assigned the index m + I.
The entries Z(I,1) and Z(I,2) contain the indices of the two component clusters that
form cluster m + I. The m – 1 higher clusters correspond to the interior nodes of the
clustering tree. Z(I,3) contains the linkage distance between the two clusters merged in
row Z(I,:).

For example, consider building a tree with 30 initial nodes. Suppose that cluster 5 and
cluster 7 are combined at step 12, and that the distance between them at that step is 1.5.
Then Z(12,:) is [5 7 1.5]. The newly formed cluster has index 12 + 30 = 42. If
cluster 42 appears in a later row, then the function is combining the cluster created at
step 12 into a larger cluster.

Data Types: single | double

Definitions

Linkages

A linkage is the distance between two clusters.

The following notation describes the linkages used by the various methods:

• Cluster r is formed from clusters p and q.
• $n_r$ is the number of objects in cluster $r$.
• $x_{ri}$ is the $i$th object in cluster $r$.

**Single linkage**, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters.

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj})), i \in (i, ..., n_r), j \in (1, ..., n_s)$$

• **Complete linkage**, also called *farthest neighbor*, uses the largest distance between objects in the two clusters.

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj})), i \in (1, ..., n_r), j \in (1, ..., n_s)$$

• **Average linkage** uses the average distance between all pairs of objects in any two clusters.

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

• **Centroid linkage** uses the Euclidean distance between the centroids of the two clusters.

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2,$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

• **Median linkage** uses the Euclidean distance between weighted centroids of the two clusters.

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2,$$

where $\tilde{x}_r$ and $\tilde{x}_s$ are weighted centroids for the clusters $r$ and $s$. If cluster $r$ was created by combining clusters $p$ and $q$, $\tilde{x}_r$ is defined recursively as
\[
\bar{x}_r = \frac{1}{2} (\bar{x}_p + \bar{x}_q)
\]

- **Ward's linkage** uses the incremental sum of squares, that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares metric is equivalent to the following distance metric \( d(r,s) \), which is the formula linkage uses.

\[
d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)} \| \bar{x}_r - \bar{x}_s \|_2},
\]

where

- \( \| \|_2 \) is the Euclidean distance.
- \( \bar{x}_r \) and \( \bar{x}_s \) are the centroids of clusters \( r \) and \( s \).
- \( n_r \) and \( n_s \) are the number of elements in clusters \( r \) and \( s \).

In some references, Ward's linkage does not use the factor of 2 multiplying \( n_r n_s \). The linkage function uses this factor so that the distance between two singleton clusters is the same as the Euclidean distance.

- **Weighted average linkage** uses a recursive definition for the distance between two clusters. If cluster \( r \) was created by combining clusters \( p \) and \( q \), the distance between \( r \) and another cluster \( s \) is defined as the average of the distance between \( p \) and \( s \) and the distance between \( q \) and \( s \).

\[
d(r,s) = \frac{(d(p,s) + d(q,s))}{2}
\]

**Tips**

- Computing linkage(y) can be slow when y is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, linkage checks whether y is a Euclidean distance. Avoid this time-consuming check by passing in X instead of y.
• The 'centroid' and 'median' methods can produce a cluster tree that is not monotonic. This result occurs when the distance from the union of two clusters, \( r \) and \( s \), to a third cluster is less than the distance between \( r \) and \( s \). In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this result, use another method. This figure shows a nonmonotonic cluster tree.

![Dendrogram](image)

In this case, cluster 1 and cluster 3 are joined into a new cluster, and the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. The result is a nonmonotonic tree.

• You can provide the output \( Z \) to other functions including \texttt{dendrogram} to display the tree, \texttt{cluster} to assign points to clusters, \texttt{inconsistent} to compute inconsistent measures, and \texttt{cophenet} to compute the cophenetic correlation coefficient.

\texttt{Introduced before R2006a}
loadCompactModel

Reconstruct model object from saved model for code generation

To generate C/C++ code for the object functions (predict, random, knnsearch, or rangesearch) of machine learning models, use saveCompactModel, loadCompactModel, and codegen. After training a machine learning model, save the model by using saveCompactModel. Define an entry-point function that loads the model by using loadCompactModel and calls an object function. Then use codegen or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use loadCompactModel for the highlighted step.

Syntax

Mdl = loadCompactModel(filename)

Description

Mdl = loadCompactModel(filename) reconstructs a classification model, regression model, or nearest neighbor searcher (Mdl) from the saved model stored in the MATLAB formatted binary file (MAT-file) named filename. You must create the filename file using saveCompactModel.

Examples
**Generate C/C++ Code for Prediction**

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.

**Train Model**

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```matlab
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` model.

**Save Model**

Save the SVM classification model to the file `SVMIris.mat` by using `saveCompactModel`.

```matlab
saveCompactModel(Mdl,'SVMIris');
```

**Define Entry-Point Function**

Define an entry-point function named `classifyIrises` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
• Load a trained SVM classification model.
• Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIrises.m

function label = classifyIrises(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
% CLASSIFYIRISES classifies the iris flower measurements in X using the
% compact SVM model in the file SVMIris.mat, and then returns class
% labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the %#codegen compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

**Note:** If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

**Generate Code**

Generate code for the entry-point function using codegen. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass X as the value of the -args option to specify that the generated code must accept an input that has the same data type and array size as the training data X. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using coder.typeof. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-57 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIrises -args {X}
```

codegen generates the MEX function classifyIrises_mex with a platform-dependent extension.

**Verify Generated Code**

Compare the labels classified using predict, classifyIrises, and classifyIrises_mex.
label1 = predict(Mdl,X);
label2 = classifyIrises(X);
label3 = classifyIrises_mex(X);
verify_label = isequal(label1,label2,label3)

verify_label = logical
1

isequal returns logical 1 (true), which means all the inputs are equal. The labels
classified all three ways are the same.

Input Arguments

filename — Name of MAT-file containing structure array representing a model object
character vector | string scalar

Name of MAT-file containing the structure array representing a model object, specified as
a character vector. You must create the filename file using saveCompactModel.

loadCompactModel reconstructs the model stored in the filename file at compile time.
For supported models, see the Mdl input argument of saveCompactModel.

The extension of the filename file must be .mat. If filename has no extension, then
loadCompactModel appends .mat.

If filename does not include a full path, then loadCompactModel loads the file from
the current folder.

Example: 'Mdl'

Data Types: char | string

Output Arguments

Mdl — Machine learning model
model object

Machine learning model, returned as one of the model objects in these tables.
## Compact classification model object

Mdl must be a compile-time constant. You cannot change it after you load it using loadCompactModel.

**Alternative Functionality**

- Use a coder configurer created by learnerCoderConfigurer for SVM models to generate C/C++ code. After training an SVM model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the predict and update functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-90.

logncdf

Lognormal cumulative distribution function

Syntax

\[ p = \text{logncdf}(x, \mu, \sigma) \]
\[ [p, plo, pup] = \text{logncdf}(x, \mu, \sigma, \text{pcov}, \alpha) \]
\[ [p, plo, pup] = \text{logncdf}(\_\_\_, 'upper') \]

Description

\[ p = \text{logncdf}(x, \mu, \sigma) \] returns values at \( x \) of the lognormal cdf with distribution parameters \( \mu \) and \( \sigma \). \( \mu \) and \( \sigma \) are the mean and standard deviation, respectively, of the associated normal distribution. \( x, \mu, \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for \( x, \mu, \) or \( \sigma \) is expanded to a constant array with the same dimensions as the other inputs. The parameters in \( \sigma \) must be positive.

\[ [p, plo, pup] = \text{logncdf}(x, \mu, \sigma, \text{pcov}, \alpha) \] returns confidence bounds for \( p \) when the input parameters \( \mu \) and \( \sigma \) are estimates. \( \text{pcov} \) is the covariance matrix of the estimated parameters. \( \alpha \) specifies \( 100(1 - \alpha)\% \) confidence bounds. The default value of \( \alpha \) is 0.05. \( plo \) and \( pup \) are arrays of the same size as \( p \) containing the lower and upper confidence bounds.

\[ [p, plo, pup] = \text{logncdf}(\_\_\_, 'upper') \] returns the complement of the lognormal cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

\text{logncdf} \text{ computes confidence bounds for } p \text{ using a normal approximation to the distribution of the estimate}

\[ \frac{x - \hat{\mu}}{\hat{\sigma}} \]

and then transforming those bounds to the scale of the output \( p \). The computed bounds give approximately the desired confidence level when you estimate \( \mu, \sigma, \) and \( \text{pcov} \).
from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

\[
p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}} dt
\]

**Examples**

**Compute the Lognormal Distribution cdf**

Compute the cdf of a lognormal distribution with \( \mu = 0 \) and \( \sigma = 1 \).

\[
x = (0:0.2:10);
y = logncdf(x,0,1);
\]

Plot the cdf.

\[
plot(x,y);
grid;
xlabel('x');
ylabel('p');
\]
Algorithms

The function logncdf uses the inverse complementary error function erfc. The relationship between normcdf and erfc is

\[
\logncdf(x, 0, 1) = \frac{1}{2} \text{erfc} \left( -\frac{\log(x)}{\sqrt{2}} \right).
\]

The complementary error function \(\text{erfc}(x)\) is defined as
erfc(x) = 1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} \, dt.

Topics
“Lognormal Distribution” on page B-95

Introduced before R2006a
lognfit

Lognormal parameter estimates

Syntax

parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...,] = lognfit(data,alpha,censoring)
[...,] = lognfit(data,alpha,censoring,freq)
[...,] = lognfit(data,alpha,censoring,freq,options)

Description

parmhat = lognfit(data) returns a vector of maximum likelihood estimates
parmhat(1) = mu and parmhat(2) = sigma of parameters for a lognormal
distribution fitting data. mu and sigma are the mean and standard deviation,
respectively, of the associated normal distribution.

[parmhat,parmci] = lognfit(data) returns 95% confidence intervals for the
parameter estimates mu and sigma in the 2-by-2 matrix parmci. The first column of the
matrix contains the lower and upper confidence bounds for parameter mu, and the second
column contains the confidence bounds for parameter sigma.

[parmhat,parmci] = lognfit(data,alpha) returns 100(1 - alpha) % confidence
intervals for the parameter estimates, where alpha is a value in the range (0 1)
specifying the width of the confidence intervals. By default, alpha is 0.05, which
corresponds to 95% confidence intervals.

[...] = lognfit(data,alpha,censoring) accepts a Boolean vector censoring, of
the same size as data, which is 1 for observations that are right-censored and 0 for
observations that are observed exactly.

[...] = lognfit(data,alpha,censoring,freq) accepts a frequency vector, freq,
of the same size as data. Typically, freq contains integer frequencies for the
corresponding elements in data, but can contain any nonnegative values. Pass in [] for alpha, censoring, or freq to use their default values.

[..., alpha, censoring, freq, options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an options structure which can be created using the function statset. Enter statset('lognfit') to see the names and default values of the parameters that lognfit accepts in the options structure. See the reference page for statset for more information about these options.

**Note** With no censoring, lognfit computes sigma using the square root of the unbiased estimator of the variance. With censoring, sigma is the maximum likelihood estimate.

**Examples**

This example generates 100 independent samples of lognormally distributed data with \( \mu = 0 \) and \( \sigma = 3 \). parmhat estimates \( \mu \) and \( \sigma \) and parmci gives 99% confidence intervals around parmhat. Notice that parmci contains the true values of \( \mu \) and \( \sigma \).

```matlab
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
   -0.2480   2.8902
parmci =
   -1.0071   2.4393
   0.5111   3.5262
```

logninv

Lognormal inverse cumulative distribution function

Syntax

\[ X = \text{logninv}(P, \mu, \sigma) \]

\[[X, XLO, XUP] = \text{logninv}(P, \mu, \sigma, \text{pcov}, \alpha)\]

Description

\[ X = \text{logninv}(P, \mu, \sigma) \] returns values at \( P \) of the inverse lognormal cdf with distribution parameters \( \mu \) and \( \sigma \). \( \mu \) and \( \sigma \) are the mean and standard deviation, respectively, of the associated normal distribution. \( \mu \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( X \). A scalar input for \( P, \mu, \) or \( \sigma \) is expanded to a constant array with the same dimensions as the other inputs. The parameters in \( \sigma \) must be positive.

\[[X, XLO, XUP] = \text{logninv}(P, \mu, \sigma, \text{pcov}, \alpha)\] returns confidence bounds for \( X \) when the input parameters \( \mu \) and \( \sigma \) are estimates. \( \text{pcov} \) is the covariance matrix of the estimated parameters. \( \alpha \) specifies 100(1 - \( \alpha \))% confidence bounds. The default value of \( \alpha \) is 0.05. \( XLO \) and \( XUP \) are arrays of the same size as \( X \) containing the lower and upper confidence bounds.

\text{logninv} \text{ computes confidence bounds for } \text{P using a normal approximation to the distribution of the estimate} \]

\[ \hat{\mu} + \hat{\sigma} q \]

where \( q \) is the \( P \)th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate \( \mu, \sigma, \) and \( \text{pcov} \) from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as
where

\[ p = F(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \int_{0}^{x} e^\frac{-\ln(t)-\mu^2}{2\sigma^2} dt \]

### Examples

**Compute the Lognormal Distribution Inverse cdf**

Compute the inverse cdf of a lognormal distribution with \( \mu = 0 \) and \( \sigma = 0.5 \).

```matlab
p = (0.005:0.01:0.995);
crit = logninv(p,1,0.5);
```

Plot the inverse cdf.

```matlab
figure;
plot(p,crit)
xlabel('Probability');
ylabel('Critical Value');
grid
```
Algorithms

The function `logninv` uses the inverse complementary error function `erfcinv`. The relationship between `norminv` and `erfcinv` is

\[ \text{logninv}(p, 0, 1) = \exp\left(-\sqrt{2}\text{erfcinv}(2p)\right). \]

The inverse complementary error function `erfcinv(x)` is defined as `erfcinv(erfc(x)) = x`, and the complementary error function `erfc(x)` is defined as...
erfc(x) = 1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt.

Topics

“Lognormal Distribution” on page B-95

Introduced before R2006a
lognlike

Lognormal negative log-likelihood

Syntax

\[ \text{nlogL} = \text{lognlike}(\text{params},\text{data}) \]
\[ [\text{nlogL},\text{avar}] = \text{lognlike}(\text{params},\text{data}) \]
\[ [...]. = \text{lognlike}(\text{params},\text{data},\text{censoring}) \]
\[ [...]. = \text{lognlike}(\text{params},\text{data},\text{censoring},\text{freq}) \]

Description

\[ \text{nlogL} = \text{lognlike}(\text{params},\text{data}) \] returns the negative log-likelihood of \text{data} for the lognormal distribution with parameters \text{params}. \text{params}(1) is the mean of the associated normal distribution, \text{mu}, and \text{params}(2) is the standard deviation of the associated normal distribution, \text{sigma}. The values of \text{mu} and \text{sigma} are scalars, and the output \text{nlogL} is a scalar. \text{params}(2) must be positive.

\[ [\text{nlogL},\text{avar}] = \text{lognlike}(\text{params},\text{data}) \] returns the inverse of Fisher's information matrix. If the input parameter value in \text{params} is the maximum likelihood estimate, \text{avar} is its asymptotic variance. \text{avar} is based on the observed Fisher's information, not the expected information.

\[ [...]. = \text{lognlike}(\text{params},\text{data},\text{censoring}) \] accepts a Boolean vector, \text{censoring}, of the same size as \text{data}, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

\[ [...]. = \text{lognlike}(\text{params},\text{data},\text{censoring},\text{freq}) \] accepts a frequency vector, \text{freq}, of the same size as \text{data}. The vector \text{freq} typically contains integer frequencies for the corresponding elements in \text{data}, but can contain any nonnegative values. Pass in [] for \text{censoring} to use its default value.
Extended Capabilities

Topics
“Lognormal Distribution” on page B-95

Introduced before R2006a
lognpdf

Lognormal probability density function

Syntax

Y = lognpdf(X,mu,sigma)

Description

Y = lognpdf(X,mu,sigma) returns values at X of the lognormal pdf with distribution parameters mu and sigma. mu and sigma are the mean and standard deviation, respectively, of the associated normal distribution. X, mu, and sigma can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y. A scalar input for X, mu, or sigma is expanded to a constant array with the same dimensions as the other inputs. The parameters in sigma must be positive.

The lognormal pdf is

\[ y = f(x \mid \mu, \sigma) = \frac{1}{x \sigma \sqrt{2\pi}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}} \]

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters \( \mu \) and \( \sigma \), then \( \log(X) \) is distributed normally with mean \( \mu \) and standard deviation \( \sigma \).

The mean \( m \) and variance \( v \) of a lognormal random variable are functions of \( \mu \) and \( \sigma \) that can be calculated with the lognstat function. They are:

\[ m = \exp\left(\mu + \frac{\sigma^2}{2}\right) \]

\[ v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right) \]

So, a lognormal distribution with mean \( m \) and variance \( v \) has parameters
\[
\mu = \log \left( \frac{m^2}{\sqrt{v + m^2}} \right) \\
\sigma = \sqrt{\log \left( \frac{v}{m^2 + 1} \right)}
\]

If you do not know the population mean and variance, \( m \) and \( v \), for the lognormal distribution, you can estimate \( \mu \) and \( \sigma \) in the following way:

\[
\text{mu} = \text{mean} (\log (X)) \\
\text{sigma} = \text{std} (\log (X))
\]

The lognormal distribution is applicable when the quantity of interest must be positive, since \( \log (X) \) exists only when \( X \) is positive.

**Examples**

**Compute the Lognormal Distribution pdf**

Compute the pdf of a lognormal distribution with \( \mu = 0 \) and \( \sigma = 1 \).

\[
x = (0:0.02:10); \\
y = \text{lognpdf} (x, 0, 1);
\]

Plot the pdf.

\[
\text{plot} (x, y); \, \text{grid}; \\
\text{xlabel} ('x'); \, \text{ylabel} ('p')
\]

Topics
“Lognormal Distribution” on page B-95

Introduced before R2006a
**lognrnd**

Lognormal random numbers

**Syntax**

\[ R = \text{lognrnd}(\mu, \sigma) \]

\[ R = \text{lognrnd}(\mu, \sigma, m, n, \ldots) \]

\[ R = \text{lognrnd}(\mu, \sigma, [m, n, \ldots]) \]

**Description**

\[ R = \text{lognrnd}(\mu, \sigma) \] returns an array of random numbers generated from the lognormal distribution with parameters \( \mu \) and \( \sigma \). \( \mu \) and \( \sigma \) are the mean and standard deviation, respectively, of the associated normal distribution. \( \mu \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \( R \). A scalar input for \( \mu \) or \( \sigma \) is expanded to a constant array with the same dimensions as the other input. The parameters in \( \sigma \) must be nonnegative. If \( \sigma \) is zero, then \( R \) is always equal to \( \exp(\mu) \).

\[ R = \text{lognrnd}(\mu, \sigma, m, n, \ldots) \] or \[ R = \text{lognrnd}(\mu, \sigma, [m, n, \ldots]) \]

generates an \( m \)-by-\( n \)-by-\( \ldots \) array. The \( \mu, \sigma \) parameters can each be scalars or arrays of the same size as \( R \).

The normal and lognormal distributions are closely related. If \( X \) is distributed lognormally with parameters \( \mu \) and \( \sigma \), then \( \log(X) \) is distributed normally with mean \( \mu \) and standard deviation \( \sigma \).

The mean \( m \) and variance \( v \) of a lognormal random variable are functions of \( \mu \) and \( \sigma \) that can be calculated with the lognstat function. They are:

\[
m = \exp\left(\mu + \frac{\sigma^2}{2}\right)
\]

\[
v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right)-1\right)
\]

A lognormal distribution with mean \( m \) and variance \( v \) has parameters
\[ \mu = \log \left( \frac{m^2}{\sqrt{v + m^2}} \right) \]
\[ \sigma = \sqrt{\log \left( \frac{v}{m^2 + 1} \right)} \]

**Examples**

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

\[ m = 1; \]
\[ v = 2; \]
\[ \mu = \log \left( \frac{m^2}{\sqrt{v + m^2}} \right); \]
\[ \sigma = \sqrt{\log \left( \frac{v}{m^2 + 1} \right)}; \]

\[ [M,V]= \text{lognstat}(\mu,\sigma) \]
\[ M = 1 \]
\[ V = 2.0000 \]

\[ X = \text{lognrnd}(\mu,\sigma,1,1e6); \]
\[ MX = \text{mean}(X) \]
\[ MX = 0.9974 \]
\[ VX = \text{var}(X) \]
\[ VX = 1.9776 \]

**References**

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

“Lognormal Distribution” on page B-95

Introduced before R2006a
**lognstat**

Lognormal mean and variance

**Syntax**

\[[M,V] = \text{lognstat}(\mu,\sigma)\]

**Description**

\[[M,V] = \text{lognstat}(\mu,\sigma)\] returns the mean of and variance of the lognormal distribution with parameters \(\mu\) and \(\sigma\). \(\mu\) and \(\sigma\) are the mean and standard deviation, respectively, of the associated normal distribution. \(\mu\) and \(\sigma\) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \(M\) and \(V\). A scalar input for \(\mu\) or \(\sigma\) is expanded to a constant array with the same dimensions as the other input. The parameters in \(\sigma\) must be positive.

The normal and lognormal distributions are closely related. If \(X\) is distributed lognormally with parameters \(\mu\) and \(\sigma\), then \(\log(X)\) is distributed normally with mean \(\mu\) and standard deviation \(\sigma\).

The mean \(m\) and variance \(v\) of a lognormal random variable are functions of \(\mu\) and \(\sigma\) that can be calculated with the `lognstat` function. They are:

\[
m = \exp\left(\mu + \sigma^2 / 2\right)
\]

\[
v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)
\]

A lognormal distribution with mean \(m\) and variance \(v\) has parameters

\[
\mu = \log\left(\frac{m^2}{\sqrt{v + m^2}}\right)
\]

\[
\sigma = \sqrt{\log\left(\frac{v}{m^2 + 1}\right)}
\]
Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```matlab
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
    1
V =
    2.0000
X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

**logP**

Log unconditional probability density for discriminant analysis classifier

**Syntax**

\[ lp = \text{logP}(obj,Xnew) \]

**Description**

\[ lp = \text{logP}(obj,Xnew) \] returns the log of the unconditional probability density of each row of \( Xnew \), computed using the discriminant analysis model \( obj \).

**Input Arguments**

- **obj**
  Discriminant analysis classifier, produced using \( \text{fitcdiscr} \).

- **Xnew**
  Matrix where each row represents an observation, and each column represents a predictor. The number of columns in \( Xnew \) must equal the number of predictors in \( obj \).

**Output Arguments**

- **lp**
  Column vector with the same number of rows as \( Xnew \). Each entry is the logarithm of the unconditional probability density of the corresponding row of \( Xnew \).

**Examples**
Compute Log Unconditional Probability Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

\[ \text{load } \text{fisheriris} \]
\[ \text{Mdl} = \text{fitcdiscr(meas,species)}; \]

Find the log probability of the discriminant model applied to an average iris.

\[ \text{logPAverage} = \logP(Mdl,\text{mean(meas)}) \]
\[ \text{logPAverage} = -1.7254 \]

Definitions

Unconditional Probability Density

The unconditional probability density of a point \( x \) of a discriminant analysis model is

\[ P(x) = \sum_{k=1}^{K} P(x, k), \]

where \( P(x, k) \) is the conditional density of the model at \( x \) for class \( k \), when the total number of classes is \( K \).

The conditional density \( P(x, k) \) is

\[ P(x, k) = \frac{P(k)P(x|k)}{P(x)}, \]

where \( P(k) \) is the prior probability of class \( k \), and \( P(x|k) \) is the conditional density of \( x \) given class \( k \). The conditional density function of the multivariate normal with mean \( \mu_k \) and covariance \( \Sigma_k \) at a point \( x \) is

\[ P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp \left( -\frac{1}{2} (x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k) \right), \]
where $|\Sigma_k|$ is the determinant of $\Sigma_k$, and $\Sigma_k^{-1}$ is the inverse matrix.

logP

Log unconditional probability density for naive Bayes classifier

Syntax

lp = logP(Mdl,tbl)
lp = logP(Mdl,X)

Description

lp = logP(Mdl,tbl) returns the log unconditional probability density on page 32-3684 of the observations (rows) in tbl using the naive Bayes model Mdl.

You can use lp to identify outliers in the training data.

lp = logP(Mdl,X) returns the log unconditional probability density on page 32-3684 of the observations (rows) in X using the naive Bayes model Mdl.

Input Arguments

Mdl — Naive Bayes classifier
ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by fitcnb or compact, respectively.

tbl — Sample data
table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional columns for the response variable and observation weights. tbl must contain all the predictors used to train Mdl. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.
If you trained \texttt{Mdl} using sample data contained in a \texttt{table}, then the input data for this method must also be in a table.

Data Types: \texttt{table}

\textbf{\textit{X — Predictor data}}

\texttt{numeric matrix}

Predictor data, specified as a numeric matrix.

Each row of \textit{X} corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of \textit{X} must be the same as the variables that trained \texttt{Mdl}.

Data Types: \texttt{double | single}

\section*{Output Arguments}

\textbf{\textit{lp — Log of unconditional probability density}}

\texttt{numeric column vector}

Log of the unconditional probability density of the predictors, returned as a numeric column vector. \textit{lp} has as many elements as rows in \textit{X}, and each element is the log probability density of the corresponding row in \textit{X}.

If any rows in \textit{X} contain at least one \texttt{NaN}, then the corresponding element of \textit{lp} is \texttt{NaN}.

\section*{Examples}

\subsection*{Compute Unconditional Probability Densities of Observations}

Load Fisher's iris data set.

\begin{verbatim}
load fisheriris
X = meas;   \% Predictors
Y = species; \% Response
\end{verbatim}

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});

Mdl is a trained ClassificationNaiveBayes classifier.

Compute the unconditional probability densities of the in-sample observations.

lp = logP(Mdl,X);
histogram(lp)
xlabel 'Log-unconditional probability'
ylabel 'Frequency'
title 'Histogram: Log-Unconditional Probability'

Identify indices of observations having log-unconditional probability less than -7.

idx = find(lp < -7)
Definitions

Unconditional Probability Density

The unconditional probability density of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

\[
P(X_1, \ldots, X_P) = \sum_{k=1}^{K} P(X_1, \ldots, X_P, Y = k) = \sum_{k=1}^{K} P(X_1, \ldots, X_P | y = k)\pi(Y = k),
\]

where \(\pi(Y = k)\) is the class prior probability. The conditional distribution of the data given the class \((P(X_1, \ldots, X_P | y = k))\) and the class prior probability distributions are training options (i.e., are specified when training the classifier).

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

“Naive Bayes Classification” on page 21-2
**loss**

Loss of $k$-nearest neighbor classifier

**Syntax**

$L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})$
$L = \text{loss}(\text{mdl}, \text{tbl}, Y)$
$L = \text{loss}(\text{mdl}, X, Y)$
$L = \text{loss}(\_, \text{Name}, \text{Value})$

**Description**

$L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})$ returns a scalar representing how well $\text{mdl}$ classifies the data in $\text{tbl}$ when $\text{tbl}.\text{ResponseVarName}$ contains the true classifications. If $\text{tbl}$ contains the response variable used to train $\text{mdl}$, then you do not need to specify $\text{ResponseVarName}$.

When computing the loss, the $\text{loss}$ function normalizes the class probabilities in $\text{tbl}.\text{ResponseVarName}$ to the class probabilities used for training, which are stored in the $\text{Prior}$ property of $\text{mdl}$.

The meaning of the classification loss ($L$) depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values. For more details, see “Classification Loss” on page 32-3690.

$L = \text{loss}(\text{mdl}, \text{tbl}, Y)$ returns a scalar representing how well $\text{mdl}$ classifies the data in $\text{tbl}$ when $Y$ contains the true classifications.

When computing the loss, the $\text{loss}$ function normalizes the class probabilities in $Y$ to the class probabilities used for training, which are stored in the $\text{Prior}$ property of $\text{mdl}$.

$L = \text{loss}(\text{mdl}, X, Y)$ returns a scalar representing how well $\text{mdl}$ classifies the data in $X$ when $Y$ contains the true classifications.

When computing the loss, the $\text{loss}$ function normalizes the class probabilities in $Y$ to the class probabilities used for training, which are stored in the $\text{Prior}$ property of $\text{mdl}$.  

32-3685
L = loss(___,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Loss Calculation

Create a k-nearest neighbor classifier for the Fisher iris data, where k = 5.

Load the Fisher iris data set.

load fisheriris

Create a classifier for five nearest neighbors.

mdl = fitcknn(meas,species,'NumNeighbors',5);

Examine the loss of the classifier for a mean observation classified as 'versicolor'.

X = mean(meas);
Y = {'versicolor'};
L = loss(mdl,X,Y)
L = 0

All five nearest neighbors classify as 'versicolor'.

Input Arguments

mdl — k-nearest neighbor classifier model
ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl
can contain one additional column for the response variable. Multicolumn variables and
cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify
`ResponseVarName` or `Y`.

If you train `mdl` using sample data contained in a table, then the input data for `loss`
must also be in a table.

Data Types: `table`

**ResponseVarName — Response variable name**

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the
response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example,
if the response variable is stored as `tbl.response`, then specify it as `'response'`.
Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as
predictors.

The response variable must be a categorical, character, or string array, logical or numeric
vector, or cell array of character vectors. If the response variable is a character array,
then each element must correspond to one row of the array.

Data Types: `char` | `string`

**X — Predictor data**

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` represents one observation,
and each column represents one variable.

Data Types: `single` | `double`

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric
vector, or cell array of character vectors. Each row of `Y` represents the classification of
the corresponding row of `X`. 32-3687
Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:
loss(mdl,tbl,'response','LossFun','exponential','Weights','w') returns the weighted exponential loss of mdl classifying the data in tbl. Here, tbl.response is the response variable, and tbl.w is the weight variable.

LossFun — Loss function

'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- The following table lists the available loss functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. By default, k-nearest neighbor models return posterior probabilities as classification scores (see predict).
• You can specify a function handle for a custom loss function using @ (for example, @lossfun). Let \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(	ext{mdl.ClassNames}) \)). Your custom loss function must have this form:

\[
\text{function lossvalue} = \text{lossfun}(C,S,W,Cost)
\]

- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in \( \text{mdl.ClassNames} \). Construct \( C \) by setting \( C(p,q) = 1 \), if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.
- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( \text{mdl.ClassNames} \). The argument \( S \) is a matrix of classification scores, similar to the output of \text{predict}.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes the weights to sum to 1.
- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification and 1 for misclassification.
- The output argument \( \text{lossvalue} \) is a scalar.

For more details on loss functions, see “Classification Loss” on page 32-3690.

Data Types: char | string | function_handle

Weights — Observation weights

\( \text{ones(size}(X,1),1) \) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl.

If you specify \text{Weights} as a numeric vector, then the size of \text{Weights} must be equal to the number of rows in \( X \) or tbl.

If you specify \text{Weights} as the name of a variable in tbl, the name must be a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify \text{Weights} as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

\text{loss} normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply \text{Weights}, \text{loss} computes the weighted classification loss.
Example: 'Weights','w'
Data Types: single | double | char | string

**Algorithms**

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 0 1 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  - $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>( L = \sum_{j=1}^{n} w_j \log{1 + \exp[-2m_j]} ).</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>( L = \sum_{j=1}^{n} w_j \exp(-m_j) ).</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>( L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j} ).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>It is the weighted fraction of misclassified observations where ( \hat{y}_j ) is the class label corresponding to the class with the maximal posterior probability. ( I{x} ) is the indicator function.</td>
</tr>
<tr>
<td>Hinge loss</td>
<td>'hinge'</td>
<td>( L = \sum_{j=1}^{n} w_j \max{0,1 - m_j} ).</td>
</tr>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>( L = \sum_{j=1}^{n} w_j \log\left(1 + \exp(-m_j)\right) ).</td>
</tr>
<tr>
<td>Loss Function</td>
<td>Value of LossFun</td>
<td>Equation</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Minimal cost</td>
<td>'mincost'</td>
<td>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1,...,n$.</td>
</tr>
</tbody>
</table>
|                    |                  | **1** Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:  
|                    |                  | $\gamma_j = f(X_j)C$.                                                   |
|                    |                  | $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the `Cost` property. |
|                    |                  | **2** For observation $j$, predict the class label corresponding to the minimum expected classification cost:  
|                    |                  | $\hat{y}_j = \min_{j=1,...,K} (\gamma_j)$.  
| Quadratic loss     | 'quadratic'      | **3** Using $C$, identify the cost incurred ($c_j$) for making the prediction. |
|                    |                  | The weighted, average, minimum cost loss is $L = \sum_{j=1}^{n} w_j c_j$. |
|                    |                  | $L = \sum_{j=1}^{n} w_j (1 - m_j)^2$. |

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 

32-3692
True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value $\text{Cost}(i,j)$ is the cost of classifying an observation into class $j$ if its true class is $i$. By default, $\text{Cost}(i,j) = 1$ if $i \neq j$, and $\text{Cost}(i,j) = 0$ if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.
Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of predict is the expected misclassification cost per observation.

Suppose you have Nobs observations that you want to classify with a trained classifier mdl, and you have K classes. You place the observations into a matrix Xnew with one observation per row. The command

[label, score, cost] = predict(mdl, Xnew)

returns a matrix cost of size Nobs-by-K, among other outputs. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the K classes. cost(n, j) is

$$
\sum_{i=1}^{K} \hat{P}(i \mid Xnew(n))C(j \mid i),
$$

where

- K is the number of classes.
- \(\hat{P}(i \mid Xnew(n))\) is the posterior probability on page 32-4943 of class i for observation Xnew(n).
- \(C(j \mid i)\) is the true misclassification cost of classifying an observation as j when its true class is i.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2012a
loss

Class: ClassificationLinear

Classification loss for linear classification models

Syntax

L = loss(Mdl,X,Y)
L = loss(___,'Name',Value)

Description

L = loss(Mdl,X,Y) returns the classification losses on page 32-3706 for the binary, linear classification model Mdl using predictor data in X and corresponding class labels in Y. L contains classification error rates for each regularization strength in Mdl.

L = loss(___,'Name',Value) uses any of the previous syntaxes and additional options specified by one or more Name,Value pair arguments. For example, you can specify that columns in the predictor data correspond to observations or specify the classification loss function.

Input Arguments

Mdl — Binary, linear classification model
ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using fitclinear.

X — Predictor data
full matrix | sparse matrix
Predictor data, specified as an $n$-by-$p$ full or sparse matrix. This orientation of $X$ indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of $Y$ and the number of observations in $X$ must be equal.

Data Types: `single` | `double`

**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of $Y$ must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in $Y$ must be a subset of `Mdl.ClassNames`.
- If $Y$ is a character array, then each element must correspond to one row of the array.
- The length of $Y$ and the number of observations in $X$ must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**LossFun — Loss function**

'`classiferror`' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.
The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

Specify your own function by using function handle notation.

Let `n` be the number of observations in `X` and `K` be the number of distinct classes (numel(Mdl.ClassNames), where Mdl is the input model). Your function must have this signature:

```matlab
lossvalue = lossfun(C,S,W,Cost)
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in Mdl.ClassNames.

Construct `C` by setting `C(p,q) = 1`, if observation `p` is in class `q`, for each row. Set all other elements of row `p` to 0.

- `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in Mdl.ClassNames. `S` is a matrix of classification scores, similar to the output of `predict`. 
• **W** is an n-by-1 numeric vector of observation weights. If you pass **W**, the software normalizes the weights to sum to 1.

• **Cost** is a K-by-K numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun',@lossfun

Data Types: char | string | function_handle

**ObservationsIn** — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in optimization-execution time.

**Weights** — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, **loss** computes the weighted classification loss.

Let \( n \) be the number of observations in \( X \).

• \( \text{numel(Weights)} \) must be \( n \).
• By default, **Weights** is \( \text{ones}(n,1) \).

**loss** normalizes **Weights** to sum up to the value of the prior probability in the respective class.

Data Types: double | single
Output Arguments

L — Classification losses  
numeric scalar | numeric row vector

Classification losses, returned as a numeric scalar or row vector. The interpretation of L depends on Weights and LossFun.

L is the same size as Mdl.Lambda. L(j) is the classification loss of the linear classification model trained using the regularization strength Mdl.Lambda(j).

Examples

Estimate Test-Sample Classification Loss

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA.

rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a ClassificationLinear model that the software trained using the training set.
Extract the training and test data from the partition definition.

\[
\text{trainIdx} = \text{training(CVMdl.Partition);}
\]

\[
\text{testIdx} = \text{test(CVMdl.Partition);}
\]

Estimate the training- and test-sample classification error.

\[
\text{ceTrain} = \text{loss(CMdl,}X(\text{trainIdx,}:),\text{Ystats(trainIdx))}
\]

\[
\text{ceTrain} = 1.3572e-04
\]

\[
\text{ceTest} = \text{loss(CMdl,}X(\text{testIdx,}:),\text{Ystats(testIdx))}
\]

\[
\text{ceTest} = 5.2804e-04
\]

Because there is one regularization strength in \text{CMdl}, \text{ceTrain} and \text{ceTest} are numeric scalars.

**Specify Custom Classification Loss**

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Classification Loss” on page 32-3700, and transpose the predictor data.

\[
\text{load nlpdata}
\]

\[
\text{Ystats = Y == 'stats';}
\]

\[
\text{X = X'};
\]

Train a binary, linear classification model. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

\[
\text{rng(1); % For reproducibility}
\]

\[
\text{CVMdl} = \text{fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...}
\]

\[
\quad \text{'ObservationsIn','columns');}
\]

\[
\text{CMdl} = \text{CVMdl.Trained{1};}
\]

\text{CVMdl} is a \text{ClassificationPartitionedLinear} model. It contains the property \text{Trained}, which is a 1-by-1 cell array holding a \text{ClassificationLinear} model that the software trained using the training set.

Extract the training and test data from the partition definition.
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);

Create an anonymous function that measures linear loss, that is,

\[ L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j} . \]

\( w_j \) is the weight for observation \( j \), \( y_j \) is response \( j \) (-1 for the negative class, and 1 otherwise), and \( f_j \) is the raw classification score of observation \( j \). Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the LossFun name-value pair argument.

\[
\text{linearloss} = @(C,S,W,Cost)\sum(-W.*\text{sum}(S.*C,2))/\text{sum}(W);
\]

Estimate the training- and test-sample classification loss using the linear loss function.

\[
\text{ceTrain} = \text{loss}(\text{CMdl},X(:,\text{trainIdx}),\text{Ystats(}\text{trainIdx}\text{)},'\text{LossFun}',\text{linearloss},...'\text{ObservationsIn}',['\text{columns}'])
\]

\( \text{ceTrain} = -7.8330 \)

\[
\text{ceTest} = \text{loss}(\text{CMdl},X(:,\text{testIdx}),\text{Ystats(}\text{testIdx}\text{)},'\text{LossFun}',\text{linearloss},...'\text{ObservationsIn}',['\text{columns}'])
\]

\( \text{ceTest} = -7.7383 \)

**Find Good Lasso Penalty Using Classification Loss**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3701.

\[
\text{load nlpdata}
\text{Ystats = Y == 'stats'};
\]
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

Lambda = logspace(-6,-0.5,11);

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
                  'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
                  'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl = classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 1
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Properties, Methods

Extract the trained linear classification model.

Md1 = CVMdl.Trained{1}

Md1 =
    ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
Beta: [34023x11 double]
Bias: [1x11 double]
Lambda: [1x11 double]
Learner: 'logistic'

Properties, Methods

Mdl is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda.

Estimate the test-sample classification error.

ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...    'Learner','logistic','Solver','sparsa','Regularization','lasso',...    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.
Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).
  - \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):
  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_2^* = [0 0 1 0]' \). The order of the classes corresponds to the order in the ClassNames property of the input model.
  - \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,
\[ \sum_{j=1}^{n} w_j = 1. \]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>

<td>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1,\ldots,n$.</td>
</tr>
</tbody>
</table>

1. Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:

$$
\gamma_j = f(X_j) C.
$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the `Cost` property.

2. For observation $j$, predict the class label corresponding to the minimum expected classification cost:

$$
\hat{y}_j = \min_{j=1,\ldots,K} (\gamma_j).
$$

3. Using $C$, identify the cost incurred ($c_j$) for making the prediction.

The weighted, average, minimum cost loss is

$$
L = \sum_{j=1}^{n} w_j c_j.
$$

| Quadratic loss  | 'quadratic'      | $L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$. |

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 

32-3708
Algorithms

By default, observation weights are prior class probabilities. If you supply weights using `Weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to estimate the weighted classification loss.
Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

ClassificationLinear | fitclinear | predict

Introduced in R2016a
loss

Classification error

Syntax

L = loss(obj,X,Y)
L = loss(obj,X,Y,Name,Value)

Description

L = loss(obj,X,Y) returns the classification loss on page 32-3714, which is a scalar representing how well obj classifies the data in X, when Y contains the true classifications.

When computing the loss, loss normalizes the class probabilities in Y to the class probabilities used for training, stored in the Prior property of obj.

L = loss(obj,X,Y,Name,Value) returns the loss with additional options specified by one or more Name,Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with fitcdiscr.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in obj.
Class labels, with the same data type as exists in obj. The number of elements of \( Y \) must equal the number of rows of \( X \).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

**LossFun**

Built-in, loss-function name (character vector or string scalar in the table) or function handle.

- The following table lists the available loss functions. Specify one using the corresponding value.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'\texttt{mincost}’ is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see \texttt{predict}).

- Specify your own function using function handle notation.

Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel}(\text{Mdl.ClassNames}) \)). Your function must have this signature
\texttt{lossvalue = lossfun(C,S,W,Cost)}

where:

- The output argument \texttt{lossvalue} is a scalar.
- You choose the function name (\texttt{lossfun}).
- \texttt{C} is an \(n\)-by-\(K\) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \texttt{Mdl.ClassNames}.
  
  Construct \texttt{C} by setting \(C(p,q) = 1\) if observation \(p\) is in class \(q\), for each row. Set all other elements of row \(p\) to 0.
- \texttt{S} is an \(n\)-by-\(K\) numeric matrix of classification scores. The column order corresponds to the class order in \texttt{Mdl.ClassNames}. \texttt{S} is a matrix of classification scores, similar to the output of \texttt{predict}.
- \texttt{W} is an \(n\)-by-1 numeric vector of observation weights. If you pass \texttt{W}, the software normalizes them to sum to 1.
- \texttt{Cost} is a \(K\)-by-\(K\) numeric matrix of misclassification costs. For example, \texttt{Cost = ones(K) - eye(K)} specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', \texttt{@lossfun}.

For more details on loss functions, see “Classification Loss” on page 32-3714.

\textbf{Default:} 'mincost'

\textbf{Weights}

Numeric vector of length \(N\), where \(N\) is the number of rows of \texttt{X}. \texttt{weights} are nonnegative. \texttt{loss} normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply \texttt{weights}, \texttt{loss} computes weighted classification loss.

\textbf{Default:} \texttt{ones(N,1)}
Output Arguments

L

Classification loss on page 32-3714, a scalar. The interpretation of L depends on the values in weights and lossfun.

Examples

Estimate Classification Error

Load Fisher's iris data set.

load fisheriris

Train a discriminant analysis model using all observations in the data.

Mdl = fitcdiscr(meas,species);

Estimate the classification error of the model using the training observations.

L = loss(Mdl,meas,species)

L = 0.0200

Alternatively, if Mdl is not compact, then you can estimate the training-sample classification error by passing Mdl to resubLoss.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.
• $L$ is the weighted average classification loss.
• $n$ is the sample size.
• For binary classification:
  • $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  • $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
• For algorithms that support multiclass classification (that is, $K \geq 3$):
  • $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_j^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  • $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  • $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through $[0,1]$. 

32-3717
Posterior Probability

The posterior probability that a point \( z \) belongs to class \( j \) is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean \( \mu_j \) and covariance \( \Sigma_j \) at a point \( z \) is

\[
P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2} (x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k) \right),
\]

where \( |\Sigma_k| \) is the determinant of \( \Sigma_k \), and \( \Sigma_k^{-1} \) is the inverse matrix.
Let $P(k)$ represent the prior probability of class $k$. Then the posterior probability that an observation $x$ is of class $k$ is

$$
\hat{P}(k \mid x) = \frac{P(x \mid k) P(k)}{P(x)},
$$

where $P(x)$ is a normalization constant, the sum over $k$ of $P(x|k)P(k)$.

**Prior Probability**

The prior probability is one of three choices:

- 'uniform' — The prior probability of class $k$ is one over the total number of classes.
- 'empirical' — The prior probability of class $k$ is the number of training samples of class $k$ divided by the total number of training samples.
- Custom — The prior probability of class $k$ is the $k$th element of the prior vector. See `fitcdiscr`.

After creating a classification model (Mdl) you can set the prior using dot notation:

Mdl.Prior = v;

where $v$ is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

**Cost**

The matrix of expected costs per observation is defined in “Cost” on page 20-8.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**loss**

Classification loss for multiclass, error-correcting output codes model

**Syntax**

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName})
\]

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, Y)
\]

\[
L = \text{loss}(\text{Mdl}, X, Y)
\]

\[
L = \text{loss}(\_\_\_, \text{Name}, \text{Value})
\]

**Description**

\(L = \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName})\) returns the classification loss (L), a scalar representing how well the trained, multiclass, error-correcting output code (ECOC) model Mdl classifies the predictor data (tbl) as compared to the true class labels (ResponseVarName). Each row of tbl and ResponseVarName is an observation.

\(L = \text{loss}(\text{Mdl}, \text{tbl}, Y)\) returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier Mdl classifies the predictor data (tbl) as compared to the true class labels (Y). Each row of tbl and Y is an observation.

\(L = \text{loss}(\text{Mdl}, X, Y)\) returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier Mdl classifies the predictor data (X) as compared to the true class labels (Y). Each row of X and Y is an observation.

\(L = \text{loss}(\_\_\_, \text{Name}, \text{Value})\) returns the classification loss with additional options specified by one or more Name, Value pair arguments, using any of the previous syntaxes. For example, you can specify a decoding scheme, classification loss function, or verbosity level.
Input Arguments

**Mdl — Full or compact, multiclass ECOC model**

ClassificationECOC model object | CompactClassificationECOC model object

Full or compact, multiclass ECOC model, specified as a ClassificationECOC or CompactClassificationECOC model object.

To create a full or compact ECOC model, see ClassificationECOC or CompactClassificationECOC.

**tbl — Sample data**

Table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional columns for the response variable and observation weights. tbl must contain all the predictors used to train Mdl. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained Mdl using sample data contained in a table, then the input data for this method must also be in a table.

**Note** If Mdl.BinaryLearners contains linear or kernel classification models (that is, ClassificationLinear or ClassificationKernel model objects), then you cannot specify sample data in a table. Instead, pass a matrix (X) and class labels (Y).

Data Types: table

**ResponseVarName — Response variable name**

Name of a variable in tbl

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored as tbl.y, then specify it as 'y'. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.
The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

### X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables composing the columns of X should be the same as the variables that trained the Mdl classifier.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

### Y — Class labels
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle
Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.

<table>
<thead>

</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle 'BinaryLoss', @`customFunction`.

`customFunction` has this form:

\[
\text{bLoss} = \text{customFunction}(M,s)
\]

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in \( \text{Mdl.CodingMatrix} \).
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( \text{bLoss} \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.
For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

- SVMs or either linear or kernel classification models of SVM learners, then BinaryLoss is 'hinge'
- Ensembles trained by AdaboostM1 or GentleBoost, then BinaryLoss is 'exponential'
- Ensembles trained by LogitBoost, then BinaryLoss is 'binodeviance'
- Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior', 1 in fitcecoc), then BinaryLoss is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding', 'lossbased'

**LossFun — Loss function**

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

You can:

- Specify the built-in function 'classiferror' for classification error, i.e., the proportion of misclassified observations.
- Specify your own function using function handle notation.
Suppose that \( n = \text{size}(X,1) \) is the sample size and \( k \) is the number of classes. Your function must have the signature \( \text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost}) \), where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( C \) is an \( n \)-by-\( k \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \( \text{Mdl.ClassNames} \).

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( k \) numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in \( \text{Mdl.ClassNames} \). \( S \) resembles the output argument \( \text{NegLoss} \) of \( \text{predict} \).

- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes its elements to sum to 1.

- \( \text{Cost} \) is a \( k \)-by-\( k \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

Data Types: char | string | function_handle

**ObservationsIn** — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. \( \text{Mdl.BinaryLearners} \) must contain linear classification models.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', you can experience a significant reduction in execution time.

**Options** — Estimation options

[] (default) | structure array returned by \text{statset}
Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

• You need a Parallel Computing Toolbox license.
• Specify 'Options', statset('UseParallel',1).

Verbose — Verbosity level

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Weights — Observation weights

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. If you supply weights, then loss computes the weighted loss.

Weights requires the same length as the number of observations in X or tbl.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify it as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you do not specify your own loss function (using LossFun), then the software normalizes Weights to sum up to the value of the prior probability in the respective class.

If Mdl.BinaryLearners contains linear classification models, then you must specify a vector.

Data Types: single | double | char | string
Output Arguments

L — Classification loss
numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or row vector. L is a generalization or
resubstitution quality measure. Its interpretation depends on the loss function and
weighting scheme, but, in general, better classifiers yield smaller loss values.

If Mdl.BinaryLearners contains linear classification models, then L is a 1-by-ℓ vector,
where ℓ is the number of regularization strengths in the linear classification models (i.e.,
numel(Mdl.BinaryLearners{1}.Lambda)). L(j) is the loss for the model trained
using regularization strength Mdl.BinaryLearners{1}.Lambda(j).

Otherwise, L is a scalar.

Examples

Determine the Test Sample Loss of ECOC Models

Load Fisher's iris data set.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Train an ECOC model using SVM binary classifiers, and specify a 15% holdout sample. It
is good practice to standardize the predictors and define the class order. Specify to
standardize the predictors using an SVM template.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
CVMdl is a ClassificationPartitionedECOC model. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationECOC model that the software trained using the training set.

Estimate the test-sample loss.

\[
L = \text{loss}(CVMdl, XTest, YTest)
\]

\[
L = 0
\]

The ECOC model correctly classifies all out-of-sample irises.

Determine ECOC Model Quality Using a Custom Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to \text{loss}.

Load Fisher's iris data set.

\[
\text{load fisheriris}
\]

\[
X = \text{meas};
\]

\[
Y = \text{categorical(species)};
\]

\[
n = \text{numel}(Y); \quad \% \text{Sample size}
\]

\[
classOrder = \text{unique}(Y) \quad \% \text{Class order}
\]

\[
classOrder = 3\times 1 \text{ categorical array}
\]

\[
\text{setosa, versicolor, virginica}
\]

\[
K = \text{numel(classOrder)}; \quad \% \text{Number of classes}
\]

\[
rng(1) \% \text{For reproducibility}
\]

Train an ECOC model using SVM binary classifiers and specifying a 15% holdout sample. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

\[
t = \text{templateSVM('Standardize',1)};
\]

\[
CVMdl = \text{fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
\]

\[
CMdl = CVMdl.Trained{1}; \quad \% \text{Extract trained, compact classifier}
\]

\[
testInds = \text{test(CVMdl.Partition)}; \quad \% \text{Extract the test test indices}
\]

32-3729
XTest = X(testInds,:);
YTest = Y(testInds,:);

CVMdl is a ClassificationPartitionedECOC model. It contains the property
Trained, which is a 1-by-1 cell array holding a CompactClassificationECOC model
that the software trained using the training set.

Compute the negated losses for the test-sample observations.
[~,negLoss] = predict(CMdl,XTest);

Create a function that takes the minimal loss for each observation, and then averages the
minimal losses across all observations.
lossfun = @(~,S,~,~)mean(min(-S,[],2));

Compute the test-sample custom loss.
loss(CMdl,XTest,YTest,'LossFun',lossfun)
ans = 0.0033

The average, minimal, binary loss in the test sample is 0.0033.

Definitions

Classification Error

The classification error is a binary classification error measure that has the form

\[
L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},
\]

where:
• \( w_j \) is the weight for observation \( j \). The software renormalizes the weights to sum to 1.
• $e_j = 1$ if the predicted class of observation $j$ differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

• $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
• $s_j$ is the score of binary learner $j$ for an observation.
• $g$ is the binary loss function.
• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$
\hat{k} = \arg\min_k \sum_{j=1}^L m_{kj} g(m_{kj}, s_j).
$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L m_{kj} g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
$$

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.
This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/\log(2)$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_j s_j)]/\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Algorithms**

If you trained Mdl specifying to standardize the predictor data, then the software standardizes the columns of $X$ using the corresponding means and standard deviations that the software stored in Mdl.BinaryLearner{j}.Mu and Mdl.BinaryLearner{j}.Sigma for learner $j$.

loss

Classification error

Syntax

L = loss(ens,tbl,ResponseVarName)
L = loss(ens,tbl,Y)
L = loss(ens,X,Y)
L = loss(___,Name,Value)

Description

L = loss(ens,tbl,ResponseVarName) returns the classification error for ensemble ens computed using table of predictors tbl and true class labels tbl.ResponseVarName.

L = loss(ens,tbl,Y) returns the classification error for ensemble ens computed using table of predictors tbl and true class labels Y.

L = loss(ens,X,Y) returns the classification error for ensemble ens computed using matrix of predictors X and true class labels Y.

L = loss(___,Name,Value) computes classification error with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

When computing the loss, loss normalizes the class probabilities in ResponseVarName or Y to the class probabilities used for training, stored in the Prior property of ens.

Input Arguments

ens

Classification ensemble created with fitcensemble, or a compact classification ensemble created with compact.
**tbl**

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. tbl must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained ens using sample data contained in a table, then the input data for this method must also be in a table.

**ResponseVarName**

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of tbl, including Y, as predictors when training the model.

**X**

Matrix of data to classify. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train ens. X should have the same number of rows as the number of elements in Y.

If you trained ens using sample data contained in a matrix, then the input data for this method must also be in a matrix.

**Y**

Class labels of observations in tbl or X. Y should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of tbl or X.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.
learners

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. loss uses only these learners for calculating loss.

Default: 1:NumTrained

Lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', 'GentleBoost', or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

  ```matlab
  ens.ScoreTransform = 'doublelogit';
  ```

- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.
Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel(ens.ClassNames)} \), \( \text{ens} \) is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \( \text{ens.ClassNames} \).

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( \text{ens.ClassNames} \). \( S \) is a matrix of classification scores, similar to the output of \( \text{predict} \).

- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun,@lossfun'.

For more details on loss functions, see “Classification Loss” on page 32-3740.

**Default:** '\text{classiferror}'

**mode**

Meaning of the output \( L \):

- 'ensemble' — \( L \) is a scalar value, the loss for the entire ensemble.
- 'individual' — \( L \) is a vector with one element per trained learner.
- 'cumulative' — \( L \) is a vector in which element \( J \) is obtained by using learners \( 1:J \) from the input list of learners.

**Default:** 'ensemble'
UseObsForLearner

A logical matrix of size \(N\)-by-\(T\), where:
- \(N\) is the number of rows of \(X\).
- \(T\) is the number of weak learners in \(ens\).

When \(\text{UseObsForLearner}(i,j)\) is true, learner \(j\) is used in predicting the class of row \(i\) of \(X\).

Default: \(\text{true}(N,T)\)

weights

Vector of observation weights, with nonnegative entries. The length of \(\text{weights}\) must equal the number of rows in \(X\). When you specify \(\text{weights}\), \(\text{loss}\) normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: \(\text{ones(size}(X,1),1)\)

Output Arguments

\(L\)

Classification loss on page 32-3740, by default the fraction of misclassified data. \(L\) can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error

Load Fisher's iris data set.

load fisheriris

Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);

Estimate the classification error of the model using the training observations.

L = loss(ens,meas,species)
L = 0.0333

Alternatively, if ens is not compact, then you can estimate the training-sample classification error by passing ens to resubLoss.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

• L is the weighted average classification loss.
• n is the sample size.
• For binary classification:
  • yj is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • f(Xj) is the raw classification score for observation (row) j of the predictor data X.
  • mj = yjf(Xj) is the classification score for classifying observation j into the class corresponding to yj. Positive values of mj indicate correct classification and do not contribute much to the average loss. Negative values of mj indicate incorrect classification and contribute significantly to the average loss.
• For algorithms that support multiclass classification (that is, K ≥ 3):
  • yj* is a vector of K - 1 zeros, with 1 in the position corresponding to the true, observed class yj. For example, if the true class of the second observation is the third class and K = 4, then yj*2 = [0 0 1 0]. The order of the classes corresponds to the order in the ClassNames property of the input model.
• $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.

• $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.

• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>$L = \sum_{j=1}^{n} w_j \log {1 + \exp[-2m_j]}.$</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>$L = \sum_{j=1}^{n} w_j \exp(-m_j).$</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>$L = \sum_{j=1}^{n} w_j I{\hat{y}_j \neq y_j}.$</td>
</tr>
<tr>
<td></td>
<td></td>
<td>It is the weighted fraction of misclassified observations where $\hat{y}_j$ is the class label corresponding to the class with the maximal posterior probability. $I{x}$ is the indicator function.</td>
</tr>
<tr>
<td>Hinge loss</td>
<td>'hinge'</td>
<td>$L = \sum_{j=1}^{n} w_j \max{0,1 - m_j}.$</td>
</tr>
<tr>
<td>Loss Function</td>
<td>Value of LossFun</td>
<td>Equation</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.</td>
</tr>
</tbody>
</table>
| Minimal cost       | 'mincost'        | Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \ldots, n$.  
1 Estimate the 1-by-$K$ vector of expected classification costs for observation $j$:  
   $$\gamma_j = f(X_j)C.$$  
   $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. $C$ is the cost matrix that the input model stores in the Cost property.  
2 For observation $j$, predict the class label corresponding to the minimum expected classification cost:  
   $$\hat{y}_j = \min_{j=1, \ldots, K} (\gamma_j).$$  
3 Using $C$, identify the cost incurred ($c_j$) for making the prediction.  
The weighted, average, minimum cost loss is  
   $$L = \sum_{j=1}^{n} w_j c_j.$$ |
| Quadratic loss     | 'quadratic'      | $L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.                                    |
This figure compares the loss functions (except 'mincost') for one observation over $m$. Some functions are normalized to pass through [0,1].

Extended Capabilities

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Classification error for naive Bayes classifier

Syntax

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName}) \\
L = \text{loss}(\text{Mdl}, \text{tbl}, Y) \\
L = \text{loss}(\text{Mdl}, X, Y) \\
L = \text{loss}(\_, \text{Name}, \text{Value})
\]

Description

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, \text{ResponseVarName}) \text{ returns the minimum classification loss (see } \text{"Classification Loss" on page 32-3751), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data in table tbl) as compared to the true class labels in tbl.\text{ResponseVarName.}
\]

\text{loss} normalizes the class probabilities in tbl.\text{ResponseVarName} to the prior class probabilities \text{fitcnb} used for training, stored in the Prior property of Mdl.

\[
L = \text{loss}(\text{Mdl}, \text{tbl}, Y) \text{ returns the minimum classification loss (L), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data in table tbl) as compared to the true class labels in Y.}
\]

\text{loss} normalizes the class probabilities in Y to the prior class probabilities \text{fitcnb} used for training, stored in the Prior property of Mdl.

\[
L = \text{loss}(\text{Mdl}, X, Y) \text{ returns the minimum classification loss (L), a scalar representing how well the trained naive Bayes classifier Mdl classifies the predictor data (X) as compared to the true class labels (Y).}
\]

\text{loss} normalizes the class probabilities in Y to the prior class probabilities \text{fitcnb} used for training, stored in the Prior property of Mdl.
L = loss(___,Name,Value) returns the classification loss with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier
ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by fitcnb or compact, respectively.

tbl — Sample data
table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional columns for the response variable and observation weights. tbl must contain all the predictors used to train Mdl. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained Mdl using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

ResponseVarName — Response variable name
name of a variable in tbl

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored as tbl.y, then specify it as 'y'. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string
\textbf{X — Predictor data}
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained Mdl.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

\textbf{Y — Class labels}
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of tbl or X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

\textbf{Name-Value Pair Arguments}

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

\textbf{LossFun — Loss function}
'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that \( n \) be the number of observations in \( X \) and \( K \) be the number of distinct classes (\( \text{numel(Mdl.ClassNames)} \), \( \text{Mdl} \) is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument \( \text{lossvalue} \) is a scalar.
- You choose the function name (\( \text{lossfun} \)).
- \( C \) is an \( n \)-by-\( K \) logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in \( \text{Mdl.ClassNames} \).

Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.
- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( \text{Mdl.ClassNames} \). \( S \) is a matrix of classification scores, similar to the output of `predict`.
- \( W \) is an \( n \)-by-\( 1 \) numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.
• Cost is a $K$-by-$K$ numeric matrix of misclassification costs. For example, $\text{Cost} = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

For more details on loss functions, see “Classification Loss” on page 32-3751.

Data Types: char | string | function_handle

**Weights — Observation weights**

ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. The software weighs the observations in each row of X or tbl with the corresponding weight in Weights.

If you specify Weights as a vector, then the size of Weights must be equal to the number of rows of X or tbl.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify Weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you do not specify your own loss function, then the software normalizes Weights to add up to 1.

Data Types: double | char | string

**Output Arguments**

**L — Classification loss**

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.
Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1); % For reproducibility

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

L = loss(CMdl,XTest,YTest)
L = 0.0476

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.
Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```matlab
CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```matlab
L = loss(CMdl,XTest,YTest,'LossFun','classiferror')
L = 0.0476
```

The classifier misclassified approximately 5% of the test sample observations.

Definitions

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.
Consider the following scenario.

- \( L \) is the weighted average classification loss.
- \( n \) is the sample size.
- For binary classification:
  - \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).
  - \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):
  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_2^* = [0\ 0\ 1\ 0]' \). The order of the classes corresponds to the order in the \text{ClassNames} property of the input model.
  - \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the \text{ClassNames} property of the input model.
  - \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.
<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td></td>
<td></td>
<td>1. Estimate the 1-by-( K ) vector of expected classification costs for observation ( j ):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[ \gamma_j = f(\mathbf{X}_j) C. ]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>( f(\mathbf{X}_j) ) is the column vector of class posterior probabilities for binary and multiclass classification. ( C ) is the cost matrix that the input model stores in the <code>Cost</code> property.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. For observation ( j ), predict the class label corresponding to the minimum expected classification cost:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[ \hat{y}<em>j = \min</em>{j=1,\ldots,K} \gamma_j. ]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. Using ( C ), identify the cost incurred ( (c_j) ) for making the prediction.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The weighted, average, minimum cost loss is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[ L = \sum_{j=1}^{n} w_j c_j. ]</td>
</tr>
<tr>
<td>Quadratic loss</td>
<td>'quadratic'</td>
<td>[ L = \sum_{j=1}^{n} w_j (1-m_j)^2. ]</td>
</tr>
</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through \([0,1]\).
**Misclassification Cost**

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let $K$ be the number of classes.

- True misclassification cost — A $K$-by-$K$ matrix, where element $(i,j)$ indicates the misclassification cost of predicting an observation into class $j$ if its true class is $i$. The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $Mdl.Cost(i,j) = 1$ if $i \neq j$, and $Mdl.Cost(i,j) = 0$ if $i = j$. 

= j. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.

- Expected misclassification cost — A $K$-dimensional vector, where element $k$ is the weighted average misclassification cost of classifying an observation into class $k$, weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^{K} \hat{P}(Y = j \mid x_1,...,x_P) \text{Cost}_{jk}.$$  

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

**Posterior Probability**

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is $k$ for a given observation $(x_1,...,x_P)$ is

$$\hat{P}(Y = k \mid x_1,...,x_P) = \frac{P(X_1,...,X_P \mid y = k)\pi(Y = k)}{P(X_1,...,X_P)},$$

where:

- $P(X_1,...,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class $k$. Mdl.DistributionNames stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. Mdl.Prior stores the prior distribution.
- $P(X_1,...,X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1,...,X_P) = \sum_{k=1}^{K} P(X_1,...,X_P \mid y = k)\pi(Y = k).$$
**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

loss

Package: classreg.learning.classif

Find classification error for support vector machine (SVM) classifier

Syntax

L = loss(SVMModel,TBL,ResponseVarName)
L = loss(SVMModel,TBL,Y)
L = loss(SVMModel,X,Y)
L = loss(___,Name,Value)

Description

L = loss(SVMModel,TBL,ResponseVarName) returns the classification error (see “Classification Loss” on page 32-3764), a scalar representing how well the trained support vector machine (SVM) classifier (SVMModel) classifies the predictor data in table TBL compared to the true class labels in TBL.ResponseVarName.

loss normalizes the class probabilities in TBL.ResponseVarName to the prior class probabilities that fitcsvm used for training, stored in the Prior property of SVMModel.

The classification loss (L) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

L = loss(SVMModel,TBL,Y) returns the classification error for the predictor data in table TBL and the true class labels in Y.

loss normalizes the class probabilities in Y to the prior class probabilities that fitcsvm used for training, stored in the Prior property of SVMModel.

L = loss(SVMModel,X,Y) returns the classification error based on the predictor data in matrix X compared to the true class labels in Y.
L = loss(___,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Determine Test Sample Classification Error of SVM Classifiers

Load the ionosphere data set.

load ionosphere
rng(1); % For reproducibility

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},... 'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

L = loss(CompactSVMModel,XTest,YTest)
L = 0.0787

The SVM classifier misclassifies approximately 8% of the test sample.

Determine Test Sample Hinge Loss of SVM Classifiers

Load the ionosphere data set.
load ionosphere
rng(1); % For reproducibility

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
     'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

L = loss(CompactSVMModel,XTest,YTest,'LossFun','hinge')
L = 0.2998

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are preferred.

Input Arguments

SVMMModel — SVM classification model
ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

TBL — Sample data
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMModel using sample data contained in a table, then the input data for loss must also be in a table.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: table

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as TBL.Y, then specify ResponseVarName as 'Y'. Otherwise, the software treats all columns of TBL, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMModel classifier.

The length of Y and the number of rows in X must be equal.

If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: double | single
**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of SVMModel.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y must equal the number of rows in TBL or the number of rows in X.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `loss(SVMModel,TBL,Y,'Weights',W)` weighs the observations in each row of TBL using the corresponding weight in each row of the variable W in TBL.

**LossFun — Loss function**
'binodeviance' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
</tbody>
</table>
'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using fitcsvm.

- Specify your own function by using function handle notation.

Suppose that n is the number of observations in X, and K is the number of distinct classes (numel(SVMModel.ClassNames)) used to create the input model (SVMModel). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in SVMModel.ClassNames.

Construct C by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- S is an n-by-K numeric matrix of classification scores, similar to the output of predict. The column order corresponds to the class order in SVMModel.ClassNames.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes the weights to sum to 1.
- Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @lossfun.

For more details on loss functions, see “Classification Loss” on page 32-3764.
Example: 'LossFun','binodeviance'
Data Types: char | string | function_handle

**Weights — Observation weights**

ones(size(X,1),1) (default) | numeric vector | name of variable in TBL

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in TBL. The software weighs the observations in each row of X or TBL with the corresponding weight in Weights.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of rows in X or TBL.

If you specify Weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.W, then specify Weights as 'W'. Otherwise, the software treats all columns of TBL, including TBL.W, as predictors.

If you do not specify your own loss function, then the software normalizes Weights to sum up to the value of the prior probability in the respective class.

Example: 'Weights','W'
Data Types: single | double | char | string

**Definitions**

**Classification Loss**

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
- \( y_j \) is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.

- \( f(X_j) \) is the raw classification score for observation (row) \( j \) of the predictor data \( X \).

- \( m_j = y_j f(X_j) \) is the classification score for classifying observation \( j \) into the class corresponding to \( y_j \). Positive values of \( m_j \) indicate correct classification and do not contribute much to the average loss. Negative values of \( m_j \) indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, \( K \geq 3 \)):

  - \( y_j^* \) is a vector of \( K - 1 \) zeros, with 1 in the position corresponding to the true, observed class \( y_j \). For example, if the true class of the second observation is the third class and \( K = 4 \), then \( y_2^* = [0 \ 0 \ 1 \ 0] \). The order of the classes corresponds to the order in the ClassNames property of the input model.

  - \( f(X_j) \) is the length \( K \) vector of class scores for observation \( j \) of the predictor data \( X \). The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.

  - \( m_j = y_j^* f(X_j) \). Therefore, \( m_j \) is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation \( j \) is \( w_j \). The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>( L = \sum_{j=1}^{n} w_j \log\left{1 + \exp\left[-2m_j\right]\right}. )</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>( L = \sum_{j=1}^{n} w_j \exp\left(-m_j\right). )</td>
</tr>
<tr>

| Minimal cost      | 'mincost'        | Minimal cost. The software computes the weighted minimal cost using this procedure for observations \( j = 1,\ldots,n \).  
1. Estimate the 1-by-\( K \) vector of expected classification costs for observation \( j \):  
   \[ \gamma_j = f(X_j) C. \]  
   \( f(X_j) \) is the column vector of class posterior probabilities for binary and multiclass classification. \( C \) is the cost matrix that the input model stores in the Cost property.  
2. For observation \( j \), predict the class label corresponding to the minimum expected classification cost:  
   \[ \hat{y}_j = \min_{j=1,\ldots,K} (\gamma_j). \]
3. Using \( C \), identify the cost incurred \( (c_j) \) for making the prediction.
   
The weighted, average, minimum cost loss is  
   \[ L = \sum_{j=1}^{n} w_j c_j. \]
| Quadratic loss    | 'quadratic'      | \[ L = \sum_{j=1}^{n} w_j (1-m_j)^2. \] |

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through [0,1].
Classification Score

The SVM classification score for classifying observation $x$ is the signed distance from $x$ to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that $x$ is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for $x$, or the score for predicting $x$ into the positive class.
\[
f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,
\]

where \((\alpha_1, ..., \alpha_n, b)\) are the estimated SVM parameters, \(G(x_j, x)\) is the dot product in the predictor space between \(x\) and the support vectors, and the sum includes the training set observations. The negative class classification score for \(x\), or the score for predicting \(x\) into the negative class, is \(-f(x)\).

If \(G(x_j, x) = x_j^\prime x\) (the linear kernel), then the score function reduces to

\[
f(x) = (x / s)^\prime \beta + b.
\]

\(s\) is the kernel scale and \(\beta\) is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-183.

Introduced in R2014a
loss

Classification error

Syntax

L = loss(tree,TBL,ResponseVarName)
L = loss(tree,TBL,Y)
L = loss(tree,X,Y)

L = loss(___,Name,Value)

[L,se,NLeaf,bestlevel] = loss(___)

Description

L = loss(tree,TBL,ResponseVarName) returns a scalar representing how well tree classifies the data in TBL, when TBL.ResponseVarName contains the true classifications.

When computing the loss, loss normalizes the class probabilities in Y to the class probabilities used for training, stored in the Prior property of tree.

L = loss(tree,TBL,Y) returns a scalar representing how well tree classifies the data in TBL, when Y contains the true classifications.

L = loss(tree,X,Y) returns a scalar representing how well tree classifies the data in X, when Y contains the true classifications.

L = loss(___,Name,Value) returns the loss with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

[L,se,NLeaf,bestlevel] = loss(___) also returns the vector of standard errors of the classification errors (se), the vector of numbers of leaf nodes in the trees of the pruning sequence (NLeaf), and the best pruning level as defined in the TreeSize name-value pair (bestlevel).
Note loss returns se and further outputs only when the LossFun name-value pair is the default 'classiferror'.

Input Arguments

tree — Trained classification tree
ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, tree is a trained classification model returned by fitctree or compact.

TBL — Sample data
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all the predictors used to train tree. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName or Y.

If you train tree using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Data to classify
numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train tree. X must have the same number of rows as the number of elements in Y.

Data Types: single | double

ResponseVarName — Response variable name
name of a variable in TBL
Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify it as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.ResponseVarName, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train tree, and its number of elements must equal the number of rows of X.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

LossFun — Loss function
'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see predict).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (numel(tree.ClassNames)). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in tree.ClassNames.

Construct C by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in tree.ClassNames. S is a matrix of classification scores, similar to the output of predict.
- W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes them to sum to 1.
• Cost is a $K$-by-$K$ numeric matrix of misclassification costs. For example, $\text{Cost} = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

For more details on loss functions, see “Classification Loss” on page 32-3780.

Data Types: char | string | function_handle

**Weights — Observation weights**

$\text{ones(size(X,1),1)}$ (default) | name of a variable in TBL | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or the name of a variable in TBL.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of rows in $X$ or TBL.

If you specify Weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.$W$, then specify it as 'W'. Otherwise, the software treats all columns of TBL, including TBL.$W$, as predictors.

loss normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply Weights, loss computes weighted classification loss.

Data Types: single | double | char | string

Name,Value arguments associated with pruning subtrees:

**Subtrees — Pruning level**

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most $\text{max(tree.PruneList)}$. 0 indicates the full, unpruned tree and $\text{max(tree.PruneList)}$ indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then loss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using $0:\text{max(tree.PruneList)}$. 

32-3775
loss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune','on', or by pruning tree using prune.

Example: 'Subtrees','all'

Data Types: single | double | char | string

**TreeSize — Tree size**

' se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- ' se' — loss returns the highest pruning level with loss within one standard deviation of the minimum (L+se, where L and se relate to the smallest value in Subtrees).
- 'min' — loss returns the element of Subtrees with smallest loss, usually the smallest element of Subtrees.

**Output Arguments**

**L — Classification loss**

vector of scalar values

Classification loss on page 32-3780, returned as a vector the length of Subtrees. The meaning of the error depends on the values in Weights and LossFun.

**se — Standard error of loss**

vector of scalar values

Standard error of loss, returned as a vector the length of Subtrees.

**NLeaf — Number of leaf nodes**

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of Subtrees.
**bestlevel — Best pruning level**

scalar value

Best pruning level as defined in the TreeSize name-value pair, returned as a scalar whose value depends on TreeSize:

- **TreeSize = 'se'** — loss returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where $L$ and $se$ relate to the smallest value in Subtrees).
- **TreeSize = 'min'** — loss returns the element of Subtrees with smallest loss, usually the smallest element of Subtrees.

By default, bestlevel is the pruning level that gives loss within one standard deviation of minimal loss.

**Examples**

**Compute the In-sample Classification Error**

Compute the resubstituted classification error for the ionosphere data set.

```matlab
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
L = 0.0114
```

**Examine the Classification Error for Each Subtree**

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

```matlab
load fisheriris
n = size(meas,1);
```
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices

Grow a classification tree using the training set.

Mdl = fitctree(meas(idxTrn,:),species(idxTrn));

View the classification tree.

view(Mdl,'Mode','graph');
The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```matlab
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 3×1
         0.0267
         0.0533
         0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```matlab
valLoss = loss(Mdl,meas(idxVal,:),species(idxVal),'SubTrees',0:m)
```

```
valLoss = 3×1
         0.0369
         0.0237
         0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 1.

```matlab
pruneMdl = prune(Mdl,'Level',1);
view(pruneMdl,'Mode','graph')
```
Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.
• $L$ is the weighted average classification loss.
• $n$ is the sample size.
• For binary classification:
  • $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  • $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  • $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
• For algorithms that support multiclass classification (that is, $K \geq 3$):
  • $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y^*_2 = [0 0 1 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  • $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  • $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
• The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$ 

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>

</tr>
</tbody>
</table>

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through \([0,1]\).
There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the Cost name-value pair when you create the classifier using the fitctree method. \( \text{Cost}(i,j) \) is the cost of classifying an observation into class \( j \) if its true class is \( i \). By default, \( \text{Cost}(i,j) = 1 \) if \( i \neq j \), and \( \text{Cost}(i,j) = 0 \) if \( i = j \). In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

**True Misclassification Cost**
**Expected Misclassification Cost**

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have \( N_{\text{obs}} \) observations that you want to classify with a trained classifier. Suppose you have \( K \) classes. You place the observations into a matrix \( X_{\text{new}} \) with one observation per row.

The expected cost matrix \( CE \) has size \( N_{\text{obs}} \)-by-\( K \). Each row of \( CE \) contains the expected (average) cost of classifying the observation into each of the \( K \) classes. \( CE(n,k) \) is

\[
\sum_{i=1}^{K} \hat{P}(i \mid X_{\text{new}}(n))C(k \mid i),
\]

where

- \( K \) is the number of classes.
- \( \hat{P}(i \mid X_{\text{new}}(n)) \) is the posterior probability of class \( i \) for observation \( X_{\text{new}}(n) \).
- \( C(k \mid i) \) is the true misclassification cost of classifying an observation as \( k \) when its true class is \( i \).

**Score (tree)**

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor \( X \) as true when \( X < 0.15 \) or \( X > 0.95 \), and \( X \) is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
```
tree = fitctree(X,Y);
view(tree,'Mode','Graph')

Prune the tree:

tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about \( .05/\ .85 = .06 \) for true, and about \( .8/\ .85 = .94 \) for false.

Compute the prediction scores for the first 10 rows of \( X \):

\[
[~, \text{score}] = \text{predict(treel, X(1:10))};
\]

\[
[\text{score} \ X(1:10, :)]
\]
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range $(.95,1)$ instead of the expected 5 observations.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

- Only one output is supported.

For more information, see “Tall Arrays” (MATLAB).

**See Also**

`edge` | `fitctree` | `margin` | `predict`
loss

Regression error

Syntax

\[ L = \text{loss}(\text{ens}, \text{tbl}, \text{ResponseVarName}) \]
\[ L = \text{loss}(\text{ens}, \text{tbl}, Y) \]
\[ L = \text{loss}(\text{ens}, X, Y) \]
\[ L = \text{loss}(__, \text{Name}, \text{Value}) \]

Description

\[ L = \text{loss}(\text{ens}, \text{tbl}, \text{ResponseVarName}) \] returns the mean squared error between the predictions of \( \text{ens} \) to the data in \( \text{tbl} \), compared to the true responses \( \text{tbl}.\text{ResponseVarName} \).

\[ L = \text{loss}(\text{ens}, \text{tbl}, Y) \] returns the mean squared error between the predictions of \( \text{ens} \) to the data in \( \text{tbl} \), compared to the true responses \( Y \).

\[ L = \text{loss}(\text{ens}, X, Y) \] returns the mean squared error between the predictions of \( \text{ens} \) to the data in \( X \), compared to the true responses \( Y \).

\[ L = \text{loss}(__, \text{Name}, \text{Value}) \] computes the error in prediction with additional options specified by one or more \text{Name,Value} pair arguments, using any of the previous syntaxes.

Input Arguments

\textbf{ens}

A regression ensemble created with \textit{fitrensemble}, or the \textit{compact} method.

\textbf{tbl}

Sample data, specified as a table. Each row of \( \text{tbl} \) corresponds to one observation, and each column corresponds to one predictor variable. \( \text{tbl} \) must contain all of the predictors.
used to train the model. Multi-column variables and cell arrays other than cell arrays of
character vectors are not allowed.

If you trained ens using sample data contained in a table, then the input data for this
method must also be in a table.

**ResponseVarName**

Response variable name, specified as the name of a variable in tbl. The response
variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example,
if the response variable Y is stored as tbl.Y, then specify it as 'Y'. Otherwise, the
software treats all columns of tbl, including Y, as predictors when training the model.

**X**

A matrix of predictor values. Each column of X represents one variable, and each row
represents one observation.

NaN values in X are taken to be missing values. Observations with all missing values for X
are not used in the calculation of loss.

If you trained ens using sample data contained in a matrix, then the input data for this
method must also be in a matrix.

**Y**

A numeric column vector with the same number of rows as tbl or X. Each entry in Y is
the response to the data in the corresponding row of tbl or X.

NaN values in Y are taken to be missing values. Observations with missing values for Y are
not used in the calculation of loss.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the
argument name and `Value` is the corresponding value. `Name` must appear inside quotes.
You can specify several name and value pair arguments in any order as
`Name1,Value1,...,NameN,ValueN`.
learners

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NumTrained

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, loss calls it as

fun(Y,Yfit,W)

where Y, Yfit, and W are numeric vectors of the same length.

- Y is the observed response.
- Yfit is the predicted response.
- W is the observation weights.

The returned value fun(Y,Yfit,W) should be a scalar.

Default: 'mse'

mode

Meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

UseObsForLearner

A logical matrix of size N-by-NumTrained, where N is the number of observations in ens.X, and NumTrained is the number of weak learners. When UseObsForLearner(I,J) is true, predict uses learner J in predicting observation I.

Default: true(N,NumTrained)
weights

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in “Weighted Mean Squared Error” on page 32-3793.

Default: ones(size(Y))

Output Arguments

L

Weighted mean squared error of predictions. The formula for loss is in “Weighted Mean Squared Error” on page 32-3793.

Examples

Find Mean-Squared Error of Ensemble Predictions

Find the loss of an ensemble predictor using the carsmall data set.

Load the carsmall data set and select engine displacement, horsepower, and vehicle weight as predictors.

load carsmall
X = [Displacement Horsepower Weight];

Train an ensemble of regression trees and find the regression error for predicting MPG.

ens = fitrensemble(X,MPG);
L = loss(ens,X,MPG)

L = 0.3463
Definitions

Weighted Mean Squared Error

Let \( n \) be the number of rows of data, \( x_j \) be the \( j \)th row of data, \( y_j \) be the true response to \( x_j \), and let \( f(x_j) \) be the response prediction of \( \text{ens} \) to \( x_j \). Let \( w \) be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: \( w \rightarrow w/\Sigma w \). The mean squared error \( L \) is

\[
L = \frac{1}{n} \sum_{j=1}^{n} w_j \left( f(x_j) - y_j \right)^2.
\]
loss

Regression error for Gaussian process regression model

Syntax

L = loss(gprMdl,Xnew,Ynew)
L = loss(gprMdl,Xnew,Ynew,Name,Value)

Description

L = loss(gprMdl,Xnew,Ynew) returns the mean squared error for the Gaussian process regression (GPR) model gpr, using the predictors in Xnew and observed response in Ynew.

L = loss(gprMdl,Xnew,Ynew,Name,Value) returns the mean squared error for the GPR model, gpr, with additional options specified by one or more Name,Value pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

gprMdl — Gaussian process regression model
RegressionGP object | CompactRegressionGP object

Gaussian process regression model, specified as a RegressionGP (full) or CompactRegressionGP (compact) object.

Xnew — New observed data
table | m-by-d matrix

New data, specified as a table or an n-by-d matrix, where m is the number of observations, and d is the number of predictor variables in the training data.

If you trained gprMdl on a table, then Xnew must be a table that contains all the predictor variables used to train gprMdl.
If Xnew is a table, then it can also contain Ynew. And if it does, then you do not have to specify Ynew.

If you trained gprMdl on a matrix, then Xnew must be a numeric matrix with d columns, and can only contain values for the predictor variables.

Data Types: single | double | table

Ynew — New response values
n-by-1 vector

New observed response values, that correspond to the predictor values in Xnew, specified as an n-by-1 vector. n is the number of rows in Xnew. Each entry in Ynew is the observed response based on the predictor data in the corresponding row of Xnew.

If Xnew is a table containing new response values, you do not have to specify Ynew.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

lossfun — Loss function
'mse' (default) | function handle

Loss function, specified as 'mse' (mean squared error) or a function handle.

If you pass a function handle, say fun, loss calls it as shown below: fun(Y,Ypred,W), where Y, Ypred and W are numeric vectors of length n, and n is the number of rows in Xnew. Y is the observed response, Ypred is the predicted response, and W is the observation weights.

Example: 'lossfun',Fct calls the loss function Fct.

Data Types: char | string | function_handle

weights — Observation weights
vector of 1s (default) | n-by-1 vector
Observation weights, specified as \( n \)-by-1 vector, where \( n \) is the number of rows in \( X_{\text{new}} \). By default, the weight of each observation is 1.

Example: 'weights',\( W \) uses the observation weights in vector \( W \).

Data Types: double | single

### Output Arguments

**L** — Regression error

scalar value

Regression error for the trained Gaussian process regression model, \( \text{gprMdl} \), returned as a scalar value.

### Examples

**Compute Regression Loss for Test Data**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','gprdata.mat'))
```

The data has 8 predictor variables and contains 500 observations in training data and 100 observations in test data. This is simulated data.

Fit a GPR model using the squared exponential kernel function with separate length scales for each predictor. Standardize the predictor values in the training data. Use the exact method for fitting and prediction.

```matlab
gprMdl = fitrgp(Xtrain,ytrain,'FitMethod','exact',... 'PredictMethod','exact','KernelFunction','ardsquaredexponential',... 'Standardize',1);
```

Compute the regression error for the test data.

```matlab
L = loss(gprMdl,Xtest,ytest)
L = 0.6928
```

Predict the responses for test data.
ypredtest = predict(gprMdl,Xtest);

Plot the test response along with the predictions.

figure;
plot(ytest,'r');
hold on;
plot(ypredtest,'b');
legend('Data','Predictions','Location','Best');

Manually compute the regression loss.

L = (ytest - ypredtest)'*(ytest - ypredtest)/length(ytest)
L = 0.6928
**Specify Custom Loss Function**

Load the sample data and store in a table.

```matlab
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
    'VariableNames',
    {'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```matlab
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```matlab
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```matlab
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = loss(mdl,tbl,'lossfun',fun)
L = 0.2345
```

**Alternatives**

You can use `resubLoss` to compute the regression error for the trained GPR model at the observations in the training data.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.
This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2015b
loss

Regression error for support vector machine regression model

Syntax

\[
L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})
\]

\[
L = \text{loss}(\text{mdl}, \text{tbl}, Y)
\]

\[
L = \text{loss}(\text{mdl}, X, Y)
\]

\[
L = \text{loss}(\_, \text{Name}, \text{Value})
\]

Description

\[
L = \text{loss}(\text{mdl}, \text{tbl}, \text{ResponseVarName})
\]
returns the loss for the predictions of the support vector machine (SVM) regression model, \text{mdl}, based on the predictor data in the table \text{tbl} and the true response values in \text{tbl.ResponseVarName}.

\[
L = \text{loss}(\text{mdl}, \text{tbl}, Y)
\]
returns the loss for the predictions of the support vector machine (SVM) regression model, \text{mdl}, based on the predictor data in the table \text{X} and the true response values in the vector \text{Y}.

\[
L = \text{loss}(\text{mdl}, X, Y)
\]
returns the loss for the predictions of the support vector machine (SVM) regression model, \text{mdl}, based on the predictor data in \text{X} and the true responses in \text{Y}.

\[
L = \text{loss}(\_, \text{Name}, \text{Value})
\]
returns the loss with additional options specified by one or more \text{Name}, \text{Value} pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

Input Arguments

\text{mdl} — SVM regression model
RegressionSVM model | CompactRegressionSVM model

SVM regression model, specified as a RegressionSVM model or CompactRegressionSVM model returned by \text{fitrsvm} or \text{compact}, respectively.
**tbl — Sample data**

Table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all of the predictors used to train `mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `mdl` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

**ResponseVarName — Response variable name**

Name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

**X — Predictor data**

Numeric matrix

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

If you trained `mdl` using a matrix of predictor values, then `X` must be a numeric matrix with `p` columns. `p` is the number of predictors used to train `mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `single` | `double`

**Y — Observed response values**

Vector of numeric values
Observed response values, specified as a vector of length \( n \) containing numeric values. Each entry in \( Y \) is the observed response based on the predictor data in the corresponding row of \( X \).

Data Types: \texttt{single} | \texttt{double}

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of 

- **Name**: the argument name
- **Value**: the corresponding value

**Name** must appear inside quotes. You can specify several name and value pair arguments in any order as 

- \texttt{Name1,Value1,...,NameN,ValueN}.

**LossFun — Loss function**

- \texttt{'mse' (default) | 'epsiloninsensitive' | function handle}

Loss function, specified as the comma-separated pair consisting of 

- **LossFun**: 'LossFun' and \texttt{'mse'}, \texttt{'epsiloninsensitive'}, or a function handle.

- The following table lists the available loss functions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Loss Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mse'</td>
<td>&quot;Weighted Mean Squared Error&quot; on page 32-3804</td>
</tr>
<tr>
<td>'epsiloninsensitive'</td>
<td>&quot;Epsilon-Insensitive Loss Function&quot; on page 32-3805</td>
</tr>
</tbody>
</table>

- Specify your own function using function handle notation.

Your function must have the signature 

\[
\text{lossvalue} = \text{lossfun}(Y,Yfit,W),
\]

- The output argument \( \text{lossvalue} \) is a scalar value.
- You choose the function name \( \text{lossfun} \).
- \( Y \) is an \( n \)-by-1 numeric vector of observed response values.
- \( Yfit \) is an \( n \)-by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in \( X \) (similar to the output of \texttt{predict})
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.

Specify your function using \texttt{'LossFun','@lossfun'}. 

32-3802
Example: 'LossFun','epsiloninsensitive'
Data Types: char | string | function_handle

Weights — Observation weights
ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. Weights must be the same length as the number of rows in X. The software weighs the observations in each row of X using the corresponding weight value in Weights.

Weights are normalized to sum to 1.
Data Types: single | double

Output Arguments

L — Regression loss
scalar value

Regression loss, returned as a scalar value.

Examples

Calculate Test Sample Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution mean square error and epsilon-insensitive error.

Load the carsmall sample data.

load carsmall
rng default  % for reproducibility

Specify Horsepower and Weight as the predictor variables (X), and MPG as the response variable (Y).

X = [Horsepower,Weight];
Y = MPG;
Train a linear SVM regression model. Standardize the data.

mdl = fitrsvm(X,Y,'Standardize',true);

mdl is a RegressionSVM model.

Determine how well the trained model generalizes to new predictor values by estimating the test sample mean square error and epsilon-insensitive error.

lossMSE = loss(mdl,X,Y)
lossEI = loss(mdl,X,Y,'LossFun','epsiloninsensitive')

lossMSE =
17.0256

lossEI =
2.2506

Definitions

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

\[ \text{mse} = \frac{\sum_{j=1}^{n} w_j (f(x_j) - y_j)^2}{\sum_{j=1}^{n} w_j}. \]

where:

- \( n \) is the number of rows of data
- \( x_j \) is the \( j \)th row of data
- \( y_j \) is the true response to \( x_j \)
• $f(x_j)$ is the response prediction of the SVM regression model mdl to $x_j$
• $w$ is the vector of weights.

The weights in $w$ are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

**Epsilon-Insensitive Loss Function**

The epsilon-insensitive loss function ignores errors that are within the distance epsilon ($\varepsilon$) of the function value. It is formally described as:

$$Loss_\varepsilon = \begin{cases} 0, & \text{if } |y - f(x)| \leq \varepsilon \\ |y - f(x)| - \varepsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^{n} w_j \max(0, |y_j - f(x_j)| - \varepsilon)}{\sum_{j=1}^{n} w_j},$$

where:

• $n$ is the number of rows of data
• $x_j$ is the $j$th row of data
• $y_j$ is the true response to $x_j$
• $f(x_j)$ is the response prediction of the SVM regression model mdl to $x_j$
• $w$ is the vector of weights.

The weights in $w$ are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.
Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldloss` instead of `loss` to calculate the regression error.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm` | `kfoldloss`

Introduced in R2015b
loss

Regression error

Syntax

L = loss(tree,tbl,ResponseVarName)
L = loss(tree,x,y)
L = loss(___,Name,Value)
[L,se,NLeaf,bestlevel] = loss(___)

Description

L = loss(tree,tbl,ResponseVarName) returns the mean squared error between the predictions of tree to the data in tbl, compared to the true responses tbl.ResponseVarName.

L = loss(tree,x,y) returns the mean squared error between the predictions of tree to the data in x, compared to the true responses y.

L = loss(___,Name,Value) computes the error in prediction with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

[L,se,NLeaf,bestlevel] = loss(___) also returns the standard error of the loss (se), the number of leaves (terminal nodes) in the tree (NLeaf), and the optimal pruning level for tree (bestlevel).

Input Arguments

tree — Trained regression tree
RegressionTree object | CompactRegressionTree object

Trained regression tree, specified as a RegressionTree object constructed by fitrtree or a CompactRegressionTree object constructed by compact.
**x — Predictor values**
matrix of floating-point values

Predictor values, specified as matrix of floating-point values. Each column of x represents one variable, and each row represents one observation.

Data Types: single | double

**ResponseVarName — Response variable name**
name of a variable in tbl

Response variable name, specified as the name of a variable in tbl. You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable y is stored as `tbl.y`, then specify `ResponseVarName` as 'y'. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.

Data Types: char | string

**y — Response data**
numeric column vector

Response data, specified as a numeric column vector with the same number of rows as x. Each entry in y is the response to the data in the corresponding row of x.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**LossFun — Loss function**

' mse' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle for loss, or 'mse' representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```matlab
fun(Y,Yfit,W)
```
- \( Y \) is the vector of true responses.
- \( Y_{\text{fit}} \) is the vector of predicted responses.
- \( W \) is the observation weights. If you pass \( W \), the elements are normalized to sum to 1.

All the vectors have the same number of rows as \( Y \).

Example: 'LossFun','mse'

Data Types: function_handle | char | string

**Subtrees — Pruning level**

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most \( \max(tree.PruneList) \). 0 indicates the full, unpruned tree and \( \max(tree.PruneList) \) indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then loss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using 0: \( \max(tree.PruneList) \).

loss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune','on', or by pruning tree using prune.

Example: 'Subtrees','all'

Data Types: single | double | char | string

**TreeSize — Tree size**

'\text{se}' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following:

- 'se' — loss returns bestlevel that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
• 'min' — loss returns bestlevel that corresponds to the minimal MSE tree.

Example: 'TreeSize','min'

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weights the observations in each row of X or tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or tbl.

If you specify the input data as a table tbl, then Weights can be the name of a variable in tbl that contains a numeric vector. In this case, you must specify Weights as a variable name. For example, if weights vector W is stored as tbl.W, then specify Weights as 'W'. Otherwise, the software treats all columns of tbl, including W, as predictors when training the model.

Data Types: single | double | char | string

Output Arguments

L — Classification error
vector of scalar values

Classification error, returned as a vector the length of Subtrees. The error for each tree is the mean squared error, weighted with Weights. If you include LossFun, L reflects the loss calculated with LossFun.

se — Standard error of loss
vector of scalar values

Standard error of loss, returned as a vector the length of Subtrees.

NLeaf — Number of leaf nodes
vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of Subtrees.

bestlevel — Best pruning level
scalar value
Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where $L$ and $se$ relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

**Examples**

**Compute the In-Sample MSE**

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```matlab
tree = fitrtree(X,MPG);
```

Estimate the in-sample MSE.

```matlab
L = loss(tree,X,MPG)
L = 4.8952
```

**Find the Pruning Level Yielding the Optimal In-sample Loss**

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.
Mdl = fitrtree(X,MPG);

View the regression tree.
view(Mdl,'Mode','graph');

Find the best pruning level that yields the optimal in-sample loss.
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG,'Subtrees','all');
bestLevel

bestLevel = 1
The best pruning level is level 1.

Prune the tree to level 1.

```matlab
pruneMdl = prune(Mdl,'Level',bestLevel);
view(pruneMdl,'Mode','graph');
```
Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

```matlab
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a regression tree using the training set.

```matlab
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```matlab
view(Mdl,'Mode','graph');
```
The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```matlab
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 7×1
        loss
32-3815
```

32-3815
The MSE for the full, unpruned tree is about 6 units.
The MSE for the tree pruned to level 1 is about 6.3 units.
The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

\[
\text{valLoss} = \text{loss(Mdl}, X(\text{idxVal}, :), Y(\text{idxVal}), 'SubTrees', 0:m) \\
\text{valLoss} = 7\times1 \\
\begin{array}{c}
32.1205 \\
31.5035 \\
32.0541 \\
30.8183 \\
26.3535 \\
30.0137 \\
38.4695
\end{array}
\]

The MSE for the full, unpruned tree (level 0) is about 32.1 units.
The MSE for the tree pruned to level 4 is about 26.4 units.
The MSE for the tree pruned to level 5 is about 30.0 units.
The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning \text{Mdl} to level 4.

\[
\text{pruneMdl} = \text{prune(Mdl}, '\text{Level}', 4); \\
\text{view(pruneMdl}, '\text{Mode}', '\text{graph}')
\]
Definitions

Mean Squared Error

The mean squared error $m$ of the predictions $f(X_n)$ with weight vector $w$ is
\[ m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}. \]

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

- Only one output is supported.

For more information, see “Tall Arrays” (MATLAB).

**See Also**
`fitrtree` | `predict`
loss

Class: FeatureSelectionNCAClassification

Evaluate accuracy of learned feature weights on test data

Syntax

\[ \text{err} = \text{loss}(\text{mdl}, X, Y) \]
\[ \text{err} = \text{loss}(\text{mdl}, X, Y, \text{Name}, \text{Value}) \]

Description

\[ \text{err} = \text{loss}(\text{mdl}, X, Y) \] computes the misclassification error of the model \( \text{mdl} \), for the predictors in \( X \) and the class labels in \( Y \).

\[ \text{err} = \text{loss}(\text{mdl}, X, Y, \text{Name}, \text{Value}) \] computes the classification error with additional options specified by one or more \text{Name}, \text{Value} pair arguments.

Input Arguments

\( \text{mdl} \) — Neighborhood component analysis model for classification
FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

\( X \) — Predictor variable values
\n-by-\( p \) matrix

Predictor variable values, specified as an \( n \)-by-\( p \) matrix, where \( n \) is the number of observations and \( p \) is the number of predictor variables.

Data Types: single | double
**Y — Class labels**
categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length \( n \) | character matrix with \( n \) rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length \( n \), or character matrix with \( n \) rows, where \( n \) is the number of observations. Element \( i \) or row \( i \) of \( Y \) is the class label corresponding to row \( i \) of \( X \) (observation \( i \)).

Data Types: single | double | logical | char | string | cell | categorical

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as

**Name1,Value1,...,NameN,ValueN**

**LossFunction — Loss function type**
'veclassiferror' (default) | 'quadratic'

Loss function type, specified as a comma-separated pair consisting of 'Loss Function' and one of the following.

- 'classiferror' — Misclassification error, defined as

\[
\frac{1}{n} \sum_{i=1}^{n} I(k_i \neq t_i),
\]

where \( k_i \) is the predicted class and \( t_i \) is the true class for observation \( i \). \( I(k_i \neq t_i) \) is the indicator for when the \( k_i \) is not the same as \( t_i \).

- 'quadratic' — Quadratic loss function, defined as

\[
\frac{1}{n} \sum_{i=1}^{n} \sum_{k=1}^{c} (p_{ik} - I(i,k))^2,
\]
where \( c \) is the number of classes, \( p_{ik} \) is the estimate probability that \( i \)th observation belongs to class \( k \), and \( I(i,k) \) is the indicator that \( i \)th observation belongs to class \( k \).

Example: 'LossFunction','quadratic'

**Output Arguments**

**err — Smaller-the-better accuracy measure for learned feature weights**
scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the `LossFunction` name-value pair argument.

**Examples**

**Tune NCA Model for Classification**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','twodimclassdata.mat'));
```

This data set is simulated using the scheme described in [1]. This is a two-class classification problem in two dimensions. Data from the first class are drawn from two bivariate normal distributions \( N(\mu_1, \Sigma) \) or \( N(\mu_2, \Sigma) \) with equal probability, where \( \mu_1 = [-0.75, -1.5] \), \( \mu_2 = [0.75, 1.5] \), and \( \Sigma = I_2 \). Similarly, data from the second class are drawn from two bivariate normal distributions \( N(\mu_3, \Sigma) \) or \( N(\mu_4, \Sigma) \) with equal probability, where \( \mu_3 = [1.5, -1.5] \), \( \mu_4 = [-1.5, 1.5] \), and \( \Sigma = I_2 \). The normal distribution parameters used to create this data set result in tighter clusters in data than the data used in [1].

Create a scatter plot of the data grouped by the class.

```matlab
figure
gscatter(X(:,1),X(:,2),y)
```
Add 100 irrelevant features to \( X \). First generate data from a Normal distribution with a mean of 0 and a variance of 20.

\[
n = \text{size}(X,1);
\text{rng('default')}
X\text{with Bad Features} = [X, \text{randn}(n,100)\times\sqrt{20}];
\]

Normalize the data so that all points are between 0 and 1.

\[
X\text{with Bad Features} = \text{bsxfun(@rdivide,}...
\text{bsxfun(@minus,X\text{with Bad Features},}\text{min(X\text{with Bad Features},[])},1)), ...
\]
range(XwithBadFeatures,1));
X = XwithBadFeatures;

Fit a neighborhood component analysis (NCA) model to the data using the default Lambda (regularization parameter, λ) value. Use the LBFGS solver and display the convergence information.

ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ... 'Solver','lbfgs');

| Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe |

Infinity norm of the final gradient = 9.404e-08
Two norm of the final step = 8.947e-04, TolX = 1.000e-06
Relative infinity norm of the final gradient = 9.404e-08, TolFun = 1.000e-06
EXIT: Local minimum found.

Plot the feature weights. The weights of the irrelevant features should be very close to zero.

figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
Predict the classes using the NCA model and compute the confusion matrix.

```matlab
ypred = predict(ncaMdl,X);
confusionmat(y,ypred)
```

```
ans =
     40     60
      6     94
```

Confusion matrix shows that 40 of the data that are in class 1 are predicted as belonging to class 1. 60 of the data from class 1 are predicted to be in class 2. Similarly, 94 of the
data from class 2 are predicted to be from class 2 and 6 of them are predicted to be from class 1. The prediction accuracy for class 1 is not good.

All weights are very close to zero, which indicates that the value of $\lambda$ used in training the model is too large. When $\lambda \to \infty$, all features weights approach to zero. Hence, it is important to tune the regularization parameter in most cases to detect the relevant features.

Use five-fold cross-validation to tune $\lambda$ for feature selection by using fscnca. Tuning $\lambda$ means finding the $\lambda$ value that will produce the minimum classification loss. To tune $\lambda$ using cross-validation:

1. Partition the data into five folds. For each fold, cvpartition assigns four-fifths of the data as a training set and one-fifth of the data as a test set. Again for each fold, cvpartition creates a stratified partition, where each partition has roughly the same proportion of classes.

   ```
cvp = cvpartition(y,'kfold',5);
numtestsets = cvp.NumTestSets;
lambdavalues = linspace(0,2,20)/length(y);
lossvalues = zeros(length(lambdavalues),numtestsets);
```

2. Train the neighborhood component analysis (nca) model for each $\lambda$ value using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the nca model. Record the loss value.

4. Repeat this process for all folds and all $\lambda$ values.

```matlab
for i = 1:length(lambdavalues)
    for k = 1:numtestsets
        % Extract the training set from the partition object
        Xtrain = X(cvp.training(k),:);
ytrain = y(cvp.training(k),:);

        % Extract the test set from the partition object
        Xtest  = X(cvp.test(k),:);
ytest  = y(cvp.test(k),:);

        % Train an NCA model for classification using the training set
        ncaMdl = fscnca(Xtrain,ytrain,'FitMethod','exact', ...
'Solver','lbfgs','Lambda',lambdavalues(i));

% Compute the classification loss for the test set using the NCA model
lossvalues(i,k) = loss(ncaMdl,Xtest,ytest, ...
    'LossFunction','quadratic');

end
end

Plot the average loss values of the folds versus the \( \lambda \) values. If the \( \lambda \) value that corresponds to the minimum loss falls on the boundary of the tested \( \lambda \) values, the range of \( \lambda \) values should be reconsidered.

figure
plot(lambdavalues,mean(lossvalues,2),'ro-')
xlabel('Lambda values')
ylabel('Loss values')
grid on
Find the $\lambda$ value that corresponds to the minimum average loss.

```
 [~,idx] = min(mean(lossvalues,2)); % Find the index
 bestlambda = lambdavalues(idx) % Find the best lambda value
```

```
bestlambda =

0.0037
```

Fit the NCA model to all of the data using the best $\lambda$ value. Use the LBFGS solver and display the convergence information.
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...  'Solver','lbfgs','Lambda',bestlambda);

o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

Infinity norm of the final gradient = 5.764e-07
Two norm of the final step    = 6.765e-04, TolX    = 1.000e-06
Relative infinity norm of the final gradient = 5.764e-07, TolFun = 1.000e-06
EXIT: Local minimum found.

Plot the feature weights.

figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
fscnca correctly figures out that the first two features are relevant and that the rest are not. The first two features are not individually informative, but when taken together result in an accurate classification model.

Predict the classes using the new model and compute the accuracy.

ypred = predict(ncaMdl,X);
confusionmat(y,ypred)

ans =

32-3829
Confusion matrix shows that prediction accuracy for class 1 has improved. 88 of the data from class 1 are predicted to be from class 1, and 12 of them are predicted to be from class 2. 92 of the data from class 2 are predicted to be from class 2 and 8 of them are predicted to be from class 1.

FeatureSelectionNCAClassification | fscnca | predict | refit

Introduced in R2016b
loss

Class: FeatureSelectionNCARegression

Evaluate accuracy of learned feature weights on test data

Syntax

err = loss(mdl,X,Y)
err = loss(mdl,X,Y,Name,Value)

Description

err = loss(mdl,X,Y) returns the mean squared error as the measure of accuracy in err, for the model mdl, predictor values in X, and response values in Y.

err = loss(mdl,X,Y,Name,Value) returns the measure of accuracy, err, with the additional option specified by the Name,Value pair argument.

Input Arguments

mdl — Neighborhood component analysis model for regression
FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, specified as a FeatureSelectionNCARegression object.

X — Predictor variable values
n-by-p matrix

Predictor variable values, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables.

Data Types: single | double

Y — Response values
numeric real vector of length n
Response values, specified as a numeric real vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

LossFunction — Loss function type

' mse ' (default) | ' mad ' 

Loss function type, specified as a comma-separated pair consisting of 'Loss Function' and one of the following.

<table>
<thead>
<tr>
<th>Loss Function Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mse'</td>
<td>Mean squared error</td>
</tr>
<tr>
<td>'mad'</td>
<td>Mean absolute deviation</td>
</tr>
</tbody>
</table>

Example: 'LossFunction', 'mse'

Output Arguments

err — Smaller-the-better accuracy measure for learned feature weights

scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the LossFunction name-value pair argument.

Examples
Tune NCA Model for Regression Using loss and predict

Load the sample data.

Download the housing data [1], from the UCI Machine Learning Repository [2]. The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```matlab
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Divide the data into training and test sets using the 4th predictor as the grouping variable for a stratified partitioning. This ensures that each partition includes similar amount of observations from each group.

```matlab
rng(1) % For reproducibility
cvp = cvpartition(X(:,4),'Holdout',56);
Xtrain = X(cvp.training,:);
ytrain = y(cvp.training,:);
Xtest  = X(cvp.test,:);
ytest  = y(cvp.test,:);
```

cvpartition randomly assigns 56 observations into a test set and the rest of the data into a training set.

Perform Feature Selection Using Default Settings

Perform feature selection using NCA model for regression. Standardize the predictor values.

```matlab
nca = fsrnca(Xtrain,ytrain,'Standardize',1);
```

Plot the feature weights.

```matlab
figure()
plot(nca.FeatureWeights,'ro')
```
The weights of irrelevant features are expected to approach zero. \texttt{fsrnca} identifies two features as irrelevant.

Compute the regression loss.

\[
L = \text{loss}(\text{nca}, X_{\text{test}}, y_{\text{test}}, \text\{'LossFunction', 'mad'\})
\]

\[
L = 2.5394
\]
Compute the predicted response values for the test set and plot them versus the actual response.

```
ypred = predict(nca,Xtest);
figure()
plot(ypred,ytest,'bo')
xlabel('Predicted response')
ylabel('Actual response')
```

A perfect fit versus the actual values forms a 45 degree straight line. In this plot, the predicted and actual response values seem to be scattered around this line. Tuning $\lambda$ (regularization parameter) value usually helps improve the performance.
Tune the regularization parameter using 10-fold cross-validation

Tuning \( \lambda \) means finding the \( \lambda \) value that will produce the minimum regression loss. Here are the steps for tuning \( \lambda \) using 10-fold cross-validation:

1. First partition the data into 10 folds. For each fold, \texttt{cvpartition} assigns 1/10th of the data as a training set, and 9/10th of the data as a test set.

   \[
   \begin{align*}
   n &= \text{length}(y\text{train}); \\
   \text{cvp} &= \text{cvpartition}(X\text{train}(:,4),\text{'kfold'},10); \\
   \text{numvalidsets} &= \text{cvp}.\text{NumTestSets};
   \end{align*}
   \]

   Assign the \( \lambda \) values for the search. Create an array to store the loss values.

   \[
   \begin{align*}
   \text{lambdavals} &= \text{linspace}(0,2,30)*\text{std}(y\text{train})/n; \\
   \text{lossvals} &= \text{zeros}([\text{length}([\text{lambdavals}]),\text{numvalidsets}]);
   \end{align*}
   \]

2. Train the neighborhood component analysis (nca) model for each \( \lambda \) value using the training set in each fold.

3. Fit a Gaussian process regression (gpr) model using the selected features. Next, compute the regression loss for the corresponding test set in the fold using the gpr model. Record the loss value.

4. Repeat this for each \( \lambda \) value and each fold.

   \[
   \begin{align*}
   \text{for} \ i &= 1: \text{length}([\text{lambdavals}]) \\
   \quad \text{for} \ k &= 1: \text{numvalidsets} \\
   & \quad X = X\text{train}(\text{cvp}.\text{training}(k),:); \\
   & \quad y = y\text{train}(\text{cvp}.\text{training}(k),:); \\
   & \quad X\text{valid} = X\text{train}(\text{cvp}.\text{test}(k),:); \\
   & \quad y\text{valid} = y\text{train}(\text{cvp}.\text{test}(k),:); \\
   & \quad \text{nca} = \text{fsrnca}(X,y,\text{'FitMethod'},\text{'exact'},... \\
   & \quad \quad \quad \text{'Lambda'},[\text{lambdavals}(i),..., \\
   & \quad \quad \quad \text{'Standardize'},1,\text{'LossFunction'},\text{'mad'}]); \\
   & \quad \text{% Select features using the feature weights and a relative} \\
   & \quad \text{% threshold.} \\
   & \quad \text{tol} = 1\text{e}-3; \\
   & \quad \text{selidx} = \text{nca}.\text{FeatureWeights} > \text{tol}\text{*max}(1,\text{max}([\text{nca}.\text{FeatureWeights}])); \\
   & \quad \text{% Fit a non-ARD GPR model using selected features.} \\
   & \quad \text{gpr} = \text{fitrgp}([X(:,\text{selidx})],y,\text{'Standardize'},1,...
   \end{align*}
   \]
Compute the average loss obtained from the folds for each $\lambda$ value. Plot the mean loss versus the $\lambda$ values.

```matlab
meanloss = mean(lossvals,2);
figure;
plot(lambdavals,meanloss,'ro-');
xlabel('Lambda');
ylabel('Loss (MSE)');
grid on;
```
Find the $\lambda$ value that produces the minimum loss value.

$$\left[~,\text{idx}\right] = \text{min}(\text{meanloss});$$

```matlab
bestlambda = lambdavals(idx)
```

$bestlambda = 0.0251$

Perform feature selection for regression using the best $\lambda$ value. Standardize the predictor values.
nca2 = fsrnca(Xtrain,ytrain,'Standardize',1,'Lambda',bestlambda,...
    'LossFunction','mad');

Plot the feature weights.

figure()
plot(nca.FeatureWeights,'ro')

Compute the loss using the new nca model on the test data, which is not used to select
the features.

L2 = loss(nca2,Xtest,ytest,'LossFunction','mad')

L2 =
Tuning the regularization parameter helps identify the relevant features and reduces the loss.

Plot the predicted versus the actual response values in the test set.

```matlab
ypred = predict(nca2,Xtest);
figure;
plot(ypred,ytest,'bo');
```

The predicted response values seem to be closer to the actual values as well.

FeatureSelectionNCARegression | fsrnca | predict | refit

Introduced in R2016b
loss

Class: RegressionLinear

Regression loss for linear regression models

Syntax

L = loss(Mdl,X,Y)
L = loss(___ ,Name,Value)

Description

L = loss(Mdl,X,Y) returns the mean squared error (MSE) for the linear regression
model Mdl using predictor data in X and corresponding responses in Y. L contains an
MSE for each regularization strength in Mdl.

L = loss(___ ,Name,Value) uses any of the previous syntaxes and additional options
specified by one or more Name,Value pair arguments. For example, specify that columns
in the predictor data correspond to observations or specify the regression loss function.

Input Arguments

Mdl — Linear regression model
RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create
a RegressionLinear model object using fitrlinear.

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix. This orientation of X indicates
that rows correspond to individual observations, and columns correspond to individual
predictor variables.
Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Response data
numeric vector

Response data, specified as an n-dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

LossFun — Loss function
'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding value. Also, in the table, \( f(x) = x\beta + b \).
  - \( \beta \) is a vector of \( p \) coefficients.
  - \( x \) is an observation from \( p \) predictor variables.
  - \( b \) is the scalar bias.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'epsiloninsensitive'</td>
<td>Epsilon-insensitive loss: $\ell[y,f(x)] = \max(0,</td>
</tr>
<tr>
<td>'mse'</td>
<td>MSE: $\ell[y,f(x)] = (y-f(x))^2$</td>
</tr>
</tbody>
</table>

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let $n$ be the number of observations in $X$. Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- $Y$ is an $n$-dimensional vector of observed responses. `loss` passes the input argument `Y` in for `Y`.
- `Yhat` is an $n$-dimensional vector of predicted responses, which is similar to the output of `predict`.
- $W$ is an $n$-by-1 numeric vector of observation weights.

Specify your function using `'LossFun'`, `@lossfun`.

Data Types: `char` | `string` | `function_handle`

**ObservationsIn — Predictor data observation dimension**

- `'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.
Weights — Observation weights
numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, loss computes the weighted classification loss.

Let \( n \) be the number of observations in \( X \).

- \text{numel(Weights)} must be \( n \).
- By default, \text{Weights} is \text{ones}(n,1).

Data Types: double | single

Output Arguments

L — Regression losses
numeric scalar | numeric row vector

Regression losses, returned as a numeric scalar or row vector. The interpretation of \( L \) depends on \text{Weights} and \text{LossFun}.

\( L \) is the same size as \text{Mdl.Lambda}. \( L(j) \) is the regression loss of the linear regression model trained using the regularization strength \text{Mdl.Lambda}(j).

\textbf{Note} If \text{Mdl.FittedLoss} is 'mse', then the loss term in the objective function is half of the MSE. loss returns the MSE by default. Therefore, if you use loss to check the resubstitution (training) error, then there is a discrepancy between the MSE and optimization results that \text{fitrlinear} returns.

Examples

Estimate Test-Sample Mean Squared Error

Simulate 10000 observations from this model

\[
y = x_{100} + 2x_{200} + e.
\]
• \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.

• \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```matlab
CVMdl = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMdl.Trained{1}
```

```matlab
Mdl =
    RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
    Bias: -0.0066
    Lambda: 1.4286e-04
    Learner: 'svm'
```

CVMdl is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample MSE.

```matlab
mseTrain = loss(Mdl,X(trainIdx,:),Y(trainIdx))
mseTrain = 0.1496
mseTest = loss(Mdl,X(testIdx,:),Y(testIdx))
mseTest = 3.2222
```
mseTest = 0.1798

Because there is one regularization strength in Mdl, mseTrain and mseTest are numeric scalars.

**Specify Custom Regression Loss**

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

CVMdl = fitrlinear(X,Y,'Holdout',0.3,'ObservationsIn','columns');
Mdl = CVMdl.Trained{1}

Mdl =
  RegressionLinear
     ResponseName: 'Y'
     ResponseTransform: 'none'
     Beta: [1000x1 double]
     Bias: -0.0066
     Lambda: 1.4286e-04
     Learner: 'svm'

Properties, Methods
CVMdl is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

\[
L = \sum_{j=1}^{n} w_j \ell_j,
\]

where

\[
\ell_j = \begin{cases} 
0.5 \hat{e}_j^2; & |\hat{e}_j| \leq 1 \\
|\hat{e}_j| - 0.5; & |\hat{e}_j| > 1.
\end{cases}
\]

$\hat{e}_j$ is the residual for observation $j$. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

```matlab
huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5))/sum(W));
```

Estimate the training set and test set regression loss using the Huber loss function.

```matlab
eTrain = loss(Mdl,X(:,trainIdx),Y(trainIdx),'LossFun',huberloss,... 'ObservationsIn','columns')
eTrain = -0.4186
```

```matlab
eTest = loss(Mdl,X(:,testIdx),Y(testIdx),'LossFun',huberloss,... 'ObservationsIn','columns')
eTest = -0.4010
```
Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, ..., x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10\% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \( 10^{-4} \) through \( 10^{-1} \).

```matlab
Lambda = logspace(-4,-1,15);
```

Hold out 30\% of the data for testing. Identify the test-sample indices.

```matlab
cvp = cvpartition(numel(Y),'Holdout',0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in \( \text{Lambda} \). Specify the regularization strengths, optimizing the objective function using SpaRSA, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```matlab
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
                   'Solver','sparsa','Regularization','lasso','CVPartition',cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

ans = 15
Mdl1 is a RegressionLinear model. Because Lambda is a 15-dimensional vector of regularization strengths, you can think of Mdl1 as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

\[
\text{mse} = \text{loss(Mdl1,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');}
\]

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

\[
\text{Mdl} = \text{fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...}
\text{'Solver','sparsa','Regularization','lasso');}
\]

\[
\text{numNZCoeff} = \text{sum(Mdl.Beta==0);}
\]

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

\[
\text{figure;}
\text{[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...}
\text{log10(Lambda),log10(numNZCoeff));}
\]

\[
\text{hL1.Marker = 'o';}
\text{hL2.Marker = 'o';}
\text{ylabel(h(1),'log}_{10}\text{ MSE')}
\text{ylabel(h(2),'log}_{10}\text{ nonzero-coefficient frequency')}
\text{xlabel('log}_{10}\text{ Lambda')}
\text{hold off}
\]
Select the index or indices of Lambda that balance minimal classification error and predictor-variable sparsity (for example, Lambda(11)).

```matlab
idx = 11;
MdlFinal = selectModels(Mdl,idx);
```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.
Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

RegressionLinear | fitrlinear | predict

Introduced in R2016a
lowerparams

Lower Pareto tail parameters

Syntax

params = lowerparams(pd)

Description

params = lowerparams(pd) returns the two-element vector params, which includes the shape and scale parameters of the generalized Pareto distribution (GPD) in the lower tail of pd.

lowerparams does not return the location parameter of the GPD. The location parameter is the quantile value corresponding to the lower tail cumulative probability. Use the boundary function to return the location parameter.

Examples

Parameters of Lower Pareto Tail

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data by using paretotails. Find the distribution parameters of the lower Pareto tail by using the object function lowerparams.

Generate a sample data set containing 20% outliers.

rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];

Create a paretotails object by fitting a piecewise distribution to x. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a
fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```matlab
pd = paretotails(x,0.1,0.9)
```

```
pd = 
Piecewise distribution with 3 segments
   -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
   -1.33251 < x < 1.80149  (0.1 < p < 0.9): interpolated empirical cdf
   1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the shape and scale parameters of the fitted GPD of the lower tail by using the `lowerparams` function.

```matlab
params = lowerparams(pd)
```

```
params = 1×2
    -0.0064    0.5670
```

You can also get the lower Pareto tail parameters by using the `LowerParameters` property. Access the `LowerParameters` property by using dot notation.

```matlab
pd.LowerParameters
ans = 1×2
    -0.0064    0.5670
```

The location parameter of the GPD is equal to the quantile value of the lower tail cumulative probability. Return the location parameter by using the `boundary` function.

```matlab
[p,q] = boundary(pd)
p = 2×1
    0.1000
    0.9000
```

```matlab
q = 2×1
    -1.3325
```
The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles. `q(2)` is the location parameter of the GPD of the lower tail.

Use the `upperparams` function or the `UpperParameters` property to get the upper Pareto tail parameters.

### Input Arguments

**pd — Piecewise distribution with Pareto tails**

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

“Generalized Pareto Distribution” on page B-55

### Introduced in R2007a
lt

Class: qrandstream

Less than relation for handles

Syntax

h1 < h2

Description

h1 < h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise < result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = lt(h1, h2) stores the result in a logical array of the same dimensions.

See Also

eq | ge | gt | le | ne | qrandstream
Isline

Add least-squares line to scatter plot

Syntax

lsline
lsline(ax)
h = lsline(__)

Description

lsline superimposes a least-squares line on each scatter plot in the current axes.

lsline ignores data points that are connected with solid, dashed, or dash-dot lines ('-', '--', or '-.') because it does not consider them to be scatter plots. To produce scatter plots, use the MATLAB scatter and plot functions.

lsline(ax) superimposes a least-squares line on the scatter plot in the axes specified by ax instead of the current axes (gca).

h = lsline(__) returns a column vector of least-squares line objects h using any of the previous syntaxes. Use h to modify the properties of a specific least-squares line after you create it. For a list of properties, see Line Properties.

Examples

Plot Least-Squares Line

Generate three sets of sample data and plot each set on the same figure.

x = 1:10;
rng default; % For reproducibility
figure;
y1 = x + randn(1,10);
scatter(x,y1,25,'b','*')
hold on

y2 = 2*x + randn(1,10);
plot(x,y2,'mo')

y3 = 3*x + randn(1,10);
plot(x,y3,'rx:')

Add a least-squares line for each set of sample data.
lsline
Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

\begin{verbatim}
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
\end{verbatim}

Define ax1 as the top half of the figure, and ax2 as the bottom half of the figure. Create the first scatter plot on the top axis using y1, and the second scatter plot on the bottom axis using y2.
```matlab
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);
scatter(ax1,x,y1)
scatter(ax2,x,y2)

lsline(ax1) % This is equivalent to reline(ax1)
mu = mean(y2);
refline(ax2,[0 mu])
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the y2 values in the bottom plot.
Use Least-Squares Line Object to Modify Line Properties

Define the x-variable and two different y-variables to use for the plots.

```matlab
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`. 
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)

Superimpose a least-squares line on the top plot. Then, use the least-squares line object h1 to change the line color to red.

h1 = lsline(ax1);
h1.Color = 'r';

Superimpose a least-squares line on the bottom plot. Then, use the least-squares line object h2 to increase the line width to 5.

h2 = lsline(ax2);
h2.LineWidth = 5;
Input Arguments

**ax — Target axes**

gca (default) | axes object

Target axes, specified as an axes object. If you do not specify the axes and if the current axes are Cartesian axes, then the lsline function uses the current axes.
Output Arguments

h — One or more least-squares line objects
scalar | vector

One or more least-squares line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific least-squares line. For a list of properties, see Chart Line.

See Also

(gca | gline | plot | refcurve | refline | scatter

Introduced before R2006a
**mad**

Mean or median absolute deviation

**Syntax**

\[
\begin{align*}
y &= \text{mad}(X) \\
y &= \text{mad}(X,1) \\
y &= \text{mad}(X,0) \\
y &= \text{mad}(X,\text{flag},'\text{all}') \\
y &= \text{mad}(X,\text{flag},\text{dim}) \\
y &= \text{mad}(X,\text{flag},\text{vecdim})
\end{align*}
\]

**Description**

\[y = \text{mad}(X)\] returns the mean absolute deviation of the values in \(X\). For vector input, \(y\) is \(\text{mean}(\text{abs}(X-\text{mean}(X)))\). For a matrix input, \(y\) is a row vector containing the mean absolute deviation of each column of \(X\). For \(N\)-dimensional arrays, \text{mad} operates along the first nonsingleton dimension of \(X\).

\[y = \text{mad}(X,1)\] returns the median absolute deviation of the values in \(X\). For vector input, \(y\) is \(\text{median}(\text{abs}(X-\text{median}(X)))\). For a matrix input, \(y\) is a row vector containing the median absolute deviation of each column of \(X\). For \(N\)-dimensional arrays, \text{mad} operates along the first nonsingleton dimension of \(X\).

\[y = \text{mad}(X,0)\] is the same as \(\text{mad}(X)\), and returns the mean absolute deviation of the values in \(X\).

\[y = \text{mad}(X,\text{flag},'\text{all}')\] returns the absolute deviation of all elements of \(X\). The \text{flag} value is 0 or 1 to indicate mean or median absolute deviation, respectively.

\[y = \text{mad}(X,\text{flag},\text{dim})\] computes the absolute deviation along the operating dimension \(\text{dim}\) of \(X\).

\[y = \text{mad}(X,\text{flag},\text{vecdim})\] returns the absolute deviation over the dimensions specified in the vector \text{vecdim}. Each element of \text{vecdim} represents a dimension of the input array \(X\). The output \(y\) has length 1 in the specified operating dimensions. The other dimension...
lengths are the same for $X$ and $y$. For example, if $X$ is a 2-by-3-by-4 array, then \texttt{mad}(X, 0, [1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the mean absolute deviation of the elements on the corresponding page of $X$.

### Examples

**Compare Robustness of Scale Estimates**

Compare the robustness of the standard deviation, mean absolute deviation, and median absolute deviation in the presence of outliers.

Create a data set $x$ of normally distributed data. Create another data set $x_0$ that contains the elements of $x$ and an additional outlier.

```matlab
rng('default') % For reproducibility
x = normrnd(0,1,1,50);
xo = [x 10];
```

Compute the ratio of the standard deviations of the two data sets.

```matlab
r1 = std(xo)/std(x)
r1 = 1.4633
```

Compute the ratio of the mean absolute deviations of the two data sets.

```matlab
r2 = mad(xo,0)/mad(x,0)
r2 = 1.1833
```

Compute the ratio of the median absolute deviations of the two data sets.

```matlab
r3 = mad(xo,1)/mad(x,1)
r3 = 1.0336
```

In this case, the median absolute deviation is less influenced by the outlier than the other two scale estimates.
Mean and Median Absolute Deviations of All Values

Find the mean and median absolute deviations of all the values in an array.

Create a 3-by-5-by-2 array \( X \) and add an outlier.

\[
X = \text{reshape}(1:30,[3 \ 5 \ 2]);
\]
\[
X(6) = 100
\]
\[
X = \]
\[
X(:,:,1) =
1  4  7  10  13
2  5  8  11  14
3 100  9  12  15
\]
\[
X(:,:,2) =
16 19 22 25 28
17 20 23 26 29
18 21 24 27 30
\]

Find the mean and median absolute deviations of the elements in \( X \).

\[
\text{meandev} = \text{mad}(X,0,'all')
\]
\[
\text{meandev} = 10.1178
\]
\[
\text{mediandev} = \text{mad}(X,1,'all')
\]
\[
\text{mediandev} = 7.5000
\]

\text{meandev} \text{ is the mean absolute deviation of all the elements in } X, \text{ and } \text{mediandev} \text{ is the median absolute deviation of all the elements in } X.

Tips

- \text{mad} \text{ treats NaNs as missing values and removes them.}
- For normally distributed data, multiply \text{mad} by one of the following factors to obtain an estimate of the normal scale parameter \( \sigma \):
• $\sigma = 1.253 \cdot \text{mad}(X, 0)$ — For mean absolute deviation
• $\sigma = 1.4826 \cdot \text{mad}(X, 1)$ — For median absolute deviation

References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The following syntaxes do not support code generation.
  • $y = \text{mad}(X, \text{flag}, 'all')$
  • $y = \text{mad}(X, \text{flag}, \text{vecdim})$
• Empty dim input is not supported.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • $y = \text{mad}(X, \text{flag}, 'all')$
• \( y = \text{mad}(X, \text{flag}, \text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**See Also**

iqr | range | std

*Introduced before R2006a*
mahal
Mahalanobis distance

Syntax

d2 = mahal(Y,X)

Description
d2 = mahal(Y,X) returns the squared Mahalanobis distance on page 32-3873 of each observation in Y to the reference samples in X.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate a correlated bivariate sample data set.

rng('default') % For reproducibility
X = mvnrnd([0;0],[1 .9;.9 1],1000);

Specify four observations that are equidistant from the mean of X in Euclidean distance.
Y = [1 1;1 -1;-1 1;-1 -1];

Compute the Mahalanobis distance of each observation in Y to the reference samples in X.

```
d2_mahal = mahal(Y,X)
d2_mahal = 4x1
     1.1095
     20.3632
     19.5939
     1.0137
```
Compute the squared Euclidean distance of each observation in Y from the mean of X.

\[
d_2_{\text{Euclidean}} = \text{sum}((Y-\text{mean}(X)).^2,2)
\]

\[
d_2_{\text{Euclidean}} = 4\times1
\]

\[
2.0931 \\
2.0399 \\
1.9625 \\
1.9094
\]

Plot X and Y by using scatter and use marker color to visualize the Mahalanobis distance of Y to the reference samples in X.

```matlab
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
scatter(Y(:,1),Y(:,2),100,d2_mahal,'o','filled')
hb = colorbar;
ylabel(hb,'Mahalanobis Distance')
legend('X','Y','Location','best')
```
All observations in $Y (\{1, 1\}, [-1, -1], [1, -1], \text{and} [-1, 1])$ are equidistant from the mean of $X$ in Euclidean distance. However, $[1, 1]$ and $[-1, -1]$ are much closer to $X$ than $[1, -1]$ and $[-1, 1]$ in Mahalanobis distance. Because Mahalanobis distance considers the covariance of the data and the scales of the different variables, it is useful for detecting outliers.

**Input Arguments**

$Y$ — Data

$n$-by-$m$ numeric matrix
Data, specified as an \(n\)-by-\(m\) numeric matrix, where \(n\) is the number of observations and \(m\) is the number of variables in each observation.

\(X\) and \(Y\) must have the same number of columns, but can have different numbers of rows.

Data Types: `single` | `double`

\(X\) — Reference samples
\(p\)-by-\(m\) numeric matrix

Reference samples, specified as a \(p\)-by-\(m\) numeric matrix, where \(p\) is the number of samples and \(m\) is the number of variables in each sample.

\(X\) and \(Y\) must have the same number of columns, but can have different numbers of rows. \(X\) must have more rows than columns.

Data Types: `single` | `double`

**Output Arguments**

\(d2\) — Squared Mahalanobis distance
\(n\)-by-1 numeric vector

Squared Mahalanobis distance on page 32-3873 of each observation in \(Y\) to the reference samples in \(X\), returned as an \(n\)-by-1 numeric vector, where \(n\) is the number of observations in \(X\).

**Definitions**

**Mahalanobis Distance**

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector \(y\) to a distribution with mean \(\mu\) and covariance \(\Sigma\) is

\[ d = \sqrt{(y - \mu) \Sigma^{-1} (y - \mu)'} \]

This distance represents how far \(y\) is from the mean in number of standard deviations.
mahal returns the squared Mahalanobis distance \( d^2 \) from an observation in \( Y \) to the reference samples in \( X \). In the \texttt{mahal} function, \( \mu \) and \( \Sigma \) are the sample mean and covariance of the reference samples, respectively.

**See Also**
mahal | pdist

**Introduced before R2006a**
**mahal**

Mahalanobis distance to class means

**Syntax**

\[
M = \text{mahal}(\text{obj},X) \]

\[
M = \text{mahal}(\text{obj},X,\text{Name},\text{Value})
\]

**Description**

\[
M = \text{mahal}(\text{obj},X) \]

returns the squared Mahalanobis distances from observations in \(X\) to the class means in \(\text{obj}\).

\[
M = \text{mahal}(\text{obj},X,\text{Name},\text{Value})
\]

computes the squared Mahalanobis distance with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

\(\text{obj}\)

Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with fitcdiscr.

\(X\)

Numeric matrix of size \(n\)-by-\(p\), where \(p\) is the number of predictors in \(\text{obj}\), and \(n\) is any positive integer. \(\text{mahal}\) computes the Mahalanobis distances from the rows of \(X\) to each of the \(K\) means of the classes in \(\text{obj}\).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**ClassLabels**

Class labels consisting of \( n \) elements of \( \text{obj}.Y \), where \( n \) is the number of rows of \( X \).

**Output Arguments**

**M**

Size and meaning of output \( M \) depends on whether the **ClassLabels** name-value pair is present:

- No **ClassLabels** — \( M \) is a numeric matrix of size \( n \)-by-\( K \), where \( K \) is the number of classes in \( \text{obj} \), and \( n \) is the number of rows in \( X \). \( M(i,j) \) is the squared Mahalanobis distance from the \( i \)th row of \( X \) to the mean of class \( j \).
- **ClassLabels** exists — \( M \) is a column vector with \( n \) elements. \( M(i) \) is the squared Mahalanobis distance from the \( i \)th row of \( X \) to the mean for the class of the \( i \)th element of **ClassLabels**.

**Examples**

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```matlab
load fisheriris
obj = fitcdiscr(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))
```

```matlab
mahadist =
    220.0667    5.0254   30.5804
```
Definitions

Mahalanobis Distance

The Mahalanobis distance \( d(x,y) \) between \( n \)-dimensional points \( x \) and \( y \), with respect to a given \( n \)-by-\( n \) covariance matrix \( S \), is

\[
d(x, y) = \sqrt{(x - y)^T S^{-1} (x - y)}.
\]

CompactClassificationDiscriminant | fitcdiscr | gmdistribution | mahal

Topics
“Discriminant Analysis Classification” on page 20-2
mahal

Mahalanobis distance to Gaussian mixture component

Syntax

d2 = mahal(gm,X)

Description

d2 = mahal(gm,X) returns the squared Mahalanobis distance of each observation in X to each Gaussian mixture component in gm.

Examples

Measure Mahalanobis Distance

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the mvnrnd function. Fit a Gaussian mixture model (GMM) to the generated data by using the fitgmdist function, and then compute Mahalanobis distances between the generated data and the mixture components of the fitted GMM.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```matlab
rng('default') % For reproducibility
mu1 = [1 2]; % Mean of the 1st component
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5]; % Mean of the 2nd component
sigma2 = [1 0; 0 1]; % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

gm = fitgmdist(X,2)
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:   -2.9617   -4.9727

Component 2:
Mixing proportion: 0.500000
Mean:    0.9539    2.0261

fitgmdist fits a GMM to X using two mixture components. The means of Component 1 and Component 2 are [-2.9617,-4.9727] and [0.9539,2.0261], which are close to mu2 and mu1, respectively.

Compute the Mahalanobis distance of each point in X to each component of gm.

d2 = mahal(gm,X);

Plot X by using scatter and use marker color to visualize the Mahalanobis distance to Component 1.

scatter(X(:,1),X(:,2),10,d2(:,1),'.') % Scatter plot with points of size 10
c = colorbar;
ylabel(c,'Mahalanobis Distance to Component 1')
Input Arguments

\( \text{gm} \) — Gaussian mixture distribution

\text{gmdistribution} \ object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a \text{gmdistribution} \ object.

You can create a \text{gmdistribution} \ object using \text{gmdistribution} \ or \text{fitgmdist}. Use the \text{gmdistribution} \ function to create a \text{gmdistribution} \ object by specifying the
distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

**X — Data**  
*n*-by-*m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

If a row of *X* contains NaNs, then `mahal` excludes the row from the computation. The corresponding value in *d2* is NaN.

Data Types: `single` | `double`

**Output Arguments**

**d2 — Squared Mahalanobis distance**  
*n*-by-*k* numeric matrix

Squared Mahalanobis distance of each observation in *X* to each Gaussian mixture component in *gm*, returned as an *n*-by-*k* numeric matrix, where *n* is the number of observations in *X* and *k* is the number of mixture components in *gm*.

*d2(i,j)* is the squared distance of observation *i* to the *j*th Gaussian mixture component.

**Definitions**

**Mahalanobis Distance**

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector *x* to a distribution with mean *μ* and covariance *Σ* is

\[ d = \sqrt{(x - \mu)\Sigma^{-1}(x - \mu)'} \]

This distance represents how far *x* is from the mean in number of standard deviations.
mahal returns the squared Mahalanobis distance $d^2$ from an observation in $X$ to a mixture component in $gm$.

**Introduced in R2007b**
maineffectsplot

Main effects plot for grouped data

Syntax

maineffectsplot(Y,GROUP)
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)  
[figh,AXESH] = maineffectsplot(...)

Description

maineffectsplot(Y,GROUP) displays main effects plots for the group means of matrix Y with groups defined by entries in GROUP, which can be a cell array or a matrix. Y is a numeric matrix or vector. If Y is a matrix, the rows represent different observations and the columns represent replications of each observation. If GROUP is a cell array, then each cell of GROUP must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If GROUP is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as Y. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of Y as a function of one grouping variable.

maineffectsplot(Y,GROUP,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:

• 'varnames' — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ...

• 'statistic' — Values that indicate whether the group mean or the group standard deviation should be plotted. Use 'mean' or 'std'. The default is 'mean'. If the value is 'std', Y is required to have multiple columns.

• 'parent' — A handle to the figure window for the plots. The default is the current figure window.
[figh,AXESH] = maineffectsplot(...) returns the handle figh to the figure window and an array of handles AXESH to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

load carsmall;

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

maineffectsplot(Weight,{Model_Year,Cylinders}, ...
    'varnames',{'Model Year','# of Cylinders'})

“Grouping Variables” on page 2-57

Introduced in R2006b
ClassificationDiscriminant.make

Class: ClassificationDiscriminant

Construct discriminant analysis classifier from parameters (to be removed)

Note ClassificationDiscriminant.make will be removed in a future release. Use makecdiscr instead.

Syntax

cobj = ClassificationDiscriminant.make(Mu,Sigma)
cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value)

Description

cobj = ClassificationDiscriminant.make(Mu,Sigma) constructs a compact discriminant analysis classifier from the class means Mu and covariance matrix Sigma.

cobj = ClassificationDiscriminant.make(Mu,Sigma,Name,Value) constructs a compact classifier with additional options specified by one or more Name,Value pair arguments.

Input Arguments

Mu — Class means
matrix of scalar values

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

Data Types: single | double
**Sigma — Within-class covariance**

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, Sigma is a symmetric, positive semidefinite matrix of size $p$-by-$p$, where $p$ is the number of predictors.
- For a quadratic discriminant, Sigma is an array of size $p$-by-$p$-by-$K$, where $K$ is the number of classes. For each $i$, $\Sigma(:,:,i)$ is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**ClassNames — Class names**

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

`ClassNames` names the classes, as ordered in `Mu`.

Default is 1:$K$, where $K$ is the number of classes (the number of rows of `Mu`).

Data Types: `single` | `double` | `logical` | `char` | `cell`

**Cost — Cost of misclassification**

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where $\text{Cost}(i,j)$ is the cost of classifying a point into class $j$ if its true class is $i$. Alternatively, Cost can be a structure $S$ having two fields: $S.ClassNames$
containing the group names as a variable of the same type as \( y \), and \( S.ClassificationCosts \) containing the cost matrix.

The default is \( \text{Cost}(i,j)=1 \) if \( i \neq j \), and \( \text{Cost}(i,j)=0 \) if \( i=j \).

Data Types: `single` | `double` | `struct`

**PredictorNames — Predictor variable names**

`{'X1','X2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in \( X \).

Data Types: `cell`

**Prior — Prior probabilities**

`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'uniform'`, a character vector meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure \( S \) with two fields:
  - \( S.ClassNames \) containing the class names as a variable of the same type as \( ClassNames \).
  - \( S.ClassProbs \) containing a vector of corresponding probabilities.

Data Types: `single` | `double` | `struct`

**ResponseName — Response variable name**

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable \( y \).

Example: `'ResponseName','Response'`

Data Types: `char`
**Output Arguments**

cobj — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

**Examples**

**Construct a Compact Linear Discriminant Analysis Classifier**

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```matlab
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
    classreg.learning.classif.CompactClassificationDiscriminant
    PredictorNames: {'x1'  'x2'  'x3'  'x4'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    DiscrimType: 'linear'
    Mu: [3x4 double]
```
Coeffs: [3x3 struct]

Properties, Methods

Topics
“Discriminant Analysis Classification” on page 20-2
makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

\[ \text{cobj} = \text{makecdiscr}(\text{Mu}, \text{Sigma}) \]
\[ \text{cobj} = \text{makecdiscr}(\text{Mu}, \text{Sigma}, \text{Name}, \text{Value}) \]

Description

\[ \text{cobj} = \text{makecdiscr}(\text{Mu}, \text{Sigma}) \] constructs a compact discriminant analysis classifier from the class means \( \text{Mu} \) and covariance matrix \( \text{Sigma} \).

\[ \text{cobj} = \text{makecdiscr}(\text{Mu}, \text{Sigma}, \text{Name}, \text{Value}) \] constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

\[ \text{load fisheriris} \]
\[ \text{mu}(1,:) = \text{mean}(	ext{meas}(1:50,:)); \]
\[ \text{mu}(2,:) = \text{mean}(	ext{meas}(51:100,:)); \]
\[ \text{mu}(3,:) = \text{mean}(	ext{meas}(101:150,:)); \]
\[ \text{mm1} = \text{repmat}(	ext{mu}(1,:),50,1); \]
\[ \text{mm2} = \text{repmat}(	ext{mu}(2,:),50,1); \]
\[ \text{mm3} = \text{repmat}(	ext{mu}(3,:),50,1); \]
\[ \text{cc} = \text{meas}; \]
\[ \text{cc}(1:50,:) = \text{cc}(1:50,:) - \text{mm1}; \]
cc(51:100,:) = cc(51:100,:) - mm2;
c(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

    cpct =
    classreg.learning.classif.CompactClassificationDiscriminant
        PredictorNames: {'x1' 'x2' 'x3' 'x4'}
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        DiscrimType: 'linear'
        Mu: [3x4 double]
        Coeffs: [3x3 struct]

Properties, Methods

Input Arguments

Mu — Class means
matrix of scalar values

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

Data Types: single | double

Sigma — Within-class covariance
matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, Sigma is a symmetric, positive semidefinite matrix of size p-by-p, where p is the number of predictors.
• For a quadratic discriminant, \( \Sigma \) is an array of size \( p \times p \times K \), where \( K \) is the number of classes. For each \( i \), \( \Sigma(:,:,i) \) is a symmetric, positive semidefinite matrix.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as

\[ \text{Name1,Value1,...,NameN,ValueN} \]

Example: 'ClassNames',{'setosa' 'versicolor' 'virginica'} specifies a discriminant analysis classifier that uses 'setosa', 'versicolor', and 'virginica' as the grouping variables.

**ClassNames — Class names**

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class names as ordered in Mu, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

The default is \( 1:K \), where \( K \) is the number of classes (the number of rows of Mu).

Example: 'ClassNames',{'setosa' 'versicolor' 'virginica'}

Data Types: single | double | logical | char | string | cell

**Cost — Cost of misclassification**

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \). Alternatively, \( \text{Cost} \) can be a structure \( S \) having two fields: \( S.\text{ClassNames} \) containing the group names as a variable of the same type as \( y \), and \( S.\text{ClassificationCosts} \) containing the cost matrix.

The default is \( \text{Cost}(i,j)=1 \) if \( i\neq j \), and \( \text{Cost}(i,j)=0 \) if \( i=j \).
Data Types: single | double | struct

**PredictorNames — Predictor variable names**

{ 'X1', 'X2', ... } (default) | string array | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X.

Data Types: string | cell

Prior — Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'uniform', meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as ClassNames
  - S.ClassProbs containing a vector of corresponding probabilities

Data Types: char | string | single | double | struct

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar containing the name of the response variable y.

Example: 'ResponseName','Response'

Data Types: char | string

**Output Arguments**

cobj — Discriminant analysis classifier
discriminant analysis classifier object
Discriminant analysis classifier, returned as a discriminant analysis classifier object of class CompactClassificationDiscriminant. You can use the predict method to predict classification labels for new data.

**Tips**

- You can change the discriminant type using dot notation after constructing cobj:

  ```
  cobj.DiscrimType = 'discrimType'
  ```

  where `discrimType` is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.

**Topics**

“Discriminant Analysis Classification” on page 20-2

**Introduced in R2014a**
makedist

Create probability distribution object

Syntax

pd = makedist(distname)
pd = makedist(distname,Name,Value)
list = makedist
makedist -reset

Description

pd = makedist(distname) creates a probability distribution object for the distribution distname, using the default parameter values.

pd = makedist(distname,Name,Value) creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

list = makedist returns a cell array list containing a list of the probability distributions that makedist can create.

makedist -reset resets the list of distributions by searching the path for files contained in a package named prob and implementing classes derived from ProbabilityDistribution.

Examples

Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

pd = makedist('Normal')
\begin{verbatim}

pd =
    NormalDistribution

    Normal distribution
    mu = 0
    sigma = 1

Compute the interquartile range of the distribution.

r = iqr(pd)

r = 1.3490

\textbf{Create a Gamma Distribution Object}

Create a gamma distribution object using the default parameter values.

pd = makedist('Gamma')

pd =
    GammaDistribution

    Gamma distribution
    a = 1
    b = 1

Compute the mean of the gamma distribution.

mean = mean(pd)

mean = 1

\textbf{Specify Parameters for a Normal Distribution Object}

Create a normal distribution object with parameter values \( \mu = 75 \) and \( \sigma = 10 \).

pd = makedist('Normal','mu',75,'sigma',10)
\end{verbatim}
pd = NormalDistribution

Normal distribution
    mu = 75
    sigma = 10

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value \( a = 3 \) and the default value \( b = 1 \).

\[
pd = \text{makedist}('\text{Gamma}', 'a', 3)
\]

\[
pd = \text{GammaDistribution}
\]

Gamma distribution
    a = 3
    b = 1

Input Arguments

distname — Distribution name
character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by distname determines the type of the returned probability distribution object.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: makedist('Normal','mu',10) specifies a normal distribution with parameter mu equal to 10, and parameter sigma equal to the default value of 1.

**Beta Distribution**

*a* — **First shape parameter**

1 (default) | positive scalar value

Example: 'a',3

Data Types: single | double

*b* — **Second shape parameter**

1 (default) | positive scalar value

Example: 'b',5

Data Types: single | double

**Binomial Distribution**

*N* — **Number of trials**

1 (default) | positive integer value

Example: 'N',25
Data Types: single | double

\( p \) — Probability of success
\( 0.5 \) (default) | scalar value in the range \([0,1]\)
Example: 'p', 0.25
Data Types: single | double

**Birnbaum-Saunders Distribution**

\( \beta \) — Scale parameter
\( 1 \) (default) | positive scalar value
Example: 'beta', 2
Data Types: single | double

\( \gamma \) — Shape parameter
\( 1 \) (default) | nonnegative scalar value
Example: 'gamma', 0
Data Types: single | double

**Burr Distribution**

\( \alpha \) — Scale parameter
\( 1 \) (default) | positive scalar value
Example: 'alpha', 2
Data Types: single | double

\( c \) — First shape parameter
\( 1 \) (default) | positive scalar value
Example: 'c', 2
Data Types: single | double

\( k \) — Second shape parameter
\( 1 \) (default) | positive scalar value
Example: 'k', 5
Data Types: single | double
Exponential Distribution

\( \mu \) — Mean parameter
1 (default) | positive scalar value
Example: 'mu',5
Data Types: single | double

Extreme Value Distribution

\( \mu \) — Location parameter
0 (default) | scalar value
Example: 'mu',-2
Data Types: single | double

\( \sigma \) — Scale parameter
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double

Gamma Distribution

\( a \) — Shape parameter
1 (default) | positive scalar value
Example: 'a',2
Data Types: single | double

\( b \) — Scale parameter
1 (default) | nonnegative scalar value
Example: 'b',0
Data Types: single | double

Generalized Extreme Value Distribution

\( k \) — Shape parameter
0 (default) | scalar value
Example: 'k',0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma', 2
Data Types: single | double

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu', 1
Data Types: single | double

**Generalized Pareto Distribution**

**k — Shape parameter**
1 (default) | scalar value
Example: 'k', 0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma', 2
Data Types: single | double

**theta — Location parameter**
1 (default) | scalar value
Example: 'theta', 2
Data Types: single | double

**Half-Normal Distribution**

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu', 1
Data Types: single | double
**sigma — Shape parameter**
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double

**Inverse Gaussian Distribution**

**mu — Scale parameter**
1 (default) | positive scalar value
Example: 'mu',2
Data Types: single | double

**lambda — Shape parameter**
1 (default) | positive scalar value
Example: 'lambda',4
Data Types: single | double

**Logistic Distribution**

**mu — Mean**
0 (default) | scalar value
Example: 'mu',2
Data Types: single | double

**sigma — Scale parameter**
1 (default) | nonnegative scalar value
Example: 'sigma',4
Data Types: single | double

**Loglogistic Distribution**

**mu — Mean of logarithmic values**
0 (default) | scalar value
Example: 'mu',2
Data Types: single | double
**sigma — Scale parameter of logarithmic values**
1 (default) | nonnegative scalar value
Example: 'sigma', 4
Data Types: single | double

**Lognormal Distribution**

**mu — Mean of logarithmic values**
0 (default) | scalar value
Example: 'mu', 2
Data Types: single | double

**sigma — Standard deviation of logarithmic values**
1 (default) | nonnegative scalar value
Example: 'sigma', 2
Data Types: single | double

**Multinomial Distribution**

**probabilities — Outcome probabilities**
[0.500 0.500] (default) | vector of scalar values in the range [0, 1]

Outcome probabilities, specified as a vector of scalar values in the range [0, 1]. The probabilities sum to 1 and correspond to outcomes [1, 2, ..., k], where k is the number of elements in the probabilities vector.
Example: 'probabilities', [0.1 0.2 0.5 0.2] gives the probabilities that the outcome is 1, 2, 3, or 4, respectively.
Data Types: single | double

**Nakagami Distribution**

**mu — Shape parameter**
1 (default) | positive scalar value
Example: 'mu', 5
Data Types: single | double
**omega — Scale parameter**
1 (default) | positive scalar value
Example: 'omega',5
Data Types: single | double

**Negative Binomial Distribution**

**R — Number of successes**
1 (default) | positive scalar value
Example: 'R',5
Data Types: single | double

**p — Probability of success**
0.5 (default) | scalar value in the range (0,1]
Example: 'p',0.1
Data Types: single | double

**Normal Distribution**

**mu — Mean**
0 (default) | scalar value
Example: 'mu',2
Data Types: single | double

**sigma — Standard deviation**
1 (default) | nonnegative scalar value
Example: 'sigma',2
Data Types: single | double

**Piecewise Linear Distribution**

**x — Data values**
1 (default) | monotonically increasing vector of scalar values
Example: 'x',[1 2 3]
Data Types: single | double
**Fx — cdf values**
1 (default) | monotonically increasing vector of scalar values that start at 0 and end at 1
Example: 'Fx', [0.2 0.5 1]
Data Types: single | double

**Poisson Distribution**

**lambda — Mean**
1 (default) | nonnegative scalar value
Example: 'lambda', 5
Data Types: single | double

**Rayleigh Distribution**

**b — Defining parameter**
1 (default) | positive scalar value
Example: 'b', 3
Data Types: single | double

**Rician Distribution**

**s — Noncentrality parameter**
1 (default) | nonnegative scalar value
Example: 's', 0
Data Types: single | double

**sigma — Scale parameter**
1 (default) | positive scalar value
Example: 'sigma', 2
Data Types: single | double

**Stable Distribution**

**alpha — First shape parameter**
2 (default) | scalar value in the range (0,2]
Example: 'alpha', 1
Data Types: single | double

**beta — Second shape parameter**
0 (default) | scalar value in the range [-1,1]
Example: 'beta', 0.5
Data Types: single | double

**gam — Scale parameter**
1 (default) | scalar value in the range (0,∞)
Example: 'gam', 2
Data Types: single | double

**delta — Location parameter**
0 (default) | scalar value
Example: 'delta', 5
Data Types: single | double

**t Location-Scale Distribution**

**mu — Location parameter**
0 (default) | scalar value
Example: 'mu', -2
Data Types: single | double

**sigma — Scale parameter**
1 (default) | positive scalar value
Example: 'sigma', 2
Data Types: single | double

**nu — Degrees of freedom**
5 (default) | positive scalar value
Example: 'nu', 20
Data Types: single | double

**Triangular Distribution**
**a — Lower limit**
0 (default) | scalar value
Example: 'a', -2
Data Types: single | double

**b — Peak location**
0.5 (default) | scalar value greater than or equal to a
Example: 'b', 1
Data Types: single | double

**c — Upper limit**
1 (default) | scalar value greater than or equal to b
Example: 'c', 5
Data Types: single | double

**Uniform Distribution**

**lower — Lower parameter**
0 (default) | scalar value
Example: 'lower', -4
Data Types: single | double

**upper — Upper parameter**
1 (default) | scalar value greater than lower
Example: 'upper', 2
Data Types: single | double

**Weibull Distribution**

**a — Scale parameter**
1 (default) | positive scalar value
Example: 'a', 2
Data Types: single | double

**b — Shape parameter**
1 (default) | positive scalar value
Example: 'b', 5
Data Types: single | double

Output Arguments

pd — Probability distribution
probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by distname.

list — List of probability distributions
cell array of character vectors

List of probability distributions that makedist can create, returned as a cell array of character vectors.

Alternative Functionality

App

The Distribution Fitter app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using distributionFitter, or click Distribution Fitter on the Apps tab.

Topics
“Working with Probability Distributions” on page 5-3
“Supported Distributions” on page 5-16
Introduced in R2013a
manova

Class: RepeatedMeasuresModel

Multivariate analysis of variance

Syntax

manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova(__)

Description

manovatbl = manova(rm) returns the results of multivariate analysis of variance (manova) for the repeated measures model rm.

manovatbl = manova(rm,Name,Value) also returns manova results with additional options, specified by one or more Name,Value pair arguments.

[manovatbl,A,C,D] = manova(__) also returns arrays A, C, and D for the hypotheses tests of the form A*B*C = D, where D is zero.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**WithinModel** — Model specifying within-subjects hypothesis test
'veparateameans' (default) | model specification using formula | r-by-nc matrix

Model specifying the within-subjects hypothesis test, specified as one of the following:

- 'separateameans' — Compute a separate mean for each group, and test for equality among the means.

- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, tbl contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.

- An r-by-nc matrix, C, specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model rm, then the output tbl contains a separate manova for each column of Y*C.

Example: 'WithinModel','separateameans'
Data Types: single | double | char | string

**By** — Single between-subjects factor
character vector | string scalar

Single between-subjects factor, specified as the comma-separated pair consisting of 'By' and a character vector or string scalar. manova performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, Drug, then you can specify that factor to perform manova as follows.

Example: 'By','Drug'
Data Types: char | string

**Output Arguments**

**manovatbl** — Results of multivariate analysis of variance

table
Results of multivariate analysis of variance for the repeated measures model rm, returned as a table.

manova uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks’ Lambda
- Pillai’s trace
- Hotelling-Lawley trace
- Roy’s maximum root statistic

For details, see “Multivariate Analysis of Variance for Repeated Measures” on page 9-84.

manova returns the results for these tests for each group. manovatbl contains the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Within</td>
<td>Within-subject terms</td>
</tr>
<tr>
<td>Between</td>
<td>Between-subject terms</td>

</tr>
<tr>
<td>pValue</td>
<td>$p$-value for the corresponding $F$-statistic value</td>
</tr>
</tbody>
</table>

Data Types: table

### A — Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of B (within time hypothesis). If manovatbl contains multiple hypothesis tests, A might be a cell array.

Data Types: single | double | cell
C — Specification based on within-subjects model
matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of B (between time hypotheses). If manovatbl contains multiple hypothesis tests, C might be a cell array.

Data Types: single | double | cell

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Perform Multivariate Analysis of Variance

Load the sample data.

load fisheriris

The column vector species consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...'
'VariableNames',
'species','meas1','meas2','meas3','meas4');

Meas = table([1 2 3 4],'
'VariableNames',
'Measurements');

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);

Perform multivariate analysis of variance.

manova(rm)

ans=8x9 table
  Within    Between    Statistic    Value    F    RSquare    df1    df2    pValue
### Return Arrays of the Hypothesis Test

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.
Store the data in a table array.

t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4), ...
'VariableNames', {'species', 'meas1', 'meas2', 'meas3', 'meas4'});
Meas = dataset([1 2 3 4], 'VarNames', {'Measurements'});

Fit a repeated measures model where the measurements are the responses and the
species is the predictor variable.

rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);

Perform multivariate analysis of variance. Also return the arrays for constructing the
hypothesis test.

[manovatbl, A, C, D] = manova(rm)

manovatbl = 8×9 table

Topics
“Model Specification for Repeated Measures Models” on page 9-78
“Multivariate Analysis of Variance for Repeated Measures” on page 9-84
**manova1**

One-way multivariate analysis of variance

**Syntax**

```markdown
d = manova1(X,group)
d = manova1(X,group,alpha)
d,p] = manova1(...)
d,p,stats] = manova1(...)
```

**Description**

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an `m`-by-`n` matrix of data values, and each row is a vector of measurements on `n` variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, character array, string array, or cell array of character vectors. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same `n`-dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in `n`-dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having `p > alpha`, where `p` is a `p`-value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of `p`-values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.
If the \( i \)th \( p \)-value is near zero, this casts doubt on the hypothesis that the group means lie on a space of \( i-1 \) dimensions. The choice of a critical \( p \)-value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument \( \alpha \)pha. It is common to declare a result significant if the \( p \)-value is less than 0.05 or 0.01.

\[[d,p,stats] = \text{manova1}(\ldots)\] also returns \( \text{stats} \), a structure containing additional MANOVA results. The structure contains the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>( W )</td>
<td>Within-groups sum of squares and cross-products matrix</td>
</tr>
<tr>
<td>( B )</td>
<td>Between-groups sum of squares and cross-products matrix</td>
</tr>
<tr>
<td>( T )</td>
<td>Total sum of squares and cross-products matrix</td>
</tr>
<tr>
<td>( \text{dfW} )</td>
<td>Degrees of freedom for ( W )</td>
</tr>
<tr>
<td>( \text{dfB} )</td>
<td>Degrees of freedom for ( B )</td>
</tr>
<tr>
<td>( \text{dfT} )</td>
<td>Degrees of freedom for ( T )</td>
</tr>
<tr>
<td>( \lambda )</td>
<td>Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.</td>
</tr>
<tr>
<td>( \text{chisq} )</td>
<td>Transformation of ( \lambda ) to an approximate chi-square distribution</td>
</tr>
<tr>
<td>( \text{chisqdf} )</td>
<td>Degrees of freedom for ( \text{chisq} )</td>
</tr>
<tr>
<td>( \text{eigenval} )</td>
<td>Eigenvalues of ( W^{-1}B )</td>
</tr>
<tr>
<td>( \text{eigenvect} )</td>
<td>Eigenvectors of ( W^{-1}B ); these are the coefficients for the canonical variables ( C ), and they are scaled so the within-group variance of the canonical variables is 1</td>
</tr>
<tr>
<td>( \text{canon} )</td>
<td>Canonical variables ( C ), equal to ( XC*eigenvect ), where ( XC ) is ( X ) with columns centered by subtracting their means</td>
</tr>
<tr>
<td>( \text{mdist} )</td>
<td>A vector of Mahalanobis distances from each point to the mean of its group</td>
</tr>
<tr>
<td>( \text{gmdist} )</td>
<td>A matrix of Mahalanobis distances between each pair of group means</td>
</tr>
</tbody>
</table>

The canonical variables \( C \) are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, \( C(:,1) \) is the linear combination of the \( X \) columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant \( F \) statistic in
a one-way analysis of variance. \( C(:,2) \) has the maximum separation subject to it being orthogonal to \( C(:,1) \), and so on.

You may find it useful to use the outputs from \texttt{manova1} along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using \texttt{gplotmatrix}. You can use \texttt{gscatter} to visualize the group separation using the first two canonical variables. You can use \texttt{manovacluster} to graph a dendrogram showing the clusters among the group means.

**Assumptions**

The MANOVA test makes the following assumptions about the data in \( X \):

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

**Examples**

you can use \texttt{manova1} to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```matlab
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
    Origin)
```

```
d =  
    3
p =  
    0
    0.0000
    0.0075
    0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. \texttt{manova1} shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

Topics
“Grouping Variables” on page 2-57

Introduced before R2006a
**manovacluster**

Dendrogram of group mean clusters following MANOVA

**Syntax**

```matlab
manovacluster(stats)
manovacluster(stats,method)
H = manovacluster(stats,method)
```

**Description**

`manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be one of these values, which identify the methods used to create the cluster hierarchy. (See `linkage` for additional information.)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'single'</td>
<td>Shortest distance (default)</td>
</tr>
<tr>
<td>'complete'</td>
<td>Largest distance</td>
</tr>
<tr>
<td>'average'</td>
<td>Average distance</td>
</tr>
<tr>
<td>'centroid'</td>
<td>Centroid distance</td>
</tr>
<tr>
<td>'ward'</td>
<td>Incremental sum of squares</td>
</tr>
</tbody>
</table>

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.
Examples

Dendrogram of Group Means After MANOVA

Load the sample data.
load carbig
Define the variable matrix.
X = [MPG Acceleration Weight Displacement];
Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight, and Displacement grouped by Origin.
[d,p,stats] = manova1(X-Origin);
Create a dendrogram plot of the group means.
manovacluster(stats)

Introduced before R2006a
margin

Margin of k-nearest neighbor classifier

Syntax

m = margin(mdl,tbl,ResponseVarName)
m = margin(mdl,tbl,Y)
m = margin(mdl,X,Y)

Description

m = margin(mdl,tbl,ResponseVarName) returns the classification margins on page 32-3928 for mdl with data tbl and classification tbl.ResponseVarName. If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName.

m is returned as a numeric vector of length size(tbl,1). Each entry in m represents the margin for the corresponding row of tbl and the corresponding true class label in tbl.ResponseVarName, computed using mdl.

m = margin(mdl,tbl,Y) returns the classification margins for mdl with data tbl and classification Y.

m = margin(mdl,X,Y) returns the classification margins for mdl with data X and classification Y. m is returned as a numeric vector of length size(X,1).

Examples

Margin Calculation

Create a k-nearest neighbor classifier for the Fisher iris data, where \( k = 5 \).

Load the Fisher iris data set.
load fisheriris

Create a classifier for five nearest neighbors.

mdl = fitcknn(meas,species,'NumNeighbors',5);

Examine the margin of the classifier for a mean observation classified as 'versicolor'.

X = mean(meas);
Y = {'versicolor'};
m = margin(mdl,X,Y)

m = 1

All five nearest neighbors classify as 'versicolor'.

**Input Arguments**

mdl — *k*-nearest neighbor classifier model
ClassificationKNN object

*k*-nearest neighbor classifier model, specified as a ClassificationKNN object.

**tbl** — Sample data
table

Sample data used to train the model, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName or Y.

If you train mdl using sample data contained in a table, then the input data for margin must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in tbl
Response variable name, specified as the name of a variable in tbl. If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable is stored as tbl.response, then specify it as 'response'. Otherwise, the software treats all columns of tbl, including tbl.response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of X represents one observation, and each column represents one variable.

Data Types: single | double

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

Data Types: categorical | char | string | logical | single | double | cell

Definitions

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.
Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-4943.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

“Classification Using Nearest Neighbors” on page 18-16

Introduced in R2012a
margin

Class: ClassificationLinear

Classification margins for linear classification models

Syntax

m = margin(Mdl,X,Y)
m = margin(___,Name,Value)

Description

m = margin(Mdl,X,Y) returns the classification margins on page 32-3940 for the binary, linear classification model Mdl using predictor data in X and corresponding class labels in Y. m contains classification margins for each regularization strength in Mdl.

m = margin(___,Name,Value) uses any of the previous syntaxes and additional options specified by one or more Name,Value pair arguments. For example, you can specify that columns in the predictor data correspond to observations.

Input Arguments

Mdl — Binary, linear classification model
ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using fitclinear.

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix. This orientation of X indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.
**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of $Y$ and the number of observations in $X$ must be equal.

Data Types: single | double

$Y$ — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of $Y$ must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in $Y$ must be a subset of `Mdl.ClassNames`.
- If $Y$ is a character array, then each element must correspond to one row of the array.
- The length of $Y$ and the number of observations in $X$ must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**ObservationsIn** — Predictor data observation dimension
'srows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in optimization-execution time.
Output Arguments

**m — Classification margins**

numeric column vector | numeric matrix

Classification margins on page 32-3940, returned as a numeric column vector or matrix.

*m* is \( n \)-by-\( L \), where \( n \) is the number of observations in `X` and \( L \) is the number of regularization strengths in `Mdl` (that is, `numel(Mdl.Lambda)`).

\( m(i,j) \) is the classification margin of observation \( i \) using the trained linear classification model that has regularization strength \( Mdl.Lambda(j) \).

Examples

Estimate Test-Sample Margins

Load the NLP data set.

```matlab
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA.

```matlab
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};
```
CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample margins.

```matlab
mTrain = margin(CMdl,X(trainIdx,:),Ystats(trainIdx));
mTest = margin(CMdl,X(testIdx,:),Ystats(testIdx));
```

Because there is one regularization strength in `CMdl`, `mTrain` and `mTest` are column vectors with lengths equal to the number of training and test observations, respectively.

Plot both sets of margins using box plots.

```matlab
figure;
boxplot([mTrain; mTest],[zeros(size(mTrain,1),1); ones(size(mTest,1),1)], ...    'Labels',{'Training set','Test set'});
h = gca;
h.YLim = [-5 60];
title 'Training- and Test-Set Margins'
```
The distributions of the margins between the training and test sets appear similar.

**Feature Selection Using Test-Sample Margins**

One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins” on page 32-3932.
load nlpdata
Ystats = Y == 'stats';
X = X';
rng(1); % For reproducibility

Create a data partition which holds out 30% of the observations for testing.

Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition); % Test-set indices
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
Partition

Partition is a cvpartition object that defines the data set partition.

Randomly choose 10% of the predictor variables.

p = size(X,1); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));

Train two binary, linear classification models: one that uses the all of the predictors and one that uses the random 10%. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

CVMdl = fitclinear(X,Ystats,'CVPartition',Partition,'Solver','sparsa',...
'ObservationsIn','columns');
PCVMdl = fitclinear(X(idxPart,:),Ystats,'CVPartition',Partition,'Solver','sparsa',...
'ObservationsIn','columns');

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Extract the trained ClassificationLinear models from the cross-validated models.

CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};

Estimate the test sample margins for each classifier. Plot the distribution of the margins sets using box plots.

fullMargins = margin(CMdl,XTest,YTest,'ObservationsIn','columns');
partMargins = margin(PCMdl,XTest(idxPart,:),YTest,...
'ObservationsIn','columns');

figure;
boxplot([fullMargins partMargins], 'Labels',...;
{'All Predictors','10% of the Predictors'});
h = gca;
h.YLim = [-20 60];
title('Test-Sample Margins')

The margin distribution of CMdl is situated higher than the margin distribution of PCMdl.

**Find Good Lasso Penalty Using Margins**

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of test-sample margins.
Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins” on page 32-3932.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';

Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^1$.

```matlab
Lambda = logspace(-8,1,11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e^{-8}$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','CVPartition',Partition,'Learner','logistic','Solver','sparsa','Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

Extract the trained linear classification model.

```matlab
Mdl = CVMdl.Trained{1}
Mdl = 
    ClassificationLinear
```
Mdl is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample margins.

```matlab
m = margin(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
size(m)
ans = 1x2
        9471     11
```

Because there are 11 regularization strengths, `m` has 11 columns.

Plot the test-sample margins for each regularization strength. Because logistic regression scores are in [0,1], margins are in [-1,1]. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```matlab
figure;
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```
Several values of \texttt{Lambda} yield margin distributions that are compacted near 10000. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the margin distributions start decreasing.

\texttt{LambdaFinal = Lambda(5)};

Train a linear classification model using the entire data set and specify the desired regularization strength.
Md1Final = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);

To estimate labels for new observations, pass Md1Final and the new data to predict.

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation \( x \), a row vector, into the positive class is defined by

\[ f_j(x) = x\beta_j + b_j. \]

For the model with regularization strength \( j \), \( \beta_j \) is the estimated column vector of coefficients (the model property Beta(:,j)) and \( b_j \) is the estimated, scalar bias (the model property Bias(j)).
The raw classification score for classifying \( x \) into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**See Also**
ClassificationLinear | edge | fitlinear | predict

*Introduced in R2016a*
**margin**

Classification margins

**Syntax**

\[ m = \text{margin}(\text{obj}, X, Y) \]

**Description**

\[ m = \text{margin}(\text{obj}, X, Y) \] returns the classification margins for the matrix of predictors \( X \) and class labels \( Y \). For the definition, see “Definitions” on page 32-3944.

**Input Arguments**

**obj**

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

**X**

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in \( X \) must equal the number of predictors in \( \text{obj} \).

**Y**

Class labels, with the same data type as exists in \( \text{obj} \). The number of elements of \( Y \) must equal the number of rows of \( X \).
Output Arguments

m

Numeric column vector of length \text{size}(X,1). Each entry in \textit{m} represents the margin for the corresponding rows of \text{X} and (true class) \text{Y}, computed using \textit{obj}.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

\begin{verbatim}
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)
\end{verbatim}

\begin{verbatim}
ans =
0.6551
0.4838
0.6551
-0.5127
0.5659
0.4611
0.4949
0.1024
0.2787
-0.1439
-0.4444
\end{verbatim}

The classifier trained on all the data is better:

\begin{verbatim}
obj = fitcdiscr(meas,species);
M = margin(obj,meas,species);
M(end-10:end)
\end{verbatim}

\begin{verbatim}
ans =
0.9983
1.0000
0.9991
0.9978
\end{verbatim}
Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-7.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

margin

Classification margins for multiclass, error-correcting output codes model

Syntax

m = margin(Mdl,tbl,ResponseVarName)
m = margin(Mdl,tbl,Y)
m = margin(Mdl,X,Y)
m = margin(Mdl,___,Name,Value)

Description

m = margin(Mdl,tbl,ResponseVarName) returns the classification margins on page 32-3957 (m) for the trained, multiclass, error-correcting output code (ECOC) model Mdl using the predictor data in table tbl and the class labels in tbl.ResponseVarName. Each row of tbl and ResponseVarName is an observation.

m = margin(Mdl,tbl,Y) returns the classification margins for the trained classifier Mdl using the predictor data in table tbl and the class labels in vector Y. Each row of tbl and Y is an observation.

m = margin(Mdl,X,Y) returns the classification margins for the trained classifier Mdl using the predictor data X and class labels Y. Each row of X and Y is an observation.

m = margin(Mdl,___,Name,Value) returns the classification margins with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify a decoding scheme, binary learner loss function, or verbosity level.

Input Arguments

Mdl — Full or compact, multiclass ECOC model
ClassificationECOC model object | CompactClassificationECOC model object
Full or compact, multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

**tbl — Sample data**

`table`

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a table, then the input data for this method must also be in a table.

**Note** If `Mdl.BinaryLearners` contains linear or kernel classification models (that is, `ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a table. Instead, pass a matrix (`X`) and class labels (`Y`).

Data Types: `table`

**ResponseVarName — Response variable name**

`name of a variable in tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

**X — Predictor data**

`numeric matrix`
Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables composing the columns of X should be the same as the variables that trained the Mdl classifier.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,..., NameN, ValueN.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j,s_j) \) is the binary loss formula.
The software normalizes binary losses such that the loss is 0.5 when \( y_j = 0 \). Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```matlab
bLoss = customFunction(M,s)
```

where:

- \( M \) is the \( K \)-by-\( L \) coding matrix stored in `Mdl.CodingMatrix`.
- \( s \) is the 1-by-\( L \) row vector of classification scores.
- \( bLoss \) is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- \( K \) is the number of classes.
- \( L \) is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 32-4978.

By default, if all binary learners are:

- SVMs or either linear or kernel classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by AdaboostM1 or GentleBoost, then BinaryLoss is 'exponential'
- Ensembles trained by LogitBoost, then BinaryLoss is 'binodeviance'
- Linear or kernel classification models of logistic regression learners, or you specify to predict class posterior probabilities (that is, set 'FitPosterior',1 in fitcecoc), then BinaryLoss is 'quadratic'

Otherwise, the default value for 'BinaryLoss' is 'hamming'. To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss','binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-4986.

Example: 'Decoding','lossbased'

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. Mdl.BinaryLearners must contain linear classification models.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', you can experience a significant reduction in execution time.

Options — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.
To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel',1).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

**Output Arguments**

**m — Classification margins**

numeric column vector | numeric matrix

Classification margins on page 32-3957, returned as a numeric column vector.

m has the same length as Y. The software estimates each entry of m using the trained ECOC model Mdl, the corresponding row of X, and the true class label Y.

If Mdl.BinaryLearners contains linear classification models, then m is an n-by-L vector, where n is the number of observations in X and L is the number of regularization strengths in the linear classification models (i.e., numel(Mdl.BinaryLearners{1}.Lambda)). m(i,j) is the margin of observation i for the model trained using regularization strength Mdl.BinaryLearners{1}.Lambda(j).

Otherwise, m is a column vector of length n.

**Examples**
Estimate Test-Sample Classification Margins of ECOC Models

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```matlab
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVMdl is a ClassificationPartitionedECOC model. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationECOC model that the software trained using the training set.

Estimate the test-sample classification margins. Display the distribution of the margins using a boxplot.

```matlab
m = margin(CMdl,XTest,YTest);
figure;
boxplot(m);
title 'Test-Sample Margins'
```
An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

**Select ECOC Model Features by Examining Test-Sample Margins**

The classifier margins measure, for each observation, the difference between the positive-class, negated loss score and the maximal negative-class, negated loss. One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);

Define these two data sets:
• fullX contains all four predictors.
• partX contains the sepal measurements.

fullX = X;
partX = X(:,1:2);

Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};

Estimate the test-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

fullMargins = margin(CMdl,XTest,YTest);
partMargins = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of Test-Sample Margins')
The margin distribution of CMd1 is situated higher, and with less variability than the margin distribution of PCMd1.

**Definitions**

**Binary Loss**

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:
• $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).

• $s_j$ is the score of binary learner $j$ for an observation.

• $g$ is the binary loss function.

• $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-222, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-222, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-221 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set $\{-1,1,0\}$), $s_j$ is the score for observation $j$, and $g(y_j, s_j)$.

<table>

</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-221.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

### Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

### Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using fitcecoc.

### Algorithms

If you trained Mdl specifying to standardize the predictor data, then the software standardizes the columns of X using the corresponding means and standard deviations that the software stored in Mdl.BinaryLearner{1}.Mu and Mdl.BinaryLearner{1}.Sigma for learner j.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `Options,statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

margin

Classification margins

Syntax

M = margin(ens,tbl,ResponseVarName)
M = margin(ens,tbl,Y)
M = margin(ens,X,Y)
M = margin(___Name,Value)

Description

M = margin(ens,tbl,ResponseVarName) returns the classification margin for the predictions of ens on data tbl, when the true classifications are tbl.ResponseVarName.

M = margin(ens,tbl,Y) returns the classification margin for the predictions of ens on data tbl, when the true classifications are Y.

M = margin(ens,X,Y) returns the classification margin for the predictions of ens on data X, when the true classifications are Y.

M = margin(___Name,Value) calculates margin with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

Input Arguments

ens

Classification ensemble created with fitensemble, or a compact classification ensemble created with compact.

tbl

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. tbl must contain all of the predictors
used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained ens using sample data contained in a table, then the input data for this method must also be in a table.

**ResponseVarName**

Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of tbl, including Y, as predictors when training the model.

**X**

Matrix of data to classify. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train ens. X should have the same number of rows as the number of elements in Y.

If you trained ens using sample data contained in a matrix, then the input data for this method must also be in a matrix.

**Y**

Class labels of observations in tbl or X. Y should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of tbl or X.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name,** **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,** **Value1,** ..., **NameN,** **ValueN.**

**learners**

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

**Default:** 1:NumTrained
UseObsForLearner

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When UseObsForLearner(i,j) is true, learner j is used in predicting the class of row i of X.

Default: true(N,T)

Output Arguments

M

A numeric column vector with the same number of rows as tbl or X. Each row of M gives the classification margin for that row of tbl or X.

Examples

Find Classification Margin

Find the margin for classifying an average flower from the fisheriris data as 'versicolor'.

Load the Fisher iris data set.

load fisheriris

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

% Weak learner template tree object
% Weak learner template tree object
ens = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t);

Classify an average flower and find the classification margin.

flower = mean(meas);
predict(ens,flower)
ans = 1x1 cell array
    {'versicolor'}

margin(ens,flower,'versicolor')
ans = 3.2140

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to $\infty$.
- Bag scores range from 0 to 1.

Extended Capabilities

margin
Classification margins for naive Bayes classifiers

Syntax

m = margin(Mdl,tbl,ResponseVarName)
m = margin(Mdl,tbl,Y)
m = margin(Mdl,X,Y)

Description

m = margin(Mdl,tbl,ResponseVarName) returns the classification margins on page 32-3971 (m) for the trained naive Bayes classifier Mdl using the predictor data in table tbl and the class labels in tbl.ResponseVarName.

m = margin(Mdl,tbl,Y) returns the classification margins (m) for the trained naive Bayes classifier Mdl using the predictor data in table tbl and the class labels in vector Y.

m = margin(Mdl,X,Y) returns the classification margins (m) for the trained naive Bayes classifier Mdl using the predictor data X and class labels Y.

Input Arguments

Mdl — Naive Bayes classifier
ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by fitcnb or compact, respectively.

tbl — Sample data
table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain additional
columns for the response variable and observation weights. \( \text{tbl} \) must contain all the predictors used to train \( \text{Mdl} \). Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained \( \text{Mdl} \) using sample data contained in a \text{table}, then the input data for this method must also be in a table.

Data Types: \text{table}

**ResponseVarName — Response variable name**

name of a variable in \( \text{tbl} \)

Response variable name, specified as the name of a variable in \( \text{tbl} \).

You must specify \text{ResponseVarName} as a character vector or string scalar. For example, if the response variable \( y \) is stored as \( \text{tbl} \cdot y \), then specify it as \'y\'. Otherwise, the software treats all columns of \( \text{tbl} \), including \( y \), as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: \text{char} | \text{string}

**\( X \) — Predictor data**

\text{numeric matrix}

Predictor data, specified as a numeric matrix.

Each row of \( X \) corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of \( X \) should be the same as the variables that trained \( \text{Mdl} \).

The length of \( Y \) and the number of rows of \( X \) must be equal.

Data Types: \text{double} | \text{single}

**\( Y \) — Class labels**

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. \( Y \) must be the same as the data type of \( \text{Mdl} \cdot \text{ClassNames} \). (The software treats string arrays as cell arrays of character vectors.)
The length of Y and the number of rows of tbl or X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Output Arguments**

m — Classification margins

numeric vector

Classification margins on page 32-3971, returned as a numeric vector.

m has the same length equal to size(X,1). Each entry of m is the classification margin of the corresponding observation (row) of X and element of Y.

**Examples**

**Estimate Test-Sample Classification Margins of Naive Bayes Classifiers**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;   % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```matlab
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVMdl.Partition);   % Extract the test indices
XTest = X(testInds,:);  
YTest = Y(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.
Estimate the test sample classification margins. Display the distribution of the margins using a boxplot.

```matlab
m = margin(CMdl,XTest,YTest);
figure;
boxplot(m);
title 'Distribution of the Test-Sample Margins';
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.
Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);

Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);

Partition defines the data set partition.

Define these two data sets:
• fullX contains all predictors.
• partX contains the last 2 predictors.

fullX = X;
partX = X(:,3:4);

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};

FullCVMdl and PartCVMdl are ClassificationPartitionedModel classifiers. They contain the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.
Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```matlab
fullM = margin(FCMdl,XTest,YTest);
partM = margin(PCMd1,XTest(:,3:4),YTest);

figure;
boxplot([fullM partM],'Labels',{'All Predictors','Two Predictors'})
h = gca;
h.YLim = [0.98 1.01]; % Modify axis to see boxes.
title 'Boxplots of Test-Sample Margins';
```

The margins have a similar distribution, but PCMd1 is less complex.
Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is $k$ for a given observation $(x_1,\ldots,x_P)$ is

$$
\hat{P}(Y = k \mid x_1,\ldots,x_P) = \frac{P(X_1,\ldots,X_P \mid y = k)\pi(Y = k)}{P(X_1,\ldots,X_P)},
$$

where:

- $P(X_1,\ldots,X_P \mid y = k)$ is the conditional joint density of the predictors given they are in class $k$. `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
\[ P(X_1,\ldots,X_p) \] is the joint density of the predictors. The classes are discrete, so

\[ P(X_1,\ldots,X_p) = \sum_{k=1}^{K} P(X_1,\ldots,X_p \mid y = k) \pi(Y = k). \]

**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

**Score**

The naive Bayes score is the class posterior probability given the observation.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**See Also**

ClassificationNaiveBayes | CompactClassificationNaiveBayes | edge | fitcnb | loss | predict

**Topics**

“Naive Bayes Classification” on page 21-2
margin

**Package:** classreg.learning.classif

Find classification margins for support vector machine (SVM) classifier

**Syntax**

```matlab
m = margin(SVMModel,TBL,ResponseVarName)
m = margin(SVMModel,TBL,Y)
m = margin(SVMModel,X,Y)
```

**Description**

`m = margin(SVMModel,TBL,ResponseVarName)` returns the classification margins on page 32-3978 (m) for the trained support vector machine (SVM) classifier `SVMModel` using the sample data in table `TBL` and the class labels in `TBL.ResponseVarName`.

`m` is returned as a numeric vector with the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

`m = margin(SVMModel,TBL,Y)` returns the classification margins (m) for the trained SVM classifier `SVMModel` using the sample data in table `TBL` and the class labels in `Y`.

`m = margin(SVMModel,X,Y)` returns the classification margins for `SVMModel` using the predictor data in matrix `X` and the class labels in `Y`.

**Examples**

**Estimate Test Sample Classification Margins of SVM Classifiers**

Load the ionosphere data set.
load ionosphere
rng(1); % For reproducibility

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);     % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample classification margins.

m = margin(CompactSVMModel,XTest,YTest);

m(10:20)

ans = 11×1
4.9948
4.5611
-4.7963
5.5127
-2.8776
1.8673
9.4986
9.5018 ...

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are preferred.
Select SVM Classifier Features by Examining Test Sample Margins

Perform feature selection by comparing test sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- fullX contains all predictors (except the removed column of 0s).
- partX contains the last 20 predictors.

```matlab
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```matlab
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

FullCVSVMModel and PartCVSVMModel are ClassificationPartitionedModel classifiers. They contain the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```matlab
fullM = margin(FCSVMModel,XTest,YTest);
partM = margin(PCSVMModel,XTest(:,end-20:end),YTest);
n = size(XTest,1);
p = sum(fullM < partM)/n
```
$p = 0.2500$

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This result suggests that the model trained with all the predictors is better.

**Input Arguments**

**SVMMModel — SVM classification model**  
ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

**TBL — Sample data**  
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMMModel using sample data contained in a table, then the input data for margin must also be in a table.

If you set 'Standardize',true in fitcsvm when training SVMMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMMModel.Mu and the standard deviations in SVMMModel.Sigma.

Data Types: table

**X — Predictor data**  
numeric matrix

Predictor data, specified as a numeric matrix.
Each row of $X$ corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of $X$ must be the same as the variables that trained the SVMModel classifier.

The length of $Y$ and the number of rows in $X$ must be equal.

If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of $X$ using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: double | single

**ResponseVarName — Response variable name**

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify ResponseVarName as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.Response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of SVMModel.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of $Y$ must equal the number of rows in TBL or the number of rows in $X$. 

32-3977
Definitions

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

\( x \) is an observation. If the true label of \( x \) is the positive class, then \( y \) is 1, and –1 otherwise. \( f(x) \) is the positive-class classification score for the observation \( x \). The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation \( x \) is the signed distance from \( x \) to the decision boundary ranging from -\( \infty \) to +\( \infty \). A positive score for a class indicates that \( x \) is predicted to be in that class. A negative score indicates otherwise.
The positive class classification score \( f(x) \) is the trained SVM classification function. \( f(x) \) is also the numerical, predicted response for \( x \), or the score for predicting \( x \) into the positive class.

\[
f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,
\]

where \((\alpha_1, ..., \alpha_n, b)\) are the estimated SVM parameters, \( G(x_j, x) \) is the dot product in the predictor space between \( x \) and the support vectors, and the sum includes the training set observations. The negative class classification score for \( x \), or the score for predicting \( x \) into the negative class, is \(-f(x)\).

If \( G(x_j, x) = x_j'x \) (the linear kernel), then the score function reduces to

\[
f(x) = (x / s)'\beta + b.
\]

\( s \) is the kernel scale and \( \beta \) is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-183.

**Algorithms**

For binary classification, the software defines the margin for observation \( j \), \( m_j \), as

\[ m_j = 2y_j f(x_j), \]

where \( y_j \in \{-1, 1\} \), and \( f(x_j) \) is the predicted score of observation \( j \) for the positive class. However, \( m_j = y_j f(x_j) \) is commonly used to define the margin.

*Introduced in R2014a*
margin

Classification margins

Syntax

m = margin(tree,TBL,ResponseVarName)  
m = margin(tree,TBL,Y)  
m = margin(tree,X,Y)

Description

m = margin(tree,TBL,ResponseVarName) returns the classification margins for the table of predictors TBL and class labels TBL.ResponseVarName. For the definition, see “Margin” on page 32-3984.

m = margin(tree,TBL,Y) returns the classification margins for the table of predictors TBL and class labels Y.

m = margin(tree,X,Y) returns the classification margins for the matrix of predictors X and class labels Y.

Input Arguments

tree — Trained classification tree  
ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, tree is a trained classification model returned by fitctree or compact.

TBL — Sample data  
table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional
columns for the response variable and observation weights. TBL must contain all the
predictors used to train tree. Multi-column variables and cell arrays other than cell
arrays of character vectors are not allowed.

If TBL contains the response variable used to train tree, then you do not need to specify
ResponseVarName or Y.

If you train tree using sample data contained in a table, then the input data for this
method must also be in a table.

Data Types: table

X — Data to classify
defined as a numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation,
and each column represents one predictor. X must have the same number of columns as
the data used to train tree. X must have the same number of rows as the number of
elements in Y.

Data Types: single | double

ResponseVarName — Response variable name
defined as the name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the
response variable used to train tree, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string
scalar. For example, if the response variable is stored as TBL.Response, then specify it
as 'Response'. Otherwise, the software treats all columns of TBL, including
TBL.ResponseVarName, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric
vector, or cell array of character vectors. If the response variable is a character array,
then each element must correspond to one row of the array.

Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell
array of character vectors
Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

### Output Arguments

**m — Margin**

column vector

Margin, returned as a numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `tree`.

### Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```matlab
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
 0.1111  
 0.1111  
 0.1111  
-0.2857  
 0.6364  
 0.6364  
 0.1111  
 0.7500  
 1.0000  
 0.6364  
 0.2000
```

The classification tree trained on all the data is better.
tree = fitctree(meas,species);
M = margin(tree,meas,species);
M(end-10:end)

ans =
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565
   0.9565

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when \( X < 0.15 \) or \( X > 0.95 \), and X is false otherwise.

Generate 100 random points and classify them:

rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);

32-3984
tree = fitctree(X,Y);
view(tree,'Mode','Graph')

Prune the tree:

tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for true, and about .8/.85=.94 for false.

Compute the prediction scores for the first 10 rows of X:

```matlab
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```
ans = 10×3

0.9059    0.0941    0.8147
0.9059    0.0941    0.9058
0         1.0000    0.1270
0.9059    0.0941    0.9134
0.9059    0.0941    0.6324
0         1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected 0.06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

margin

Class: CompactTreeBagger

Classification margin

Syntax

mar = margin(B,TBLnew,Ynew)
mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)

Description

mar = margin(B,TBLnew,Ynew) computes the classification margins for the predictors contained in the table TBLnew given true response Ynew. You can omit Ynew if TBLnew contains the response variable. If you trained B using sample data contained in a table, then the input data for this method must also be in a table.

mar = margin(B,Xnew,Ynew) computes the classification margins for the predictors contained in the matrix Xnew given true response Ynew.

Ynew can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. mar is a numeric array of size Nobs-by-NTrees, where Nobs is the number of rows of TBLnew and Ynew, and NTrees is the number of trees in the ensemble B. For observation I and tree J, mar(I,J) is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...) or mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...) specifies optional parameter name-value pairs:
| 'Mode' | How the method computes errors. If set to 'cumulative' (default), `margin` computes cumulative errors and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives error from `trees(1)`, second column gives error from `trees(1:2)` etc., up to `trees(1:NTrees)`. If set to 'individual', `mar` is a `Nobs`-by-`NTrees` matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', `mar` a single column of length `Nobs` showing the cumulative margins for the entire ensemble. |
| 'Trees' | Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc. |
| 'TreeWeights' | Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode. |
| 'UseInstanceForTree' | Logical matrix of size `Nobs`-by-`NTrees` indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations. |

CompactTreeBagger.margin
**margmean**

**Class:** RepeatedMeasuresModel

Estimate marginal means

**Syntax**

```
tbl = margmean(rm,vars)
tbl = margmean(rm,vars,'alpha',alpha)
```

**Description**

```
tbl = margmean(rm,vars) returns the estimated marginal means for the variables vars, in the table tbl.
```

```
tbl = margmean(rm,vars,'alpha',alpha) returns the 100*(1-alpha)% confidence intervals for the marginal means.
```

**Input Arguments**

- **rm — Repeated measures model**
  RepeatedMeasuresModel object

  Repeated measures model, returned as a RepeatedMeasuresModel object.

  For properties and methods of this object, see RepeatedMeasuresModel.

- **vars — Variables for which to compute the marginal means**
  character vector | string scalar | string array | cell array of character vectors

  Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between or within-subjects factor in rm, or a string array or cell array of character vectors representing the names of multiple variables. Each between-subjects factor must be categorical.
For example, if you want to compute the marginal means for the variables Drug and Gender, then you can specify as follows.

Example: {'Drug','Gender'}

Data Types: char | string | cell

**alpha — Confidence level**

0.05 (default) | scalar value in the range of 0 to 1

Confidence level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is 100*(1–alpha)%.

For example, you can specify a 99% confidence level as follows.

Example: 'alpha',0.01

Data Types: double | single

**Output Arguments**

**tbl — Estimated marginal means**

table

Estimated marginal means, returned as a table. tbl contains one row for each combination of the groups of the variables you specify in vars, one column for each variable, and the following columns.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean</td>
<td>Estimated marginal means</td>
</tr>
<tr>
<td>StdErr</td>
<td>Standard errors of the estimates</td>
</tr>
<tr>
<td>Lower</td>
<td>Lower limit of a 95% confidence interval for the true population mean</td>
</tr>
<tr>
<td>Upper</td>
<td>Upper limit of a 95% confidence interval for the true population mean</td>
</tr>
</tbody>
</table>

**Examples**
Compute Marginal Means Grouped by Two Factors

Load the sample data.

load repeatedmeas

The table between includes the between-subject variables age, IQ, group, gender, and eight repeated measures y1 to y8 as responses. The table within includes the within-subject variables w1 and w2. This is simulated data.

Fit a repeated measures model, where the repeated measures y1 to y8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Compute the marginal means grouped by the factors Group and Gender.

```
M = margmean(rm,{'Group' 'Gender'})
```

<table>
<thead>
<tr>
<th>Group</th>
<th>Gender</th>
<th>Mean</th>
<th>StdErr</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Female</td>
<td>15.946</td>
<td>5.6153</td>
<td>4.3009</td>
<td>27.592</td>
</tr>
<tr>

<td>Male</td>
<td>-13.551</td>
<td>5.7283</td>
<td>-25.431</td>
<td>-1.6712</td>
</tr>
</tbody>
</table>

Display the description for table M.

```
M.Properties.Description
```

ans =

'Estimated marginal means
Means computed with Age=13.7, IQ=98.2667'
Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

load fisheriris

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4),...
'VariableNames',
'betweenNames',
'WithinDesign',
'VarNames',

Meas = dataset([1 2 3 4],,...
'VarNames',

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);

Compute the marginal means grouped by the factor species.

```
margmean(rm, 'species')
```

<table>
<thead>
<tr>
<th>species</th>
<th>Mean</th>
<th>StdErr</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>'setosa'</td>
<td>2.5355</td>
<td>0.042807</td>
<td>2.4509</td>
<td>2.6201</td>
</tr>
<tr>
<td>'versicolor'</td>
<td>3.573</td>
<td>0.042807</td>
<td>3.4884</td>
<td>3.6576</td>
</tr>
<tr>
<td>'virginica'</td>
<td>4.285</td>
<td>0.042807</td>
<td>4.2004</td>
<td>4.3696</td>
</tr>
</tbody>
</table>

The `StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm, 'species', 'alpha', 0.01)
```

<table>
<thead>
<tr>
<th>species</th>
<th>Mean</th>
<th>StdErr</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>'setosa'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'versicolor'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'virginica'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>

mauchly

Class: RepeatedMeasuresModel

Mauchly’s test for sphericity

Syntax

\[
\text{tbl} = \text{mauchly}(\text{rm})
\]
\[
\text{tbl} = \text{mauchly}(\text{rm},\text{C})
\]

Description

\[
\text{tbl} = \text{mauchly}(\text{rm}) \text{ returns the result of the Mauchly's test for sphericity for the repeated measures model } \text{rm}.
\]

It tests the null hypothesis that the sphericity assumption is true for the response variables in \text{rm}.

For more information, see “Mauchly’s Test of Sphericity” on page 9-82.

\[
\text{tbl} = \text{mauchly}(\text{rm},\text{C}) \text{ returns the result of the Mauchly's test based on the contrast matrix } \text{C}.
\]

Input Arguments

\text{rm} — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

\text{C} — Contrasts
matrix
Contrasts, specified as a matrix. The default value of C is the Q factor in a QR decomposition of the matrix M, where M is defined so that Y*M is the difference between all successive pairs of columns of the repeated measures matrix Y.

Data Types: single | double

**Output Arguments**

tbl — Results of Mauchly’s test of sphericity
table

Results of Mauchly’s test for sphericity for the repeated measures model rm, returned as a table.

tbl contains the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>Value of Mauchly’s W statistic</td>
</tr>
<tr>
<td>ChiStat</td>
<td>Chi-square statistic value</td>
</tr>
<tr>
<td>DF</td>
<td>Degrees of freedom of the Chi-square statistic</td>
</tr>
<tr>
<td>pValue</td>
<td>p-value corresponding to the Chi-square statistic</td>
</tr>
</tbody>
</table>

Data Types: table

**Examples**

**Perform Mauchly’s Test**

Load the sample data.

load fisheriris

The column vector species consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix meas consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.
Store the data in a table array.

```matlab
t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4),... 'VariableNames', {'species', 'meas1', 'meas2', 'meas3', 'meas4'});
Meas = dataset([1 2 3 4], 'VarNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform Mauchly’s test to assess the sphericity assumption.

```matlab
mauchly(rm)
```

```
ans = 1×4 table
     W      ChiStat   DF    pValue
   ______    _______    __    __________
     0.55814    84.976     5     7.6149e-17
```

The small $p$-value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the $p$-values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected $p$-values using the `ranova` method.

**See Also**
epsilon | fitrm | ranova

**Topics**
“Mauchly’s Test of Sphericity” on page 9-82
“Compound Symmetry Assumption and Epsilon Corrections” on page 9-80
mat2dataset

Convert matrix to dataset array

**Note** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)

**Description**

ds = mat2dataset(X) converts a matrix to a dataset array.

ds = mat2dataset(X,Name,Value) performs the conversion using additional options specified by one or more Name,Value pair arguments.

**Examples**

**Convert Matrix to Dataset Array**

Convert a matrix to a dataset array using the default options.

Load sample data.

```matlab
load('fisheriris')
X = meas;
size(X)
```

ans = 1×2
Convert the matrix to a dataset array.

```matlab
ds = mat2dataset(X);
size(ds)
ans = 1×2
    150     4
ds(1:5,:)
ans =
    X1   X2   X3   X4
   5.1   3.5   1.4   0.2
   4.9   3.0   1.4   0.2
   4.7   3.2   1.3   0.2
   4.6   3.1   1.5   0.2
   5.0   3.6   1.4   0.2
```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

**Convert Matrix to Dataset Array with Variable Names**

Load sample data.

```matlab
load('fisheriris')
X = meas;
size(X)
ans = 1×2
    150     4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of `X`.

```matlab
load('fisheriris')
X = meas;
size(X)
ans = 1×2
    150     4
```
ds = mat2dataset(X,'VarNames',{'SLength','SWidth','PLength','PWidth'});
size(ds)

ans = 1×2
   150     4

ds(1:5,:)

ans =
   SLength   SWidth   PLength   PWidth
    5.1       3.5       1.4       0.2
    4.9       3.0       1.4       0.2
    4.7       3.2       1.3       0.2
    4.6       3.1       1.5       0.2
    5.0       3.6       1.4       0.2

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

load('fisheriris')
X = meas;
size(X)

ans = 1×2
   150     4

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named SepalMeas, and the petal measurements (third and fourth columns) into one variable names PetalMeas.

ds = mat2dataset(X,'NumCols',[2,2],...
   'VarNames',{ 'SepalMeas', 'PetalMeas'});
ds(1:5,:)

32-4002
ans =
  SepalMeas          PetalMeas
  5.1       3.5   1.4       0.2
  4.9       3.0   1.4       0.2
  4.7       3.2   1.3       0.2
  4.6       3.1   1.5       0.2
  5.0       3.6   1.4       0.2

The output dataset array has 150 observations and 2 variables.

size(ds)
ans = 1x2
  150     2

**Input Arguments**

**X** — Input matrix
matrix

Input matrix to convert to a dataset array, specified as an M-by-N numeric matrix. Each column of X becomes a variable in the output M-by-N dataset array.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name,Value** arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: 'NumCols',[1,1,2,1] specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

**VarNames** — Variable names for output dataset array
string array | cell array of character vectors
Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors. You must provide a variable name for each variable in ds. The names must be valid MATLAB identifiers, and must be unique.

Example: 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

**ObsNames** — Observation names for output dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

**NumCols** — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in ds, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, mat2dataset combines multiple columns in X into a single variable in ds. The vector you assign to NumCols must sum to size(X,2).

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].

### Output Arguments

**ds** — Output dataset array
dataset array

Output dataset array, returned by default with a variable for each column of X, and an observation for each row of X. If you specify NumCols, then the number of variables in ds is equal to the length of the specified vector of column numbers.

Introduced in R2012b
m scaled

Nonclassical multidimensional scaling

Syntax

Y = mdscale(D,p)
[Y,stress] = mdscale(D,p)
[Y,stress,disparities] = mdscale(D,p)
[...] = mdscale(D,p,'Name',value)

Description

Y = mdscale(D,p) performs nonmetric multidimensional scaling on the n-by- n dissimilarity matrix D, and returns Y, a configuration of n points (rows) in p dimensions (columns). The Euclidean distances between points in Y approximate a monotonic transformation of the corresponding dissimilarities in D. By default, mdscale uses Kruskal's normalized stress criterion.

You can specify D as either a full n-by-n matrix, or in upper triangle form such as is output by pdist. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. mdscale treats NaNs in D as missing values, and ignores those elements. Inf is not accepted.

You can also specify D as a full similarity matrix, with ones along the diagonal and all other elements less than one. mdscale transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in Y approximate \( \sqrt{1-D} \). To use a different transformation, transform the similarities prior to calling mdscale.

[Y,stress] = mdscale(D,p) returns the minimized stress, i.e., the stress evaluated at Y.

[Y,stress,disparities] = mdscale(D,p) returns the disparities, that is, the monotonic transformation of the dissimilarities D.
[...] = mdscale(D,p,'Name',value) specifies one or more optional parameter name/value pairs that control further details of mdscale. Specify Name in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that mdscale performs. Choices for non-metric scaling are:
  - 'stress' — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
  - 'sstress' — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

  - 'metricstress' — Stress, normalized with the sum of squares of the dissimilarities.
  - 'metricsstress' — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
  - 'sammon' — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
  - 'strain' — A criterion equivalent to that used in classical multidimensional scaling.

- **Weights** — A matrix or vector the same size as D, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of D in computing and minimizing stress. Elements of D corresponding to zero weights are effectively ignored.

Note When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of D do not enter into the stress calculation.

- **Start** — Method used to choose the initial configuration of points for Y. The choices are
  - 'cmdscale' — Use the classical multidimensional scaling solution. This is the default. 'cmdscale' is not valid when there are zero weights.
  - 'random' — Choose locations randomly from an appropriately scaled p-dimensional normal distribution with uncorrelated coordinates.
• An $n$-by-$p$ matrix of initial locations, where $n$ is the size of the matrix $D$ and $p$ is the number of columns of the output matrix $Y$. In this case, you can pass in $[]$ for $p$ and `mdscale` infers $p$ from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.

• Replicates — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.

• Options — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```matlab
opts = statset('param1',val1,'param2',val2,...);
[y,stress,disp] = mdscale(dissimilarities,2,'Options',opts)
```

The choices of `statset` parameters are

• 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.

• 'MaxIter' — Maximum number of iterations allowed. The default is 200.

• 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is $1e^{-4}$.

• 'TolX' — Termination tolerance for the configuration location step size. The default is $1e^{-4}$.

**Examples**

```matlab
load cereal.mat
X = [Calories Protein Fat Sodium Fiber ...
    Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K',cellstr(Mfg)),:);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
[Y,stress,disp] = mdscale(dissimilarities,2);
distances = pdist(Y);
[dum,ord] = sortrows([disp; dissimilarities]);
plot(dissimilarities,distances,'bo',...
dissimilarities(ord), disparities(ord), 'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'},'Location','NW');

% Do metric scaling on the same dissimilarities.
figure
[Y, stress] = ...
mdscale(dissimilarities,2, 'criterion', 'metricsstress');
distances = pdist(Y);
plot(dissimilarities, distances, 'bo', ...
[0 max(dissimilarities)], [0 max(dissimilarities)], 'r.-');
xlabel('Dissimilarities'); ylabel('Distances')

Introduced before R2006a
mdsprox

**Class:** CompactTreeBagger

Multidimensional scaling of proximity matrix

**Syntax**

```matlab
[SC,EIGEN] = mdsprox(B,X)
[SC,EIGEN] = mdsprox(B,X,'param1',val1,'param2',val2,...)
```

**Description**

```matlab
[SC,EIGEN] = mdsprox(B,X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix X, and returns scaled coordinates SC and eigenvalues EIGEN of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as 1-prox, where prox is the proximity matrix returned by the proximity method.
```

You can supply the proximity matrix directly by using the 'Data' parameter.

```matlab
[SC,EIGEN] = mdsprox(B,X,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:
```

- **'Data'** Flag indicating how the method treats the X input argument. If set to 'predictors' (default), mdsprox assumes X to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Colors'</td>
<td>If you supply this argument, <code>mdsprox</code> makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, <code>mdsprox</code> plots only the first C classes, where C is the number of letters in the supplied value. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X.</td>
</tr>
<tr>
<td>'Labels'</td>
<td>Vector of true class labels for a classification ensemble. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. mdsprox

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

\[ [S,E] = \text{mdsprox}(B) \]
\[ [S,E] = \text{mdsprox}(B,'\text{param1}',\text{val1},'\text{param2}',\text{val2},...) \]

Description

\[ [S,E] = \text{mdsprox}(B) \] returns scaled coordinates, \( S \), and eigenvalues, \( E \), for the proximity matrix in the ensemble \( B \). An earlier call to \( \text{fillprox}(B) \) must create the proximity matrix.

\[ [S,E] = \text{mdsprox}(B,'\text{param1}',\text{val1},'\text{param2}',\text{val2},...) \] specifies optional parameter name/value pairs:

'Keep'  
Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.

'Colors'  
If you supply this argument, \( \text{mdsprox} \) makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, \( \text{mdsprox} \) plots only the first \( C \) classes, where \( C \) is the number of letters in the supplied value. For regression, the method uses the first color for all observations in \( X \).
'MDSCoordinates' Indices of the two scaled coordinates to plot. By default, mdsprox makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

**mean**

**Package:** prob

Mean of probability distribution

**Syntax**

\[ m = \text{mean}(pd) \]

**Description**

\[ m = \text{mean}(pd) \] returns the mean \( m \) of the probability distribution \( pd \).

**Examples**

**Mean of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students’ exam grade data.

```matlab
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```matlab
pd = \text{fitdist}(x,\text{'Normal'})
```

\[ pd = \]

NormalDistribution

Normal distribution

\[
\begin{align*}
\mu &= 75.0083 & [73.4321, 76.5846] \\
\sigma &= 8.7202 & [7.7391, 9.98843]
\end{align*}
\]

Compute the mean of the fitted distribution.
m = mean(pd)
m = 75.0083

The mean of the normal distribution is equal to the parameter mu.

**Mean of a Skewed Distribution**

Create a Weibull probability distribution object.

```matlab
pd = makedist('Weibull','a',5,'b',2)
pd =
    WeibullDistribution
        Weibull distribution
            A = 5
            B = 2
```

Compute the mean of the distribution.

```matlab
mean = mean(pd)
mean = 4.4311
```

**Mean of a Uniform Distribution**

Create a uniform distribution object

```matlab
pd = makedist('Uniform','lower',-3,'upper',5)
pd =
    UniformDistribution
        Uniform distribution
            Lower = -3
            Upper =  5
```

Compute the mean of the distribution.

```matlab
m = mean(pd)
```
Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```matlab
load carsmall;
pd = fitdist(MPG,'Kernel')
```

```matlab
pd =  
    KernelDistribution

    Kernel = normal
    Bandwidth = 4.11428
    Support = unbounded
```

Compute the mean of the distribution.

```matlab
mean(pd)
```

```matlab
ans = 23.7181
```

Input Arguments

**pd — Probability distribution**

Probability distribution object of type `KernelDistribution`.

Probability distribution, specified as a probability distribution object created using one of the following.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>

Introduced in R2013a
meanMargin

**Class:** CompactTreeBagger

Mean classification margin

**Syntax**

mar = meanMargin(B,TBLnew,Ynew)
mar = meanMargin(B,Xnew,Ynew)
mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)

**Description**

mar = meanMargin(B,TBLnew,Ynew) computes average classification margins for the predictors contained in the table TBLnew given the true response Ynew. You can omit Ynew if TBLnew contains the response variable. If you trained B using sample data contained in a table, then the input data for this method must also be in a table.

mar = meanMargin(B,Xnew,Ynew) computes average classification margins for the predictors contained in the matrix Xnew given true response Ynew. If you trained B using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Ynew can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector, or logical vector. meanMargin averages the margins over all observations (rows) in TBLnew or Xnew for each tree. mar is a matrix of size 1-by-NTrees, where NTrees is the number of trees in the ensemble B. This method is available for classification ensembles only.

mar = meanMargin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...) or mar = meanMargin(B,Xnew,Ynew,'param1',val1,'param2',val2,...) specifies optional parameter name-value pairs:
'Mode' | How `meanMargin` computes errors. If set to 'cumulative' (default), is a vector of length NTrees where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc., up to `trees(1:NTrees)`. If set to 'individual', `mar` is a vector of length NTrees, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', `mar` is a scalar showing the cumulative mean margin for the entire ensemble.

'Trees' | Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

'TreeWeights' | Vector of tree weights. This vector must have the same length as the 'Trees' vector. `meanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

meansurrvarassoc

**Class:** classregtree

(Removed) Mean predictive measure of association for surrogate splits in decision tree

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[
MA = \text{meansurrvarassoc}(T) \\
MA = \text{meansurrvarassoc}(T,N)
\]

**Description**

\[
MA = \text{meansurrvarassoc}(T)
\]

returns a \( p \)-by-\( p \) matrix, \( MA \), with predictive measures of association for \( p \) predictors. Element \( MA(i,j) \) is the predictive measure of association averaged over surrogate splits on predictor \( j \) for which predictor \( i \) is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor \( i \) and surrogate splits on predictor \( j \) and dividing by the total number of optimal splits on predictor \( i \), including splits for which the predictive measure of association between predictors \( i \) and \( j \) is negative.

\[
MA = \text{meansurrvarassoc}(T,N)
\]

takes an array \( N \) of node numbers and returns the predictive measure of association averaged over the specified nodes.

surrogateAssociation

Mean predictive measure of association for surrogate splits in decision tree

Syntax

\[
\text{ma} = \text{surrogateAssociation}(\text{tree}) \\
\text{ma} = \text{surrogateAssociation}(\text{tree}, \text{N})
\]

Description

\[
\text{ma} = \text{surrogateAssociation}(\text{tree}) \text{ returns a matrix of predictive measures of association for the predictors in } \text{tree}.
\]

\[
\text{ma} = \text{surrogateAssociation}(\text{tree}, \text{N}) \text{ returns a matrix of predictive measures of association averaged over the nodes in vector } \text{N}.
\]

Input Arguments

tree

A classification tree constructed with \text{fitctree}, or a compact regression tree constructed with \text{compact}.

N

Vector of node numbers in \text{tree}.

Output Arguments

ma

\[
\text{ma} = \text{surrogateAssociation}(\text{tree}) \text{ returns a } P\text{-by-}P \text{ matrix, where } P \text{ is the number of predictors in } \text{tree}. \text{ma}(i,j) \text{ is the predictive measure of association on}
\]
page 32-4026 between the optimal split on variable i and a surrogate split on variable j. For more details, see “Algorithms” on page 32-4027.

- ma = surrogateAssociation(tree,N) returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector N. N contains node numbers from 1 to max(tree.NumNodes).

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load Fisher's iris data set.

load fisheriris

Definitions

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2087 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose $x_j$ and $x_k$ are predictor variables $j$ and $k$, respectively, and $j \neq k$. At node $t$, the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - PL_Lk - PR_Rk)}{\min(P_L, P_R)}.$$  

- $P_L$ is the proportion of observations in node $t$, such that $x_j < u$. The subscript $L$ stands for the left child of node $t$.
- $P_R$ is the proportion of observations in node $t$, such that $x_j \geq u$. The subscript $R$ stands for the right child of node $t$.
- $PL_Lk$ is the proportion of observations at node $t$, such that $x_j < u$ and $x_k < v$.
- $PR_Rk$ is the proportion of observations at node $t$, such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for $x_j$ or $x_k$ do not contribute to the proportion calculations.

$\lambda_{jk}$ is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$. 

$0.7600 \ 0.5000 \ 1.0000 \ 1.0000$

$0.4130 \ 0.2826 \ 0.8043 \ 1.0000$
Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2562.

Algorithms

Element \( ma(i,j) \) is the predictive measure of association averaged over surrogate splits on predictor \( j \) for which predictor \( i \) is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor \( i \) and surrogate splits on predictor \( j \) and dividing by the total number of optimal splits on predictor \( i \), including splits for which the predictive measure of association between predictors \( i \) and \( j \) is negative.

See Also

ClassificationTree | fitctree
**surrogateAssociation**

Mean predictive measure of association for surrogate splits in decision tree

**Syntax**

```matlab
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

**Description**

- `ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.
- `ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

**Input Arguments**

- `tree`
  A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.
- `N`
  Vector of node numbers in `tree`.

**Output Arguments**

- `ma`
  - `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association on
page 32-4030 between the optimal split on variable \( i \) and a surrogate split on variable \( j \). For more details, see “Algorithms” on page 32-4031.

- \( \text{ma} = \text{surrogateAssociation}(\text{tree}, N) \) returns a \( P \)-by-\( P \) representing the predictive measure of association between variables averaged over nodes in the vector \( N \). \( N \) contains node numbers from 1 to \( \text{max}(\text{tree.NumNodes}) \).

### Examples

**Estimate Predictive Measures of Association for Surrogate Splits**

Load the `carsmall` data set. Specify `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using `MPG` as the response. Specify to use surrogate splits for missing values.

```
tree = fitrtree(X,MPG,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
ma = 3×3
    1.0000    0.2167    0.5083
   0.4521    1.0000    0.3769
   0.2540    0.2659    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in \( \text{tree} \).

```
N = 1:2:tree.NumNodes;
ma = surrogateAssociation(tree,N)
ma = 3×3
    1.0000    0.1250    0.6875

Definitions

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2087 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose $x_j$ and $x_k$ are predictor variables $j$ and $k$, respectively, and $j \neq k$. At node $t$, the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$
\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_k}R_k - P_{R_k}R_k)}{\min(P_L, P_R)}.
$$

- $P_L$ is the proportion of observations in node $t$, such that $x_j < u$. The subscript $L$ stands for the left child of node $t$.
- $P_R$ is the proportion of observations in node $t$, such that $x_j \geq u$. The subscript $R$ stands for the right child of node $t$.
- $P_{L_jL}$ is the proportion of observations at node $t$, such that $x_j < u$ and $x_k < v$.
- $P_{R_jR}$ is the proportion of observations at node $t$, such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for $x_j$ or $x_k$ do not contribute to the proportion calculations.

\( \lambda_{jk} \) is a value in \((-\infty, 1]\). If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$. 

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2562.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor $j$ for which predictor $i$ is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor $i$ and surrogate splits on predictor $j$ and dividing by the total number of optimal splits on predictor $i$, including splits for which the predictive measure of association between predictors $i$ and $j$ is negative.

**median**

**Package:** prob

Median of probability distribution

**Syntax**

\[ m = \text{median}(pd) \]

**Description**

\[ m = \text{median}(pd) \] returns the median \( m \) for the probability distribution \( pd \)

**Examples**

**Median of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```matlab
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```matlab
pd = fitdist(x,'Normal')
```

```
pd =
    NormalDistribution

    Normal distribution
    mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the median of the fitted distribution.
m = median(pd)
m = 75.0083

For a symmetrical distribution such as the normal distribution, the median is equal to the mean, \( \mu \).

**Median of a Skewed Distribution**

Create a Weibull probability distribution object.

\[
pd = \text{makedist('Weibull','a',5,'b',2)}
\]

\[
pd = \text{WeibullDistribution}
\]

\[
\text{Weibull distribution}
\]

\[
A = 5
\]

\[
B = 2
\]

Compute the median of the distribution.

\[
m = \text{median(pd)}
\]

\[
m = 4.1628
\]

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

\[
\text{mean} = \text{mean(pd)}
\]

\[
\text{mean} = 4.4311
\]

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

\[
x = [0:.1:15];
\]

\[
\text{pdf} = \text{pdf(pd,x)};
\]

\[
\text{plot}(x,\text{pdf})
\]
Input Arguments

pd — Probability distribution
 probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.
## Function or App

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>

mergelevels

Merge levels of nominal or ordinal arrays

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

\[ B = \text{mergelevels}(A,\text{oldlevels}) \]
\[ B = \text{mergelevels}(A,\text{oldlevels},\text{newlevel}) \]

**Description**

\[ B = \text{mergelevels}(A,\text{oldlevels}) \] merges two or more levels of \( A \).

- If \( A \) is a nominal array, \text{mergelevels} uses the first label in oldlevels as the new level.
- If \( A \) is an ordinal array, the levels specified by oldlevels must be consecutive, and \text{mergelevels} uses the label corresponding to the lowest level in oldlevels as the label for the new level.

\[ B = \text{mergelevels}(A,\text{oldlevels},\text{newlevel}) \] merges two or more levels into the new level with label newlevel.

**Examples**

**Create New Category From Merged Levels**

Create a nominal array from data in a cell array.

\[
\text{colors} = \text{nominal} (\{ 'r', 'b', 'g'; 'g', 'r', 'b'; 'b', 'r', 'g'},..., \\
\{ 'blue', 'green', 'red' \})
\]
colors = 3x3 nominal array
    red       blue      green
    green     red       blue
    blue      red       green

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

colors = mergelevels(colors,{'red','blue'},'purple')

colors = 3x3 nominal array
    purple     purple      green
    green      purple      purple
    purple     purple      green

Display the levels of colors.

getlevels(colors)

ans = 1x2 nominal array
    purple     green

Input Arguments

A — Nominal or ordinal array
    nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with
nominal or ordinal.

oldlevels — Levels to merge
    string array | cell array of character vectors | 2-D character array

Levels to merge, specified as a string array, cell array of character vectors, or 2-D
character array. For ordinal arrays, the levels in oldlevels must be consecutive.

Data Types: char | string | cell

newlevel — Level to create
    character vector | string scalar
Level to create from the merged levels, specified as a character vector or string scalar that gives the label for the new level.

Data Types: char | string

**Output Arguments**

**B — Nominal or ordinal array**

nominal array | ordinal array

Nominal or ordinal array, returned as a nominal or ordinal array object.

**See Also**

addlevels | droplevels | nominal | ordinal | reorderlevels

mhsample

Metropolis-Hastings sample

Syntax

```matlab
smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd)
smpl = mhsample(...,'symmetric',sym)
smpl = mhsample(...,'burnin',K)
smpl = mhsample(...,'thin',m)
smpl = mhsample(...,'nchain',n)
[smpl,accept] = mhsample(...)
```

Description

```matlab
smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd) draws nsamples random samples from a target stationary distribution pdf using the Metropolis-Hastings algorithm.

start is a row vector containing the start value of the Markov Chain, nsamples is an integer specifying the number of samples to be generated, and pdf, proppdf, and proprnd are function handles created using @. proppdf defines the proposal distribution density, and proprnd defines the random number generator for the proposal distribution. pdf and proprnd take one argument as an input with the same type and size as start. proppdf takes two arguments as inputs with the same type and size as start.

smpl is a column vector or matrix containing the samples. If the log density function is preferred, 'pdf' and 'proppdf' can be replaced with 'logpdf' and 'logproppdf'. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution \( q(x,y) \) gives the probability density for choosing \( x \) as the next point when \( y \) is the current point. It is sometimes written as \( q(x|y) \).

If the proppdf or logproppdf satisfies \( q(x,y) = q(y,x) \), that is, the proposal distribution is symmetric, mhsample implements Random Walk Metropolis-Hastings sampling. If the
proppdf or logproppdf satisfies \( q(x,y) = q(x) \), that is, the proposal distribution is independent of current values, \texttt{mhsample} implements Independent Metropolis-Hastings sampling.

\[
\text{smpl} = \text{mhsample}(...,'symmetric',\text{sym}) \]
draws \( n_{\text{samples}} \) random samples from a target stationary distribution \texttt{pdf} using the Metropolis-Hastings algorithm. \texttt{sym} is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If \texttt{sym} is true, for example, the proposal distribution is symmetric, \texttt{proppdf} and \texttt{logproppdf} are optional.

\[
\text{smpl} = \text{mhsample}(...,'burnin',K) \]
generates a Markov chain with values between the starting point and the \( k^{\text{th}} \) point omitted in the generated sequence. Values beyond the \( k^{\text{th}} \) point are kept. \( k \) is a nonnegative integer with default value of \( 0 \).

\[
\text{smpl} = \text{mhsample}(...,'thin',m) \]
generates a Markov chain with \( m-1 \) out of \( m \) values omitted in the generated sequence. \( m \) is a positive integer with default value of \( 1 \).

\[
\text{smpl} = \text{mhsample}(...,'nchain',n) \]
generates \( n \) Markov chains using the Metropolis-Hastings algorithm. \( n \) is a positive integer with a default value of \( 1 \). \texttt{smpl} is a matrix containing the samples. The last dimension contains the indices for individual chains.

\[
[\text{smpl},\text{accept}] = \text{mhsample}(...) \]
also returns \texttt{accept}, the acceptance rate of the proposed distribution. \texttt{accept} is a scalar if a single chain is generated and is a vector if multiple chains are generated.

**Examples**

**Estimate Moments Using Independent Metropolis-Hastings Sampling**

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```matlab
rng default; % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
```
exprnd(floor(alpha)/alpha,floor(alpha),1));
nsamples = 5000;
smpl = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
    'proppdf',proppdf);

Plot the results.

xxhat = cumsum(smpl.^2)./(1:nsamples)';
figure;
plot(1:nsamples,xxhat)
Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```matlab
rng default  % For reproducibility
delta = .5;
df = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);

% Plot the sample data.
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

mle

Maximum likelihood estimates

Syntax

phat = mle(data)
phat = mle(data,'distribution',dist)

phat = mle(data,'pdf',pdf,'start',start)
phat = mle(data,'pdf',pdf,'start',start,'cdf',cdf)

phat = mle(data,'logpdf',logpdf,'start',start)
phat = mle(data,'logpdf',logpdf,'start',start,'logsf',logsf)

phat = mle(data,'nloglf',nloglf,'start',start)

phat = mle(___,Name,Value)
[phat,pci] = mle(___)

Description

phat = mle(data) returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector data.

phat = mle(data,'distribution',dist) returns parameter estimates for a distribution specified by dist.

phat = mle(data,'pdf',pdf,'start',start) returns parameter estimates for a custom distribution specified by the probability density function pdf. You must also specify the initial parameter values, start.

phat = mle(data,'pdf',pdf,'start',start,'cdf',cdf) returns parameter estimates for a custom distribution specified by the probability density function pdf and custom cumulative distribution function cdf.
phat = mle(data,'logpdf',logpdf,'start',start) returns parameter estimates for a custom distribution specified by the log probability density function logpdf. You must also specify the initial parameter values, start.

phat = mle(data,'logpdf',logpdf,'start',start,'logsf',logsf) returns parameter estimates for a custom distribution specified by the log probability density function logpdf and custom log survival function on page 32-4062 logsf.

phat = mle(data,'nloglf',nloglf,'start',start) returns parameter estimates for the custom distribution specified by the negative loglikelihood function nloglf. You must also specify the initial parameter values, start.

phat = mle(___,Name,Value) specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data, frequency of observations, and confidence level.

[phat,pci] = mle(___) also returns the 95% confidence intervals for the parameters.

**Examples**

**Estimate Parameters of Burr Distribution**

Load the sample data.

load carbig

The variable MPG has the miles per gallon for different models of cars.

Draw a histogram of MPG data.

    histogram(MPG)
The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```matlab
phat = mle(MPG,'distribution','burr')
```

```matlab
phat = 1×3
    34.6447    3.7898    3.5722
```
The maximum likelihood estimates for the scale parameter $\alpha$ is 34.6447. The estimates for the two shape parameters $c$ and $k$ of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

**Estimate Parameters of a Noncentral Chi-Square Distribution**

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 8 and noncentrality parameter 3.

```matlab
rng default % for reproducibility
x = ncx2rnd(8,3,1000,1);
```

Estimate the parameters of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```matlab
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,d),'start',[1,1])
```

```matlab
phat = 1x2
     8.1052   2.6693
```

```matlab
pci = 2x2
     7.1121   1.6025
     9.0983   3.7362
```

The estimate for the degrees of freedom is 8.1052 and the noncentrality parameter is 2.6693. The 95% confidence interval for the degrees of freedom is (7.1121,9.0983) and the noncentrality parameter is (1.6025,3.7362). The confidence intervals include the true parameter values of 8 and 3, respectively.

**Fit Custom Distribution to Censored Data**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'))
```
The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

\[
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
\]

Estimate the parameter, lambda, of the custom distribution for the censored sample data.

\[
phat = mle(ReadmissionTime,'pdf',custpdf,'cdf',custcdf,'start',0.05,'Censoring',Censored)
\]

\[
phat = 0.1096
\]

**Fit Custom Log pdf and Survival Function**

The data includes ReadmissionTime, which has readmission times for 100 patients. The column vector Censored has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

\[
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)+(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
\]

Estimate the parameters, lambda and k, of the custom distribution for the censored sample data.

\[
phat = mle(ReadmissionTime,'logpdf',custlogpdf,'logsf',custlogsf,...
        'start',[1,0.75],'Censoring',Censored)
\]

\[
phat = 1x2
\]

\[
9.2090    1.4223
\]
The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

**Fit Custom Log Negative Likelihood Function**

Load the sample data.

load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'));

The data includes ReadmissionTime, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

custnloglf = @(lambda,data,cens,freq) - length(data)*log(lambda) + nansum(lambda*data);

Estimate the parameters of the defined distribution.

phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)

phat = 0.1462

**Estimate Probability of Success**

Generate 100 random observations from a binomial distribution with the number of trials, \( n = 20 \), and the probability of success, \( P = 0.75 \).

data = binornd(20,0.75,100,1);

Estimate the probability of success and 95% confidence limits using the simulated sample data.

[phat,pci] = mle(data,'distribution','binomial','alpha',.05,'ntrials',20)

phat = 0.7615
pci = 2×1

0.7422
The estimate of probability of success is 0.7615 and the lower and upper limits of the 95% confidence interval are 0.7422 and 0.78. This interval covers the true value used to simulate the data.

**Fit Distribution with Known Parameter**

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 10 and noncentrality parameter 5.

```matlab
rng default % for reproducibility
x = ncx2rnd(10,5,1000,1);
```

Suppose the noncentrality parameter is fixed at the value 5. Estimate the degrees of freedom of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the `pdf` input argument.

```matlab
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,5),'start',1)
```

```matlab
phat = 9.9307
pci = 2×1
    9.5626
    10.2989
```

The estimate for the noncentrality parameter is 9.9307, with a 95% confidence interval of 9.5626 and 10.2989. The confidence interval includes the true parameter value of 10.

**Fit Rician Distribution with Known Scale Parameter**

Generate sample data of size 1000 from a Rician distribution with noncentrality parameter of 8 and scale parameter of 5. First create the Rician distribution.

```matlab
r = makedist('Rician','s',8,'sigma',5);
```
Now, generate sample data from the distribution you created above.

```matlab
rng default % For reproducibility
x = random(r,1000,1);
```

Suppose the scale parameter is known, and estimate the noncentrality parameter from sample data. To do this using `mle`, you must custom define the Rician probability density function.

```matlab
[phat,pci] = mle(x,'pdf',@(x,s,sigma) pdf('rician',x,s,5),'start',10)
```

```
phat = 7.8953
pci = 2×1
    7.5405
    8.2501
```

The estimate for the noncentrality parameter is 7.8953, with a 95% confidence interval of 7.5404 and 8.2501. The confidence interval includes the true parameter value of 8.

**Fit a Distribution with Additional Parameter**

Add a scale parameter to the chi-square distribution for adapting to the scale of data and fit it. First, generate sample data of size 1000 from a chi-square distribution with degrees of freedom 5, and scale it by the factor of 100.

```matlab
rng default % For reproducibility
x = 100*chi2rnd(5,1000,1);
```

Estimate the degrees of freedom and the scaling factor. To do this, custom define the chi-square probability density function using the `pdf` input argument. The density function requires a \( \frac{1}{s} \) factor for data scaled by \( s \).

```matlab
[phat,pci] = mle(x,'pdf',@(x,v,s)chi2pdf(x/s,v)/s,'start',[1,200])
```

```
phat = 1×2
    5.1079   99.1681
```
pci = 2×2

4.6862   90.1215
5.5297   108.2146

The estimate for the degrees of freedom is 5.1079 and the scale is 99.1681. The 95% confidence interval for the degrees of freedom is (4.6862,5.5279) and the scale parameter is (90.1215,108.2146). The confidence intervals include the true parameter values of 5 and 100, respectively.

**Input Arguments**

data — Sample data
vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: single | double

dist — Distribution type
character vector or string scalar of distribution type

Distribution type to estimate parameters for, specified as one of the following.

Example: 'rician'

**pdf — Custom probability density function**

*function handle*

Custom probability distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

Example: `@newpdf`

Data Types: `function_handle`

**cdf — Custom cumulative distribution function**

*function handle*

Custom cumulative distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`
\textbf{logpdf — Custom log probability density function}

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector \texttt{data} and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is \texttt{customlogpdf}, then you can specify the function handle in \texttt{mle} as follows.

Example: \texttt{@customlogpdf}

Data Types: \texttt{function_handle}

\textbf{logsf — Custom log survival function}

function handle

Custom log survival function on page 32-4062, specified as a function handle created using @.

This custom function accepts the vector \texttt{data} and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define \texttt{logsf} with \texttt{logpdf} if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify \texttt{logsf} while using \texttt{logpdf}.

For example, if the name of the custom log survival function is \texttt{logsurvival}, then you can specify the function handle in \texttt{mle} as follows.

Example: \texttt{@logsurvival}

Data Types: \texttt{function_handle}

\textbf{nloglf — Custom negative loglikelihood function}

function handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.
params | Vector of distribution parameter values. `mle` detects the number of parameters from the number of elements in `start`.
---|---
data | Vector of data.
cens | Boolean vector of censored values.
freq | Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write 'nloglf' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'Options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: `@negloglik`

Data Types: `function_handle`

**start — Initial parameter values**

`scalar | vector`

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `0.05`

Example: `[100,2]`

Data Types: `single` | `double`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. 

32-4057
Example: 'Censoring', Cens, 'Alpha', 0.01, 'Options', Opt specifies that mle estimates the parameters for the distribution of censored data specified by array Cens, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure Opt.

**Censoring — Indicator for censoring**
array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'Censoring' and a Boolean array of the same size as data. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For example, if the censored data information is in the binary array called Censored, then you can specify the censored data as follows.

Example: 'Censoring', Censored

mle supports censoring for the following distributions:

- Birnbaum-Saunders
- Burr
- Exponential
- Extreme Value
- Gamma
- Inverse Gaussian
- Kernel
- Log-Logistic
- Logistic
- Lognormal
- Nakagami
- Normal
- Rician
- t Location-Scale
- Weibull

Data Types: logical

**Frequency — Frequency of observations**
array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'Frequency' and an array containing nonnegative integer counts, which is the same size as data. The default is one observation per element of data.

For example, if the observation frequencies are stored in an array named Freq, you can specify the frequencies as follows.

Example: 'Frequency', Freq
Data Types: single | double

**Alpha — Confidence level**
0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of parameter estimates, pci, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The confidence level of pci is $100(1-\text{Alpha})\%$. The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

**NTrials — Number of trials**
scalar value | vector

Number of trials for the corresponding element of data, specified as the comma-separated pair consisting of 'Ntrials' and a scalar or a vector of the same size as data.

Applies only to binomial distribution.

Example: 'Ntrials',total

Data Types: single | double

**mu — Location parameter**
0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of 'mu' and a scalar value.

Applies only to half-normal distribution.

Example: 'mu',1

Data Types: single | double

**Options — Fitting algorithm control parameters**
structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'Options' and a structure returned by `statset`. 
Not applicable to all distributions.

Use the 'Options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'GradObj'</td>
<td>Default is 'off'. 'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output. <code>mle</code> ignores 'GradObj' when using <code>fminsearch</code>.</td>
</tr>
<tr>
<td>'DerivStep'</td>
<td>Default is $\text{eps}^{(1/3)}$. The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'. <code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</td>
</tr>
<tr>
<td>'FunValCheck'</td>
<td>Default is 'on'. 'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity. A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</td>
</tr>
<tr>
<td>'TolBnd'</td>
<td>Default is $1e-6$. An offset for lower and upper bounds when using <code>fmincon</code>. <code>mle</code> treats lower and upper bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified lower and upper bounds by <code>TolBnd</code>.</td>
</tr>
</tbody>
</table>
Example: 'Options', statset('mlecustom')
Data Types: struct

**LowerBound — Lower bounds for distribution parameters**

- $\infty$ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'Lowerbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logcdf, or nloglf input arguments.

Example: 'Lowerbound', 0
Data Types: single | double

**UpperBound — Upper bounds for distribution parameters**

$\infty$ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'Upperbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Upperbound', 1
Data Types: single | double

**OptimFun — Optimization function**

'fminsearch' (default) | 'fmincon'

Optimization function mle uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'Optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.

You can only specify 'fmincon' if Optimization Toolbox is available.

The 'Optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Optimfun', 'fmincon'
Output Arguments

`phat — Parameter estimates`  
scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

`pci — Confidence intervals for parameter estimates`  
2-by-`k` matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of `phat`.

`pci` is a 2-by-`k` matrix, where `k` is the number of parameters `mle` estimates. The first and second rows of the `pci` show the lower and upper confidence limits, respectively.

Definitions

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, \( F(t) \), is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, \( S(t) \), is the complement of the cumulative distribution function: \( S(t) = 1 - F(t) \).

Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

Introduced before R2006a
mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```matlab
acov = mlecov(params, data, 'pdf', pdf)
acov = mlecov(params, data, 'pdf', pdf, 'cdf', cdf)
acov = mlecov(params, data, 'logpdf', logpdf)
acov = mlecov(params, data, 'logpdf', logpdf, 'logsf', logsf)
acov = mlecov(params, data, 'nloglf', nloglf)
acov = mlecov(___, Name, Value)
```

Description

```matlab
acov = mlecov(params, data, 'pdf', pdf) returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function pdf.

mlecov computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates params, given the observed data, and returns the negative inverse of that Hessian.

acov = mlecov(params, data, 'pdf', pdf, 'cdf', cdf) returns acov for a distribution specified by the custom probability density function pdf and cumulative distribution function cdf.

acov = mlecov(params, data, 'logpdf', logpdf) returns acov for a distribution specified by the custom log probability density function logpdf.

acov = mlecov(params, data, 'logpdf', logpdf, 'logsf', logsf) returns acov for a distribution specified by the custom log probability density function logpdf and custom log survival function on page 32-4073 logsf.
```
acov = mlecov(params, data, 'nloglf', nloglf) returns acov for a distribution specified by the custom negative loglikelihood function nloglf.

acov = mlecov(___, Name, Value) specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data, frequency of observations, and confidence level.

**Examples**

**Custom Probability Density Function**

Load the sample data.

load carbig

The vector Weight shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as lognormpdf.m.

```matlab
function newpdf = lognormpdf(data, mu, sigma)
    newpdf = exp((-log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
end
```

Estimate the parameters, mu and sigma, of the custom-defined distribution.

phat = mle(Weight, 'pdf', @lognormpdf, 'start', [4.5 0.3])

phat =

```
    7.9600   0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

acov = mlecov(phat, Weight, 'pdf', @lognormpdf)

acov =

```
        1.0e-03 *
    0.1937  -0.0000
  -0.0000   0.0968
```
Estimate the standard errors of estimates.

\[
se = \sqrt{\text{diag}(acov)}
\]

\[
se = \\
0.0139 \\
0.0098
\]

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

**Custom Log Probability Density Function**

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```matlab
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaln(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```matlab
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat = 
    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```matlab
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov = 
0.0810    0.1646 \\
0.1646    0.6074
```

**Custom Log pdf and Survival Function**

Load the sample data.
The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```matlab
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ... +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```matlab
phat = mle(ReadmissionTime,'logpdf',custlogpdf,... 'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```matlab
phat = 1x2
     9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```matlab
acov = mlecov(phat,ReadmissionTime,... 'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)
```

```matlab
acov = 2x2
         0.5653    0.0102
     0.0102         0.0163
```

**Custom Log Negative Likelihood Function**

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'));
```
The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```matlab
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```matlab
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat = 0.1462
```

Compute the variance of the parameter estimate.

```matlab
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov = 2.1374e-04
```

Compute the standard error.

```matlab
sqrt(acov)
```

```
an = 0.0146
```

### Input Arguments

- **params** — Parameter estimates
  
  scalar value | vector
  
  Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

  Data Types: `single` | `double`

- **data** — Sample data
  
  vector
  
  Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

  Data Types: `single` | `double`
pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is newpdf, then you can specify the function handle in mlecov as follows.

Example: @newpdf

Data Types: function_handle

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define cdf with pdf if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify cdf while using pdf.

For example, if the name of the custom cumulative distribution function is newcdf, then you can specify the function handle in mlecov as follows.

Example: @newcdf

Data Types: function_handle

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is customlogpdf, then you can specify the function handle in mlecov as follows.
Example: @customlogpdf
Data Types: function_handle

**logsf — Custom log survival function**
function handle

Custom log survival function on page 32-4073, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define logsf with logpdf if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify logsf while using logpdf.

For example, if the name of the custom log survival function is logsurvival, then you can specify the function handle in mlecov as follows.

Example: @logsurvival
Data Types: function_handle

**nloglf — Custom negative loglikelihood function**
function handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

<table>
<thead>
<tr>
<th>params</th>
<th>Vector of distribution parameter values</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Vector of data</td>
</tr>
<tr>
<td>cens</td>
<td>Boolean vector of censored values</td>
</tr>
<tr>
<td>freq</td>
<td>Vector of integer data frequencies</td>
</tr>
</tbody>
</table>

nloglf must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write 'nloglf' to ignore cens and freq arguments in that case.

nloglf returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'Options').
If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Censoring',cens,'Options',opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

**Censoring — Indicator for censoring**

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'Censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'Censoring',Censored`

Data Types: `logical`

**Frequency — Frequency of observations**

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'Frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`. 
For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: 'Frequency',Freq

Data Types: single | double

**Options — Numerical options**
structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of 'Options' and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
</table>
| 'GradObj'      | Default is 'off'.
                 | 'on' or 'off', indicating whether or not the function provided with   |
                 | the `nloglf` input argument can return the gradient vector of the     |
                 | negative log-likelihood as a second output.                         |
| 'DerivStep'    | Default is `eps^(1/4)`.                                             |
                 | Relative step size used in finite difference for Hessian calculations.|
                 | It can be a scalar, or the same size as `params`. A smaller value    |
                 | than the default might be appropriate if 'GradObj' is 'on'.          |

Example: 'Options',statset('mlecov')

Data Types: struct

**Output Arguments**

`acov — Approximation to asymptotic covariance matrix`

*p*-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`. 
Definitions

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

“What Is Survival Analysis?” on page 14-2

Introduced before R2006a
mnpdf
Multinomial probability density function

Syntax
Y = mnpdf(X,PROB)

Description
Y = mnpdf(X,PROB) returns the pdf for the multinomial distribution with probabilities PROB, evaluated at each row of X. X and PROB are m-by-k matrices or 1-by-k vectors, where k is the number of multinomial bins or categories. Each row of PROB must sum to one, and the sample sizes for each observation (rows of X) are given by the row sums sum(X,2). Y is an m-by-1 vector, and mnpdf computes each row of Y using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of n = 10. The probabilities are p = 1/2 for outcome 1, p = 1/3 for outcome 2, and p = 1/6 for outcome 3.

p = [1/2 1/3 1/6];
n = 10;
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n-(X1+X2);

Compute the pdf of the distribution.

Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));
Plot the pdf on a 3-dimensional figure.

\[
Y = \text{reshape}(Y,n+1,n+1);
\]

\[
\text{bar3}(Y)
\]

\[
h = \text{gca};
\]

\[
h.\text{XTickLabel} = [0:n];
\]

\[
h.\text{YTickLabel} = [0:n];
\]

\[
\text{xlabel(}'x_1'\)
\]

\[
\text{ylabel(}'x_2'\)
\]

\[
\text{zlabel(}'Probability Mass'\)
\]

\[
\text{title(}'Trinomial Distribution'\)
\]

Note that the visualization does not show \(x_3\), which is determined by the constraint \(x_1 + x_2 + x_3 = n\).

“Multinomial Distribution” on page B-99

Introduced in R2006b
mnrfit
Multinomial logistic regression

Syntax

B = mnrfit(X,Y)
B = mnrfit(X,Y,Name,Value)
[B,dev,stats] = mnrfit(___)

Description

B = mnrfit(X,Y) returns a matrix, B, of coefficient estimates for a multinomial logistic regression of the nominal responses in Y on the predictors in X.

B = mnrfit(X,Y,Name,Value) returns a matrix, B, of coefficient estimates for a multinomial model fit with additional options specified by one or more Name,Value pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

[B,dev,stats] = mnrfit(___ ) also returns the deviance of the fit, dev, and the structure stats for any of the previous input arguments. stats contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

load fisheriris
The column vector, \texttt{species}, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix \texttt{meas} consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

\begin{verbatim}
sp = categorical(species);
\end{verbatim}

Fit a multinomial regression model to predict the species using the measurements.

\begin{verbatim}
[B,dev,stats] = mnrfit(meas,sp);
\end{verbatim}

\begin{verbatim}
B = 5×2
10^3 ×

    1.9345   0.0426
    0.6460   0.0025
   -0.5449   0.0067
   -0.4948  -0.0094
   -2.6472  -0.0183
\end{verbatim}

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of \texttt{meas}. The first row of \texttt{B} contains the intercept terms for the relative risk of the first two response categories, setosa and versicolor versus the reference category, virginica. The last four rows contain the slopes for the models for the first two categories. \texttt{mnrfit} accepts the third category as the reference category.

The relative risk of an iris flower being species 2 (versicolor) versus species 3 (virginica) is the ratio of the two probabilities (the probability of being species 2 and the probability of being species 3). The model for the relative risk is

\[
\ln \left( \frac{\pi_{\text{versicolor}}}{\pi_{\text{virginica}}} \right) = 42.6 + 2.5X_1 + 6.7X_2 - 9.4X_3 - 18.3X_4.
\]

The coefficients express both the effects of the predictor variables on the relative risk and the log odds of being in one category versus the reference category. For example, the estimated coefficient 2.5 indicates that the relative risk of being species 2 (versicolor) versus species 3 (virginica) increases \(\exp(2.5)\) times for each unit increase in \(X_1\), the first
measurement, given all else is equal. The relative log odds of being versicolor versus virginica increases 2.5 times with a one-unit increase in $X_1$, given all else is equal.

If the coefficients are converging toward infinity or negative infinity, the estimated coefficients can vary slightly depending on your operating system.

Check the statistical significance of the model coefficients.

```
stats.p
ans = 5x2
     0    0.0000
     0    0.0281
     0    0.0000
     0    0.0000
     0    0.0000
```

The small $P$-values indicate that all measures are significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3) and being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```
stats.se
ans = 5x2
     12.4038   5.2719
     3.5783   1.1228
     3.1760   1.4789
     3.5403   1.2934
     7.1203   2.0967
```

Calculate the 95% confidence limits for the coefficients.

```
LL = stats.beta - 1.96.*stats.se;
UL = stats.beta + 1.96.*stats.se;
```

Display the confidence intervals for the coefficients of the model for the relative risk of being a setosa versus a virginica (the first column of coefficients in B).
Find the confidence intervals for the coefficients of the model for the relative risk of being a versicolor versus a virginica (the second column of coefficients in B).

\[
\begin{bmatrix}
[LL(:,2) \quad UL(:,2)]
\end{bmatrix}
\]

\[
\text{ans} = 5 \times 2
\]

\[
\begin{tabular}{rr}
32.3049 & 52.9707 \\
0.2645 & 4.6660 \\
3.7823 & 9.5795 \\
-11.9644 & -6.8944 \\
-22.3957 & -14.1766
\end{tabular}
\]

**Multinominal Regression for Ordinal Responses**

Fit a multinominal regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```matlab
load carbig
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);

Fit an ordinal response model for the response variable miles.

[B,dev,stats] = mnrfit(X,miles,'model','ordinal');

B

B = 7×1

-16.6895
-11.7208
-8.0606
0.1048
0.0103
0.0645
0.0017

The first three elements of B are the intercept terms for the models, and the last four elements of B are the coefficients of the covariates, assumed common across all categories. This model corresponds to parallel regression, which is also called the proportional odds model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions','off' name-value pair argument, which is the default for ordinal models.

[B(1:3)'; repmat(B(4:end),1,3)]

ans = 5×3

-16.6895 -11.7208 -8.0606
0.1048 0.1048 0.1048
0.0103 0.0103 0.0103
0.0645 0.0645 0.0645
0.0017 0.0017 0.0017

The link function in the model is logit ('link','logit'), which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

32-4081
For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of \( \exp(0.01048) \) given all else is equal.

Assess the significance of the coefficients.

stats.p

ans = 7×1

0.0000
0.0000
0.0000
0.1899
0.0350
0.0000
0.0118

The \( P \)-values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

**Hierarchical Multinomial Regression Model**

Fit a hierarchical multinomial regression model.
Load the sample data.

load(fullfile(matlabroot,'examples','stats','smoking.mat'));

The data set smoking contains five variables: sex, age, weight, and systolic and diastolic blood pressure. Sex is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

Y = categorical(smoking.Smoker);

The data in Smoker has four categories:

• 0: Nonsmoker, 0 cigarettes a day
• 1: Smoker, 1–5 cigarettes a day
• 2: Smoker, 6–10 cigarettes a day
• 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

X = [smoking.Sex smoking.Age smoking.Weight ...
    smoking.SystolicBP smoking.DiastolicBP];

Fit a hierarchical multinomial model.

[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');

B

B = 6×3

   43.8148    5.9571   44.0712
     1.8709   -0.0230   -0.0662
     0.0188    0.0625    0.1335
     0.0046   -0.0072   -0.0130
    -0.2170    0.0416   -0.0324
    -0.2273   -0.1449   -0.4824

The first column of B includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column
includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions','on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

\[
\ln\left(\frac{P(y = 0)}{P(y > 0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}
\]

\[
\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A - 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}
\]

\[
\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}
\]

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by \(\exp(1.8709) = 6.49\) times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

\[
\text{stats.p}
\]

\[
\text{ans} = 6\times3
\]

\[
\begin{array}{ccc}
0.0000 & 0.5363 & 0.2149 \\
0.3549 & 0.9912 & 0.9835 \\
0.6850 & 0.2676 & 0.2313 \\
0.9032 & 0.8523 & 0.8514 \\
0.0009 & 0.5187 & 0.8165 \\
0.0004 & 0.0483 & 0.0545
\end{array}
\]

Sex, age, or weight don’t appear significant on any level. The \(p\)-values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The \(p\)-value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the \(p\)-value of 0.0545 indicates that
diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```matlab
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```
The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```matlab
X = double([smoking.Sex smoking.SystolicBP...
smoking.DiastolicBP]);
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');
B

B = 4×3
    44.8456    5.3230   25.0248
    1.6045    0.2330    0.4982
   -0.2161    0.0497    0.0179
   -0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by \( \exp(1.6045) = 4.97 \) times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an \( \exp(-0.2161) = 0.8056 \) decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an \( \exp(-0.2222) = 0.8007 \) decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```matlab
stats.p
```

ans = 4×3

```
    0.0000    0.4715    0.2325
    0.0210    0.7488    0.6362
    0.0010    0.4107    0.8899
    0.0003    0.0483    0.0718
```

The \( P \)-values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the \( P \)-value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1-5 cigarettes.
versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the $P$-values on the third column are less than 0.05, you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6-10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

**Input Arguments**

*X* — **Observations on predictor variables**  

$n$-by-$p$ matrix  

**Note**  

*mnrfit* automatically includes a constant term (intercept) in all models. Do not include a column of 1s in $X$.

Data Types: *single* | *double*

*Y* — **Response values**  

$n$-by-$k$ matrix | $n$-by-1 column vector  

Response values, specified as a column vector or a matrix. $Y$ can be one of the following:

- An $n$-by-$k$ matrix, where $Y(i,j)$ is the number of outcomes of the multinomial category $j$ for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An $n$-by-1 column vector of scalar integers from 1 to $k$ indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An $n$-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Model','ordinal','Link','probit' specifies an ordinal model with a probit link function.

**Model — Type of model to fit**

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'Model' and one of the following.

| 'nominal' | Default. There is no ordering among the response categories. |
| 'ordinal' | There is a natural ordering among the response categories. |
| 'hierarchical' | The choice of response category is sequential/nested. |

Example: 'Model','ordinal'

**Interactions — Indicator for interaction between multinomial categories and coefficients**

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'Interactions' and one of the following.

| 'on' | Default for nominal and hierarchical models. Fit a model with different coefficients across categories. |
| 'off' | Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as parallel regression or the proportional odds model. |

In all cases, the model has different intercepts across categories. The choice of 'Interactions' determines the dimensions of the output array B.

Example: 'Interactions','off'

**Link — Link function**

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'Link' and one of the following.
The link function defines the relationship between response probabilities and the linear combination of predictors, \(X\beta\). The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, \(\gamma\) represents the cumulative probability of being in categories 1 to \(j\) and the model with a logit link function as follows:

\[
\ln \left( \frac{\gamma}{1-\gamma} \right) = \ln \left( \frac{\pi_1 + \pi_2 + \cdots + \pi_j}{\pi_{j+1} + \cdots + \pi_k} \right) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_p X_p,
\]

where \(k\) represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

\[
\ln \left( \frac{\pi_j}{\pi_r} \right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \cdots + \beta_{jp} X_{jp}, \quad j = 1, \ldots, k - 1,
\]

where \(\pi\) stands for a categorical probability, and \(r\) corresponds to the reference category. \texttt{mnrfit} uses the last category as the reference category for nominal models.

Example: 'Link', 'loglog'

**EstDisp — Indicator for estimating dispersion parameter**

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

| 'off' | Default. Use the theoretical dispersion value of 1. |
'on' | Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: 'EstDisp','on'

Output Arguments

B — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y, returned as a vector or a matrix.

- If 'Interaction' is 'off', then B is a \( k - 1 + p \) vector. The first \( k - 1 \) rows of B correspond to the intercept terms, one for each \( k - 1 \) multinomial categories, and the remaining \( p \) rows correspond to the predictor coefficients, which are common for all of the first \( k - 1 \) categories.
- If 'Interaction' is 'on', then B is a \(( p + 1)\)-by-\((k - 1)\) matrix. Each column of B corresponds to the estimated intercept term and predictor coefficients, one for each of the first \( k - 1 \) multinomial categories.

The estimates for the \( k \)th category are taken to be zero as mnrfit takes the last category as the reference category.

dev — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

\[
dev = 2 \sum_{i}^{n} \sum_{j}^{k} y_{ij} \log \left( \frac{y_{ij}}{\pi_{ij} \cdot m_i} \right) = \sum_{i}^{n} rd_i,
\]

where \( rd_i \) are the deviance residuals. For deviance residuals see stats.

stats — Model statistics

structure

32-4090
Model statistics, returned as a structure that contains the following fields.

</tbody>
</table>

where \(\pi_{ij}\) is the categorical, cumulative or conditional probability, and \(m_i\) is the corresponding sample size.
Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:

\[ rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \left\{ \begin{array}{l} i = 1, \ldots, n \\ j = 1, \ldots, k \end{array} \right. \]

where \( \pi_{ij} \) is the categorical, cumulative, or conditional probability, and \( m_i \) is the corresponding sample size.

Deviance residuals:

\[ rd_i = 2 * \sum_{j=1}^{k} r_{ij} * \log \left( \frac{y_{ij}}{\pi_{ij} * m_i} \right), \quad i = 1, \ldots, n. \]

where \( \pi_{ij} \) is the categorical, cumulative, or conditional probability, and \( m_i \) is the corresponding sample size.

## Algorithms

`mnrfit` treats NaNs in either X or Y as missing values, and ignores them.

Introduced in R2006b
mnrnd

Multinomial random numbers

Syntax

r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)

Description

r = mnrnd(n,p) returns random values r from the multinomial distribution with parameters n and p. n is a positive integer specifying the number of trials (sample size) for each multinomial outcome. p is a 1-by-k vector of multinomial probabilities, where k is the number of multinomial bins or categories. p must sum to one. (If p does not sum to one, r consists entirely of NaN values.) r is a 1-by-k vector, containing counts for each of the k multinomial bins.

R = mnrnd(n,p,m) returns m random vectors from the multinomial distribution with parameters n and p. R is a m-by-k matrix, where k is the number of multinomial bins or categories. Each row of R corresponds to one multinomial outcome.

R = mnrnd(N,P) generates outcomes from different multinomial distributions. P is a m-by-k matrix, where k is the number of multinomial bins or categories and each of the m rows contains a different set of multinomial probabilities. Each row of P must sum to one. (If any row of P does not sum to one, the corresponding row of R consists entirely of NaN values.) N is a m-by-1 vector of positive integers or a single positive integer (replicated by mnrnd to a m-by-1 vector). R is a m-by-k matrix. Each row of R is generated using the corresponding rows of N and P.

Examples

Generate 2 random vectors with the same probabilities:
n = 1e3;
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
   215   282   503
   194   303   503

Generate 2 random vectors with different probabilities:

n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3;];

Topics
“Multinomial Distribution” on page B-99

Introduced in R2006b
**mnrval**

Multinomial logistic regression values

**Syntax**

```matlab
pihat = mnrval(B,X)
[pihat,dlow,dhi] = mnrval(B,X,stats)
[pihat,dlow,dhi] = mnrval(B,X,stats,Name,Value)

tyhat = mnrval(B,X,ssize)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value)
```

**Description**

`pihat = mnrval(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, `X`, and the coefficient estimates, `B`.

`pihat` is an n-by-k matrix of predicted probabilities for each multinomial category. `B` is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And `X` is an n-by-p matrix which contains n observations for p predictors.

**Note** `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

`[pihat,dlow,dhi] = mnrval(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.
[pihat,dlow,dhi] = mnrval(B,X,stats,Name,Value) returns the predicted probabilities and 95% error bounds on the predicted probabilities pihat, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

yhat = mnrval(B,X,ssize) returns the predicted category counts for sample sizes, ssize.

[yhat,dlow,dhi] = mnrval(B,X,ssize,stats) also computes 95% error bounds on the predicted counts yhat, using the statistics in the structure, stats, returned by mnrfit.

The lower and upper confidence bounds for yhat are yhat minus dlo and yhat plus dhi, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

[yhat,dlow,dhi] = mnrval(B,X,ssize,stats,Name,Value) returns the predicted category counts and 95% error bounds on the predicted counts yhat, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

load fisheriris

The column vector, species, consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.
Define the nominal response variable.

```matlab
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```matlab
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.3, 2.8, 4.9, 1.7).

```matlab
x = [6.3, 2.8, 4.9, 1.7];
pihat = mnrval(B,x);
pihat
```

```matlab
pihat = 1×3
0    0.3977    0.6023
```

The probability of an iris flower having the measurements (6.3, 2.8, 4.9, 1.7) being a setosa is 0, a versicolor is 0.3977, and a virginica is 0.6023.

**Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses**

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```matlab
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).
Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```matlab
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```
Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable `miles`. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```
Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with \( x = (12, 113, 110, 2670) \).

```matlab
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrval(B,x,stats,'model','ordinal');
pihat
```

```
pihat = 1×4
0.0615    0.8426    0.0932    0.0027
```
Calculate the confidence bounds for the category probability estimates.

```matlab
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
```

```
ans = 2×4
0.0073    0.7829    0.0283   -0.0003
0.1157    0.9022    0.1580    0.0057
```

**Estimate Category Counts and Error Bounds for Nominal Responses**

Fit a multinomial regression for nominal outcomes and estimate the category counts.
Load the sample data.

```matlab
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```matlab
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species setosa, versicolor, and virginica, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```matlab
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.3, 2.8, 4.9, 1.7).

```matlab
x = [6.3, 2.8, 4.9, 1.7];
yhat = mnrval(B,x,18)
```

```matlab
yhat = 1×3
         0   7.1578   10.8422
```

Estimate the error bounds for the counts.

```matlab
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```matlab
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
```

```matlab
ans = 2×3
         0   3.3019    6.9863
         0  11.0137   14.6981
```
**Plot the Count Estimates**

Create sample data with one predictor variable and a categorical response variable with three categories.

```matlab
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10;...
    5 14 6; 7 13 5; 8 11 6];
[Y x]
ans = 7×4
     1    11    13     -3
     2     9    14     -2
     6    14     5     -1
     5    10    10     0
     5    14     6     1
     7    13     5     2
     8    11     6     3
```

There are observations on seven different values of the predictor variable `x`. The response variable `Y` has three categories and the data shows how many of the 25 individuals are in each category of `Y` for each observation of `x`. For example, when `x` is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when `x` is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the `x` values, on a stacked bar graph.

```matlab
bar(x,Y,'stacked');
ylim([0 25]);
```
Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x, for each category.

\[
\text{betaHatNom} = \text{mnrfit}(x, Y, 'model', 'nominal', ... \\
'interactions', 'on')
\]

\[
\text{betaHatNom} = 2 \times 2 \\
\begin{array}{cc}
-0.6028 & 0.3832 \\
0.4068 & 0.1948
\end{array}
\]
The first row of \texttt{betaHatOrd} contains the intercept terms for the first two response categories. The second row contains the slopes. \texttt{mnrfit} accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

\begin{verbatim}
xx = linspace(-4,4)';
piHatNom = mnrval(betaHatNom,xx,'model','nominal',...'
            'interactions','on');
\end{verbatim}

The probability of being in the third category is simply $1 - P(y = 1) - P(y = 2)$.

Plot the estimated cumulative number in each category on the bar graph.

\begin{verbatim}
line(xx,cumsum(25*piHatNom,2),'
            'LineWidth',2);
\end{verbatim}
The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, \( x \), across all categories:

\[
\text{betaHatOrd} = \text{mnrfit}(x, Y, \text{'model', 'ordinal'}, ...
\text{    'interactions', 'off'})
\]

betaHatOrd = 3\times1

-1.5001
0.7266
0.2642
The first two elements of \texttt{betaHatOrd} are the intercept terms for the first two response categories. The last element of \texttt{betaHatOrd} is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

\begin{verbatim}
piHatOrd = mnrval(betaHatOrd,xx,'type','cumulative',...
    'model','ordinal','interactions','off');
\end{verbatim}

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

\begin{verbatim}
figure()
bar(x,cumsum(Y,2),'grouped');
ylim([0 25]);
line(xx,25*piHatOrd,'LineWidth',2);
\end{verbatim}
Input Arguments

**B — Coefficient estimates**
vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrval(B,X)`

Data Types: `single` | `double`
\(X\) — **Sample data**

matrix

Sample data on predictors, specified as an \(n\)-by-\(p\). \(X\) contains \(n\) observations for \(p\) predictors.

**Note** \texttt{mnrval} automatically includes a constant term in all models. Do not enter a column of 1s in \(X\).

Example: \(\text{pihat} = \text{mnrval}(B,X)\)

Data Types: \texttt{single} | \texttt{double}

\texttt{stats} — **Model statistics**

structure returned by \texttt{mnrfit}

Model statistics, specified as a structure returned by \texttt{mnrfit}. You must use the \texttt{stats} input argument in \texttt{mnrval} to compute the lower and upper error bounds on the category probabilities and counts.

Example: \([B,\text{dev},\text{stats}] = \text{mnrfit}(X,y);[\text{pihat},\text{dlo},\text{dhi}] = \text{mnrval}(B,X,\text{stats})\)

\texttt{ssize} — **Sample sizes**

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an \(n\)-by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is \(y_1\), \(y_2\), and \(y_3\), respectively, then the sample size, \(m\), for that observation is \(m = y_1 + y_2 + y_3\).

If the sample sizes for \(n\) observations are in vector \texttt{sample}, then you can enter the sample sizes as follows.

Example: \(\text{yhat} = \text{mnrval}(B,X,\text{sample})\)

Data Types: \texttt{single} | \texttt{double}
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'model', 'ordinal', 'link', 'probit', 'type', 'cumulative' specifies that mnrval returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

**model — Type of multinomial model**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nominal'</td>
<td>Default. Specify when there is no ordering among the response categories.</td>
</tr>
<tr>
<td>'ordinal'</td>
<td>Specify when there is a natural ordering among the response categories.</td>
</tr>
<tr>
<td>'hierarchical'</td>
<td>Specify when the choice of response category is sequential.</td>
</tr>
</tbody>
</table>

Example: 'model', 'ordinal'

**interactions — Indicator for interaction between multinomial categories and coefficients**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'on'</td>
<td>Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.</td>
</tr>
<tr>
<td>'off'</td>
<td>Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as parallel regression or proportional odds model.</td>
</tr>
</tbody>
</table>

Example: 'interactions', 'off'
Data Types: logical

**link — Link function**
'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

<table>
<thead>
<tr>
<th>'logit'</th>
<th>Default. ( f(\gamma) = \ln(\gamma/(1 - \gamma)) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'probit'</td>
<td>( f(\gamma) = \Phi^{-1}(\gamma) ) — error term is normally distributed with variance 1</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>Complementary log-log ( f(\gamma) = \ln(-\ln(1 - \gamma)) )</td>
</tr>
<tr>
<td>'loglog'</td>
<td>( f(\gamma) = \ln(-\ln(\gamma)) )</td>
</tr>
</tbody>
</table>

The link function defines the relationship between response probabilities and the linear combination of predictors, \( X\beta \).

\( \gamma \) might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

\[
\ln \left( \frac{\pi_j}{\pi_r} \right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \ldots, k - 1,
\]

where \( \pi \) stands for a categorical probability, and \( r \) corresponds to the reference category. \( k \) is the total number of response categories, \( p \) is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'link','loglog'

**type — Type of probabilities or counts to estimate**
'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including 'type' and one of the following.
'category'  
Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.

'cumulative'  
Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first k - 1 multinomial categories, as an n-by-(k - 1) matrix. The predicted cumulative probability for the kth category is always 1.

'conditional'  
Specify to return predictions and error bounds in terms of the first k - 1 conditional category probabilities (counts), i.e., the probability (count) for category j, given an outcome in category j or higher. When 'type' is 'conditional', and you supply the sample size argument ssize, the predicted counts at each row of X are conditioned on the corresponding element of ssize, across all categories.

Example: 'type', 'cumulative'

**confidence — Confidence level**

0.95 (default) | scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: 'confidence', 0.99

Data Types: single | double

**Output Arguments**

**pihat — Probability estimates**

n-by-(k - 1) matrix

Probability estimates for each multinomial category, returned as an n-by-(k - 1) matrix, where n is the number of observations, and k is the number of response categories.

**yhat — Count estimates**

n-by-k-1 matrix
Count estimates for the number in each response category, returned as an \( n \)-by-\( k - 1 \) matrix, where \( n \) is the number of observations, and \( k \) is the number of response categories.

\textbf{dlow} — Lower error bound

\textbf{column vector}

Lower error bound to compute the lower confidence bound for \( \hat{p} \) or \( \hat{y} \), returned as a column vector.

The lower confidence bound for \( \hat{p} \) is \( \hat{p} \) minus \( \text{dlow} \). Similarly, the lower confidence bound for \( \hat{y} \) is \( \hat{y} \) minus \( \text{dlow} \). Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

\textbf{dhi} — Upper error bound

\textbf{column vector}

Upper error bound to compute the upper confidence bound for \( \hat{p} \) or \( \hat{y} \), returned as a column vector.

The upper confidence bound for \( \hat{p} \) is \( \hat{p} \) plus \( \text{dhi} \). Similarly, the upper confidence bound for \( \hat{y} \) is \( \hat{y} \) plus \( \text{dhi} \). Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

\textbf{Introduced in R2006b}
moment

Central moments

Syntax

\[
m = \text{moment}(X,\text{order})
\]
\[
m = \text{moment}(X,\text{order},'\text{all}')
\]
\[
m = \text{moment}(X,\text{order},\text{dim})
\]
\[
m = \text{moment}(X,\text{order},\text{vecdim})
\]

Description

\[
m = \text{moment}(X,\text{order})\] returns the central sample moment of \(X\) specified by the positive integer \(\text{order}\). For vectors, \(\text{moment}(x,\text{order})\) returns the central moment of the specified order for the elements of \(x\). For matrices, \(\text{moment}(X,\text{order})\) returns the central moment of the specified order for each column. For N-dimensional arrays, \(\text{moment}\) operates along the first nonsingleton dimension of \(X\).

\[
m = \text{moment}(X,\text{order},'\text{all}')\] returns the moment of the specified order for all elements of \(X\).

\[
m = \text{moment}(X,\text{order},\text{dim})\] takes the moment along the operating dimension \(\text{dim}\) of \(X\).

\[
m = \text{moment}(X,\text{order},\text{vecdim})\] returns the moment over the dimensions specified in the vector \(\text{vecdim}\). Each element of \(\text{vecdim}\) represents a dimension of the input array \(X\). The output \(m\) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \(X\) and \(m\). For example, if \(X\) is a 2-by-3-by-4 array, then \(\text{moment}(X, 1, [1 2])\) returns a 1-by-1-by-4 array. Each element of the output array is the first moment of the elements on the corresponding page of \(X\).

Examples
Find Central Moment for Specified Order

Set the random seed for reproducibility of the results.

```matlab
rng('default')
```

Generate a matrix with 6 rows and 5 columns.

```matlab
X = randn(6,5)
```

```
6×5
0.5377   -0.4336    0.7254    1.4090    0.4889
1.8339    0.3426   -0.0631    1.4172    1.0347
-2.2588    3.5784    0.7147    0.6715    0.7269
0.8622    2.7694   -0.2050   -1.2075   -0.3034
0.3188   -1.3499   -0.1241    0.7172    0.2939
-1.3077    3.0349    1.4897    1.6302   -0.7873
```

Find the third order central moment of X.

```matlab
m = moment(X,3)
```

```
1×5
-1.1143   -0.9973    0.1234   -1.1023   -0.1045
```

m is a row vector containing the third order central moment of each column in X.

Find Central Moment Along Vector of Dimensions

Find the central moment over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

```matlab
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```matlab
X = randn(4,3,2)
```
X =
X(:,:,1) =
   0.5377    0.3188    3.5784
   1.8339   -1.3077    2.7694
  -2.2588   -0.4336   -1.3499
   0.8622    0.3426    3.0349

X(:,:,2) =
   0.7254   -0.1241    0.6715
  -0.0631    1.4897   -1.2075
   0.7147    1.4090    0.7172
  -0.2050    1.4172    1.6302

Find the third order central moment of X.

mall = moment(X,3,'all')
mall = 0.2431

mall is the third order central moment of the entire input data set X.

Find the third order moment of each page of X by specifying the first and second dimensions.

mpage = moment(X,3,[1 2])

mpage =
mpage(:,:,1) =
   0.6002

mpage(:,:,2) =
  -0.3475

For example, mpage(1,1,2) is the third order central moment of the elements in X(:,:,2).
Find the third order moment of the elements in each \( X(i,:,:) \) slice by specifying the second and third dimensions.

\[
m_{\text{row}} = \text{moment}(X,3,[2 3])
\]

\[
m_{\text{row}} = \begin{bmatrix} 2.7552 \\ 0.0443 \\ -0.7585 \\ 0.5340 \end{bmatrix}
\]

For example, \( m_{\text{row}}(1) \) is the third order central moment of the elements in \( X(1,:,:). \)

**Tips**

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of \( n \) rather than \( n - 1 \), where \( n \) is the length of the vector \( x \) or the number of rows in the matrix \( X \).

The central moment of order \( k \) of a distribution is defined as

\[
m_k = E((x - \mu)^k)
\]

where \( E(x) \) is the expected value of \( x \).

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
• \( m = \text{moment}(X, \text{order}, 'all') \)
• \( m = \text{moment}(X, \text{order}, \text{vecdim}) \)
• If \( \text{order} \) is nonintegral and \( X \) is real, use \( \text{moment}(	ext{complex}(X), \text{order}) \).

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • \( m = \text{moment}(X, \text{order}, 'all') \)
  • \( m = \text{moment}(X, \text{order}, \text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

*Introduced before R2006a*
multcompare

Multiple comparison test

Syntax

c = multcompare(stats)
c = multcompare(stats,Name,Value)
[c,m] = multcompare(__)
[c,m,h] = multcompare(__)
[c,m,h,gnames] = multcompare(__)

Description

c = multcompare(stats) returns a matrix c of the pairwise comparison results from a multiple comparison test using the information contained in the stats structure. multcompare also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

c = multcompare(stats,Name,Value) returns a matrix of pairwise comparison results, c, using additional options specified by one or more Name,Value pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

[c,m] = multcompare(__) also returns a matrix, m, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

[c,m,h] = multcompare(__) also returns a handle, h, to the comparison graph.

[c,m,h,gnames] = multcompare(__) also returns a cell array, gnames, which contains the names of the groups.
Examples

Multiple Comparison of Group Means

Load the sample data.

load carsmall

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

[p,t,stats] = anova1(MPG,Origin,'off');

Perform a multiple comparison of the group means.

[c,m,h,nms] = multcompare(stats);
multicorpare displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

[nms num2cell(m)]

ans = 6x3 cell array
{'USA' } {[21.1328]} {[0.8814]}
{'Japan' } {[31.8000]} {[1.8206]}
{'Germany'} {[28.4444]} {[2.3504]}
{'France' } {[23.6667]} {[4.0711]}
{'Sweden' } {[22.5000]} {[4.9860]}
Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```matlab
load popcorn
popcorn
popcorn = 6×3
    5.5000  4.5000  3.5000
    5.5000  4.5000  4.0000
    6.0000  4.0000  3.0000
    6.5000  5.0000  4.0000
    7.0000  5.5000  5.0000
    7.0000  5.0000  4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```matlab
[~,~,stats] = anova2(popcorn,3,'off')
```

```matlab
stats = struct with fields:
    source: 'anova2'
    sigmasq: 0.1389
    colmeans: [6.2500 4.7500 4]
    coln: 6
    rowmeans: [4.5000 5.5000]
    rown: 9
    inter: 1
    pval: 0.7462
    df: 12
```

The `stats` structure includes
• The mean squared error (sigmasq)
• The estimates of the mean yield for each popcorn brand (colmeans)
• The number of observations for each popcorn brand (coln)
• The estimate of the mean yield for each popper type (rowmeans)
• The number of observations for each popper type (rown)
• The number of interactions (inter)
• The $p$-value that shows the significance level of the interaction term (pval)
• The error degrees of freedom (df).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

$c = \text{multcompare}(\text{stats})$

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.
The first two columns of $c$ show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the $p$-value for a hypothesis test that the corresponding mean difference is equal to zero. All $p$-values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.
The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```matlab
    c = multcompare(stats,'Estimate','row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.
c = 1×6

1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001

The small p-value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

**Multiple Comparisons for Three-Way ANOVA**

Load the sample data.

```matlab
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

y is the response vector and g1, g2, and g3 are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation y(1) is associated with level 1 of factor g1, level 'hi' of factor g2, and level 'may' of factor g3. Similarly, observation y(6) is associated with level 2 of factor g1, level 'hi' of factor g2, and level 'june' of factor g3.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```matlab
[~,~,stats] = anovan(y,[g1 g2 g3], 'model','interaction',...
   'varnames', {'g1','g2','g3'});
```
The \( p \)-value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor g3 are not significantly different. The \( p \)-value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor g1 are significantly different. Similarly, the \( p \)-value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor g2 are significantly different.

Perform multiple comparison tests to find out which groups of the factors g1 and g2 are significantly different.

\[
\text{results} = \text{multcompare}(	ext{stats},'\text{Dimension}',[1 2])
\]
multcompare compares the combinations of groups (levels) of the two grouping variables, $g_1$ and $g_2$. In the results matrix, the number 1 corresponds to the combination of level 1 of $g_1$ and level hi of $g_2$, the number 2 corresponds to the combination of level 2 of $g_1$ and level hi of $g_2$. Similarly, the number 3 corresponds to
the combination of level 1 of g1 and level lo of g2, and the number 4 corresponds to the
combination of level 2 of g1 and level lo of g2. The last column of the matrix contains the
p-values.

For example, the first row of the matrix shows that the combination of level 1 of g1 and
level hi of g2 has the same mean response values as the combination of level 2 of g1 and
level hi of g2. The p-value corresponding to this test is 0.0280, which indicates that the
mean responses are significantly different. You can also see this result in the figure. The
blue bar shows the comparison interval for the mean response for the combination of
level 1 of g1 and level hi of g2. The red bars are the comparison intervals for the mean
response for other group combinations. None of the red bars overlap with the blue bar,
which means the mean response for the combination of level 1 of g1 and level hi of g2 is
significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for
the group. The bar you click on turns to blue. The bars for the groups that are
significantly different are red. The bars for the groups that are not significantly different
are gray. For example, if you click on the comparison interval for the combination of level
1 of g1 and level lo of g2, the comparison interval for the combination of level 2 of g1
and level lo of g2 overlaps, and is therefore gray. Conversely, the other comparison
intervals are red, indicating significant difference.

**Input Arguments**

`stats — Test data
structure`

Test data, specified as a structure. You can create a structure using one of the following
functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — N-way analysis of variance.
- `aoctool` — Interactive analysis of covariance tool.
- `friedman` — Friedman’s test.
- `kruskalwallis` — Kruskal-Wallis test.
multcompare does not support multiple comparisons using anovan output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: struct

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Alpha',0.01,'CType','bonferroni','Display','off' computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

Alpha — Significance level
0.05 (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The value specified for 'Alpha' determines the 100 × (1 – α) confidence levels of the intervals returned in the matrix c and in the figure.

Example: 'Alpha',0.01

Data Types: single | double

CType — Type of critical value
'tukey-kramer' (default) | 'hsd' | 'lsd' | 'bonferroni' | 'dunn-sidak' | 'scheffe'

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of 'CType' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'tukey-kramer'</td>
<td>Tukey's honest significant difference criterion on page 9-32</td>
</tr>
<tr>
<td>'hsd'</td>
<td>Tukey's honest significant difference criterion on page 9-32</td>
</tr>
<tr>
<td>'bonferroni'</td>
<td>Bonferroni method on page 9-33</td>
</tr>
<tr>
<td>'dunn-sidak'</td>
<td>Dunn and Sidák’s approach on page 9-33</td>
</tr>
</tbody>
</table>
Value | Description
---|---
'lsd' | Fisher's least significant difference procedure on page 9-34
'scheffe' | Scheffé's S procedure on page 9-35

Example: 'CType', 'bonferroni'

**Display — Display toggle**

' on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either ' on' or ' off'. If you specify ' on', then multcompare displays a graph of the estimates and their comparison intervals. If you specify ' off', then multcompare omits the graph.

Example: 'Display', 'off'

**Dimension — Dimension over which to calculate marginal means**

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure stats using the function anovan.

For example, if you specify 'Dimension' as 1, then multcompare compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension' as [1,3], then multcompare computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at
each combination does have meaning, population marginal means may be harder to interpret.

Example: 'Dimension',[1,3]

Data Types: single | double

**Estimate — Estimates to be compared**
'column' (default) | 'row' | 'slope' | 'intercept' | 'pmm'

Estimates to be compared, specified as the comma-separated pair consisting of 'Estimate' and an allowable value. The allowable values for 'Estimate' depend on the function used to generate the input structure `stats`, according to the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>anova1</td>
<td>None. This name-value pair is ignored, and <code>multcompare</code> always compares the group means.</td>
</tr>
<tr>
<td>anova2</td>
<td>Either 'column' to compare column means, or 'row' to compare row means.</td>
</tr>
<tr>
<td>anovan</td>
<td>None. This name-value pair is ignored, and <code>multcompare</code> always compares the population marginal means as specified by the 'Dimension' name-value pair argument.</td>
</tr>
<tr>
<td>aoctool</td>
<td>Either 'slope', 'intercept', or 'pmm' to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then 'slope' is not allowed. If it did not include separate intercepts, then no comparisons are possible.</td>
</tr>
<tr>
<td>friedman</td>
<td>None. This name-value pair is ignored, and <code>multcompare</code> always compares the average column ranks.</td>
</tr>
<tr>
<td>kruskalwallis</td>
<td>None. This name-value pair is ignored, and <code>multcompare</code> always compares the average group ranks.</td>
</tr>
</tbody>
</table>

Example: 'Estimate','row'

**Output Arguments**

**`c` — Matrix of multiple comparison results**
matrix of scalar values
Matrix of multiple comparison results, returned as an \( p \)-by-6 matrix of scalar values, where \( p \) is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the \( p \)-value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

\[
2.0000 \quad 5.0000 \quad 1.9442 \quad 8.2206 \quad 14.4971 \quad 0.0432
\]

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is \([1.9442, 14.4971]\). The \( p \)-value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The \( p \)-value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

\[\textbf{m} \quad \textbf{— Matrix of estimates}\]

\text{matrix of scalar values}

Matrix of the estimates, returned as a matrix of scalar values. The first column of \( m \) contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

\[\textbf{h} \quad \textbf{— Handle to the figure}\]

\text{handle}

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the x-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the x-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

\[
\text{title('')} \\
\text{xlabel('')}
\]

\[\textbf{gnames} \quad \textbf{— Group names}\]

\text{cell array of character vectors}

32-4131
Group names, returned as a cell array of character vectors. Each row of \texttt{gnames} contains the name of a group.

**Definitions**

**Multiple Comparison Tests**

Analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A multiple comparison test can provide this information.

When you perform a simple \textit{t}-test of one group mean against another, you specify a significance level that determines the cutoff value of the \textit{t}-statistic. For example, you can specify the value \texttt{alpha = 0.05} to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5\% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary \textit{t}-test in this situation, the \texttt{alpha} value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that \textit{any} comparison will be incorrectly found significant.

\texttt{anova1|anova2|anovan|aocotool|friedman|kruskalwallis}
Introduced before R2006a
multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

tbl = multcompare(rm,var)
tbl = multcompare(rm,var,Name,Value)

Description

tbl = multcompare(rm,var) returns multiple comparisons of the estimated marginal means based on the variable var in the repeated measures model rm.

tbl = multcompare(rm,var,Name,Value) returns multiple comparisons of the estimated marginal means with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

var — Variables for which to compute marginal means
character vector | string scalar

32-4134
Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between- or within-subjects factor in rm. If var is a between-subjects factor, it must be categorical.

Data Types: char | string

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Alpha — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 through 1. The confidence level is 100*(1-alpha)%.

Example: 'alpha',0.01

Data Types: double | single

By — Factor to perform comparisons by

character vector | string scalar

Factor to do the comparisons by, specified as the comma-separated pair consisting of 'By' and a character vector or string scalar. The comparison between levels of var occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, A, B, and C, and if you want to do the comparisons of A levels separately for each level of C, then specify A as the var argument and specify C using the 'By' argument as follows.

Example: 'By',C

Data Types: char | string

ComparisonType — Type of critical value to use

'tukey-kramer' (default) | 'dunn-sidak' | 'bonferroni' | 'scheffe' | 'lsd'

Type of critical value to use, specified as the comma-separated pair consisting of 'ComparisonType' and one of the following.
<table>
<thead>
<tr>
<th>Comparison Type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>'tukey-kramer'</td>
<td>Default. Also called Tukey’s Honest Significant Difference procedure. It is based on the Studentized range distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.</td>
</tr>
</tbody>
</table>
| 'dunn-sidak'       | Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is  
\[
|t| = \frac{|\bar{y}_i - \bar{y}_j|}{\sqrt{MSE \left( \frac{1}{n_i} + \frac{1}{n_j} \right)}} > t_{1-\eta/2,\nu},
\]
where  
\[
\eta = 1 - (1 - \alpha)^{1/\nu}
\]
and ng is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure. |
### Comparison Type

| 'bonferroni' | Use critical values from the \( t \) distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is 
\[
    t_{\frac{\alpha}{2} \left( \frac{ng}{2} \right)^2},
\]
where \( ng \) is the number of groups (marginal means), and \( v \) is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure. |

| 'scheffe' | Use critical values from Scheffé's \( S \) procedure, derived from the \( F \) distribution. The critical value is 
\[
    \sqrt{(ng - 1)F_{\alpha, ng-1, v}},
\]
where \( ng \) is the number of groups (marginal means), and \( v \) is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs. |

| 'lsd' | Least significant difference. This option uses plain \( t \)-tests. The critical value is 
\[
    t_{\frac{\alpha}{2}, v},
\]
where \( v \) is the error degrees of freedom. It provides no protection against the multiple comparison problem. |

Example: 'ComparisonType','dunn-sidak'
Output Arguments

**tbl** — Results of multiple comparison table

Results of multiple comparisons of estimated marginal means, returned as a table. **tbl** has the following columns.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Difference</td>
<td>Estimated difference between the corresponding two marginal means</td>
</tr>
<tr>
<td>StdErr</td>
<td>Standard error of the estimated difference between the corresponding two marginal means</td>
</tr>
<tr>
<td>pValue</td>
<td>p-value for a test that the difference between the corresponding two marginal means is 0</td>
</tr>
<tr>
<td>Lower</td>
<td>Lower limit of simultaneous 95% confidence intervals for the true difference</td>
</tr>
<tr>
<td>Upper</td>
<td>Upper limit of simultaneous 95% confidence intervals for the true difference</td>
</tr>
</tbody>
</table>

Examples

**Multiple Comparison of Estimated Marginal Means**

Load the sample data.

```matlab
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```matlab
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...'VariableNames',
    {'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4],'VarNames',
    {'Measurements'});```
Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```matlab
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```matlab
tbl = multcompare(rm,'species')
```

<table>
<thead>
<tr>
<th>species_1</th>
<th>species_2</th>
<th>Difference</th>
<th>StdErr</th>
<th>pValue</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>'setosa'</td>
<td>'versicolor'</td>
<td>-1.0375</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>-1.1794</td>
<td>-0.89562</td>
</tr>
<tr>
<td>'setosa'</td>
<td>'virginica'</td>
<td>-1.7495</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>-1.8914</td>
<td>-1.6076</td>
</tr>
<tr>
<td>'versicolor'</td>
<td>'setosa'</td>
<td>1.0375</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>0.89562</td>
<td>1.1794</td>
</tr>
<tr>
<td>'versicolor'</td>
<td>'virginica'</td>
<td>-0.712</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>-0.85388</td>
<td>-0.57012</td>
</tr>
<tr>
<td>'virginica'</td>
<td>'setosa'</td>
<td>1.7495</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>1.6076</td>
<td>1.8914</td>
</tr>
<tr>
<td>'virginica'</td>
<td>'versicolor'</td>
<td>0.712</td>
<td>0.060539</td>
<td>9.5606e-10</td>
<td>0.57012</td>
<td>0.85388</td>
</tr>
</tbody>
</table>

The small \( P \)-values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

**Perform Multiple Comparisons with Specified Options**

Load the sample data.

```matlab
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```matlab
R = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`. 

32-4139
The small $p$-value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The $p$-value of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```matlab
T = multcompare(R,'Group','ComparisonType','Scheffe')
```

</tbody>
</table>

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding $p$-values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding $p$-values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females ($p$-value is 0.049957), it is not significantly different from 0 for males ($p$-value is 0.14414).

fitrm | margmean | plotprofile
multivarichart

Multivari chart for grouped data

Syntax

multivarichart(y,GROUP)
multivarichart(Y)
multivarichart(...,param1,val1,param2,val2,...)
[charthandle,AXESH] = multivarichart(...)

Description

multivarichart(y,GROUP) displays the multivari chart for the vector y grouped by entries in GROUP that can be a cell array or a matrix. If GROUP is a cell array, then each cell in GROUP must contain a grouping variable that is a categorical vector, numeric vector, character matrix, string array, or single-column cell array of character vectors. If GROUP is a numeric matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of elements as y. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The x-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (i,j) is the multivari chart for the subset of y at the ith level of the third grouping variable and the jth level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

multivarichart(Y) displays the multivari chart for a matrix Y. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

multivarichart(...,param1,val1,param2,val2,...) specifies one or more of the following name/value pairs:
• 'varnames' — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ....

• 'plotorder' — 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the x-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charhandle,AXESH] = multivarichart(...) returns a handle charhandle to the figure window and a matrix AXESH of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

Display a multivari chart for data with two grouping variables.

rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
Display a multivari chart for data with four grouping variables.

\[
y = \text{randn}(1000,1); \quad \% \text{ Randomly generate response}
group = \{\text{ceil}(2\times\text{rand}(1000,1)), \text{ceil}(3\times\text{rand}(1000,1)), \ldots
\text{ceil}(2\times\text{rand}(1000,1)), \text{ceil}(3\times\text{rand}(1000,1))\};
\text{multivarichart}(y, \text{group})

Introduced in R2006b
mvksdensity

Kernel smoothing function estimate for multivariate data

Syntax

\[ f = \text{mvksdensity}(x, \text{pts}, '\text{Bandwidth}', \text{bw}) \]
\[ f = \text{mvksdensity}(x, \text{pts}, '\text{Bandwidth}', \text{bw}, \text{Name}, \text{Value}) \]

Description

\[ f = \text{mvksdensity}(x, \text{pts}, '\text{Bandwidth}', \text{bw}) \] computes a probability density estimate of the sample data in the \( n \)-by-\( d \) matrix \( x \), evaluated at the points in \( pts \) using the required name-value pair argument value \( bw \) for the bandwidth value. The estimation is based on a product Gaussian kernel function.

For univariate or bivariate data, use \( \text{ksdensity} \) instead.

\[ f = \text{mvksdensity}(x, \text{pts}, '\text{Bandwidth}', \text{bw}, \text{Name}, \text{Value}) \] returns any of the previous output arguments, using additional options specified by one or more \( \text{Name}, \text{Value} \) pair arguments. For example, you can define the function type that \( \text{mvksdensity} \) evaluates, such as probability density, cumulative probability, or survivor function. You can also assign weights to the input values.

Examples

Estimate Multivariate Kernel Density

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix \texttt{ingredients} contains the percent composition for each of four cement
ingredients. The response matrix heat contains the heat of hardening (in cal/g) after 180 days.

Estimate the kernel density for the first three observations in ingredients.

\[
\begin{align*}
\xi &= \text{ingredients}(1:3,:); \\
\mathbf{f} &= \text{mvksdensity}(\text{ingredients}, \xi, 'Bandwidth', 0.8);
\end{align*}
\]

### Estimate Multivariate Kernel Density Using Grids

Load the Hald cement data.

```matlab
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix ingredients contains the percent composition for each of four cement ingredients. The response matrix heat contains the heat of hardening (in cal/g) after 180 days.

Create a array of points at which to estimate the density. First, define the range and spacing for each variable, using a similar number of points in each dimension.

\[
\begin{align*}
gridx1 &= 0:2:22; \\
gridx2 &= 20:5:80; \\
gridx3 &= 0:2:24; \\
gridx4 &= 5:5:65;
\end{align*}
\]

Next, use \texttt{ndgrid} to generate a full grid of points using the defined range and spacing.

\[
[x1, x2, x3, x4] = \text{ndgrid}(gridx1, gridx2, gridx3, gridx4);
\]

Finally, transform and concatenate to create an array that contains the points at which to estimate the density. This array has one column for each variable.

\[
\begin{align*}
x1 &= x1(:,:,:)'; \\
x2 &= x2(:,:,:)'; \\
x3 &= x3(:,:,:)'; \\
x4 &= x4(:,:,:)'; \\
\xi &= [x1(:) x2(:) x3(:) x4(:)];
\end{align*}
\]

Estimate the density.
[f,bw] = mvksdensity(ingredients,xi,...
   'Bandwidth',[4.0579 10.7345 4.4185 11.5466],...
   'Kernel','normpdf');

View the size of xi and f to confirm that mvksdensity calculates the density at each point in xi.

size_xi = size(xi)
size_xi = 1×2
         26364           4

size_f = size(f)
size_f = 1×2
         26364           1

Input Arguments

x — Sample data
numeric matrix

Sample data for which mvksdensity returns the probability density estimate, specified as an n-by-d matrix of numeric values. n is the number of data points (rows) in x, and d is the number of dimensions (columns).

Data Types: single | double

pts — Points at which to evaluate f
matrix

Points at which to evaluate the probability density estimate f, specified as a matrix with the same number of columns as x. The returned estimate f has the same length as pts.

Data Types: single | double

bw — Value for the bandwidth of the kernel smoothing window
scalar value | d-element vector
Value for the bandwidth of the kernel-smoothing window, specified as a scalar value or \(d\)-element vector. \(d\) is the number of dimensions (columns) in the sample data \(x\). If \(bw\) is a scalar value, it applies to all dimensions.

If you specify 'BoundaryCorrection' as 'log' (default) and 'Support' as either 'positive' or a two-row matrix, \(mvksdensity\) converts bounded data to be unbounded by using log transformation. The value of \(bw\) is on the scale of the transformed values.

Silverman's rule of thumb for the bandwidth is

\[
b_i = \sigma_i \left[ \frac{4}{(d+2)n} \right]^{1/(d+4)} , \quad i = 1,2,\ldots,d,
\]

where \(d\) is the number of dimensions, \(n\) is the number of observations, and \(\sigma_i\) is the standard deviation of the \(i\)th variate [4].

Example: 'Bandwidth',0.8
Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: 'Kernel','triangle','Function,'cdf' specifies that \(mvksdensity\) estimates the cdf of the sample data using the triangle kernel function.

\textbf{BoundaryCorrection — Boundary correction method}

'log' (default) | 'reflection'

Boundary correction method, specified as the comma-separated pair consisting of 'BoundaryCorrection' and either 'log' or 'reflection'.
### Value Description

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'log' | mvksdensity converts bounded data to be unbounded by using one of the following transformations. Then, it transforms back to the original bounded scale after density estimation.  
- If you specify 'Support','positive', then mvksdensity applies log(x_j) for each dimension, where x_j is the jth column of the input argument x.  
- If you specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then mvksdensity applies log((x_j-L_j)/(U_j-x_j)) for each dimension, where L_j and U_j are the lower and upper limits of the jth dimension, respectively.  

The value of bw is on the scale of the transformed values. |
| 'reflection' | mvksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 32-4154. |

mvksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection','reflection'

**Function — Function to estimate**

'pdf' (default) | 'cdf' | 'survivor'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pdf'</td>
<td>Probability density function</td>
</tr>
<tr>
<td>'cdf'</td>
<td>Cumulative distribution function</td>
</tr>
<tr>
<td>'survivor'</td>
<td>Survivor function</td>
</tr>
</tbody>
</table>

Example: 'Function','cdf'

**Kernel — Type of kernel smoother**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | function name
Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'normal'</td>
<td>Normal (Gaussian) kernel</td>
</tr>
<tr>
<td>'box'</td>
<td>Box kernel</td>
</tr>
<tr>
<td>'triangle'</td>
<td>Triangular kernel</td>
</tr>
<tr>
<td>'epanechnikov'</td>
<td>Epanechnikov kernel</td>
</tr>
</tbody>
</table>

You can also specify a custom kernel function as a function handle (for example, @normpdf) or a function name in single quotes (for example, 'normpdf'). This calls the specified function using one argument that is an array of distances between data values and locations where the density is evaluated, normalized by the bandwidth in that dimension. The function must return an array of the same size containing the corresponding values of the kernel function.

`mvksdensity` applies the same kernel to each dimension.

Example: 'Kernel','box'

**Support — Support for the density**

'unbounded' (default) | 'positive' | 2-by-d matrix

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'unbounded'</td>
<td>Allow the density to extend over the whole real line</td>
</tr>
<tr>
<td>'positive'</td>
<td>Restrict the density to positive values</td>
</tr>
<tr>
<td>2-by-d matrix</td>
<td>Specify the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. Each column contains the limits for one dimension of x.</td>
</tr>
</tbody>
</table>

'Support' can also be a combination of positive, unbounded, and bounded variables specified as [0 -Inf L ; Inf Inf U].
Example: 'Support','positive'
Data Types: single | double | char | string

Weights — Weights for sample data
vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length size(x,1), where x is the sample data.
Example: 'Weights',xw
Data Types: single | double

Output Arguments

f — Estimated function values
vector

Estimated function values, returned as a vector of the same length as x.

Definitions

Multivariate Kernel Distribution

A multivariate kernel distribution is a nonparametric representation of the probability density function (pdf) of a random vector. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A multivariate kernel distribution is defined by a smoothing function and a bandwidth matrix, which control the smoothness of the resulting density curve.

The multivariate kernel density estimator is the estimated pdf of a random vector. Let \( x = (x_1, x_2, \ldots, x_d)' \) be a \( d \)-dimensional random vector with a density function \( f \) and let \( y_i = (y_{i1}, y_{i2}, \ldots, y_{id})' \) be a random sample drawn from \( f \) for \( i = 1, 2, \ldots, n \), where \( n \) is the number of random samples. For any real vectors of \( x \), the multivariate kernel density estimator is given by
\[ \hat{f}_H(x) = \frac{1}{n} \sum_{i=1}^{n} K_H(x - y_i), \]

where \( K_H(x) = |H|^{-1/2} K(H^{-1/2}x) \), \( K(\cdot) \) is the kernel smoothing function, and \( H \) is the \( d \)-by-\( d \) bandwidth matrix.

mvksdensity uses a diagonal bandwidth matrix and a product kernel. That is, \( H^{1/2} \) is a square diagonal matrix with the elements of vector \((h_1, h_2, ..., h_d)\) on the main diagonal.

\( K(x) \) takes the product form \( K(x) = k(x_1)k(x_2)\cdots k(x_d) \), where \( k(\cdot) \) is a one-dimensional kernel smoothing function. Then, the multivariate kernel density estimator becomes

\[ \hat{f}_H(x) = \frac{1}{n} \sum_{i=1}^{n} K_H(x - y_i) = \frac{1}{nh_1h_2\cdots h_d} \sum_{i=1}^{n} K \left( \frac{x_1 - y_{i1}}{h_1}, \frac{x_2 - y_{i2}}{h_2}, \ldots, \frac{x_d - y_{id}}{h_d} \right) = \frac{1}{nh_1h_2\cdots h_d} \sum_{i=1}^{n} \prod_{j=1}^{d} k \left( \frac{x_j - y_{ij}}{h_j} \right). \]

The kernel estimator for the cumulative distribution function (cdf), for any real vectors of \( x \), is given by

\[ \hat{F}_H(x) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \cdots \int_{-\infty}^{x_d} \hat{f}_H(t) dt_d \cdots dt_1 = \frac{1}{n} \sum_{i=1}^{n} \prod_{j=1}^{d} G \left( \frac{x_j - y_{ij}}{h_j} \right), \]

where \( G(x_j) = \int_{-\infty}^{x_j} k(t_j) dt_j \).

### Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify 'BoundaryCorrection', 'reflection', mvksdensity uses the reflection method.

If you additionally specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then mvksdensity finds the kernel estimator as follows.

- If 'Function' is 'pdf', then the kernel density estimator is
\[ \hat{f}_H(x) = \frac{1}{nh_1h_2\ldots h_d} \sum_{i=1}^{n} \prod_{j=1}^{d} k \left( \frac{x_j - y_{ij}}{h_j} \right) + k \left( \frac{x_j - y_{ij}}{h_j} \right) \] for \( L_j \leq x_j \leq U_j \),

where \( y_{ij} = 2L_j - y_{ij}, y_{ij}^+ = 2U_j - y_{ij} \), and \( y_{ij} \) is the \( j \)th element of the \( i \)th sample data corresponding to \( x(i,j) \) of the input argument \( x \). \( L_j \) and \( U_j \) are the lower and upper limits of the \( j \)th dimension, respectively.

- If 'Function' is 'cdf', then the kernel estimator for cdf is

\[ \hat{F}_H(x) = \frac{1}{n} \sum_{i=1}^{n} \prod_{j=1}^{d} \left( G \left( \frac{x_j - y_{ij}}{h_j} \right) + G \left( \frac{x_j - y_{ij}}{h_j} \right) - G \left( \frac{L_j - y_{ij}}{h_j} \right) - G \left( \frac{L_j - y_{ij}}{h_j} \right) \right) \]

- To obtain a kernel estimator for a survivor function (when 'Function' is 'survivor'), \texttt{mvksdensity} uses both \( \hat{f}_H(x) \) and \( \hat{F}_H(x) \).

If you additionally specify 'Support' as 'positive' or a matrix including \([0 \inf] \), then \texttt{mvksdensity} finds the kernel density estimator by replacing \([L_j U_j] \) with \([0 \inf] \) in the above equations.

Introduced in R2016a
mvncdf

Multivariate normal cumulative distribution function

Syntax

\[ y = \text{mvncdf}(X) \]
\[ y = \text{mvncdf}(X,\mu,\text{SIGMA}) \]
\[ y = \text{mvncdf}(\text{xl},\text{xu},\mu,\text{SIGMA}) \]
\[ [y,\text{err}] = \text{mvncdf}(\ldots) \]
\[ [\ldots] = \text{mvncdf}(\ldots,\text{options}) \]

Description

\[ y = \text{mvncdf}(X) \] returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of \( X \). Rows of the \( n \)-by-\( d \) matrix \( X \) correspond to observations or points, and columns correspond to variables or coordinates. \( y \) is an \( n \)-by-1 vector.

\[ y = \text{mvncdf}(X,\mu,\text{SIGMA}) \] returns the cumulative probability of the multivariate normal distribution with mean \( \mu \) and covariance \( \text{SIGMA} \), evaluated at each row of \( X \). \( \mu \) is a 1-by-\( d \) vector; and \( \text{SIGMA} \) is a \( d \)-by-\( d \) symmetric, positive definite matrix. \( \mu \) can also be a scalar value, which \text{mvncdf} replicates to match the size of \( X \). If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, \( \text{SIGMA} \) may also be specified as a 1-by-\( d \) vector containing just the diagonal. Pass in the empty matrix [ ] for \( \mu \) to use as its default value when you want to only specify \( \text{SIGMA} \).

The multivariate normal cumulative probability at \( X \) is defined as the probability that a random vector \( V \), distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by \( X \), for example, \( \Pr\{V(1) \leq X(1), V(2) \leq X(2), \ldots, V(d) \leq X(d)\} \).

\[ y = \text{mvncdf}(\text{xl},\text{xu},\mu,\text{SIGMA}) \] returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by \( \text{xl} \) and \( \text{xu} \), respectively.
[\text{y, err}] = \text{mvncdf(...) returns an estimate of the error in y. For bivariate and trivariate distributions, mvncdf uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is } 1 \times 10^{-8}.\text{ For four or more dimensions, mvncdf uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is } 1 \times 10^{-4}.\text{ }

[\ldots] = \text{mvncdf(..., options) specifies control parameters for the numerical integration used to compute y. This argument can be created by a call to statset. Choices of statset parameters:}

- 'TolFun' — Maximum absolute error tolerance. Default is $1 \times 10^{-8}$ when $d < 4$, or $1 \times 10^{-4}$ when $d \geq 4$.
- 'MaxFunEvals' — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1 \times 10^{7}$. 'MaxFunEvals' is ignored when $d < 4$.
- 'Display' — Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when $d < 4$.

**Examples**

**Compute the Multivariate Normal cdf**

Compute and plot the cdf of a multivariate normal distribution with parameters $\text{mu} = [1 \ -1]$ and $\text{SIGMA} = [0.9 \ 0.4; \ 0.4 \ 0.3]$.

\begin{verbatim}
mu = [1 -1];
SIGMA = [0.9 0.4; 0.4 0.3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
\end{verbatim}

mvnpdf

Multivariate normal probability density function

Syntax

\[
y = \text{mvnpdf}(X) \\
y = \text{mvnpdf}(X, \text{MU}) \\
y = \text{mvnpdf}(X, \text{MU}, \text{SIGMA})
\]

Description

\(y = \text{mvnpdf}(X)\) returns the \(n\)-by-1 vector \(y\), containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the \(n\)-by-\(d\) matrix \(X\). Rows of \(X\) correspond to observations and columns correspond to variables or coordinates.

\(y = \text{mvnpdf}(X, \text{MU})\) returns the density of the multivariate normal distribution with mean \(\text{mu}\) and identity covariance matrix, evaluated at each row of \(X\). \(\text{MU}\) is a 1-by-\(d\) vector, or an \(n\)-by-\(d\) matrix. If \(\text{MU}\) is a matrix, the density is evaluated for each row of \(X\) with the corresponding row of \(\text{MU}\). \(\text{MU}\) can also be a scalar value, which \text{mvnpdf} replicates to match the size of \(X\).

\(y = \text{mvnpdf}(X, \text{MU}, \text{SIGMA})\) returns the density of the multivariate normal distribution with mean \(\text{MU}\) and covariance \(\text{SIGMA}\), evaluated at each row of \(X\). \(\text{SIGMA}\) is a \(d\)-by-\(d\) matrix, or a \(d\)-by-\(d\)-by-\(n\) array, in which case the density is evaluated for each row of \(X\) with the corresponding page of \(\text{SIGMA}\), i.e., \text{mvnpdf} computes \(y(i)\) using \(X(i,:)\) and \(\text{SIGMA}(:, :, i)\). If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, \(\text{SIGMA}\) may also be specified as a 1-by-\(d\) vector or a 1-by-\(d\)-by-\(n\) array, containing just the diagonal. Specify \([\ ]\) for \(\text{MU}\) to use its default value when you want to specify only \(\text{SIGMA}\).

If \(X\) is a 1-by-\(d\) vector, \text{mvnpdf} replicates it to match the leading dimension of \(\text{MU}\) or the trailing dimension of \(\text{SIGMA}\).
Examples

mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
X = mvnrnd(mu,SIGMA,10);
p = mvnpdf(X,mu,SIGMA);

Introduced before R2006a
mvregress

Multivariate linear regression

Syntax

beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress(___)
[beta,Sigma,E,CovB,logL] = mvregress(__)

Description

beta = mvregress(X,Y) returns the estimated coefficients for a multivariate normal regression on page 32-4178 of the d-dimensional responses in Y on the design matrices in X.

beta = mvregress(X,Y,Name,Value) returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

[beta,Sigma] = mvregress(__) also returns the estimated d-by-d variance-covariance matrix of Y, using any of the input arguments from the previous syntaxes.

[beta,Sigma,E,CovB,logL] = mvregress(__) also returns a matrix of residuals E, estimated variance-covariance matrix of the regression coefficients CovB, and the value of the log likelihood objective function after the last iteration logL.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.
Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so \( n = 52 \). The dimension of the responses corresponds to the regions, so \( d = 9 \). The predictors in `x` are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;
regions = flu.Properties.VarNames(2:end-1);
plot(x,Y,'x')
legend(regions,'Location','NorthWest')
```
Fit the multivariate regression model

\[ y_{ij} = \alpha_j + \beta x_{ij} + \epsilon_{ij}, \]

where \( i = 1, \ldots, n \) and \( j = 1, \ldots, d \), with between-region concurrent correlation

\[ COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}. \]

There are \( K = 10 \) regression coefficients to estimate: nine intercept terms and a common slope. The input argument \( X \) should be an \( n \)-element cell array of \( d \)-by- \( K \) design matrices.
\( X = \text{cell}(n,1); \)
\[ \text{for } i = 1:n \]
\[ \quad X\{i\} = [\text{eye}(d) \ \text{repmat}(x(i),d,1)]; \]
\[ \text{end} \]
\[ [\beta, \Sigma] = \text{mvregress}(X,Y); \]

\( \beta \) contains estimates of the \( K \)-dimensional coefficient vector
\[ (\alpha_1, \alpha_2, \ldots, \alpha_9, \beta)' . \]

\( \Sigma \) contains estimates of the \( d \)-by- \( d \) variance-covariance matrix \( (\sigma_{ij})_{d \times d}, \)
\( i, j = 1, \ldots, d \) for the between-region concurrent correlations.

Plot the fitted regression model.

\[ B = [\beta(1:d)'; \ \text{repmat}(\beta(\text{end}),1,d)]; \]
\[ xx = \text{linspace}(0.5,3.5)'; \]
\[ \text{fits} = [\text{ones}(\text{size}(xx)), xx] \ast B; \]

\[ \text{figure}; \]
\[ h = \text{plot}(x,Y,'x', xx, \text{fits}, '-'); \]
\[ \text{for } i = 1:d \]
\[ \quad \text{set}(h(d+i), '\text{color}', \text{get}(h(i), '\text{color}')); \]
\[ \text{end} \]
\[ \text{legend(regions, 'Location', 'NorthWest');} \]
The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

**Multivariate Regression for Panel Data with Different Slopes**

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```
The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

\[
Y = \text{double(}flu(:,2:end-1)));
\]
\[
[n,d] = \text{size}(Y);
\]
\[
x = flu.WtdILI;
\]

The responses in \(Y\) are the nine regional flu estimates. Observations exist for every week over a one-year period, so \(n = 52\). The dimension of the responses corresponds to the regions, so \(d = 9\). The predictors in \(x\) are the weekly national flu estimates.

Fit the multivariate regression model

\[
y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij},
\]

where \(i = 1, \ldots, n\) and \(j = 1, \ldots, d\), with between-region concurrent correlation

\[
\text{COV}(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.
\]

There are \(K = 18\) regression coefficients to estimate: nine intercept terms, and nine slope terms. \(X\) is an \(n\)-element cell array of \(d\)-by- \(K\) design matrices.

\[
X = \text{cell}(n,1);
\]
\[
\text{for } i = 1:n
\]
\[
X\{i\} = [\text{eye}(d) \times(i)*\text{eye}(d)];
\]
\[
\text{end}
\]
\[
[beta,Sigma] = \text{mvregress}(X,Y,'algorithm','cwls');
\]

`beta` contains estimates of the \(K\)-dimensional coefficient vector

\[
(\alpha_1, \alpha_2, \ldots, \alpha_9, \beta_1, \beta_2, \ldots, \beta_9)'.
\]

Plot the fitted regression model.

\[
B = [beta(1:d)';beta(d+1:end)'];
\]
\[
xx = \text{linspace}(.5,3.5)';
\]
\[
\text{fits} = [\text{ones(size(xx))},xx]*B;
\]
\[
\text{figure};
\]
\[
h = \text{plot}(x,Y,'x',xx,\text{fits},'-');
\]
\[
\text{for } i = 1:d
\]
The plot shows that each regression line has a different intercept and slope.

**Multivariate Regression With a Single Design Matrix**

Fit a multivariate regression model using a single $n$-by-$P$ design matrix for all response dimensions.
Load the sample data.

```matlab
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

```matlab
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so `n = 52`. The dimension of the responses corresponds to the regions, so `d = 9`. The predictors in `x` are the weekly national flu estimates.

Create an `n`-by-`P` design matrix `X`. Add a column of ones to include a constant term in the regression.

```matlab
X = [ones(size(x)),x];
```

Fit the multivariate regression model

\[
y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij},
\]

where \( i = 1, \ldots, n \) and \( j = 1, \ldots, d \), with between-region concurrent correlation

\[
COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.
\]

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```matlab
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

`beta` contains estimates of the `P`-by-`d` coefficient matrix. `Sigma` contains estimates of the `d`-by-`d` variance-covariance matrix for the between-region concurrent correlations. `E` is a matrix of the residuals. `CovB` is the estimated variance-covariance matrix of the regression coefficients. `logL` is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');
The plot shows that each regression line has a different intercept and slope.

**Input Arguments**

**X — Design matrices**

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. \( n \) is the number of observations in the data, \( K \) is the number of regression coefficients to estimate, \( p \) is the number of predictor variables, and \( d \) is the number of dimensions in the response variable matrix \( Y \).

- If \( d = 1 \), then specify \( X \) as a single \( n \)-by-\( K \) design matrix.
- If \( d > 1 \) and all \( d \) dimensions have the same design matrix, then you can specify \( X \) as a single \( n \)-by-\( p \) design matrix (not in a cell array).
- If \( d > 1 \) and all \( n \) observations have the same design matrix, then you can specify \( X \) as a cell array containing a single \( d \)-by-\( K \) design matrix.
- If \( d > 1 \) and all \( n \) observations do not have the same design matrix, then specify \( X \) as a cell array of length \( n \) containing \( d \)-by-\( K \) design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in \( X \) as missing values, and ignores rows in \( X \) with missing values.

Data Types: single | double | cell

**Y — Response variables**

matrix

Response variables, specified as an \( n \)-by-\( d \) matrix. \( n \) is the number of observations in the data, and \( d \) is the number of dimensions in the response. When \( d = 1 \), `mvregress` treats the values in \( Y \) like \( n \) independent response values.

`mvregress` treats NaN values in \( Y \) as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

Data Types: single | double
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'algorithm','cwls','covar0',C specifies covariance-weighted least squares estimation using the covariance matrix C.

algorithm — Estimation algorithm
'mvn' | 'ecm' | 'cwls'

Estimation algorithm, specified as the comma-separated pair consisting of 'algorithm' and one of the following.

| 'mvn' | Ordinary multivariate normal maximum likelihood estimation. |
| 'ecm' | Maximum likelihood estimation via the ECM algorithm. |
| 'cwls' | Covariance-weighted least squares estimation. |

The default algorithm depends on the presence of missing data.

- For complete data, the default is 'mvn'.
- If there are any missing responses (indicated by NaN), the default is 'ecm', provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is 'cwls'.

**Note** If algorithm has the value 'mvn', then mvregress removes observations with missing response values before estimation.

Example: 'algorithm','ecm'

beta0 — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of 'beta0' and a vector with K elements. The default value is a vector of 0s.

The beta0 argument is not used if the estimation algorithm is 'mvn'.

32-4173
**covar0 — Initial estimate for variance-covariance matrix**

Initial estimate for the variance-covariance matrix, Sigma, specified as the comma-separated pair consisting of 'covar0' and a symmetric, positive definite, d-by-d matrix. The default value is the identity matrix.

If the estimation algorithm is 'cwls', then mvregress uses covar0 as the weighting matrix at each iteration, without changing it.

**covtype — Type of variance-covariance matrix**

'full' (default) | 'diagonal'

Type of variance-covariance matrix to estimate for Y, specified as the comma-separated pair consisting of 'covtype' and one of the following.

- 'full' Estimate all $d(d + 1)/2$ variance-covariance elements.
- 'diagonal' Estimate only the $d$ diagonal elements of the variance-covariance matrix.

Example: 'covtype','diagonal'

**maxiter — Maximum number of iterations**

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of 'maxiter' and a positive integer.

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are 0, then mvregress performs maxiter iterations with no convergence tests.

Example: 'maxiter',50

**outputfcn — Function to evaluate each iteration**

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical true or false. At each iteration, mvregress evaluates the function. If the result is true,
iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns true if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:
  - `Covar` — Current value of the variance-covariance matrix
  - `iteration` — Current iteration number
  - `fval` — Current value of the loglikelihood objective function
- Text that takes these three values:
  - `'init'` — When the function is called during initialization
  - `'iter'` — When the function is called after an iteration
  - `'done'` — When the function is called after completion

### `tolbeta` — Convergence tolerance for regression coefficients

```matlab
tolbeta = sqrt(eps) (default) | positive scalar value
```

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let \( \mathbf{b}^t \) denote the estimate of the coefficient vector at iteration \( t \), and \( \tau_\beta \) be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

\[
\| \mathbf{b}^t - \mathbf{b}^{t-1} \| < \tau_\beta \sqrt{K} \left( 1 + \| \mathbf{b}^t \| \right),
\]

where \( K \) is the length of \( \mathbf{b}^t \) and \( \| \mathbf{v} \| \) is the norm of a vector \( \mathbf{v} \).

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolbeta',1e-5"
**tolobj — Convergence tolerance for loglikelihood objective function**

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of 'tolobj' and a positive scalar value.

Let $L^t$ denote the value of the loglikelihood objective function at iteration $t$, and $\tau^t$ be the tolerance specified by tolobj. The convergence criterion for the objective function is

$$\left| L^t - L^{t-1} \right| < \tau^t \left( 1 + \left| L^t \right| \right).$$

Iterations continue until estimates are within the convergence tolerances tolbeta and tolobj, or the maximum number of iterations specified by maxiter is reached. If both tolbeta and tolobj are 0, then mvregress performs maxiter iterations with no convergence tests.

Example: 'tolobj',1e-5

**varformat — Format for parameter estimate variance-covariance matrix**

'beta' (default) | 'full'

Format for the parameter estimate variance-covariance matrix, CovB, specified as the comma-separated pair consisting of 'varformat' and one of the following.

'beta' Return the variance-covariance matrix for only the regression coefficient estimates, beta.

'full' Return the variance-covariance matrix for both the regression coefficient estimates, beta, and the variance-covariance matrix estimate, Sigma.

Example: 'varformat','full'

**vartype — Type of variance-covariance matrix for parameter estimates**

'hessian' (default) | 'fisher'

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then mvregress uses the Hessian, or observed information, matrix to compute CovB.
• If the value is 'fisher', then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute CovB.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype','fisher'

### Output Arguments

**beta — Estimated regression coefficients**

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify `X` as a single `n`-by-`K` design matrix, then `mvregress` returns `beta` as a column vector of length `K`. For example, if `X` is a 20-by-5 design matrix, then `beta` is a 5-by-1 column vector.
- If you specify `X` as a cell array containing one or more `d`-by-`K` design matrices, then `mvregress` returns `beta` as a column vector of length `K`. For example, if `X` is a cell array containing 2-by-10 design matrices, then `beta` is a 10-by-1 column vector.
- If you specify `X` as a single `n`-by-`p` design matrix (not in a cell array), and `Y` has dimension `d` > 1, then `mvregress` returns `beta` as a `p`-by-`d` matrix. For example, if `X` is a 20-by-5 design matrix, and `Y` has two dimensions such that `d` = 2, then `beta` is a 5-by-2 matrix, and the fitted `Y` values are `X` × `beta`.

**Sigma — Estimated variance-covariance matrix**

square matrix

Estimated variance-covariance matrix for the responses in `Y`, returned as a `d`-by-`d` square matrix.

**Note** The estimated variance-covariance matrix, `Sigma`, is not the sample covariance matrix of the residual matrix, `E`.

**E — Residuals**

matrix

Residuals for the fitted regression model, returned as an `n`-by-`d` matrix.
If algorithm has the value 'ecm' or 'cwls', then mvregress computes the residual values corresponding to missing values in Y as the difference between the conditionally imputed values on page 32-4179 and the fitted values.

**Note** If algorithm has the value 'mvn', then mvregress removes observations with missing response values before estimation.

**CovB — Parameter estimate variance-covariance matrix**

Square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If varformat has the value 'beta' (default), then CovB is the estimated variance-covariance matrix of the coefficient estimates in beta.
- If varformat has the value 'full', then CovB is the estimated variance-covariance matrix of the combined estimates in beta and Sigma.

**logL — Loglikelihood objective function value**

Scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

**Definitions**

**Multivariate Normal Regression**

Multivariate normal regression is the regression of a d-dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

\[ y_i = X_i \beta + e_i, \quad i = 1, \ldots, n, \]

where

- \( y_i \) is a d-dimensional vector of responses.
• \( X_i \) is a design matrix of predictor variables.
• \( \beta \) is vector or matrix of regression coefficients.
• \( e_i \) is a \( d \)-dimensional vector of error terms, with multivariate normal distribution
  \[ e_i \sim MVN_d(0, \Sigma). \]

**Conditionally Imputed Values**

The expectation/conditional maximization (‘ecm’) and covariance-weighted least squares (‘cwls’) estimation algorithms include imputation of missing response values.

Let \( \tilde{y} \) denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, \( E(\tilde{y} \mid y) \).

The joint distribution of the missing and observed responses is a multivariate normal distribution,

\[
\begin{pmatrix}
\tilde{y} \\
y
\end{pmatrix}
\sim MVN
\begin{pmatrix}
\begin{pmatrix}
\tilde{X}\beta \\
y
\end{pmatrix} \\
\Sigma_{\tilde{y}\tilde{y}}
\end{pmatrix}
\begin{pmatrix}
\Sigma_{\tilde{y}}^{-1} & \Sigma_{\tilde{y}y} \\
\Sigma_{y\tilde{y}} & \Sigma_y
\end{pmatrix}
\].

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

\[
E(\tilde{y} \mid y) = \tilde{X}\beta + \Sigma_{\tilde{y}y}^{-1}(y - X\beta).
\]

**Note** `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

Introduced in R2006b
mvregresslike

Negative log-likelihood for multivariate regression

Syntax

\[
\text{nlogL} = \text{mvregresslike}(X,Y,b,\text{SIGMA},\text{alg})
\]

\[
[\text{nlogL},\text{COVB}] = \text{mvregresslike}(\ldots)
\]

\[
[\text{nlogL},\text{COVB}] = \text{mvregresslike}(\ldots,\text{type},\text{format})
\]

Description

\[
\text{nlogL} = \text{mvregresslike}(X,Y,b,\text{SIGMA},\text{alg})
\]
computes the negative log-likelihood \( \text{nlogL} \) for a multivariate regression of the \( d \)-dimensional multivariate observations in the \( n \)-by-\( d \) matrix \( Y \) on the predictor variables in the matrix or cell array \( X \), evaluated for the \( p \)-by-1 column vector \( b \) of coefficient estimates and the \( d \)-by-\( d \) matrix \( \text{SIGMA} \) specifying the covariance of a row of \( Y \). If \( d = 1 \), \( X \) can be an \( n \)-by-\( p \) design matrix of predictor variables. For any value of \( d \), \( X \) can also be a cell array of length \( n \), with each cell containing a \( d \)-by-\( p \) design matrix for one multivariate observation. If all observations have the same \( d \)-by-\( p \) design matrix, \( X \) can be a single cell.

\( \text{NaN} \) values in \( X \) or \( Y \) are taken as missing. Observations with missing values in \( X \) are ignored. Treatment of missing values in \( Y \) depends on the algorithm specified by \( \text{alg} \).

\( \text{alg} \) should match the algorithm used by \text{mvregress} to obtain the coefficient estimates \( b \), and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwls' — Least squares conditionally weighted by \( \text{SIGMA} \)
- 'mvn' — Multivariate normal estimates computed after omitting rows with any missing values in \( Y \)

\[
[\text{nlogL},\text{COVB}] = \text{mvregresslike}(\ldots)
\] also returns an estimated covariance matrix \( \text{COVB} \) of the parameter estimates \( b \).

\[
[\text{nlogL},\text{COVB}] = \text{mvregresslike}(\ldots,\text{type},\text{format})
\] specifies the type and format of \( \text{COVB} \).
*type* is either:

- `'hessian'` — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- `'fisher'` — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

*format* is either:

- `'beta'` — To compute COVB for b only. This is the default.
- `'full'` — To compute COVB for both b and SIGMA.

“Multivariate Normal Distribution” on page B-102

*Introduced in R2007a*
mvnrnd

Multivariate normal random numbers

Syntax

R = mvnrnd(MU, SIGMA)
r = mvnrnd(MU, SIGMA, cases)

Description

R = mvnrnd(MU, SIGMA) returns an \( n \)-by-\( d \) matrix \( R \) of random vectors chosen from the multivariate normal distribution with mean \( MU \), and covariance \( SIGMA \). \( MU \) is a vector or \( n \)-by-\( d \) matrix, and \( mvnrnd \) generates each row of \( R \) using the corresponding row of \( MU \). \( SIGMA \) is a \( d \)-by-\( d \) symmetric positive semi-definite matrix, or a \( d \)-by-\( d \)-by-\( n \) array. If \( SIGMA \) is an array, \( mvnrnd \) generates each row of \( R \) using the corresponding page of \( SIGMA \), i.e., \( mvnrnd \) computes \( R(i,:) \) using \( MU(i,:) \) and \( SIGMA(:, :, i) \). If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, \( SIGMA \) may also be specified as a 1-by-\( d \) vector or a 1-by-\( d \)-by-\( n \) array, containing just the diagonal. If \( MU \) is a 1-by-\( d \) vector, \( mvnrnd \) replicates it to match the trailing dimension of \( SIGMA \).

\[ r = mvnrnd(MU, SIGMA, cases) \] returns a cases-by-\( d \) matrix \( R \) of random vectors chosen from the multivariate normal distribution with a common 1-by-\( d \) mean vector \( MU \), and a common \( d \)-by-\( d \) covariance matrix \( SIGMA \).

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from a multivariate normal distribution with parameters \( mu = [2 3] \) and \( sigma = [1 1.5; 1.5 3] \).

\[ mu = [2 3]; \]
\[ sigma = [1 1.5; 1.5 3]; \]
rng default  % For reproducibility
R = mvnrnd(mu,sigma,100);

Plot the random numbers.

Topics
“Multivariate Normal Distribution” on page B-102

Introduced before R2006a
**mvtcdf**

Multivariate $t$ cumulative distribution function

**Syntax**

\[
y = \text{mvtcdf}(X,C,\text{DF}) \\
y = \text{mvtcdf}(x_l,x_u,C,\text{DF}) \\
[y,\text{err}] = \text{mvtcdf}(...) \\
[...]) = \text{mvntdf}(...,\text{options})
\]

**Description**

\[
y = \text{mvtcdf}(X,C,\text{DF}) \text{ returns the cumulative probability of the multivariate } t \\
\text{distribution with correlation parameters } C \text{ and degrees of freedom } \text{DF}, \text{ evaluated at each} \\
\text{row of } X. \text{ Rows of the } n\text{-by-}d \text{ matrix } X \text{ correspond to observations or points, and columns} \\
\text{correspond to variables or coordinates. } y \text{ is an } n\text{-by-}1 \text{ vector.}
\]

\[
C \text{ is a symmetric, positive definite, } d\text{-by-}d \text{ matrix, typically a correlation matrix. If its} \\
\text{diagonal elements are not 1, } \text{mvtcdf scales } C \text{ to correlation form. } \text{mvtcdf does not} \\
\text{rescale } X. \text{ DF is a scalar, or a vector with } n \text{ elements.}
\]

The multivariate $t$ cumulative probability at $X$ is defined as the probability that a random \[
\text{vector } T, \text{ distributed as multivariate } t, \text{ will fall within the semi-infinite rectangle with} \\
\text{upper limits defined by } X, \text{ i.e., } \text{Pr}\{T(1) \leq X(1), T(2) \leq X(2), \ldots T(d) \leq X(d)\}.
\]

\[
y = \text{mvtcdf}(x_l,x_u,C,\text{DF}) \text{ returns the multivariate } t \text{ cumulative probability evaluated} \\
\text{over the rectangle with lower and upper limits defined by } x_l \text{ and } x_u, \text{ respectively.}
\]

\[
[y,\text{err}] = \text{mvtcdf}(...) \text{ returns an estimate of the error in } y. \text{ For bivariate and} \\
\text{trivariate distributions, } \text{mvtcdf uses adaptive quadrature on a transformation of the } t \\
\text{density, based on methods developed by Genz, as described in the references. The default} \\
\text{absolute error tolerance for these cases is } 1e-8. \text{ For four or more dimensions, } \text{mvtcdf} \\
\text{uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and} \\
\text{Bretz, as described in the references. The default absolute error tolerance for these cases} \\
\text{is } 1e-4.
\]
[...] = mvntdf(...,options) specifies control parameters for the numerical integration used to compute y. This argument can be created by a call to statset. Choices of statset parameters are:

- 'TolFun' — Maximum absolute error tolerance. Default is 1e-8 when \(d < 4\), or 1e-4 when \(d \geq 4\).
- 'MaxFunEvals' — Maximum number of integrand evaluations allowed when \(d \geq 4\). Default is 1e7. 'MaxFunEvals' is ignored when \(d < 4\).
- 'Display' — Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when \(d < 4\).

### Examples

#### Compute the Multivariate t Distribution cdf

Compute the cdf of a multivariate \(t\) distribution with correlation parameters \(C = [1 \quad .4; \quad .4 \quad 1]\) and 2 degrees of freedom.

```matlab
C = [1 .4; .4 1];
df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
```

Plot the cdf.

```matlab
figure;
surf(X1,X2,reshape(p,25,25));
```

“Multivariate t Distribution” on page B-108

**Introduced in R2006a**
**mvtpdf**

Multivariate t probability density function

**Syntax**

\[
y = \text{mvtpdf}(X,C,df)
\]

**Description**

\[
y = \text{mvtpdf}(X,C,df)
\]

returns the probability density of the multivariate t distribution with correlation parameters \(C\) and degrees of freedom \(df\), evaluated at each row of \(X\). Rows of the \(n\)-by-\(d\) matrix \(X\) correspond to observations or points, and columns correspond to variables or coordinates. \(C\) is a symmetric, positive definite, \(d\)-by-\(d\) matrix, typically a correlation matrix. If its diagonal elements are not 1, \(\text{mvtpdf}\) scales \(C\) to correlation form. \(\text{mvtcdf}\) does not rescale \(X\). \(df\) is a scalar, or a vector with \(n\) elements. \(y\) is an \(n\)-by-1 vector.

**Examples**

**Compute the Multivariate t Distribution pdf**

Compute the pdf of a multivariate t distribution with correlation parameters \(C = [1 \quad .4; \quad .4 \quad 1]\) and 2 degrees of freedom.

\[
\begin{align*}
[X1,X2] &= \text{meshgrid}(\text{linspace}(-2,2,25)',\text{linspace}(-2,2,25)'); \\
X &= [X1(:) \quad X2(:)]; \\
C &= [1 \quad .4; \quad .4 \quad 1]; \\
df &= 2; \\
p &= \text{mvtpdf}(X,C,df);
\end{align*}
\]

Plot the pdf.

\[
\begin{align*}
\text{figure;} \\
\text{surf}(X1,X2,\text{reshape}(p,25,25))
\end{align*}
\]

mvtcdf | mvtrnd

Topics

“Multivariate t Distribution” on page B-108

Introduced in R2006b
**mvtrnd**

Multivariate $t$ random numbers

**Syntax**

$R = \text{mvtrnd}(C, df, \text{cases})$

$R = \text{mvtrnd}(C, df)$

**Description**

$R = \text{mvtrnd}(C, df, \text{cases})$ returns a matrix of random numbers chosen from the multivariate $t$ distribution, where $C$ is a correlation matrix. $df$ is the degrees of freedom and is either a scalar or is a vector with $\text{cases}$ elements. If $p$ is the number of columns in $C$, then the output $R$ has $\text{cases}$ rows and $p$ columns.

Let $t$ represent a row of $R$. Then the distribution of $t$ is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix $C$, divided by an independent chi-square random value having $df$ degrees of freedom. The rows of $R$ are independent.

$C$ must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if $C$ is a covariance matrix rather than a correlation matrix), $\text{mvtrnd}$ rescales $C$ to transform it to a correlation matrix before generating the random numbers.

$R = \text{mvtrnd}(C, df)$ returns a single random number from the multivariate $t$ distribution.

**Examples**

**Generate Multivariate $t$ Distribution Random Numbers**

Generate random numbers from a multivariate $t$ distribution with correlation parameters $\text{SIGMA} = [1 \ 0.8; 0.8 \ 1]$ and 3 degrees of freedom.
rng default; % For reproducibility
SIGMA = [1 0.8; 0.8 1];
R = mvtrnd(SIGMA,3,100);

Plot the random numbers.

figure;
plot(R(:,1),R(:,2),'+')

mvtcdf | mvtpdf
Topics
“Multivariate t Distribution” on page B-108

Introduced before R2006a
NumObservations property

Class: cvpartition

Number of observations (including observations with missing group values)

Description

Number of observations (including observations with missing group values).
nancov

Covariance ignoring NaN values

Syntax

Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')

Description

Y = nancov(X) is the covariance cov of X, computed after removing observations with NaN values.

For vectors x, nancov(x) is the sample variance of the remaining elements, once NaN values are removed. For matrices X, nancov(X) is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

Y = nancov(X1,X2), where X1 and X2 are matrices with the same number of elements, is equivalent to nancov(X), where X = [X1(:) X2(:)].

nancov removes the mean from each variable (column for matrix X) before calculating Y. If n is the number of remaining observations after removing observations with NaN values, nancov normalizes Y by either n - 1 or n, depending on whether n > 1 or n = 1, respectively. To specify normalization by n, use Y = nancov(...,1).

Y = nancov(...,'pairwise') computes Y(i,j) using rows with no NaN values in columns i or j. The result Y may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:
\[
X = \text{rand}(10,2);
p = \text{randperm}(	ext{numel}(X));
X(p(1:5)) = \text{NaN}
\]

\[
X = \\
\begin{bmatrix}
0.8147 & 0.1576 & \\
NaN & NaN & \\
0.1270 & 0.9572 & \\
0.9134 & NaN & \\
0.6324 & NaN & \\
0.0975 & 0.1419 & \\
0.2785 & 0.4218 & \\
0.5469 & 0.9157 & \\
0.9575 & 0.7922 & \\
0.9649 & NaN & \\
\end{bmatrix}
\]

Establish a correlation between a third variable and the other two variables:

\[
X(:,3) = \text{sum}(X,2)
\]

\[
X = \\
\begin{bmatrix}
0.8147 & 0.1576 & 0.9723 \\
NaN & NaN & NaN \\
0.1270 & 0.9572 & 1.0842 \\
0.9134 & NaN & NaN \\
0.6324 & NaN & NaN \\
0.0975 & 0.1419 & 0.2394 \\
0.2785 & 0.4218 & 0.7003 \\
0.5469 & 0.9157 & 1.4626 \\
0.9575 & 0.7922 & 1.7497 \\
0.9649 & NaN & NaN \\
\end{bmatrix}
\]

Compute the covariance matrix for the three variables after removing observations (rows) with \text{NaN} values:

\[
Y = \text{nancov}(X)
\]

\[
Y = \\
\begin{bmatrix}
0.1311 & 0.0096 & 0.1407 \\
0.0096 & 0.1388 & 0.1483 \\
0.1407 & 0.1483 & 0.2890 \\
\end{bmatrix}
\]
Alternative Functionality

Instead of using nancov, you can use the MATLAB function cov with the input argument nanflag. For example, instead of nancov(X), use cov(X,'omitrows'), and instead of nancov(X,'pairwise'), use cov(X,'partialrows').

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• If the input is variable-size and is [] at run time, the generated code returns [] not NaN.

See Also

NaN | cov | nanvar | var

Introduced before R2006a
**nanmax**

Maximum, ignoring NaN values

**Syntax**

```matlab
y = nanmax(X)
y = nanmax(X,[],dim)
[y,indices] = nanmax(___)
y = nanmax(X,[],'all')
y = nanmax(X,[],vecdim)
Y = nanmax(X1,X2)
```

**Description**

`y = nanmax(X)` is the maximum `max` of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(___)` also returns the row indices of the maximum values for each column in the vector `indices`.

`y = nanmax(X,[],'all')` returns the maximum of all elements of `X`, computed after removing NaN values.

`y = nanmax(X,[],vecdim)` returns the maximum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmax(X,[],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the maximum of the elements on the corresponding page of `X`.  

32-4199
Y = nanmax(X1,X2) returns an array Y the same size as X1 and X2 with \( Y(i,j) = \) nanmax\( (X1(i,j),X2(i,j)) \). Scalar inputs are expanded to an array of the same size as the other input.

## Examples

### Maximum of Matrix Data

Find the column maximum values and their indices for matrix data with missing values.

\[
X = \text{magic}(3);
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
[y,\text{indices}] = \text{nanmax}(X)
\]

\[
y = \begin{bmatrix}
4 \\
5 \\
\text{NaN}
\end{bmatrix}
\]

\[
\text{indices} = \begin{bmatrix}
3 \\
2 \\
1
\end{bmatrix}
\]

### Maximum of All Values

Find the maximum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array \( X \) with some missing values.

\[
X = \text{reshape}(1:30,[2 5 3]);
X([10:12 25]) = \text{NaN}
\]
Find the maximum of the elements of \( X \).

\[
y = \text{nanmax}(X,[],'all')
\]

\[
y = 30
\]

**Alternative Functionality**

Instead of using `nanmax`, you can use the MATLAB function `max` with the input argument `nanflag` specified as the value `'omitnan'`.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The following syntaxes do not support code generation.
  
  • \( y = \text{nanmax}(X, [], 'all') \)
  • \( y = \text{nanmax}(X, [], \text{vecdim}) \)

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

• The following syntaxes do not support GPU arrays as input arguments.
  
  • \( y = \text{nanmax}(X, [], 'all') \)
  • \( y = \text{nanmax}(X, [], \text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**See Also**

Na\(\text{N}\) | max | nanmin

**Introduced before R2006a**
**nanmean**

Mean, ignoring NaN values

**Syntax**

\[
\begin{align*}
y &= \text{nanmean}(X) \\
y &= \text{nanmean}(X, 'all') \\
y &= \text{nanmean}(X, \text{dim}) \\
y &= \text{nanmean}(X, \text{vecdim})
\end{align*}
\]

**Description**

\[y = \text{nanmean}(X)\] returns the mean of the elements of \(X\), computed after removing all NaN values.

- If \(X\) is a vector, then \(\text{nanmean}(X)\) is the mean of all the non-NaN elements of \(X\).
- If \(X\) is a matrix, then \(\text{nanmean}(X)\) is a row vector of column means, computed after removing NaN values.
- If \(X\) is a multidimensional array, then \(\text{nanmean}\) operates along the first nonsingleton dimension of \(X\). The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. \(\text{nanmean}\) removes all NaN values.

For information on how \text{nanmean} treats arrays of all NaN values, see “Tips” on page 32-4209.

\[y = \text{nanmean}(X, 'all')\] returns the mean of all elements of \(X\), computed after removing NaN values.

\[y = \text{nanmean}(X, \text{dim})\] returns the mean along the operating dimension \(\text{dim}\) of \(X\), computed after removing NaN values.

\[y = \text{nanmean}(X, \text{vecdim})\] returns the mean over the dimensions specified in the vector \(\text{vecdim}\). The function computes the means after removing NaN values. For example, if \(X\) is a matrix, then \(\text{nanmean}(X, [1 2])\) is the mean of all non-NaN elements of \(X\) because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.
Examples

Mean of Matrix Data

Find the column means for matrix data with missing values.

\[
X = \text{magic}(3);
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
y = \text{nanmean}(X)
\]

\[
y = \begin{bmatrix}
3.5000 \\
3.0000 \\
\text{NaN}
\end{bmatrix}
\]

Mean of All Values

Find the mean of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array \(X\) with some missing values.

\[
X = \text{reshape}(1:30,[2 5 3]);
X([10:12 25]) = \text{NaN}
\]

\[
X = 
X(:,:,1) = 
\begin{bmatrix}
1 & 3 & 5 & 7 & 9 \\
2 & 4 & 6 & 8 & \text{NaN}
\end{bmatrix}
\]

\[
X(:,:,2) = 
\]
Find the mean of the elements of \(X\).

\[
y = \text{nanmean}(X,'all')
\]

\[
y = 15.6538
\]

**Mean Along Scalar Dimension**

Find the row means for matrix data with missing values by specifying to compute the means along the second dimension.

\[
X = \text{magic}(3);
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
y = \text{nanmean}(X,2)
\]

\[
y = \begin{bmatrix}
1 \\
4 \\
4
\end{bmatrix}
\]
Mean Along Vector Dimension

Find the mean of a multidimensional array over multiple dimensions.

Create a 2-by-5-by-3 array X with some missing values.

```matlab
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```matlab
X(:,:,1) =
    1     3     5     7     9
    2     4     6     8   NaN

X(:,:,2) =
   NaN    13    15    17    19
   NaN    14    16    18    20

X(:,:,3) =
    21    23   NaN    27    29
    22    24    26    28    30
```

Find the mean of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```matlab
ypage = nanmean(X,[1 2])
```

```matlab
ypage(:,:,1) =
    5

ypage(:,:,2) =
    16.5000

ypage(:,:,3) =
```
For example, \texttt{ypage(1,1,1)} is the mean of the non-\texttt{NaN} elements in \texttt{X(:,:,1)}.

Find the mean of the elements in each \texttt{X(i,:,:) slice by specifying dimensions 2 and 3 as the operating dimensions.}

\begin{verbatim}
yrow = nanmean(X,[2 3])
yrow = 2x1
14.5385
16.7692
\end{verbatim}

For example, \texttt{yrow(2)} is the mean of the non-\texttt{NaN} elements in \texttt{X(2,:,:)}. 

**Input Arguments**

\texttt{X} — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If \texttt{X} is an empty array, then \texttt{nanmean(X)} is \texttt{NaN}. For more details, see “Tips” on page 32-4209.

Data Types: \texttt{single} \texttt{| double}

\texttt{dim} — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

\texttt{dim} indicates the dimension whose length reduces to 1. \texttt{size(y,dim)} is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array \texttt{X}:
• If \( \text{dim} \) is equal to 1, then \( \text{nanmean}(X, 1) \) returns a row vector containing the mean for each column.
• If \( \text{dim} \) is equal to 2, then \( \text{nanmean}(X, 2) \) returns a column vector containing the mean for each row.

If \( \text{dim} \) is greater than \( \text{ndims}(X) \) or if \( \text{size}(X, \text{dim}) \) is 1, then \( \text{nanmean} \) returns \( X \).

Data Types: \text{single} | \text{double}

vecdim — Vector of dimensions
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of \( \text{vecdim} \) represents a dimension of the input array \( X \). The output \( y \) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \( X \) and \( y \).

For example, if \( X \) is a 2-by-3-by-3 array, then \( \text{nanmean}(X, [1 \ 2]) \) returns a 1-by-1-by-3 array. Each element of the output is the mean of the elements on the corresponding page of \( X \).
Tips

- When nanmean computes the mean of an array of all NaN values, the array is empty once the NaN values are removed and, therefore, the sum of the remaining elements is 0. Because the mean calculation involves division by 0, the mean value is NaN. The output NaN is not a mean of NaN values.

Alternative Functionality

Instead of using nanmean, you can use the MATLAB function mean with the input argument nanflag specified as the value 'omitnan'.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- The following syntaxes do not support code generation.
  - \( y = \text{nanmean}(X,'all') \)
  - \( y = \text{nanmean}(X,\text{vecdim}) \)

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
- The following syntaxes do not support GPU arrays as input arguments.
  - \( y = \text{nanmean}(X,'all') \)
  - \( y = \text{nanmean}(X,\text{vecdim}) \)
For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also
NaN | mean | nanmedian

Introduced before R2006a
**nanmedian**

Median, ignoring NaN values

**Syntax**

\[
y = \text{nanmedian}(X)
y = \text{nanmedian}(X,'all')
y = \text{nanmedian}(X,dim)
y = \text{nanmedian}(X,vecdim)
\]

**Description**

\( y = \text{nanmedian}(X) \) is the median of \( X \), computed after removing NaN values.

For vectors \( x \), \( \text{nanmedian}(x) \) is the median of the remaining elements, once NaN values are removed. For matrices \( X \), \( \text{nanmedian}(X) \) is a row vector of column medians, once NaN values are removed. For multidimensional arrays \( X \), \( \text{nanmedian} \) operates along the first nonsingleton dimension.

\( y = \text{nanmedian}(X,'all') \) returns the median of all elements of \( X \), computed after removing NaN values.

\( y = \text{nanmedian}(X,dim) \) takes the median along the operating dimension \( \text{dim} \) of \( X \).

\( y = \text{nanmedian}(X,vecdim) \) returns the median over the dimensions specified in the vector \( \text{vecdim} \), computed after removing NaN values. Each element of \( \text{vecdim} \) represents a dimension of the input array \( X \). The output \( y \) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \( X \) and \( y \). For example, if \( X \) is a 2-by-3-by-4 array, then \( \text{nanmedian}(X,[1 2]) \) returns a 1-by-1-by-4 array. Each element of the output array is the median of the elements on the corresponding page of \( X \).

**Examples**
**Median of Matrix Data**

Find the column medians for matrix data with missing values.

\[
X = \text{magic}(3); \\
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
y = \text{nanmedian}(X)
\]

\[
y = \begin{bmatrix}
3.5000 \\
3.0000 \\
\text{NaN}
\end{bmatrix}
\]

**Median Along Vector Dimension**

Find the median of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array \(X\) with some missing values.

\[
X = \text{reshape}(1:30,[3 5 2]); \\
X([10:12 25]) = \text{NaN}
\]

\[
X =
\begin{align*}
X(:,:,1) & = \\
& = \\
& = \\
X(:,:,2) & = \\
& = 
\end{align*}
\]

\[
X(:, :, 1) = \\
& = \\
& = \\
X(:, :, 2) = \\
& = \\
& =
\]

32-4212
Find the median of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

\[
\text{ypage} = \text{nanmedian}(X,[1 2])
\]

\[
\text{ypage} = \\
\text{ypage}(,:,:1) = \\
6.5000
\]

\[
\text{ypage}(,:,:2) = \\
22.5000
\]

For example, \( \text{ypage}(1,1,1) \) is the median of the non-NaN elements in \( X(:,:,1) \).

Find the median of the elements in each \( X(:,i,:) \) slice by specifying dimensions 1 and 3 as the operating dimensions.

\[
\text{ycol} = \text{nanmedian}(X,[1 3])
\]

\[
\text{ycol} = 1\times5 \\
9.5000 \ 12.5000 \ 15.5000 \ 26.5000 \ 21.5000
\]

For example, \( \text{ycol}(4) \) is the median of the non-NaN elements in \( X(:,4,:) \).

**Alternative Functionality**

Instead of using \( \text{nanmedian} \), you can use the MATLAB function \( \text{median} \) with the input argument \( \text{nanflag} \) specified as the value 'omitnan'.
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The following syntaxes do not support code generation.
  • y = nanmedian(X,'all')
  • y = nanmedian(X,vecdim)

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • y = nanmedian(X,'all')
  • y = nanmedian(X,vecdim)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also
NaN | median | nanmean

Introduced before R2006a
**nanmin**

Minimum, ignoring NaN values

**Syntax**

```matlab
y = nanmin(X)
y = nanmin(X,[],dim)
[y,indices] = nanmin(__)
y = nanmin(X,[],'all')
y = nanmin(X,[],vecdim)
Y = nanmin(X1,X2)
```

**Description**

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(__)` also returns the row indices of the minimum values for each column in the vector `indices`.

`y = nanmin(X,[],'all')` returns the minimum of all elements of `X`, computed after removing NaN values.

`y = nanmin(X,[],vecdim)` returns the minimum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmin(X,[],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the minimum of the elements on the corresponding page of `X`. 
$Y = \text{nanmin}(X1,X2)$ returns an array $Y$ the same size as $X1$ and $X2$ with $Y(i,j) = \text{nanmin}(X1(i,j),X2(i,j))$. Scalar inputs are expanded to an array of the same size as the other input.

**Examples**

**Minimum of Matrix Data**

Find the column minimum values and their indices for matrix data with missing values.

```matlab
X = magic(3);
X([1 6:9]) = NaN
X = 3×3
    NaN     1     NaN
    3     5     NaN
    4   NaN   NaN

[y,indices] = nanmin(X)
y = 1×3
    3     1     NaN
indices = 1×3
    2     1     1
```

**Minimum of All Values**

Find the minimum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array $X$ with some missing values.

```matlab
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```
\[
X = \\
X(:,:,1) = \\
\begin{bmatrix}
1 & 3 & 5 & 7 & 9 \\
2 & 4 & 6 & 8 & \text{NaN}
\end{bmatrix}
\]

\[
X(:,:,2) = \\
\begin{bmatrix}
\text{NaN} & 13 & 15 & 17 & 19 \\
\text{NaN} & 14 & 16 & 18 & 20
\end{bmatrix}
\]

\[
X(:,:,3) = \\
\begin{bmatrix}
21 & 23 & \text{NaN} & 27 & 29 \\
22 & 24 & 26 & 28 & 30
\end{bmatrix}
\]

Find the minimum of the elements of \(X\).

\[
y = \text{nanmin}(X,[],'all')
\]

\[
y = 1
\]

**Alternative Functionality**

Instead of using \texttt{nanmin}, you can use the MATLAB function \texttt{min} with the input argument \texttt{nanflag} specified as the value \texttt{'omitnan'}.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
• The following syntaxes do not support code generation.
  • \texttt{y = nanmin(X,[],'all')}  
  • \texttt{y = nanmin(X,[],vecdim)}

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • \texttt{y = nanmin(X,[],'all')}  
  • \texttt{y = nanmin(X,[],vecdim)}

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**See Also**

\texttt{NaN} | \texttt{min} | \texttt{nanmax}

\textit{Introduced before R2006a}
nanstd

Standard deviation, ignoring NaN values

Syntax

\[ y = \text{nanstd}(X) \]
\[ y = \text{nanstd}(X, \text{flag}) \]
\[ y = \text{nanstd}(X, \text{flag}, 'all') \]
\[ y = \text{nanstd}(X, \text{flag}, \text{dim}) \]
\[ y = \text{nanstd}(X, \text{flag}, \text{vecdim}) \]

Description

\[ y = \text{nanstd}(X) \] is the standard deviation \text{std} of \( X \), computed after removing all NaN values.

- If \( X \) is a vector, then \( \text{nanstd}(X) \) is the sample standard deviation of all the non-NaN elements of \( X \).
- If \( X \) is a matrix, then \( \text{nanstd}(X) \) is a row vector of column sample standard deviations, computed after removing NaN values.
- If \( X \) is a multidimensional array, then \( \text{nanstd} \) operates along the first nonsingleton dimension of \( X \). The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. \( \text{nanstd} \) removes all NaN values.
- By default, \( \text{nanstd} \) normalizes \( y \) by \( n - 1 \), where \( n \) is the number of remaining observations after removing observations with NaN values.

\[ y = \text{nanstd}(X, \text{flag}) \] returns the standard deviation of \( X \) based on the normalization specified by flag. The flag is 0 (default) or 1 to specify normalization by \( n - 1 \) or \( n \), respectively, where \( n \) is the number of remaining observations after removing observations with NaN values.

\[ y = \text{nanstd}(X, \text{flag}, 'all') \] returns the standard deviation of all elements of \( X \), computed after removing NaN values.
\( y = \text{nanstd}(X, \text{flag}, \text{dim}) \) returns the standard deviation along the operating dimension \( \text{dim} \) of \( X \), computed after removing NaN values.

\( y = \text{nanstd}(X, \text{flag}, \text{vecdim}) \) returns the standard deviation over the dimensions specified in the vector \( \text{vecdim} \). The function computes the standard deviations after removing NaN values. For example, if \( X \) is a matrix, then \( \text{nanstd}(X, 0, [1 2]) \) is the sample standard deviation of all non-NaN elements of \( X \) because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

**Examples**

**Standard Deviation of Matrix Data**

Find the column standard deviations for matrix data with missing values.

\[
X = \text{magic}(3);
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
y = \text{nanstd}(X)
\]

\[
y = \begin{bmatrix}
0.7071 & 2.8284 & \text{NaN}
\end{bmatrix}
\]

**Standard Deviation for Population vs. Sample**

Load the carsmall data set.

\[
\text{load carsmall}
\]
Compute the population and sample standard deviations for the Horsepower data. The `nanstd` function ignores the missing value in Horsepower.

\[
y_1 = \text{nanstd}(\text{Horsepower}, 1) \quad \% \text{ Population formula}
\]

\[
y_1 = 45.2963
\]

\[
y_2 = \text{nanstd}(\text{Horsepower}, 0) \quad \% \text{ Sample formula}
\]

\[
y_2 = 45.5268
\]

**Standard Deviation of All Values**

Find the standard deviation of all the values in an array, ignoring missing values.

Create a 3-by-4-by-2 array \(X\) with some missing values.

\[
X = \text{reshape}(1:24, [3 4 2]);
X([8:10 18]) = \text{NaN}
\]

\[
X = \\
X(:,:,1) = \\
\begin{array}{cccc}
1 & 4 & 7 & \text{NaN} \\
2 & 5 & \text{NaN} & 11 \\
3 & 6 & \text{NaN} & 12 \\
\end{array}
\]

\[
X(:,:,2) = \\
\begin{array}{cccc}
13 & 16 & 19 & 22 \\
14 & 17 & 20 & 23 \\
15 & \text{NaN} & 21 & 24 \\
\end{array}
\]

Find the sample standard deviation of the elements of \(X\).

\[
y = \text{nanstd}(X, 0, \text{'}all\text{'})
\]

\[
y = 7.5385
\]
**Standard Deviation Along Scalar Dimension**

Find the row standard deviations for matrix data with missing values. Specify to compute the sample standard deviations along the second dimension.

```
X = magic(3);
X([1 6:9]) = NaN
X = magic(3);
X([1 6:9]) = NaN
X = 3×3
   NaN     1     NaN
   3     5     NaN
   4     NaN     NaN
```

```
y = nanstd(X,0,2)
y = 3×1
   0
   1.4142
   0
```

**Standard Deviation Along Vector Dimension**

Find the standard deviation of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array X with some missing values.

```
X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN
X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN
X(:,:,1) =
   1     4     7     NaN
   2     5     NaN     11
   3     6     NaN     12
X(:,:,2) =
X(:,:,2) =
```

```
X(:,:,1) =
   1     4     7     NaN
   2     5     NaN     11
   3     6     NaN     12
X(:,:,2) =
```
Find the sample standard deviation of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

ypage = nanstd(X,0,[1 2])

ypage =
ypage(:,:,1) =
    3.8079

ypage(:,:,2) =
    3.7779

For example, ypage(1,1,2) is the sample standard deviation of the non-NaN elements in X(:,:,2).

Find the sample standard deviation of the elements in each X(i,:,:) slice by specifying dimensions 2 and 3 as the operating dimensions.

yrow = nanstd(X,0,[2 3])

yrow = 3×1
    7.9102
    7.6904
    8.2158

For example, yrow(3) is the sample standard deviation of the non-NaN elements in X(3,:,:).

**Input Arguments**

X — Input data
scalar | vector | matrix | multidimensional array
Input data, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: single | double

**flag — Indicator for normalization**

0 (default) | 1

Indicator for the normalization used to compute the standard deviation, specified as 0 or 1.

- If `flag` is 0 (default), then `nanstd` returns the sample standard deviation on page 32-4225 of `X`. `nanstd(X,0)` is the same as `nanstd(X)`.
- If `flag` is 1, then `nanstd` returns the population standard deviation on page 32-4226 of `X`.

Data Types: single | double

**dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y,dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nanstd(X,0,1)` returns a row vector containing the sample standard deviation for each column.
- If `dim` is equal to 2, then `nanstd(X,0,2)` returns a column vector containing the sample standard deviation for each row.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `nanstd` returns an array of zeros with the same dimensions and missing values as `X`.

Data Types: single | double

**vecdim — Vector of dimensions**

positive integer vector
Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nanstd(X, 0, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the sample standard deviation of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

### Output Arguments

`y` — Standard deviation values

scalar | vector | matrix | multidimensional array

Standard deviation values, returned as a scalar, vector, matrix, or multidimensional array.

### Definitions

#### Sample Standard Deviation

The sample standard deviation `S` is given by

\[
S = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{X})^2}{n-1}}.
\]
S is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples. \( \bar{X} \) is the sample mean.

Notice that the denominator in this variance formula is \( n - 1 \).

**Population Standard Deviation**

If the data is the entire population of values, then you can use the *population standard deviation*,

\[
\sigma = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \mu)^2}{n}}.
\]

If \( X \) is a random sample from a population, then the mean \( \mu \) is estimated by the sample mean, and \( \sigma \) is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is \( n \).

**Alternative Functionality**

Instead of using `nanstd`, you can use the MATLAB function `std` with the input argument `nanflag` specified as the value `'omitnan'`.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
• \( y = \text{nanstd}(X, \text{flag}, 'all') \)
• \( y = \text{nanstd}(X, \text{flag}, \text{vecdim}) \)

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
• The following syntaxes do not support GPU arrays as input arguments.
  • \( y = \text{nanstd}(X, \text{flag}, 'all') \)
  • \( y = \text{nanstd}(X, \text{flag}, \text{vecdim}) \)

*Introduced before R2006a*
nansum

Sum, ignoring NaN values

Syntax

y = nansum(X)
y = nansum(X,'all')
y = nansum(X,dim)
y = nansum(X,vecdim)

Description

y = nansum(X) returns the sum of the elements of X, computed after removing all NaN values.

- If X is a vector, then nansum(X) is the sum of all the non-NaN elements of X.
- If X is a matrix, then nansum(X) is a row vector of column sums, computed after removing NaN values.
- If X is a multidimensional array, then nansum operates along the first nonsingleton dimension of X. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. nansum removes all NaN values.

For information on how nansum treats arrays of all NaN values, see “Tips” on page 32-4234.

y = nansum(X,'all') returns the sum of all elements of X, computed after removing NaN values.

y = nansum(X,dim) returns the sum along the operating dimension dim of X, computed after removing NaN values.

y = nansum(X,vecdim) returns the sum over the dimensions specified in the vector vecdim. The function computes the sums after removing NaN values. For example, if X is a matrix, then nansum(X,[1 2]) is the sum of all non-NaN elements of X because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.
Examples

Sum of Matrix Data

Find the column sums for matrix data with missing values.

```matlab
X = magic(3);
X([1 6:9]) = NaN
X = 3×3
    NaN     1   NaN
    3     5   NaN
    4   NaN   NaN
```

```matlab
y = nansum(X)
y = 1×3
    7     6     0
```

Sum of All Values

Find the sum of all the values in an array, ignoring missing values.

Create a 2-by-4-by-3 array `X` with some missing values.

```matlab
X = reshape(1:24,[2 4 3]);
X([5:6 20]) = NaN
X = 
X(:,:,1) =
    1     3   NaN     7
    2     4   NaN     8
```
Find the sum of the elements of \( X \).

\[
y = \text{nansum}(X, 'all')
\]

\[
y = 269
\]

**Sum Along Scalar Dimension**

Find the row sums for matrix data with missing values by specifying to compute the sums along the second dimension.

\[
X = \text{magic}(3);
X([1 6:9]) = \text{NaN}
\]

\[
X = \begin{bmatrix}
\text{NaN} & 1 & \text{NaN} \\
3 & 5 & \text{NaN} \\
4 & \text{NaN} & \text{NaN}
\end{bmatrix}
\]

\[
y = \text{nansum}(X, 2)
\]

\[
y = \begin{bmatrix}
1 \\
8 \\
4
\end{bmatrix}
\]
Sum Along Vector Dimension

Find the sum of a multidimensional array over multiple dimensions.

Create a 2-by-4-by-3 array X with some missing values.

\[
X = \text{reshape}(1:24, [2 4 3]); \\
X([5:6 20]) = \text{NaN}
\]

\[
X(:,:,1) = \\
\begin{bmatrix}
1 & 3 & \text{NaN} & 7 \\
2 & 4 & \text{NaN} & 8 \\
\end{bmatrix}
\]

\[
X(:,:,2) = \\
\begin{bmatrix}
9 & 11 & 13 & 15 \\
10 & 12 & 14 & 16 \\
\end{bmatrix}
\]

\[
X(:,:,3) = \\
\begin{bmatrix}
17 & 19 & 21 & 23 \\
18 & \text{NaN} & 22 & 24 \\
\end{bmatrix}
\]

Find the sum of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

\[
y\text{page} = \text{nansum}(X, [1 2])
\]

\[
y\text{page} = \\
y\text{page}(:,:,1) = \\
25
\]

\[
y\text{page}(:,:,2) = \\
100
\]

\[
y\text{page}(:,:,3) = 
\]
For example, \texttt{ypage(1,1,1)} is the sum of the non-\texttt{NaN} elements in \texttt{X(:,:,1)}.

Find the sum of the elements in each \texttt{X(i,:,:)} slice by specifying dimensions 2 and 3 as the operating dimensions.

\begin{verbatim}
yrow = nansum(X,[2 3])
\end{verbatim}

\begin{verbatim}
yrow = 2x1
139
130
\end{verbatim}

For example, \texttt{yrow(2)} is the sum of the non-\texttt{NaN} elements in \texttt{X(2,:,:)}.

\section*{Input Arguments}

\texttt{X — Input data}

\begin{verbatim}
scalar | vector | matrix | multidimensional array
\end{verbatim}

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If \texttt{X} is an empty array, then \texttt{nansum(X)} is \texttt{0}.

Data Types: \texttt{single} | \texttt{double}

\texttt{dim — Dimension to operate along}

\begin{verbatim}
positive integer scalar
\end{verbatim}

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

\texttt{dim} indicates the dimension whose length reduces to 1. \texttt{size(y,dim)} is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array \texttt{X}:
• If \( \text{dim} \) is equal to 1, then \( \text{nansum}(X,1) \) returns a row vector containing the sum for each column.

• If \( \text{dim} \) is equal to 2, then \( \text{nansum}(X,2) \) returns a column vector containing the sum for each row.

If \( \text{dim} \) is greater than \( \text{ndims}(X) \) or if \( \text{size}(X,\text{dim}) \) is 1, then \( \text{nansum} \) returns \( X \), with 0 values in the place of any missing values.

Data Types: \( \text{single} \) | \( \text{double} \)

**vecdim — Vector of dimensions**
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of \( \text{vecdim} \) represents a dimension of the input array \( X \). The output \( y \) has length 1 in the specified operating dimensions. The other dimension lengths are the same for \( X \) and \( y \).

For example, if \( X \) is a 2-by-3-by-3 array, then \( \text{nansum}(X, [1 \ 2]) \) returns a 1-by-1-by-3 array. Each element of the output array is the sum of the elements on the corresponding page of \( X \).

Data Types: \( \text{single} \) | \( \text{double} \)

**Output Arguments**

**\( y \) — Sum values**
scalar | vector | matrix | multidimensional array

Sum values, returned as a scalar, vector, matrix, or multidimensional array.
Tips

• When `nansum` computes the sum of an array of all `NaN` values, the array is empty once the `NaN` values are removed and, therefore, the sum of the remaining elements is 0. The output 0 is not a sum of `NaN` values.

Alternative Functionality

Instead of using `nansum`, you can use the MATLAB function `sum` with the input argument `nanflag` specified as the value 'omitnan'.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The following syntaxes do not support code generation.
  
  • `y = nansum(X,'all')`
  
  • `y = nansum(X,vecdim)`

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

• The following syntaxes do not support GPU arrays as input arguments.
  
  • `y = nansum(X,'all')`
  
  • `y = nansum(X,vecdim)`
For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also
NaN | sum

Introduced before R2006a
nanvar

Variance, ignoring NaN values

Syntax

y = nanvar(X)
y = nanvar(X,w)
y = nanvar(X,w,'all')
y = nanvar(X,w,dim)
y = nanvar(X,w,vecdim)

Description

y = nanvar(X) is the variance var of X, computed after removing NaN values.
For vectors x, nanvar(x) is the sample variance of the remaining elements, once NaN values are removed. For matrices X, nanvar(X) is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays X, nanvar operates along the first nonsingleton dimension.

nanvar removes the mean from each variable (column for matrix X) before calculating y. If n is the number of remaining observations after removing observations with NaN values, nanvar normalizes y by either n - 1 or n, depending on whether n > 1 or n = 1, respectively.

y = nanvar(X,w) computes the variance of X according to the weighting scheme w. When w is 0 (default), X is normalized by n - 1, where n is the number of non-NaN observations. When w is 1, w is normalized by the number of non-NaN observations. Otherwise, w can be a weight vector containing nonnegative elements. The length of w must equal the length of the dimension over which nanvar operates. Elements of X corresponding to NaN values of w are ignored.

y = nanvar(X,w,'all') returns the variance over all elements of X when w = 0 or w = 1. The nanvar function computes the variance after removing NaN values.

y = nanvar(X,w,dim) returns the variance along the operating dimension dim of X.
y = nanvar(X,w,vecdim) returns the variance over the dimensions specified in the vector vecdim, computed after removing NaN values. Each element of vecdim represents a dimension of the input array X. The output y has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and y. For example, if X is a 2-by-3-by-4 array, then nanvar(X,[],[1 2]) returns a 1-by-1-by-4 array. Each element of the output array is the variance of the elements on the corresponding page of X. This syntax is supported when w = 0 or w = 1.

Examples

Variance of Matrix Data

Find the column variances for matrix data with missing values.

X = magic(3);
X([1 6:9]) = NaN
X = 3×3
     NaN     1     NaN
     3     5     NaN
     4     NaN     NaN

y = nanvar(X)
y = 1×3
    0.5000    8.0000       NaN

Variance Along Vector Dimension

Find the variance of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array X with some missing values.

X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN
X =
X(:,:,1) =
   1     4     7   NaN
   2     5   NaN    11
   3     6   NaN    12

X(:,:,2) =
   13    16    19    22
   14    17    20    23
   15   NaN    21    24

Find the sample variance of each page of X by specifying dimensions 1 and 2 as the operating dimensions.
ypage = nanvar(X,0,[1 2])
ypage =
ypage(:,:,1) =
   14.5000
ypage(:,:,2) =
   14.2727

For example, ypage(1,1,2) is the sample variance of the non-NaN elements in X(:,,:2).

Find the sample variance of the elements in each X(:,i,:) slice by specifying dimensions 1 and 3 as the operating dimensions.
ycol = nanvar(X,0,[1 3])
ycol = 1x4
   44.0000   40.3000   42.9167   40.3000

For example, ycol(4) is the sample variance of the non-NaN elements in X(:,4,:).
Alternative Functionality

Instead of using \texttt{nanvar}, you can use the MATLAB function \texttt{var} with the input argument \texttt{nanflag} specified as the value 'omitnan'.

Extended Capabilities

\textbf{C/C++ Code Generation}

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- The following syntaxes do not support code generation.
  - \( y = \text{nanvar}(X,w,'all') \)
  - \( y = \text{nanvar}(X,w,\text{vecdim}) \)

\textbf{GPU Arrays}

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:
- The following syntaxes do not support GPU arrays as input arguments.
  - \( y = \text{nanvar}(X,w,'all') \)
  - \( y = \text{nanvar}(X,w,\text{vecdim}) \)

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

\textbf{See Also}

Introduced before R2006a
nbincdf

Negative binomial cumulative distribution function

Syntax

\[ y = \text{nbincdf}(x, R, p) \]
\[ y = \text{nbincdf}(x, R, p, \text{'upper'}) \]

Description

\[ y = \text{nbincdf}(x, R, p) \] computes the negative binomial cdf at each of the values in \( x \) using the corresponding number of successes, \( R \) and probability of success in a single trial, \( p \). \( x, R, \) and \( p \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( y \). A scalar input for \( x, R, \) or \( p \) is expanded to a constant array with the same dimensions as the other inputs.

\[ y = \text{nbincdf}(x, R, p, \text{'upper'}) \] returns the complement of the negative binomial cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

\[
y = F(x | r, p) = \sum_{i=0}^{x} \binom{r + i - 1}{i} p^r q^i I_{(0,1,...)}(i)
\]

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability \( p \) of success. The number of extra trials you must perform in order to observe a given number \( R \) of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, \text{nbincdf} \ allows \( R \) to be any positive value, including nonintegers. When \( R \) is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

\[
\frac{\Gamma(r + i)}{\Gamma(r)\Gamma(i + 1)}
\]
Examples

Compute Negative Binomial Distribution CDF

```matlab
x = (0:15);
p = nbincdf(x,3,0.5);
stairs(x,p)
```

nbinfit

Negative binomial parameter estimates

Syntax

parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)

Description

parmhat = nbinfit(data) returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector data.

[parmhat,parmci] = nbinfit(data,alpha) returns MLEs and 100(1-alpha) percent confidence intervals. By default, alpha = 0.05, which corresponds to 95% confidence intervals.

[...] = nbinfit(data,alpha,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an options structure which you can create using the function statset. Enter statset('nbinfit') to see the names and default values of the parameters that nbinfit accepts in the options structure. See the reference page for statset for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in data is less than its sample mean, nbinfit cannot compute MLEs. You should use the poissfit function instead.

“Negative Binomial Distribution” on page B-116

Introduced before R2006a
**nbininv**

Negative binomial inverse cumulative distribution function

**Syntax**

\[ X = \text{nbininv}(Y,R,P) \]

**Description**

\[ X = \text{nbininv}(Y,R,P) \] returns the inverse of the negative binomial cdf with corresponding number of successes, \( R \) and probability of success in a single trial, \( P \). Since the binomial distribution is discrete, \( \text{nbininv} \) returns the least integer \( X \) such that the negative binomial cdf evaluated at \( X \) equals or exceeds \( Y \). \( Y, R, \) and \( P \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( X \). A scalar input for \( Y, R, \) or \( P \) is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability \( P \) of success. The number of extra trials you must perform in order to observe a given number \( R \) of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, \( \text{nbininv} \) allows \( R \) to be any positive value, including nonintegers.

**Examples**

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

\[
\text{flips} = \text{nbininv}(0.99,10,0.5) + 10
\]

\[
\text{flips} = 33
\]

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.
Extended Capabilities

**nbinpdf**

Negative binomial probability density function

**Syntax**

\[ Y = \text{nbinpdf}(X,R,P) \]

**Description**

\[ Y = \text{nbinpdf}(X,R,P) \] returns the negative binomial pdf at each of the values in \( X \) using the corresponding number of successes, \( R \) and probability of success in a single trial, \( P \). \( X, R, \) and \( P \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( Y \). A scalar input for \( X, R, \) or \( P \) is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in \( X \) are integers.

The negative binomial pdf is

\[
y = f(x \mid r, p) = \binom{r + x - 1}{x} p^r q^x I_{(0,1,\ldots)}(x)
\]

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability \( P \) of success. The number of extra trials you must perform in order to observe a given number \( R \) of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, \text{nbinpdf} allows \( R \) to be any positive value, including nonintegers. When \( R \) is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

\[
\frac{\Gamma(r + x)}{\Gamma(r)\Gamma(x + 1)}
\]
Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters \( R = 3 \) and \( p = 0.5 \).

\[
\begin{align*}
x &= 0:10; \\
y &= \text{nbinpdf}(x,3,0.5);
\end{align*}
\]

Plot the pdf.

\[
\begin{align*}
\text{figure; } & \\
\text{plot}(x,y,'+') & \\
\text{xlim([-0.5,10.5])}
\end{align*}
\]

“Negative Binomial Distribution” on page B-116

Introduced before R2006a
nbinrnd

Negative binomial random numbers

Syntax

RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])

Description

RND = nbinrnd(R,P) is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, R and probability of success in a single trial, P. R and P can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of RND. A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

RND = nbinrnd(R,P,m,n,...) or RND = nbinrnd(R,P,[m,n,...]) generates an m-by-n-by-... array. The R, P parameters can each be scalars or arrays of the same size as R.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of extra trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbinrnd allows R to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

r = nbinrnd(3,0.01,1,6)+3
r =
   496   142   420   396   851   178
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

• The output is nonscalar.
• An input parameter is invalid for the distribution.

“Negative Binomial Distribution” on page B-116

Introduced before R2006a
**nbinstat**

Negative binomial mean and variance

**Syntax**

\[ [M,V] = \text{nbinstat}(R,P) \]

**Description**

\[ [M,V] = \text{nbinstat}(R,P) \] returns the mean of and variance for the negative binomial distribution with corresponding number of successes, \( R \) and probability of success in a single trial, \( P \). \( R \) and \( P \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( M \) and \( V \). A scalar input for \( R \) or \( P \) is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters \( r \) and \( p \) is \( rq / p \), where \( q = 1 - p \). The variance is \( rq / p^2 \).

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability \( P \) of success. The number of extra trials you must perform in order to observe a given number \( R \) of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, \( \text{nbinstat} \) allows \( R \) to be any positive value, including nonintegers.

**Examples**

```matlab
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =
    9.0000  18.0000  27.0000  36.0000  45.0000
       2.3333  4.6667   7.0000  9.3333  11.6667

FeatureSelectionNCAClassification class

Feature selection for classification using neighborhood component analysis (NCA)

Description

FeatureSelectionNCAClassification object contains the data, fitting information, feature weights, and other parameters of a neighborhood component analysis (NCA) model. fscnca learns the feature weights using a diagonal adaptation of NCA and returns an instance of a FeatureSelectionNCAClassification object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a FeatureSelectionNCAClassification object using fscnca.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: double

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of ModelParameters using dot notation.

For example, for a FeatureSelectionNCAClassification object named mdl, you can access the LossFunction value using mdl.ModelParameters.LossFunction.
Data Types: struct

**Lambda — Regularization parameter**

 scalar

Regularization parameter used for training this model, stored as a scalar. For \( n \) observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of \( 1/n \).

Data Types: double

**FitMethod — Name of fitting method**

`'exact' | 'none' | 'average'`

Name of the fitting method used to fit this model, stored as one of the following:

- `'exact'` — Perform fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- `'average'` — Divide the data into partitions (subsets), fit each partition using the exact method, and return the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

**Solver — Name of the solver used to fit this model**

`'lbfgs' | 'sgd' | 'minibatch-lbfgs'`

Name of the solver used to fit this model, stored as one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — stochastic gradient descent with LBFGS algorithm applied to mini-batches

**GradientTolerance — Relative convergence tolerance on gradient norm**

 scalar

Relative convergence tolerance on the gradient norm for the `'lbfgs'` and `'minibatch-lbfgs'` solvers, stored as a positive scalar value.

Data Types: double
**IterationLimit** — Maximum number of iterations for optimization

positive integer

Maximum number of iterations for optimization, stored as a positive integer value.

Data Types: double

**PassLimit** — Maximum number of passes

positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.

Data Types: double

**InitialLearningRate** — Initial learning rate

positive real scalar

Initial learning rate for the 'sgd' and 'minibatch-lbfgs' solvers, stored as a positive real scalar. The learning rate decays over iterations starting at the value specified for InitialLearningRate.

Use the NumTuningIterations and TuningSubsetSize name-value pair arguments to control the automatic tuning of initial learning rate in the call to fscnca.

Data Types: double

**Verbose** — Verbosity level indicator

nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

**InitialFeatureWeights** — Initial feature weights

p-by-1 vector of positive real scalars
Initial feature weights, stored as a $p$-by-1 vector of positive real scalars, where $p$ is the number of predictors in $X$.

Data Types: double

**FeatureWeights — Feature weights**

$p$-by-1 vector of real scalars

Feature weights, stored as a $p$-by-1 vector of real scalars, where $p$ is the number of predictors in $X$.

If `FitMethod` is 'average', then `FeatureWeights` is a $p$-by-$m$ matrix. $m$ is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to `fscnca`.

The absolute value of `FeatureWeights(k)` is a measure of the importance of predictor $k$. A `FeatureWeights(k)` value that is close to 0 indicates that predictor $k$ does not influence the response in $Y$.

Data Types: double

**FitInfo — Fit information**

structure

Fit information, stored as a structure with the following fields.

<table>
<thead>
<tr>
<th><strong>Field Name</strong></th>
<th><strong>Meaning</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Iteration</td>
<td>Iteration index</td>
</tr>
<tr>
<td>Objective</td>
<td>Regularized objective function for minimization</td>
</tr>
<tr>
<td>UnregularizedObjective</td>
<td>Unregularized objective function for minimization</td>
</tr>
<tr>
<td>Gradient</td>
<td>Gradient of regularized objective function for minimization</td>
</tr>
</tbody>
</table>

- For classification, `UnregularizedObjective` represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, `UnregularizedObjective` represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.
• For the 'lbfgs' solver, Gradient is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, Gradient is the final mini-batch gradient.

• If FitMethod is 'average', then FitInfo is an m-by-1 structure array, where m is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of FitInfo using dot notation. For example, for a FeatureSelectionNCAClassificationobject named mdl, you can access the Objective field using mdl.FitInfo.Objective.

Data Types: struct

Mu — Predictor means
p-by-1 vector | []

Predictor means, stored as a p-by-1 vector for standardized training data. In this case, the predict method centers predictor matrix X by subtracting the respective element of Mu from every column.

If data is not standardized during training, then Mu is empty.

Data Types: double

Sigma — Predictor standard deviations
p-by-1 vector | []

Predictor standard deviations, stored as a p-by-1 vector for standardized training data. In this case, the predict method scales predictor matrix X by dividing every column by the respective element of Sigma after centering the data using Mu.

If data is not standardized during training, then Sigma is empty.

Data Types: double

X — Predictor values
n-by-p matrix

Predictor values used to train this model, stored as an n-by-p matrix. n is the number of observations and p is the number of predictor variables in the training data.

Data Types: double

Y — Response values
numeric vector of size n
Response values used to train this model, stored as a numeric vector of size \( n \), where \( n \) is the number of observations.

Data Types: double

\( W \) — Observation weights
numeric vector of size \( n \)

Observation weights used to train this model, stored as a numeric vector of size \( n \). The sum of observation weights is \( n \).

Data Types: double

**Methods**

- **loss**
  Evaluate accuracy of learned feature weights on test data
- **predict**
  Predict responses using neighborhood component analysis (NCA) classifier
- **refit**
  Refit neighborhood component analysis (NCA) model for classification

**Examples**

**Explore FeatureSelectionNCAClassification Object**

Load the sample data.

```matlab
load ionosphere
```

The data set has 34 continuous predictors. The response variable is the radar returns, labeled as b (bad) or g (good).

Fit a neighborhood component analysis (NCA) model for classification to detect the relevant features.

```matlab
mdl = fscnca(X,Y);
```

The returned NCA model, \( mdl \), is a FeatureSelectionNCAClassification object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.
Plot the feature weights.

```matlab
figure()
plot(mdl.FeatureWeights,'ro')
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```

The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to fscnca displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```matlab
figure
plot(mdl.FitInfo.Iteration,mdl.FitInfo.Objective,'ro-')
```
The `ModelParameters` property is a `struct` that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.

```matlab
mdl.ModelParameters.Standardize
ans = logical
    0
```
0 means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the 'Standardize', 1 name-value pair argument in the call to fscnca.

**Introduced in R2016b**
FeatureSelectionNCARegression class

Feature selection for regression using neighborhood component analysis (NCA)

Description

FeatureSelectionNCARegression contains the data, fitting information, feature weights, and other model parameters of a neighborhood component analysis (NCA) model. fsrnca learns the feature weights using a diagonal adaptation of NCA and returns an instance of FeatureSelectionNCARegression object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a FeatureSelectionNCAClassification object using fsrnca.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: double

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of ModelParameters using dot notation.

For example, for a FeatureSelectionNCARegression object named mdl, you can access the LossFunction value using mdl.ModelParameters.LossFunction.
Data Types: struct

**Lambda — Regularization parameter**
scalar

Regularization parameter used for training this model, stored as a scalar. For \( n \) observations, the best \( \text{Lambda} \) value that minimizes the generalization error of the NCA model is expected to be a multiple of \( 1/n \).

Data Types: double

**FitMethod — Name of the fitting method used to fit this model**
'exact' | 'none' | 'average'

Name of the fitting method used to fit this model, stored as one of the following:

- 'exact' — Perform fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to \texttt{fsrnca}.
- 'average' — The software divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the NumPartitions name-value pair argument.

**Solver — Name of the solver used to fit this model**
'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Name of the solver used to fit this model, stored as one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — stochastic gradient descent with LBFGS algorithm applied to mini-batches

**GradientTolerance — Relative convergence tolerance on gradient norm**
positive scalar

Relative convergence tolerance on the gradient norm for the 'lbfgs' and 'minibatch-lbfgs' solvers, stored as a positive scalar value.

Data Types: double
**IterationLimit** — Maximum number of iterations for optimization
positive integer

Maximum number of iterations for optimization, stored as a positive integer value.
Data Types: double

**PassLimit** — Maximum number of passes
positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.
Data Types: double

**InitialLearningRate** — Initial learning rate
positive real scalar

Initial learning rate for 'sgd' and 'minibatch-lbfgs' solvers. The learning rate decays over iterations starting at the value specified for InitialLearningRate.

Use the NumTuningIterations and TuningSubsetSize to control the automatic tuning of initial learning rate in the call to fsrnca.
Data Types: double

**Verbose** — Verbosity level indicator
nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:
- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

**InitialFeatureWeights** — Initial feature weights
p-by-1 vector of positive real scalars

Initial feature weights, stored as a p-by-1 vector of positive real scalars, where p is the number of predictors in X.
Data Types: double

**FeatureWeights — Feature weights**

*p*-by-1 vector of real scalar values

Feature weights, stored as a *p*-by-1 vector of real scalar values, where *p* is the number of predictors in \( X \).

For 'FitMethod' equal to 'average', FeatureWeights is a *p*-by-*m* matrix, where *m* is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to fsrnca.

The absolute value of FeatureWeights\((k)\) is a measure of the importance of predictor \( k \). If FeatureWeights\((k)\) is close to 0, then this indicates that predictor \( k \) does not influence the response in \( Y \).

Data Types: double

**FitInfo — Fit information**

structure

Fit information, stored as a structure with the following fields.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iteration</td>
<td>Iteration index</td>
</tr>
<tr>
<td>Objective</td>
<td>Regularized objective function for minimization</td>
</tr>
<tr>
<td>UnregularizedObjective</td>
<td>Unregularized objective function for minimization</td>
</tr>
<tr>
<td>Gradient</td>
<td>Gradient of regularized objective function for minimization</td>
</tr>
</tbody>
</table>

- For classification, UnregularizedObjective represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, UnregularizedObjective represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.
- For the 'lbfgs' solver, Gradient is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, Gradient is the final mini-batch gradient.
• If `FitMethod` is 'average', then `FitInfo` is an `m`-by-1 structure array, where `m` is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of `FitInfo` using dot notation. For example, for a `FeatureSelectionNCARegression` object named `mdl`, you can access the `Objective` field using `mdl.FitInfo.Objective`.

Data Types: `struct`

**Mu — Predictor means**

`p`-by-1 vector | `[]`

Predictor means, stored as a `p`-by-1 vector for standardized training data. In this case, the `predict` method centers predictor matrix `X` by subtracting the respective element of `Mu` from every column.

If data is not standardized during training, then `Mu` is empty.

Data Types: `double`

**Sigma — Predictor standard deviations**

`p`-by-1 vector | `[]`

Predictor standard deviations, stored as a `p`-by-1 vector for standardized training data. In this case, the `predict` method scales predictor matrix `X` by dividing every column by the respective element of `Sigma` after centering the data using `Mu`.

If data is not standardized during training, then `Sigma` is empty.

Data Types: `double`

**X — Predictor values**

`n`-by-`p` matrix

Predictor values used to train this model, stored as an `n`-by-`p` matrix. `n` is the number of observations and `p` is the number of predictor variables in the training data.

Data Types: `double`

**Y — Response values**

numeric vector of size `n`

Response values used to train this model, stored as a numeric vector of size `n`, where `n` is the number of observations.
Data Types: double

**W — Observation weights**
numeric vector of size \( n \)

Observation weights used to train this model, stored as a numeric vector of size \( n \). The sum of observation weights is \( n \).

Data Types: double

### Methods

- **loss**  Evaluate accuracy of learned feature weights on test data
- **predict**  Predict responses using neighborhood component analysis (NCA) regression model
- **refit**  Refit neighborhood component analysis (NCA) model for regression

### Examples

**Explore FeatureSelectionNCARegression Object**

Load the sample data.

```matlab
load imports-85
```

The first 15 columns contain the continuous predictor variables, whereas the 16th column contains the response variable, which is the price of a car. Define the variables for the neighborhood component analysis model.

```matlab
Predictors = X(:,1:15);
Y = X(:,16);
```

Fit a neighborhood component analysis (NCA) model for regression to detect the relevant features.

```matlab
mdl = fsrnca(Predictors,Y);
```
The returned NCA model, mdl, is a FeatureSelectionNCARegression object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.

Plot the feature weights.

```matlab
figure()
plot(mdl.FeatureWeights,'ro')
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```
The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to `fsrnca` displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```matlab
figure()
plot(mdl.FitInfo.Iteration, mdl.FitInfo.Objective, 'ro-')
grid on
xlabel('Iteration Number')
ylabel('Objective')
```

The `ModelParameters` property is a struct that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.
mdl.ModelParameters.Standardize

ans = logical
   0

0 means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the 'Standardize',1 name-value pair argument in the call to fsrnca.

Introduced in R2016b
ncfcdf

Noncentral $F$ cumulative distribution function

Syntax

$p = 	ext{ncfcdf}(x, 
u_1, 
u_2, \delta)$
$p = 	ext{ncfcdf}(x, 
u_1, 
u_2, \delta, \text{'upper'})$

Description

$p = 	ext{ncfcdf}(x, 
u_1, 
u_2, \delta)$ computes the noncentral $F$ cdf at each value in $x$ using the corresponding numerator degrees of freedom in $\nu_1$, denominator degrees of freedom in $\nu_2$, and positive noncentrality parameters in $\delta$. $\nu_1$, $\nu_2$, and $\delta$ can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of $p$. A scalar input for $x$, $\nu_1$, $\nu_2$, or $\delta$ is expanded to a constant array with the same dimensions as the other inputs.

$p = 	ext{ncfcdf}(x, 
u_1, 
u_2, \delta, \text{'upper'})$ returns the complement of the noncentral $F$ cdf at each value in $x$, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral $F$ cdf is

$$F(x \mid \nu_1, \nu_2, \delta) = \sum_{j=0}^{\infty} \left( \frac{1}{2} \delta \right)^j \frac{-\delta}{j!} e^{-\frac{\delta}{2}} I \left( \frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \left| \frac{v_1}{2} + j, \frac{v_2}{2} \right. \right)$$

where $I(x|a,b)$ is the incomplete beta function with parameters $a$ and $b$.

Examples
Compute Noncentral F Distribution cdf

Compare the noncentral $F$ cdf with $\delta = 10$ to the $F$ cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```matlab
x = (0.01:0.1:10.01)';
p1 = ncfcdf(x,5,20,10);
p = fcdf(x,5,20);
plot(x,p,'-',x,p1,'-')
```

ncfinv

Noncentral $F$ inverse cumulative distribution function

Syntax

$X = \text{ncfinv}(P, NU1, NU2, \text{DELTA})$

Description

$X = \text{ncfinv}(P, NU1, NU2, \text{DELTA})$ returns the inverse of the noncentral $F$ cdf with numerator degrees of freedom $NU1$, denominator degrees of freedom $NU2$, and positive noncentrality parameter $\text{DELTA}$ for the corresponding probabilities in $P$. $P$, $NU1$, $NU2$, and $\text{DELTA}$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of $X$. A scalar input for $P$, $NU1$, $NU2$, or $\text{DELTA}$ is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an $F$ distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```matlab
critical = \text{finv}(0.95, 5, 20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```matlab
prob = 1 - \text{ncfcdf}(\text{critical}, 5, 20, 2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the $F$ statistic?
ncfinv(0.5,5,20,2)
ans =
    1.2786

ncfpdf

Noncentral $F$ probability density function

Syntax

$Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$

Description

$Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$ computes the noncentral $F$ pdf at each of the values in $X$ using the corresponding numerator degrees of freedom in $\text{NU1}$, denominator degrees of freedom in $\text{NU2}$, and positive noncentrality parameters in $\text{DELTA}$. $X$, $\text{NU1}$, $\text{NU2}$, and $\text{B}$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of $Y$. A scalar input for $P$, $\text{NU1}$, $\text{NU2}$, or $\text{DELTA}$ is expanded to a constant array with the same dimensions as the other inputs.

The $F$ distribution is a special case of the noncentral $F$ where $\delta = 0$. As $\delta$ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral $F$ Distribution pdf

Compute the pdf of a noncentral $F$ distribution with degrees of freedom $\text{NU1} = 5$ and $\text{NU2} = 20$, and noncentrality parameter $\text{DELTA} = 10$. For comparison, also compute the pdf of an $F$ distribution with the same degrees of freedom.

```plaintext
x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral $F$ distribution and the pdf of the $F$ distribution on the same figure.

ncfrnd

Noncentral $F$ random numbers

**Syntax**

```matlab
R = ncfrnd(NU1,NU2,DELTA)
R = ncfrnd(NU1,NU2,DELTA,m,n,...)
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])
```

**Description**

$R = \text{ncfrnd}(NU1,NU2,DELTA)$ returns a matrix of random numbers chosen from the noncentral $F$ distribution with corresponding numerator degrees of freedom in $NU1$, denominator degrees of freedom in $NU2$, and positive noncentrality parameters in $DELTA$. $NU1$, $NU2$, and $DELTA$ can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of $R$. A scalar input for $NU1$, $NU2$, or $DELTA$ is expanded to a constant matrix with the same dimensions as the other inputs.

$R = \text{ncfrnd}(NU1,NU2,DELTA,m,n,...)$ or $R = \text{ncfrnd}(NU1,NU2,DELTA,[m,n,...])$ generates an $m$-by-$n$-by-... array. The $NU1$, $NU2$, $DELTA$ parameters can each be scalars or arrays of the same size as $R$.

**Examples**

Compute six random numbers from a noncentral $F$ distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, $\delta$, of 4.0. Compare this to the $F$ distribution with the same degrees of freedom.

```matlab
r = ncfrnd(10,100,4,1,6)
r =
  2.5995  0.8824  0.8220  1.4485  1.4415  1.4864

r1 = frnd(10,100,1,6)
r1 =
  0.9826  0.5911  1.0967  0.9681  2.0096  0.6598
```

Noncentral F mean and variance

Syntax

\[ [M,V] = \text{ncfstat}(NU1,NU2,DELTA) \]

Description

\[ [M,V] = \text{ncfstat}(NU1,NU2,DELTA) \] returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in \( NU1 \), denominator degrees of freedom in \( NU2 \), and positive noncentrality parameters in \( DELTA \). \( NU1, NU2, \) and \( DELTA \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( M \) and \( V \). A scalar input for \( NU1, NU2, \) or \( DELTA \) is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters \( \nu_1, \nu_2, \) and \( \delta \) is

\[
\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}
\]

where \( \nu_2 > 2 \).

The variance is

\[
2 \left( \frac{\nu_2}{\nu_1} \right)^2 \left[ \frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]
\]

where \( \nu_2 > 4 \).

Examples

\[ [m,v] = \text{ncfstat}(10,100,4) \]
\[ m = \]
\[
\begin{align*}
v &= 1.4286 \\
0.4252
\end{align*}
\]

Noncentral t cumulative distribution function

Syntax

\[ p = \text{nctcdf}(x,\nu,\delta) \]
\[ p = \text{nctcdf}(x,\nu,\delta, 'upper') \]

Description

\[ p = \text{nctcdf}(x,\nu,\delta) \] computes the noncentral t cdf at each value in \( x \) using the corresponding degrees of freedom in \( \nu \) and noncentrality parameters in \( \delta \). \( x, \nu, \) and \( \delta \) can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of \( p \). A scalar input for \( x, \nu, \) or \( \delta \) is expanded to a constant array with the same dimensions as the other inputs.

\[ p = \text{nctcdf}(x,\nu,\delta, 'upper') \] returns the complement of the noncentral t cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Noncentral t Distribution cdf

Compare the noncentral t cdf with \( \text{DELTA} = 1 \) to the t cdf with the same number of degrees of freedom (10).

\[ x = (-5:0.1:5)'; \]
\[ p1 = \text{nctcdf}(x,10,1); \]
\[ p = \text{tcdf}(x,10); \]
\[ \text{plot}(x,p,'-',x,p1,':') \]

**nctstat**

Noncentral $t$ mean and variance

**Syntax**

$[M,V] = \text{nctstat}(NU,\text{DELTA})$

**Description**

$[M,V] = \text{nctstat}(NU,\text{DELTA})$ returns the mean of and variance for the noncentral $t$ pdf with $NU$ degrees of freedom and noncentrality parameter $\text{DELTA}$. $NU$ and $\text{DELTA}$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of $M$ and $V$. A scalar input for $NU$ or $\text{DELTA}$ is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral $t$ distribution with parameters $\nu$ and $\delta$ is

$$
\frac{\delta (\nu / 2)^{1/2} \Gamma((\nu - 1) / 2)}{\Gamma(\nu / 2)}
$$

where $\nu > 1$.

The variance is

$$
\frac{\nu}{(\nu - 2)} (1 + \delta^2) - \frac{\nu}{2} \delta^2 \left[ \frac{\Gamma((\nu - 1) / 2)}{\Gamma(\nu / 2)} \right]^2
$$

where $\nu > 2$.

**Examples**

$[m,v] = \text{nctstat}(10,1)$
m = 1.0837

v = 1.3255

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

\[ p = \text{ncx2cdf}(x,v,delta) \]
\[ p = \text{ncx2cdf}(x,v,delta,'upper') \]

Description

\( p = \text{ncx2cdf}(x,v,delta) \) computes the noncentral chi-square cdf at each value in \( x \) using the corresponding degrees of freedom in \( v \) and positive noncentrality parameters in \( \delta \). \( x, v, \) and \( \delta \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( p \). A scalar input for \( x, v, \) or \( \delta \) is expanded to a constant array with the same dimensions as the other inputs.

\( p = \text{ncx2cdf}(x,v,delta,'upper') \) returns the complement of the noncentral chi-square cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

\[
F(x | v, \delta) = \sum_{j=0}^{\infty} \left( \frac{1}{2} \delta \right)^j \frac{(-\delta)^j}{j!} e^{-\frac{x}{2}} \Pr \left[ \chi^2_{v+2j} \leq x \right]
\]

Examples
Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with DELTA = 2 to the chi-square cdf with the same number of degrees of freedom (4):

```matlab
x = (0:0.1:10)';
npx2 = ncx2cdf(x,4,2);
chi2 = chi2cdf(x,4);

plot(x,ncx2,'b-','LineWidth',2)
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2','Location','NW')
```

R = ncx2rnd(V,DELTA)
R = ncx2rnd(V,DELTA,m,n,...)
R = ncx2rnd(V,DELTA,[m,n,...])

Description

R = ncx2rnd(V,DELTA) returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in V and positive noncentrality parameters in DELTA. V and DELTA can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for V or DELTA is expanded to a constant array with the same dimensions as the other input.

R = ncx2rnd(V,DELTA,m,n,...) or R = ncx2rnd(V,DELTA,[m,n,...]) generates an m-by-n-by-... array. The V, DELTA parameters can each be scalars or arrays of the same size as R.

Examples

ncx2rnd(4,2,6,3)
ans =
   6.8552   5.9650  11.2961
   5.2631   4.2640   5.9495
   9.1939   6.7162   3.8315
  10.3100   4.4828   7.1653
   2.1142   1.9826   4.6400
   3.8852   5.3999   0.9282
References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

“Noncentral Chi-Square Distribution” on page B-121

Introduced before R2006a
ncx2stat

Noncentral chi-square mean and variance

Syntax

\[ [M, V] = \text{ncx2stat}(\nu, \delta) \]

Description

\[ [M, V] = \text{ncx2stat}(\nu, \delta) \]
returns the mean of and variance for the noncentral chi-square pdf with \( \nu \) degrees of freedom and noncentrality parameter \( \delta \). \( \nu \) and \( \delta \) can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of \( M \) and \( V \). A scalar input for \( \nu \) or \( \delta \) is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters \( \nu \) and \( \delta \) is \( \nu + \delta \), and the variance is \( 2(\nu + 2\delta) \).

Examples

\[ [m, v] = \text{ncx2stat}(4, 2) \]
\[
m =
\begin{array}{c}
6 \\
\end{array}
\]
\[
v =
\begin{array}{c}
16 \\
\end{array}
\]

ndims

Class: dataset

Number of dimensions of dataset array

Note  The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

n = ndims(A)

Description

n = ndims(A) returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

See Also

size
ndims

Class: qrandset

Number of dimensions in matrix

Syntax

n = ndims(p)

Description

n = ndims(p) returns the number of dimensions in the matrix that is created by the syntax p(:,:). Since this is always a 2-D matrix, n is always equal to 2.

See Also

qrandset | size
ne

Class: qrandstream

Not equal relation for handles

Syntax

h1  ~=  h2

Description

Handles are equal if they are handles for the same object and are unequal otherwise. 

h1  ~=  h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise ~= result.

If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = ne(h1, h2) stores the result in a logical array of the same dimensions.

negloglik

Package: prob

Negative loglikelihood of probability distribution

Syntax

nll = negloglik(pd)

Description

nll = negloglik(pd) returns the value of the negative loglikelihood function for the data used to fit the probability distribution pd.

Examples

Negative Log Likelihood for a Fitted Distribution

Load the sample data.

load carsmall

Create a Weibull distribution object by fitting it to the mile per gallon (MPG) data.

pd = fitdist(MPG,'Weibull')

pd =
    WeibullDistribution

    Weibull distribution
    A = 26.5079    [24.8333, 28.2954]
    B = 3.27193    [2.79441, 3.83104]

Compute the negative log likelihood for the fitted Weibull distribution.
wnll = negloglik(pd)
wnll = 327.4942

**Negative Loglikelihood for a Kernel Distribution**

Load the sample data. Fit a kernel distribution to the miles per gallon (MPG) data.

```matlab
load carsmall;
pd = fitdist(MPG,'Kernel')
```

```matlab
pd =
   KernelDistribution
     Kernel = normal
     Bandwidth = 4.11428
     Support = unbounded
```

Compute the negative loglikelihood.

```matlab
nll = negloglik(pd)
nll = 327.3139
```

**Input Arguments**

*pd — Probability distribution*
probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td><strong>Distribution Fitter</strong></td>
<td>Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
</tbody>
</table>
Output Arguments

nll — Negative loglikelihood
numeric value

Negative loglikelihood value for the data used to fit the distribution, returned as a numeric value.

“Supported Distributions” on page 5-16

Introduced in R2013a
net

Class: qrandset

Generate quasi-random point set

Syntax

X = net(p,n)

Description

X = net(p,n) returns the first n points X from the point set p of the qrandset on page 32-5254 class. X is n-by-d, where d is the dimension of the point set.

Objects p of the @qrandset class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until p is accessed using net or parenthesis indexing.

Examples

Use haltonset to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```matlab
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =   Halton point set in 3 dimensions (8.918019e+013 points)
   Properties:
       Skip : 1000
       Leap : 100
       ScrambleMethod : none
```

Use scramble to apply reverse-radix scrambling:

```matlab
p = scramble(p,'RR2')
p =   Halton point set in 3 dimensions (8.918019e+013 points)
```
Properties:

- Skip : 1000
- Leap : 100
- ScrambleMethod : RR2

Use net to generate the first four points:

\[
X_0 = \text{net}(p, 4)
\]

\[
X_0 = \\
\begin{pmatrix}
0.0928 & 0.6950 & 0.0029 \\
0.6958 & 0.2958 & 0.8269 \\
0.3013 & 0.6497 & 0.4141 \\
0.9087 & 0.7883 & 0.2166 \\
\end{pmatrix}
\]

Use parenthesis indexing to generate every third point, up to the 11th point:

\[
X = p(1:3:11,:) 
\]

\[
X = \\
\begin{pmatrix}
0.0928 & 0.6950 & 0.0029 \\
0.9087 & 0.7883 & 0.2166 \\
0.3843 & 0.9840 & 0.9878 \\
0.6831 & 0.7357 & 0.7923 \\
\end{pmatrix}
\]

**See Also**

haltonset | qrandstream | sobolset
**nLinearCoeffs**

Number of nonzero linear coefficients

**Syntax**

```matlab
ncoeffs = nLinearCoeffs(obj)
ncoeffs = nLinearCoeffs(obj,delta)
```

**Description**

`ncoeffs = nLinearCoeffs(obj)` returns the number of nonzero linear coefficients in the linear discriminant model `obj`.

`ncoeffs = nLinearCoeffs(obj,delta)` returns the number of nonzero linear coefficients for threshold parameter `delta`.

**Input Arguments**

- **obj**
  Discriminant analysis classifier, produced using `fitcdiscr`.

- **delta**
  Scalar or vector value of the Delta parameter. See “Gamma and Delta” on page 32-4320.

**Output Arguments**

- **ncoeffs**
  Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model `obj`. 
If you call `nLinearCoeffs` with a `delta` argument, `ncoeffs` is the number of nonzero linear coefficients for threshold parameter `delta`. If `delta` is a vector, `ncoeffs` is a vector with the same number of elements.

If `obj` is a quadratic discriminant model, `ncoeffs` is the number of predictors in `obj`.

**Examples**

**Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier**

Find the number of nonzero coefficients in a discriminant analysis classifier for various `Delta` values.

Create a discriminant analysis classifier from the `fisheriris` data.

```matlab
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```matlab
ncoeffs = nLinearCoeffs(obj)
ncoeffs = 4
```

Find the number of nonzero coefficients for `delta` = 1, 2, 4, and 8.

```matlab
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
ncoeffs = 4×1
   4
   4
   3
   0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

```matlab
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```
Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, \( \gamma \) and \( \delta \), that control regularization as follows. \texttt{cvshrink} helps you select appropriate values of the parameters.

Let \( \Sigma \) represent the covariance matrix of the data \( X \), and let \( \hat{X} \) be the centered data (the data \( X \) minus the mean by class). Define

\[
D = \text{diag}(\hat{X}^T \ast \hat{X}).
\]

The regularized covariance matrix \( \hat{\Sigma} \) is

\[
\hat{\Sigma} = (1 - \gamma) \Sigma + \gamma D.
\]

Whenever \( \gamma \geq \text{MinGamma} \), \( \hat{\Sigma} \) is nonsingular.

Let \( \mu_k \) be the mean vector for those elements of \( X \) in class \( k \), and let \( \mu_0 \) be the global mean vector (the mean of the rows of \( X \)). Let \( C \) be the correlation matrix of the data \( X \), and let \( \hat{C} \) be the regularized correlation matrix:

\[
\hat{C} = (1 - \gamma)C + \gamma I,
\]

where \( I \) is the identity matrix.
The linear term in the regularized discriminant analysis classifier for a data point \( x \) is

\[
(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[ (x - \mu_0)^T D^{-1/2} \right] \left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].
\]

The parameter \( \delta \) enters into this equation as a threshold on the final term in square brackets. Each component of the vector \( \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \) is set to zero if it is smaller in magnitude than the threshold \( \delta \). Therefore, for class \( k \), if component \( j \) is thresholded to zero, component \( j \) of \( x \) does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When \( \delta \geq \text{DeltaPredictor}(i) \), all classes \( k \) have

\[
\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.
\]

Therefore, when \( \delta \geq \text{DeltaPredictor}(i) \), the regularized classifier does not use predictor \( i \).

“Discriminant Analysis Classification” on page 20-2
nlinfit

Nonlinear regression

Syntax

\begin{align*}
\beta &= \text{nlinfit}(X,Y,\text{modelfun},\beta_0) \\
\beta &= \text{nlinfit}(X,Y,\text{modelfun},\beta_0,\text{options}) \\
\beta &= \text{nlinfit}(\text{__},\text{Name},\text{Value}) \\
[\beta,R,J,\text{CovB},\text{MSE},\text{ErrorModelInfo}] &= \text{nlinfit}(\text{__})
\end{align*}

Description

\(\beta = \text{nlinfit}(X,Y,\text{modelfun},\beta_0)\) returns a vector of estimated coefficients for the nonlinear regression of the responses in \(Y\) on the predictors in \(X\) using the model specified by \(\text{modelfun}\). The coefficients are estimated using iterative least squares estimation, with initial values specified by \(\beta_0\).

\(\beta = \text{nlinfit}(X,Y,\text{modelfun},\beta_0,\text{options})\) fits the nonlinear regression using the algorithm control parameters in the structure \(\text{options}\). You can return any of the output arguments in the previous syntaxes.

\(\beta = \text{nlinfit}(\text{__},\text{Name},\text{Value})\) uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

\([\beta,R,J,\text{CovB},\text{MSE},\text{ErrorModelInfo}] = \text{nlinfit}(\text{__})\) additionally returns the residuals, \(R\), the Jacobian of \(\text{modelfun}\), \(J\), the estimated variance-covariance matrix for the estimated coefficients, \(\text{CovB}\), an estimate of the variance of the error term, \(\text{MSE}\), and a structure containing details about the error model, \(\text{ErrorModelInfo}\).

Examples
Nonlinear Regression Model Using Default Options

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```matlab
beta = nlinfit(X,y,@hougen,beta0)
```

```matlab
beta = 5×1
     1.2526
     0.0628
     0.0400
     0.1124
     1.1914
```

Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model 

\[ y = b_1 + b_2 \cdot \exp\{-b_3 x\} + \epsilon, \]

where \( b_1, b_2, \) and \( b_3 \) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```matlab
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```matlab
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```matlab
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.
beta0 = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)
beta = 3×1
    1.0041
    3.0997
    2.1483

**Nonlinear Regression Using Observation Weights**

Load sample data.

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Specify a vector of known observation weights.

W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';

Fit the Hougen-Watson model to the rate data using the specified observation weights.

[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);
beta

beta = 5×1
    2.2068
    0.1077
    0.0766
    0.1818
    0.6516

Display the coefficient standard errors.

sqrt(diag(CovB))
an = 5×1
Nonlinear Regression Using Weights Function Handle

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```matlab
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```matlab
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
beta
```

```matlab
beta = 5×1
    0.8308
    0.0409
    0.0251
    0.0801
    1.8261
```

Display the coefficient standard errors.

```matlab
sqrt(diag(CovB))
```

```matlab
ans = 5×1
```
Nonlinear Regression Using Nonconstant Error Model

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```matlab
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

beta

```
beta = 5×1

1.2526
0.0628
0.0400
0.1124
1.1914
```

Display the error model information.

ErrorModelInfo

```
ErrorModelInfo = struct with fields:
    ErrorModel: 'combined'
    ErrorParameters: [0.1517 5.6783e-08]
    ErrorVariance: [function_handle]
    MSE: 1.6245
    ScheffeSimPred: 6
    WeightFunction: 0
    FixedWeights: 0
```
**Input Arguments**

**X — Predictor variables**

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, X is a design matrix of predictor (independent variable) values, with one row for each value in Y, and one column for each predictor. However, X can be any array that modelfun can accept.

Data Types: single | double

**Y — Response values**

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

Data Types: single | double

**modelfun — Nonlinear regression model function**

function handle

Nonlinear regression model function, specified as a function handle. modelfun must accept two input arguments, a coefficient vector and an array X—in that order—and return a vector of fitted response values.

For example, to specify the hougen nonlinear regression function, use the function handle @hougen.

Data Types: function_handle

**beta0 — Initial coefficient values**

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

**Note** Poor starting values can lead to a solution with large residual error.
Data Types: single | double

options — Estimation algorithm options
structure created using statset

Estimation algorithm options, specified as a structure you create using statset. The following statset parameters are applicable to nlinfit.

DerivStep — Relative difference for finite difference gradient
eps^(1/3) (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as beta. Use a vector to specify a different relative difference for each coefficient.

Display — Level of output display
'off' (default) | 'iter' | 'final'

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

FunValCheck — Indicator for whether to check for invalid values
'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

MaxIter — Maximum number of iterations
100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by MaxIter is reached.

RobustWgtFun — Weight function
character vector | string scalar | function handle | []

Weight function for robust fitting, specified as a valid character vector, string scalar, or function handle.

Note RobustWgtFun must have value [] when you use observation weights, W.
The following table describes the possible character vectors and string scalars. Let $r$ denote normalized residuals and $w$ denote robust weights. The indicator function $I[x]$ is equal to 1 if the expression $x$ is true, and 0 otherwise.

<table>
<thead>
<tr>
<th>Weight Function</th>
<th>Equation</th>
<th>Default Tuning Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>' '(default)'</code></td>
<td>No robust fitting</td>

<tr>
<td><code>'huber'</code></td>
<td>$w = \frac{1}{\max(1,</td>
<td>r</td>
</tr>
<tr>
<td><code>'logistic'</code></td>
<td>$w = \tanh(r) / r$</td>
<td>1.205</td>
</tr>
<tr>
<td><code>'talwar'</code></td>
<td>$w = I[</td>
<td>r</td>
</tr>
<tr>
<td><code>'welsch'</code></td>
<td>$w = \exp[-r^2]$</td>
<td>2.985</td>
</tr>
</tbody>
</table>

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a `Tune` constant.

**Tune — Tuning constant**

*positive scalar value*

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`. 

32-4329
If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

**TolFun — Termination tolerance on residual sum of squares**
1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

**TolX — Termination tolerance on estimated coefficients**
1e-8 (default) | positive scalar value

Termination tolerance on the estimated coefficients, `beta`, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

**Robust — Indicator for robust fitting**
'off' (default) | 'on'

Indicator for robust fitting, specified as 'off' or 'on'.

**Note** Robust will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

**WgtFun — Weight function for robust fitting**
character vector | string scalar | function handle

Weight function for robust fitting, specified as a character vector or string scalar indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value 'on'.

**Note** `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.
You can specify several name and value pair arguments in any order as 
Name1,Value1,...,NameN,ValueN.

Example: 'ErrorModel','proportional','ErrorParameters',0.5 specifies a 
proportional error model, with initial value 0.5 for the error parameter estimation

**ErrorModel — Form of error term**
'constant' (default) | 'proportional' | 'combined'

Form of the error term, specified as the comma-separated pair consisting of
'ErrorModel' and 'constant', 'proportional', or 'combined' indicating the 
error model. Each model defines the error using a standard mean-zero and unit-variance 
variable e in combination with independent components: the function value f, and one or 
two parameters a and b.

'constant' (default) 
\[ y = f + ae \]

'proportional'  
\[ y = f + bfe \]

'combined'  
\[ y = f + (a + b|f|)e \]

The only allowed error model when using Weights is 'constant'.

**Note** options.RobustWgtFun must have value [] when using an error model other 
than 'constant'.

**ErrorParameters — Initial estimates for error model parameters**
1 or [1,1] (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen ErrorModel, specified as 
the comma-separated pair consisting of 'ErrorParameters' and a scalar value or two-
element vector.

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>'proportional'</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>'combined'</td>
<td>a, b</td>
<td>[1,1]</td>
</tr>
</tbody>
</table>
For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters',[1,2]

You can only use the 'constant' error model when using Weights.

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

Data Types: double | single

**Weights — Observation weights**

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If W is a vector, then it must be the same size as Y.
- If W is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

**Note** options.RobustWgtFun must have value [] when you use observation weights.

Data Types: double | single | function_handle

**Output Arguments**

**beta — Estimated regression coefficients**

vector

Estimated regression coefficients, returned as a vector. The number of elements in beta equals the number of elements in beta0.
Let \( f(X_i, b) \) denote the nonlinear function specified by `modelfun`, where \( x_i \) are the predictors for observation \( i, i = 1, \ldots, N \), and \( b \) are the regression coefficients. The vector of coefficients returned in `beta` minimizes the weighted least squares equation,

\[
\sum_{i=1}^{N} w_i [y_i - f(x_i, b)]^2.
\]

For unweighted nonlinear regression, all of the weight terms are equal to 1.

**R — Residuals**

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument `Weights`, then `R` contains weighted residuals on page 32-4334.
- If you specify an error model other than `'constant'` using the name-value pair argument `ErrorModel`, then you can no longer interpret `R` as model fit residuals.

**J — Jacobian**

matrix

Jacobian of the nonlinear regression model, `modelfun`, returned as an \( N \)-by-\( p \) matrix, where \( N \) is the number of observations and \( p \) is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then `J` is the weighted model function Jacobian on page 32-4335.
- If you specify an error model other than `'constant'` using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

**CovB — Estimated variance-covariance matrix**

matrix

Estimated variance-covariance matrix for the fitted coefficients, \( \beta \), returned as a \( p \)-by-\( p \) matrix, where \( p \) is the number of estimated coefficients. If the model Jacobian, \( J \), has full column rank, then \( \text{CovB} = \text{inv}(J' * J) * \text{MSE} \), where MSE is the mean squared error.

**MSE — Mean squared error**

scalar value
Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, J, has full column rank, then \( \text{MSE} = (R' * R) / (N - p) \), where \( N \) is the number of observations, and \( p \) is the number of estimated coefficients.

**ErrorModelInfo — Information about error model fit structure**

Information about the error model fit, returned as a structure with the following fields:

- **ErrorModel**: Chosen error model
- **ErrorParameters**: Estimated error parameters
- **ErrorVariance**: Function handle that accepts an \( N \)-by-\( p \) matrix, \( X \), and returns an \( N \)-by-1 vector of error variances using the estimated error model
- **MSE**: Mean squared error
- **ScheffeSimPred**: Schéffé parameter for simultaneous prediction intervals when using the estimated error model
- **WeightFunction**: Logical with value true if you used a custom weight function previously in `nlinfit`
- **FixedWeights**: Logical with value true if you used fixed weights previously in `nlinfit`
- **RobustWeightFunction**: Logical with value true if you used robust fitting previously in `nlinfit`

**Definitions**

**Weighted Residuals**

A weighted residual is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, \( \mathbf{b} \), the residual for observation \( i \) is

\[
r_i = y_i - f(x_i, \mathbf{b}),
\]
where $y_i$ is the observed response and $f(x_i, b)$ is the fitted response at predictors $x_i$.

When you fit a weighted nonlinear regression with weights $w_i, i = 1,...,N$, `nlinfit` returns the weighted residuals,

$$r^*_i = \sqrt{w_i} (y_i - f(x_i, b)).$$

**Weighted Model Function Jacobian**

The weighted model function Jacobian is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, $b$, the estimated model Jacobian, $J$, for the nonlinear function $f(x_i, b)$ has elements

$$J_{ij} = \frac{\partial f(x_i, b)}{\partial b_j},$$

where $b_j$ is the $j$th element of $b$.

When you fit a weighted nonlinear regression with diagonal weights matrix $W$, `nlinfit` returns the weighted Jacobian matrix,

$$J^* = W^{1/2}J.$$ 

**Tips**

- To produce error estimates on predictions, use the optional output arguments $R$, $J$, $CovB$, or $MSE$ as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, $beta$, use the optional output arguments $R$, $J$, $CovB$, or $MSE$ as inputs to `nlparci`.
- If you use the robust fitting option, `RobustWgtFun`, you must use $CovB$—and might need $MSE$—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.
Algorithms

- `nlinfit` treats NaN values in Y or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation’s residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

Topics

“Nonlinear Regression” on page 13-2

Introduced before R2006a
nlintool

Interactive nonlinear regression

Syntax

nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')

Description

nlintool(X,y,fun,beta0) is a graphical user interface to the nlinfit function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

nlintool(X,y,fun,beta0,alpha) shows 100(1-alpha)% confidence bands. These are simultaneous confidence bounds for the function value. Using the Bounds menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

nlintool(X,y,fun,beta0,alpha,'xname','yname') labels the plots using the character matrix or string array 'xname' for the predictors and the character vector or string scalar 'yname' for the response.

Examples

The data in reaction.mat are partial pressures of three chemical reactants and the corresponding reaction rates. The function hougen implements the nonlinear Hougén-Watson model for reaction rates. The following fits the model to the data:
load reaction
nlintool(reactants, rate, @hougen, beta, 0.01, xn, yn)

Introduced before R2006a
nlmefit

Nonlinear mixed-effects estimation

Syntax

beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)

Description

beta = nlmefit(X,y,group,V,fun,beta0) fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in beta. By default, nlmefit fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

X is an n-by-h matrix of n observations on h predictors.

y is an n-by-1 vector of responses.

group is a grouping variable indicating m groups in the observations. group is a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors. For more information on grouping variables, see “Grouping Variables” on page 2-57.

V is an m-by-g matrix or cell array of g group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of V are assigned to groups using grp2idx, according to the order specified by grp2idx(group). Use a cell array for V if group predictors vary in size across groups. Use [] for V if there are no group-specific predictors.

fun is a handle to a function that accepts predictor values and model parameters and returns fitted values. fun has the form

yfit = modelfun(PHI,XFUN,VFUN)
The arguments are:

- **PHI** — A 1-by-$p$ vector of model parameters.
- **XFUN** — A $k$-by-$h$ array of predictors, where:
  - $k = 1$ if XFUN is a single row of $X$.
  - $k = n_i$ if XFUN contains the rows of $X$ for a single group of size $n_i$.
  - $k = n$ if XFUN contains all rows of $X$.
- **VFUN** — Group-specific predictors given by one of:
  - A 1-by-$g$ vector corresponding to a single group and a single row of $V$.
  - An $n$-by-$g$ array, where the $j$th row is $V(I, :)$ if the $j$th observation is in group $I$.

If $V$ is empty, nlmefit calls modelfun with only two inputs.

- **yfit** — A $k$-by-1 vector of fitted values

When either PHI or VFUN contains a single row, it corresponds to all rows in the other two input arguments.

**Note** If modelfun can compute yfit for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

`beta0` is a $q$-by-1 vector with initial estimates for $q$ fixed effects. By default, $q$ is the number of model parameters $p$.

nlmefit fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta, PSI] = nlmefit(X, y, group, V, fun, beta0)` also returns PSI, an $r$-by-$r$ estimated covariance matrix for the random effects. By default, $r$ is equal to the number of model parameters $p$.

`[beta, PSI, stats] = nlmefit(X, y, group, V, fun, beta0)` also returns stats, a structure with fields:
- **dfe** — The error degrees of freedom for the model
- **logl** — The maximized loglikelihood for the fitted model
- **rmse** — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- **errorparam** — The estimated parameters of the error variance model
- **aic** — The Akaike information criterion, calculated as $\text{aic} = -2 \times \text{logl} + 2 \times \text{numParam}$, where $\text{numParam}$ is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and $\text{logl}$ is a field in the $\text{stats}$ structure
- **bic** — The Bayesian information criterion, calculated as $\text{bic} = -2 \times \text{logl} + \log(M) \times \text{numParam}$
  - $M$ is the number of groups.
  - $\text{numParam}$ and $\text{logl}$ are defined as in $\text{aic}$.

Note that some literature suggests that the computation of $\text{bic}$ should be $\text{bic} = -2 \times \text{logl} + \log(N) \times \text{numParam}$, where $N$ is the number of observations.

- **covb** — The estimated covariance matrix of the parameter estimates
- **sebeta** — The standard errors for $\beta$
- **ires** — The population residuals $(y - y_{\text{population}})$, where $y_{\text{population}}$ is the individual predicted values
- **pres** — The population residuals $(y - y_{\text{population}})$, where $y_{\text{population}}$ is the population predicted values
- **iwres** — The individual weighted residuals
- **pwres** — The population weighted residuals
- **cwres** — The conditional weighted residuals

$[\text{beta}, \text{PSI}, \text{stats}, B] = \text{nlmefit}(X, y, \text{group}, V, \text{fun}, \text{beta0})$ also returns $B$, an $r$-by-$m$ matrix of estimated random effects for the $m$ groups. By default, $r$ is equal to the number of model parameters $p$.

$[\text{beta}, \text{PSI}, \text{stats}, B] = \text{nlmefit}(X, y, \text{group}, V, \text{fun}, \text{beta0}, 'Name', value)$ specifies one or more optional parameter name/value pairs. Specify $Name$ inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both FEConstDesign and REConstDesign to $\text{eye}(p)$, or by
setting both \texttt{FEParamsSelect} and \texttt{REParamsSelect} to 1:p.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The \texttt{nlmefit} function requires you to specify at least one fixed effect and one random effect.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{FEParamsSelect}</td>
<td>A vector specifying which elements of the parameter vector \texttt{PHI} include a fixed effect, given as a numeric vector of indices from 1 to (p) or as a 1-by-(p) logical vector. If (q) is the specified number of elements, then the model includes (q) fixed effects.</td>
</tr>
<tr>
<td>\texttt{FEConstDesign}</td>
<td>A (p)-by-(q) design matrix \texttt{ADESIGN}, where \texttt{ADESIGN*beta} are the fixed components of the (p) elements of \texttt{PHI}.</td>

</tr>
</tbody>
</table>

Use the following parameters to control the iterative algorithm for maximizing the likelihood:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RefineBeta0</td>
<td>Determines whether nlmefit makes an initial refinement of beta0 by first fitting modelfun without random effects and replacing beta0 with beta. Choices are 'on' and 'off'. The default value is 'on'.</td>
</tr>
<tr>
<td>ErrorModel</td>
<td>A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are:</td>
</tr>
<tr>
<td></td>
<td>• 'constant': ( y = f + a*e )</td>
</tr>
<tr>
<td></td>
<td>• 'proportional': ( y = f + b<em>f</em>e )</td>
</tr>
<tr>
<td></td>
<td>• 'combined': ( y = f + (a+b*f)*e )</td>
</tr>
<tr>
<td></td>
<td>• 'exponential': ( y = f*\exp(a<em>e) ), or equivalently ( \log(y) = \log(f) + a</em>e )</td>
</tr>
<tr>
<td></td>
<td>If this parameter is given, the output stats.errorparam field has the value</td>
</tr>
<tr>
<td></td>
<td>• a for 'constant' and 'exponential'</td>

<tr>
<td></td>
<td>• b for 'proportional'</td>
</tr>
<tr>
<td></td>
<td>• [a b] for 'combined'</td>
</tr>
<tr>
<td>ApproximationType</td>
<td>The method used to approximate the likelihood of the model. Choices are:</td>
</tr>
<tr>
<td></td>
<td>• 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of beta and B. This is the default.</td>
</tr>
<tr>
<td></td>
<td>• 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of beta and B.</td>
</tr>
<tr>
<td></td>
<td>• 'FO' — First-order Laplacian approximation without random effects.</td>
</tr>
<tr>
<td></td>
<td>• 'FOCE' — First-order Laplacian approximation at the conditional estimates of B.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Vectorization</td>
<td>Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to modelfun. Choices are:</td>
</tr>
<tr>
<td></td>
<td>• 'SinglePhi' — modelfun can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. nlmefit calls modelfun in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default.</td>
</tr>
<tr>
<td></td>
<td>• 'SingleGroup' — modelfun can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row.</td>
</tr>
<tr>
<td></td>
<td>• 'Full' — modelfun can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to modelfun, but may require modelfun to perform singleton expansion on PHI or V.</td>
</tr>
<tr>
<td>CovParameterization</td>
<td>Specifies the parameterization used internally for the scaled covariance matrix. Choices are 'chol' for the Cholesky factorization or 'logm' the matrix logarithm. The default is 'logm'.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CovPattern</td>
<td>Specifies an $r$-by-$r$ logical or numeric matrix $P$ that defines the pattern of the random-effects covariance matrix $PSI$. $nlmefit$ estimates the variances along the diagonal of $PSI$ and the covariances specified by nonzeros in the off-diagonal elements of $P$. Covariances corresponding to zero off-diagonal elements in $P$ are constrained to be zero. If $P$ does not specify a row-column permutation of a block diagonal matrix, $nlmefit$ adds nonzero elements to $P$ as needed. The default value of $P$ is $\text{eye}(r)$, corresponding to uncorrelated random effects. Alternatively, $P$ may be a 1-by-$r$ vector containing values in $1:r$, with equal values specifying groups of random effects. In this case, $nlmefit$ estimates covariances only within groups, and constrains covariances across groups to be zero.</td>
</tr>
</tbody>
</table>
| ParamTransform  | A vector of $p$-values specifying a transformation function $f()$ for each of the $P$ parameters: $XB = ADESIGN*BETA + BDESIGN*B PHI = f(XB)$. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:  
  - 0: $PHI = XB$ (default for all parameters)  
  - 1: $\log(PHI) = XB$  
  - 2: $\text{probit}(PHI) = XB$  
  - 3: $\text{logit}(PHI) = XB$ |
### Options

A structure of the form returned by `statset.nlmefit` uses the following `statset` parameters:

- **'DerivStep'** — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters \( p \). The default is \( \text{eps}^{(1/3)} \).
- **'Display'** — Level of iterative display during estimation. Choices are:
  - 'off' (default) — Displays no information
  - 'final' — Displays information after the final iteration
  - 'iter' — Displays information at each iteration
- **'FunValCheck'** — Check for invalid values, such as NaN or Inf, from `modelfun`. Choices are 'on' and 'off'. The default is 'on'.
- **'MaxIter'** — Maximum number of iterations allowed. The default is 200.
- **'OutputFcn'** — Function handle specified using @, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration.
- **'TolFun'** — Termination tolerance on the loglikelihood function. The default is \( 1 \times 10^{-4} \).
- **'TolX'** — Termination tolerance on the estimated fixed and random effects. The default is \( 1 \times 10^{-4} \).

### OptimFun

Specifies the optimization function used in maximizing the likelihood. Choices are 'fminsearch' to use `fminsearch` or 'fminunc' to use `fminunc`. The default is 'fminsearch'. You can specify 'fminunc' only if Optimization Toolbox software is installed.
Examples

Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

CIRC = [30 58 87 115 120 142 145; 33 69 111 156 172 203 203; 30 51 75 115 139 140; 32 62 112 167 179 209 214; 30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];

h = plot(time,CIRC,'o','LineWidth',2);
xlabel('Time (days)')
ylabel('Circumference (mm)')
title('{\bf Orange Tree Growth}')
legend([repmat('Tree ',5,1),num2str((1:5))],...
  'Location','NW')
grid on
hold on
Use an anonymous function to specify a logistic growth model.

\[
\text{model} = @(\text{PHI},t)(\text{PHI}(:,1))/(1+\exp(-((t-\text{PHI}(:,2))/\text{PHI}(:,3))));
\]

Fit the model using \texttt{nlmefit} with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

\[
\text{TIME} = \text{repmat(time,5,1)};
\]
\[
\text{NUMS} = \text{repmat}((1:5)',\text{size(time)});
\]

\[
\text{beta0} = [100 100 100];
\]
\[
[\text{beta1,PSII,stats1}] = \text{nlmefit}\text{(TIME(:,),CIRC(:,),NUMS(:,),...}
\]
\[
[],\text{model,}\text{beta0})
\]
beta1 = 3×1

191.3189
723.7608
346.2517

PSI1 = 3×3

962.1535         0         0
0    0.0000         0
0         0  297.9880

stats1 = struct with fields:
    dfe: 28
    logl: -131.5457
    mse: 59.7882
    rmse: 7.9016
    errorparam: 7.7323
    aic: 277.0913
    bic: 274.3574
    covb: [3x3 double]
    sebeta: [15.2249 33.1579 26.8235]
    ires: [35x1 double]
    pres: [35x1 double]
    iwres: [35x1 double]
    pwres: [35x1 double]
    cwres: [35x1 double]

The negligible variance of the second random effect, PSI1(2,2), suggests that it can be removed to simplify the model.

[beta2,PSI2,stats2,b2] = nlmefit(TIME(:),CIRC(:),...
    NUMS(:),[],model,beta0,'REParamsSelect',[1 3])

beta2 = 3×1

191.3193
723.7629
346.2532

PSI2 = 2×2
The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria (`aic` and `bic`) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```matlab
PHI = repmat(beta2,1,5) + ... % Fixed effects
     [b2(1,:);zeros(1,5);b2(2,:)]; % Random effects

for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
                       PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',h(I).Color, ...
         'LineWidth',2)
end
```

“Mixed-Effects Models” on page 13-22
“Grouping Variables” on page 2-57

**Introduced in R2008b**
nlmefitsa

Fit nonlinear mixed-effects model with stochastic EM algorithm

Syntax

\[
[BETA, PSI, STATS, B] = nlmefitsa(X, Y, GROUP, V, MODELFUN, BETA0)
\]

\[
[BETA, PSI, STATS, B] = nlmefitsa(X, Y, GROUP, V, MODELFUN, BETA0, 'Name', Value)
\]

Description

\[
[BETA, PSI, STATS, B] = nlmefitsa(X, Y, GROUP, V, MODELFUN, BETA0)
\]
fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

\[
[BETA, PSI, STATS, B] = nlmefitsa(X, Y, GROUP, V, MODELFUN, BETA0, 'Name', Value)
\]
accepts one or more comma-separated parameter name/value pairs. Specify Name inside single quotes.

Input Arguments

Definitions:

In the following list of arguments, the following variable definitions apply:
• $n$ — number of observations
• $h$ — number of predictor variables
• $m$ — number of groups
• $g$ — number of group-specific predictor variables
• $p$ — number of parameters
• $f$ — number of fixed effects

**X**

An $n$-by-$h$ matrix of $n$ observations on $h$ predictor variables.

**Y**

An $n$-by-1 vector of responses.

**GROUP**

A grouping variable indicating to which of $m$ groups each observation belongs. `GROUP` can be a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors.

**V**

An $m$-by-$g$ matrix of $g$ group-specific predictor variables for each of the $m$ groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of $V$ are ordered according to `GRP2IDX(GROUP)`. Use an $m$-by-$g$ cell array for $V$ if any of the group-specific predictor values vary in size across groups. Specify [] for $V$ if there are no group predictors.

**MODELFUN**

A handle to a function that accepts predictor values and model parameters, and returns fitted values. `MODELFUN` has the form $YFIT = MODELFUN(PHI, XFUN, VFUN)$ with input arguments

• $PHI$ — A 1-by-$p$ vector of model parameters.
• $XFUN$ — An $l$-by-$h$ array of predictor variables where
  • $l$ is 1 if $XFUN$ is a single row of $X$
  • $l$ is $n_i$ if $XFUN$ contains the rows of $X$ for a single group of size $n_i$
• \( l \) is \( n \) if \( X\text{FUN} \) contains all rows of \( X \).
• \( V\text{FUN} \) — Either
  • A 1-by-\( g \) vector of group-specific predictors for a single group, corresponding to a single row of \( V \)
  • An \( n \)-by-\( g \) matrix, where the \( k \)-th row of \( V\text{FUN} \) is \( V(i,:) \) if the \( k \)-th observation is in group \( i \).

If \( V \) is empty, \texttt{nlmefitsa} calls \texttt{MODELFUN} with only two inputs.

\texttt{MODELFUN} returns an \( l \)-by-1 vector of fitted values \( Y\text{FIT} \). When either \( \text{PHI} \) or \( V\text{FUN} \) contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if \texttt{MODELFUN} can compute \( Y\text{FIT} \) for more than one vector of model parameters in one call.

\texttt{BETA0}

An \( f \)-by-1 vector with initial estimates for the \( f \) fixed effects. By default, \( f \) is equal to the number of model parameters \( p \). \texttt{BETA0} can also be an \( f \)-by-\( \text{REPS} \) matrix, and the estimation is repeated \( \text{REPS} \) times using each column of \texttt{BETA0} as a set of starting values.

\textbf{Name-Value Pair Arguments}

By default, \texttt{nlmefitsa} fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way \texttt{nlmefitsa} calls \texttt{MODELFUN}, as described further below.

\texttt{FEParamsSelect}

A vector specifying which elements of the model parameter vector \( \text{PHI} \) include a fixed effect, as a numeric vector with elements in \( 1:p \), or as a 1-by-\( p \) logical vector. The model will include \( f \) fixed effects, where \( f \) is the specified number of elements.

\texttt{FEConstDesign}

A \( p \)-by-\( f \) design matrix \( \text{ADesign} \), where \( \text{ADesign} \times \text{BETA} \) are the fixed components of the \( p \) elements of \( \text{PHI} \).
FEGroupDesign
A p-by-f-by-m array specifying a different p-by-f fixed effects design matrix for each of the m groups.

REParamsSelect
A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in 1:p, or as a 1-by-p logical vector. The model will include r random effects, where r is the specified number of elements.

REConstDesign
A p-by-r design matrix BDESIGN, where BDESIGN*B are the random components of the p elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to eye(p), or to setting both FEParamsSelect and REParamsSelect to 1:p.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

CovPattern
Specifies an r-by-r logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is eye(r), corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by-r vector containing values in 1:r. In this case, elements of PAT with equal values define groups of random effects, nlmefitsa estimates covariances only within groups, and constrains covariances across groups to be zero.

Cov0
Initial value for the covariance matrix PSI. Must be an r-by-r positive definite matrix. If empty, the default value depends on the values of BETA0.
**ComputeStdErrors**

true to compute standard errors for the coefficient estimates and store them in the output STATS structure, or false (default) to omit this computation.

**ErrorModel**

A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable $e$, the function value $f$, and one or two parameters $a$ and $b$. Choices are

- 'constant' — $y = f + a e$
- 'proportional' — $y = f + b f e$
- 'combined' — $y = f + (a + b f) e$
- 'exponential' — $y = f \exp(a e)$, or equivalently $\log(y) = \log(f) + a e$

If this parameter is given, the output STATS.errorparam field has the value

- $a$ for 'constant' and 'exponential'
- $b$ for 'proportional'
- $[a \ b]$ for 'combined'

**ErrorParameters**

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the $a$, $b$, or $[a \ b]$ values depending on the ErrorModel parameter.

**LogLikMethod**

Specifies the method for approximating the loglikelihood. Choices are:

- 'is' — Importance sampling
- 'gq' — Gaussian quadrature
- 'lin' — Linearization
- 'none' — Omit the loglikelihood approximation (default)

**NBurnIn**

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.
NChains

Number \( c \) of "chains" simulated. Default is 1. Setting \( c > 1 \) causes \( c \) simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

NIterations

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

1. simulated annealing
2. full step size
3. reduced step size

Default is \([150 \ 150 \ 100]\). A scalar is distributed across the three phases in the same proportions as the default.

NMCMCIterations

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

1. full multivariate update
2. single coordinate update
3. multiple coordinate update

Default is \([2 \ 2 \ 2]\). A scalar value is treated as a three-element vector with all elements equal to the scalar.

OptimFun

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

Options

A structure created by a call to statset. nlmefitsa uses the following statset parameters:
• 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is eps^(1/3).

• Display — Level of display during estimation.
  • 'off' (default) — Displays no information
  • 'final' — Displays information after the final iteration of the estimation algorithm
  • 'iter' — Displays information at each iteration

• FunValCheck
  • 'on' (sdefault) — Check for invalid values (such as NaN or Inf) from MODELFUN
  • 'off' — Skip this check

• OutputFcn — Function handle specified using @, a cell array with function handles or an empty array. nlmefitsa calls all output functions after each iteration. See nlmefitoutputfcn.m (the default output function for nlmefitsa) for an example of an output function.

**ParamTransform**

A vector of p-values specifying a transformation function f() for each of the p parameters:

\[
XB = ADESIGN*BETA + BDESIGN*B \\
PHI = f(XB)
\]

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:

• 0: PHI = XB (default for all parameters)
• 1: log(PHI) = XB
• 2: probit(PHI) = XB
• 3: logit(PHI) = XB

**Replicates**

Number REPS of estimations to perform starting from the starting values in the vector BETA0. If BETA0 is a matrix, REPS must match the number of columns in BETA0. Default is the number of columns in BETA0.
Vectorization

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.

- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.

- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

Output Arguments

BETA

Estimates of the fixed effects

PSI

An r-by-r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p.

STATS

A structure with the following fields:
• logl — The maximized loglikelihood for the fitted model; empty if the LogLikMethod parameter has its default value of 'none'

• rmse — The square root of the estimated error variance (computed on the log scale for the exponential error model)

• errorparam — The estimated parameters of the error variance model

• aic — The Akaike information criterion (empty if logl is empty), calculated as \( \text{aic} = -2 \times \text{logl} + 2 \times \text{numParam} \), where

  • logl is the maximized loglikelihood.

  • numParam is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.

• bic — The Bayesian information criterion (empty if logl is empty), calculated as \( \text{bic} = -2 \times \text{logl} + \log(M) \times \text{numParam} \)

  • M is the number of groups.

  • logl and numParam are defined as in aic.

Note that some literature suggests that the computation of bic should be \( \text{bic} = -2 \times \text{logl} + \log(N) \times \text{numParam} \), where N is the number of observations. To adjust the value of the output you can redefine bic as follows: \( \text{bic} = \text{bic} - \text{numel(\text{unique(\text{group}))} + \text{numel(Y)} \)

• sebeta — The standard errors for BETA (empty if the ComputeStdErrors parameter has its default value of false)

• covb — The estimated covariance of the parameter estimates (empty if ComputeStdErrors is false)

• dfe — The error degrees of freedom

• pres — The population residuals \((y - y\_population)\), where \(y\_population\) is the population predicted values

• ires — The population residuals \((y - y\_population)\), where \(y\_population\) is the individual predicted values

• pwres — The population weighted residuals

• cwres — The conditional weighted residuals

• iwres — The individual weighted residuals
Examples

Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

load indomethacin

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phi0 = [1 1 1 1];
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
subject,[],model,phi0,'ParamTransform',xform)

Plot the data along with an overall population fit

```matlab
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx),'linewidth',2,'color','k')
```
Plot individual curves based on random-effect estimates.

```matlab
for j=1:6
    phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```
Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

\[ p(y | \beta, \sigma^2, \Sigma) = \int p(y | \beta, \sigma^2) p(b | \Sigma) \, db \]

where
• $y$ is the response data
• $\beta$ is the vector of population coefficients
• $\sigma^2$ is the residual variance
• $\Sigma$ is the covariance matrix for the random effects
• $b$ is the set of unobserved random effects

Each $p()$ function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

1 Simulation: Generate simulated values of the random effects $b$ from the posterior density $p(b|\Sigma)$ given the current parameter estimates.
2 Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
3 Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

Introduced in R2010a
nlparci

Nonlinear regression parameter confidence intervals

Syntax

ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)

Description

$\text{ci} = \text{nlparci}(\text{beta}, \text{resid}, '\text{covar}', \text{sigma})$ returns the 95% confidence intervals $\text{ci}$ for the nonlinear least squares parameter estimates $\text{beta}$. Before calling $\text{nlparci}$, use $\text{nlinfit}$ to fit a nonlinear regression model and get the coefficient estimates $\text{beta}$, residuals $\text{resid}$, and estimated coefficient covariance matrix $\text{sigma}$.

$\text{ci} = \text{nlparci}(\text{beta}, \text{resid}, '\text{jacobian}', \text{J})$ is an alternative syntax that also computes 95% confidence intervals. $\text{J}$ is the Jacobian computed by $\text{nlinfit}$. If the 'robust' option is used with $\text{nlinfit}$, use the 'covar' input rather than the 'jacobian' input so that the required $\text{sigma}$ parameter takes the robust fitting into account.

$\text{ci} = \text{nlparci}(..., '\text{alpha}', \text{alpha})$ returns $100(1-\alpha)\%$ confidence intervals.

$\text{nlparci}$ treats NaNs in $\text{resid}$ or $\text{J}$ as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of $\text{resid}$ exceeds the length of $\text{beta}$ and $\text{J}$ has full column rank. When $\text{J}$ is ill-conditioned, confidence intervals may be inaccurate.
Examples

Fit to exponential decay

Suppose you have data, and want to fit a model of the form

\[ y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i. \]

Here the \( a_i \) are the parameters you want to estimate, \( x_i \) are the data points, the \( y_i \) are the responses, and the \( \varepsilon_i \) are noise terms.

1. Write a function handle that represents the model:

   \[
   \text{mdl} = @(a,x)(a(1) + a(2)*\exp(-a(3)*x));
   \]

2. Generate synthetic data with parameters \( a = [1;3;2] \), with the \( x \) data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation 0.1:

   \[
   \text{rng}(9845,'twister') \text{ for reproducibility}
   \]
   \[
   a = [1;3;2];
   \]
   \[
   x = \text{exprnd}(2,100,1);
   \]
   \[
   \text{epsn} = \text{normrnd}(0,0.1,100,1);
   \]
   \[
   y = \text{mdl}(a,x) + \text{epsn};
   \]

3. Fit the model to data starting from the arbitrary guess \( a_0 = [2;2;2] \):

   \[
   a0 = [2;2;2];
   \]
   \[
   [\text{ahat},r,J,\text{cov},\text{mse}] = \text{nlinfit}(x,y,\text{mdl},a0);
   \]
   \[
   \text{ahat}
   \]
   \[
   \begin{array}{c}
   1.0153 \\
   3.0229 \\
   2.1070
   \end{array}
   \]

4. Check whether \([1;3;2]\) is in a 95% confidence interval using the Jacobian argument in nlparci:

   \[
   \text{ci} = \text{nlparci}(\text{ahat},r,'\text{Jacobian}',J)
   \]

   \[
   \begin{array}{cccc}
   0.9869 & 1.0438 \\
   2.9401 & 3.1058 \\
   1.9963 & 2.2177
   \end{array}
   \]
You can obtain the same result using the covariance argument:

```matlab
ci = nlparci(ahat,r,'covar',cov)
```

```matlab
ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

**Introduced before R2006a**
nlpredci

Nonlinear regression prediction confidence intervals

Syntax

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)

Description

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and variance-covariance matrix, CovB.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value) uses additional options specified by one or more name-value pair arguments.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and Jacobian, J.

If you use a robust option with nlinfit, then you should use the Covar syntax rather than the Jacobian syntax. The variance-covariance matrix, CovB, is required to properly take the robust fitting into account.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value) uses additional options specified by one or more name-value pair arguments.
Examples

Confidence Interval for Nonlinear Regression Curve

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```matlab
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```matlab
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```matlab
ypred = 5.4622
delta = 0.1921
```

Compute the 95% confidence interval for the value of the curve.

```matlab
[ypred-delta,ypred+delta]
ans = 1×2
    5.2702    5.6543
```

Prediction Interval for New Observation

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```
Fit the Hougen-Watson model to the rate data using the initial values in beta0.

\[
[beta, R, J] = \text{nlinfit}(X, y, @hougen, beta0);
\]

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels \([100, 100, 100]\).

\[
[y_{\text{pred}}, \delta] = \text{nlpredci}(\text{hougen}, [100, 100, 100], beta, R, '\text{Jacobian}', J, ...
'\text{PredOpt}', '\text{observation}')
\]

\[
y_{\text{pred}} = 1.8346
\]
\[
\delta = 0.5101
\]

Compute the 95% prediction interval for the new observation.

\[
[y_{\text{pred}} - \delta, y_{\text{pred}} + \delta]
\]

\[
\text{ans} = 1\times2
\]

\[
1.3245  \quad 2.3447
\]

### Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model \(y = b_1 + b_2 \cdot \exp\{b_3 x\} + \epsilon\), where \(b_1, b_2, \text{ and } b_3\) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

\[
\text{modelfun} = @(b,x)(b(1)+b(2)*\exp(-b(3)*x));
\]

\[
\text{rng('default') } \% \text{ for reproducibility}
\]
\[
b = [1;3;2];
\]
\[
x = \text{exprnd}(2,100,1);
\]
\[
y = \text{modelfun}(b,x) + \text{normrnd}(0,0.5,100,1);
\]

Fit the nonlinear model using robust fitting options.

\[
\text{opts} = \text{statset('nlinfit')};
\]
\[
\text{opts.RobustWgtFun} = '\text{bisquare'};
\]
\[
beta0 = [2;2;2];
\]
\[
[beta, R, J, \text{CovB}, \text{MSE}] = \text{nlinfit}(x, y, \text{modelfun}, beta0, opts);
\]
Plot the fitted regression model and simultaneous 95% confidence bounds.

```matlab
xrange = min(x):.01:max(x);
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...
    'MSE',MSE,'SimOpt','on');
lower = ypred - delta;
upper = ypred + delta;

figure()
plot(x,y,'ko') % observed data
hold on
plot(xrange,ypred,'k','LineWidth',2)
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```
**Confidence Interval Using Observation Weights**

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```matlab
a = 1; b = 1;
weights = @(yhat) 1 ./ ((a + b*abs(yhat)).^2);
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels `[100,100,100]` using the observation weight function.

```matlab
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
ans = 1×2
    1.5264    2.1033
```

**Confidence Interval Using Nonconstant Error Model**

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```matlab
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```
Compute the 95% prediction interval for a new observation with reactant levels [100, 100, 100] using the fitted error variance model.

```matlab
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
ans = 1×2
    1.3245    2.3447
```

### Input Arguments

**modelfun** — Nonlinear regression model function
function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array `X`—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

**X** — Input values for predictions
matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of `X`. There should be a column in `X` for each coefficient in the model.

Data Types: `single` | `double`

**beta** — Estimated regression coefficients
vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

Data Types: `single` | `double`
**R — Residuals**
vector returned by `nlinfit`

Residuals for the fitted `modelfun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

**CovB — Estimated variance-covariance matrix**
matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinfit`.

**J — Estimated Jacobian**
matrix returned by `nlinfit`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinfit`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.1,'PredOpt','observation'` specifies 90% prediction intervals for new observations.

**Alpha — Significance level**
0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value $\alpha$, then `nlpredci` returns intervals with $100 \times (1-\alpha)$% confidence level.

The default confidence level is 95% ($\alpha = 0.05$).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

**ErrorModelInfo — Information about error model fit**
structure returned by `nlinfit`
Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to nlinfit.

ErrorModelInfo only has an effect on the returned prediction interval when PredOpt has the value 'observation'. If you do not use ErrorModelInfo, then nlpredci assumes the error variance model is 'constant'.

The error model structure returned by nlinfit has the following fields:

- **ErrorModel**: Chosen error model
- **ErrorParameters**: Estimated error parameters
- **ErrorVariance**: Function handle that accepts an \( N \times p \) matrix, \( X \), and returns an \( N \times 1 \) vector of error variances using the estimated error model
- **MSE**: Mean squared error
- **ScheffeSimPred**: Schéffé parameter for simultaneous prediction intervals when using the estimated error model
- **WeightFunction**: Logical with value true if you used a custom weight function previously in nlinfit
- **FixedWeights**: Logical with value true if you used fixed weights previously in nlinfit
- **RobustWeightFunction**: Logical with value true if you used robust fitting previously in nlinfit

**MSE — Mean squared error**

MSE returned by nlinfit

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to nlinfit.

If you use a robust option with nlinfit, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then nlpredci computes the MSE from the residuals, \( R \), and does not take the robust fitting into account.

For example, if \( \text{mse} \) is the MSE value returned by nlinfit, then you can specify 'MSE', \( \text{mse} \).

Data Types: single | double
**PredOpt — Prediction interval to compute**
'curve' (default) | 'observation'

Prediction interval to compute, specified as the comma-separated pair consisting of 'PredOpt' and either 'curve' or 'observation'.

- If you specify the value 'curve', then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations X.
- If you specify the value 'observation', then `nlpredci` returns prediction intervals for new observations at X.

If you specify 'observation' after using a robust option with `nlinfit`, then you must also specify a value for `MSE` to provide the robust estimate of the mean squared error.

Example: 'PredOpt', 'observation'

**SimOpt — Indicator for specifying simultaneous bounds**
'off' (default) | 'on'

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of 'SimOpt' and either 'off' or 'on'. Use the value 'off' to compute nonsimultaneous bounds, and 'on' for simultaneous bounds.

**Weights — Observation weights**
vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X.
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W, `nlpredci` estimates the error variance at observation i by $\text{mse} \times (1/W(i))$, where `mse` is the mean squared error value specified using `MSE`.

Example: 'Weights', @WFun

Data Types: double | single | function_handle
Output Arguments

**Ypred — Predicted responses**
vector

Predicted responses, returned as a vector with the same number of rows as `X`.

**delta — Confidence interval half-widths**
vector

Confidence interval half-widths, returned as a vector with the same number of rows as `X`. By default, `delta` contains the half-widths for nonsimultaneous 95% confidence intervals for `modelfun` at the observations in `X`. You can compute the lower and upper bounds of the confidence intervals as `Ypred - delta` and `Ypred + delta`, respectively.

If 'PredOpt' has value 'observation', then `delta` contains the half-widths for prediction intervals of new observations at the values in `X`.

Definitions

Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any estimable prediction points.

For example, suppose you fit the linear function \( f(x, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} \) at the points in the design matrix

\[
X = \begin{pmatrix}
1 & 1 & 0 \\
1 & 1 & 0 \\
1 & 1 & 0 \\
1 & 0 & 1 \\
1 & 0 & 1 \\
1 & 0 & 1 \\
\end{pmatrix}
\]
The estimated Jacobian at the values in \( X \) is the design matrix itself, \( J = X \). Thus, the Jacobian is not of full rank:

```matlab
rng('default') % For reproducibility
y = randn(6,1);
linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];
[beta,R,J] = nlinfit(X,y,linfun,beta0);
```

Warning: The Jacobian at the solution is ill-conditioned, and some model parameters may not be estimated well (they are not identifiable). Use caution in making predictions.

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

\[ x_{i1} = x_{i2} + x_{i3}. \]

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns `NaN` for the corresponding interval half-widths:

```matlab
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)
```

```
ypred =
     -0.0035
      0.0798
    -0.0047

delta =
       NaN
     3.8102
     3.8102
```

Here, the first element of `delta` is `NaN` because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.
**Tips**

- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:

1. Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.
2. Concatenate the real and imaginary parts of the response vector `Y` as a single vector.
3. Modify your model function `modelfun` to accept `X` and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

**Algorithms**

- `nlpredci` treats NaN values in the residuals, `R`, or the Jacobian, `J`, as missing values, and ignores the corresponding observations.
- If the Jacobian, `J`, does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions on page 32-4381, and returns NaN for those that are not.

Nonnegative matrix factorization

Syntax

\[ [W,H] = \text{nnmf}(A,k) \]
\[ [W,H] = \text{nnmf}(A,k,\text{param1, val1, param2, val2, ...}) \]
\[ [W,H,D] = \text{nnmf}(...) \]

Description

\[ [W,H] = \text{nnmf}(A,k) \] factors the nonnegative \( n \)-by-\( m \) matrix \( A \) into nonnegative factors \( W \) (\( n \)-by-\( k \)) and \( H \) (\( k \)-by-\( m \)). The factorization is not exact; \( W*H \) is a lower-rank approximation to \( A \). The factors \( W \) and \( H \) are chosen to minimize the root-mean-squared residual \( D \) between \( A \) and \( W*H \):

\[ D = \frac{\text{norm}(A-W*H,'fro')}{\sqrt{N*M}} \]

The factorization uses an iterative method starting with random initial values for \( W \) and \( H \). Because the root-mean-squared residual \( D \) may have local minima, repeated factorizations may yield different \( W \) and \( H \). Sometimes the algorithm converges to a solution of lower rank than \( k \), which may indicate that the result is not optimal.

\( W \) and \( H \) are normalized so that the rows of \( H \) have unit length. The columns of \( W \) are ordered by decreasing length.

\[ [W,H] = \text{nnmf}(A,k,\text{param1, val1, param2, val2, ...}) \] specifies optional parameter name/value pairs from the following table.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'algorithm'</td>
<td>Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm. In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a good choice when using 'replicates' to find W and H from multiple random starting values.</td>
</tr>
<tr>
<td>'w0'</td>
<td>An n-by-k matrix to be used as the initial value for W.</td>
</tr>
<tr>
<td>'h0'</td>
<td>A k-by-m matrix to be used as the initial value for H.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>---------------</td>
<td>-------</td>
</tr>
<tr>
<td>'options'</td>
<td>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Display — Level of display. Choices:</td>
<td></td>
</tr>
<tr>
<td>• 'off' (default) — No display</td>
<td></td>
</tr>
<tr>
<td>• 'final' — Display final result</td>
<td></td>
</tr>
<tr>
<td>• 'iter' — Iterative display of intermediate results</td>
<td></td>
</tr>
<tr>
<td>MaxIter — Maximum number of iterations. Default is 100. Unlike in optimization settings, reaching MaxIter iterations is treated as convergence.</td>
<td></td>
</tr>
<tr>
<td>TolFun — Termination tolerance on change in size of the residual. Default is 1e-4.</td>
<td></td>
</tr>
<tr>
<td>TolX — Termination tolerance on relative change in the elements of W and H. Default is 1e-4.</td>
<td></td>
</tr>
<tr>
<td>UseParallel — Set to true to compute in parallel. Default is false.</td>
<td></td>
</tr>
<tr>
<td>UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
<td></td>
</tr>
<tr>
<td>Streams — A RandStream object or cell array of such objects. If you do not specify Streams, <code>nnmf</code> uses the default stream or streams. If you choose to specify Streams, use a single object except in the case</td>
<td></td>
</tr>
<tr>
<td>• You have an open Parallel pool</td>
<td></td>
</tr>
<tr>
<td>• UseParallel is true</td>
<td></td>
</tr>
<tr>
<td>• UseSubstreams is false</td>
<td></td>
</tr>
</tbody>
</table>

In that case, use a cell array the same size as the Parallel pool.

To compute in parallel, you need Parallel Computing Toolbox.
### Parameter Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'replicates'</td>
<td>The number of times to repeat the factorization, using new random starting values for $W$ and $H$, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.</td>
</tr>
</tbody>
</table>

$[W,H,D] = \text{nnmf}(\ldots)$ also returns $D$, the root mean square residual.

### Examples

#### Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```matlab
clear all
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```matlab
rng(1) \% For reproducibility
[W,H] = nnmf(meas,2);
```

```matlab
H
```

```
H = 2x4

0.6945 0.2856 0.6220 0.2218
0.8020 0.5683 0.1834 0.0149
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6945 and 0.6220, respectively) provide relatively strong weights to the first column of $W$. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8020 and 0.5683) provide relatively strong weights to the second column of $W$.

Create a biplot of the data and the variables in `meas` in the column space of $W$.

```matlab
biplot(H,'scores',W,'varlabels',{'sl','sw','pl','pw'});
xlabel('Column 1')
ylabel('Column 2')
```
Change Algorithm

Starting from a random array \( X \) with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

\[
X = \text{rand}(100,20) * \text{rand}(20,50);
\]
\[
\text{opt} = \text{statset}('\text{MaxIter}',5,'\text{Display}','\text{final}');
\]
\[
[W0,H0] = \text{nnmf}(X,5,'\text{replicates}',10,...
             '\text{options}',\text{opt},...
             '\text{algorithm}','\text{mult}');
\]
| rep | iteration | rms resid | |delta x| |
|-----|-----------|-----------|----------------|
| 1   | 5         | 0.560887  | 0.0245182      |
| 2   | 5         | 0.66418   | 0.0364471      |
| 3   | 5         | 0.609125  | 0.0358355      |
| 4   | 5         | 0.608894  | 0.0415491      |
| 5   | 5         | 0.619291  | 0.0455135      |
| 6   | 5         | 0.621549  | 0.0299965      |
| 7   | 5         | 0.640549  | 0.0438758      |
| 8   | 5         | 0.673015  | 0.0366856      |
| 9   | 5         | 0.606835  | 0.0318931      |
| 10  | 5         | 0.633526  | 0.0319591      |

Final root mean square residual = 0.560887

Continue with more iterations from the best of these results using alternating least squares:

```matlab
opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...
    'options',opt,...
    'algorithm','als');
```

| rep | iteration | rms resid | |delta x| |
|-----|-----------|-----------|----------------|
| 1   | 24        | 0.257336  | 0.00271859     |

Final root mean square residual = 0.257336

References

Extended Capabilities

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.
To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

Introduced in R2008a
nodeclass

Class: classregtree

(Removed) Class values of nodes of classification tree

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

```
NAME=nodeclass(T)
NAME=nodeclass(T,J)
[NAME,ID]=nodeclass(...)
```

**Description**

`NAME=nodeclass(T)` returns an `n`-element cell array with the names of the most probable classes in each node of the tree `T`, where `n` is the number of nodes in the tree. Every element of this array is a character vector equal to one of the class names returned by `classname(T)`. For regression trees, `nodeclass` returns an empty cell array.

`NAME=nodeclass(T,J)` takes an array `J` of node numbers and returns the class names for the specified nodes.

```
[NAME,ID]=nodeclass(...) also returns a numeric array with the class index for each node. The class index is determined by the order of classes `classname` returns.
```

**See Also**

classname | classregtree | numnodes
nodeerr

Class: classregtree

(Removed) Return vector of node errors

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

e = nodeerr(t)
e = nodeerr(t,nodes)

Description

e = nodeerr(t) returns an n-element vector e of the errors of the nodes in the tree t, where n is the number of nodes. For a regression tree, the error e(i) for node i is the variance of the observations assigned to node i. For a classification tree, e(i) is the misclassification probability for node i.

e = nodeerr(t,nodes) takes a vector nodes of node numbers and returns the errors for the specified nodes.

The error e is the so-called resubstitution error computed by applying the tree to the same data used to create the tree. This error is likely to underestimate the error you would find if you applied the tree to new data. The test function provides options to compute the error (or cost) using cross-validation or a test sample.

classregtree | numnodes | test
nodemean

Class: classregtree

(Removed) Mean values of nodes of regression tree

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

NM = nodemean(T)
NM = nodemean(T,J)

Description

NM = nodemean(T) returns an n-element numeric array with mean values in each node of the tree T, where n is the number of nodes in the tree. Every element of this array is computed by averaging true Y values over all observations in the node. For classification trees, nodemean returns an empty numeric array.

NM = nodemean(T,J) takes an array J of node numbers and returns the mean values for the specified nodes.

See Also

classregtree | numnodes
nodeprob

Class: classregtree

(Removed) Node probabilities

**Note** classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

**Syntax**

\[
p = \text{nodeprob}(t)
\]

\[
p = \text{nodeprob}(t,\text{nodes})
\]

**Description**

\[
p = \text{nodeprob}(t)
\]

returns an \( n \)-element vector \( p \) of the probabilities of the nodes in the tree \( t \), where \( n \) is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.

\[
p = \text{nodeprob}(t,\text{nodes})
\]

takes a vector \( \text{nodes} \) of node numbers and returns the probabilities for the specified nodes.

**References**

**See Also**

classregtree | nodesize | numnodes
nodesize

Class: classregtree

(Removed) Return node size

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

sizes = nodesize(t)
sizes = nodesize(t,nodes)

Description

sizes = nodesize(t) returns an n-element vector sizes of the sizes of the nodes in the tree t, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

sizes = nodesize(t,nodes) takes a vector nodes of node numbers and returns the sizes for the specified nodes.

nominal

Arrays for nominal data

Note The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Description

Nominal data are discrete, nonnumeric values that do not have a natural ordering. nominal array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate nominal arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use nominal arrays as grouping variables when the elements indicate the group to which an observation belongs.

Creation

Syntax

B = nominal(X)
B = nominal(X,labels)
B = nominal(X,labels,levels)
B = nominal(X,labels,[],edges)

Description

B = nominal(X) creates a nominal array B from the array X. nominal creates the levels of B from the sorted unique values in X, and creates default labels for the levels.

B = nominal(X,labels) labels the levels in B according to labels.
B = nominal(X,labels,levels) creates a nominal array with possible levels defined by levels.

B = nominal(X,labels,[],edges) creates a nominal array by binning the numeric array X with bin edges given by the numeric vector edges.

**Input Arguments**

**X — Input array**
numeric | logical | character | string | categorical | cell array of character vectors

Input array to convert to nominal, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting nominal array correspond to the sorted unique values in X.

**labels — Labels for discrete levels**
character array | string array | cell array of character vectors

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, nominal assigns labels to the levels in B in order of the sorted unique values in X.

You can include duplicate labels in labels to merge multiple values in X into a single level in B.

Data Types: char | string | cell

**levels — Possible nominal levels**
vector

Possible nominal levels for the output nominal array, specified as a vector whose values can be compared to those in X using the equality operator. nominal assigns labels to each level from the corresponding elements of labels. If X contains any values not present in levels, the levels of the corresponding elements of B are undefined.

**edges — Bin edges**
numeric vector

Bin edges used to create the nominal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. nominal assigns labels to each level in the resulting nominal array from the corresponding
elements of labels. When you specify the edges input argument, it must have one more element than labels.

**Output Arguments**

**B — Nominal array**

nominal array object

Nominal array, returned as a nominal array object.

By default, an element of B is undefined if the corresponding element of X is NaN (when X is numeric), an empty character vector (when X is a character), an empty or missing string (when X is a string), or undefined (when X is categorical). nominal treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the levels input argument and include NaN, the empty character vector, the empty or missing string, or an undefined element.

**Properties**

**labels — Level labels**

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using getlabels.

Data Types: cell

**undeflabel — Label for undefined levels**

'undefined' (default)

This property is read-only.

Label for undefined levels, specified as 'undefined'. You can find undefined elements in categorical arrays by using isundefined.
Object Functions

addlevels    Add levels to nominal or ordinal arrays
droplevels   Drop levels from a nominal or ordinal array
getlabels    Access nominal or ordinal array labels
getlevels    Access nominal or ordinal array levels
islevel      Determine if levels are in nominal or ordinal array
levelcounts  Element counts by level of a nominal or ordinal array
mergelevels  Merge levels of nominal or ordinal arrays
reorderlevels Reorder levels of nominal or ordinal arrays
setlabels    Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with nominal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.
double       Double-precision arrays
histogram     Histogram plot
isequal       Determine array equality
isundefined   Find undefined elements in categorical array
pie           Pie chart
summary       Print summary of table, timetable, or categorical array
times         Element-wise multiplication

Examples

Create and Label Nominal Arrays

Create nominal arrays from a cell array of character vectors and from integer data. Provide explicit labels.

Create a nominal array from a cell array of character vectors with values 'r', 'g', and 'b'. Label these levels 'red', 'green', and 'blue', respectively. nominal assigns the labels according to the sorted (alphabetical) order of the elements in X.

```
X = {'r' 'b' 'g';'g' 'r' 'b';'b' 'r' 'g'}
```

```
X =

3x3 cell array
```
labels = {'blue','green','red'};
B = nominal(X,labels)

B =

3x3 nominal array

red blue green
green red blue
blue red green

Create a nominal array from integer data with values 1 to 4, merging odd and even values into two nominal levels with the labels 'odd' and 'even'. Merge the values by duplicating the labels.

X = randi([1 4],5,2)

X =

4 1
4 2
1 3
4 4
3 4

labels = {'odd','even','odd','even'};
B = nominal(X,labels)

B =

5x2 nominal array

even odd
even even
Create and Manipulate Nominal Arrays

Create a nominal array from data in a cell array.

```matlab
X = {'r','b','g';'g','r','b';'b','r','g'};
labels = {'blue','green','red'};
colors = nominal(X,labels)

colors = 3x3 nominal array
    red       blue       green
    green     red       blue
    blue      red       green
```

Identify the elements in `colors` that are members of the level 'red'. A value of 1 in the resulting array indicates that the corresponding element of `colors` is a member of 'red'.

```matlab
colors == 'red'
ans = 3x3 logical array
    1   0   0
    0   1   0
    0   1   0
```

Identify the elements in `colors` that are members of either the level 'red' or 'blue'.

```matlab
ismember(colors,{'red','blue'})
ans = 3x3 logical array
    1   1   0
    0   1   1
    1   1   0
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```matlab
nominal
colors = mergelevels(colors,{'red','blue'},'purple')

colors = 3x3 nominal array
  purple    purple    green
  green    purple    purple
  purple    purple    green

Display the levels of colors.

getlevels(colors)

ans = 1x2 nominal array
  purple    green

Summarize the number of elements in each level. By default, summary returns counts for each column of the input array.

summary(colors)

  purple  2   3   1
  green   1   0   2

Create a pie chart for the data in colors.

pie(colors)

Introduced in R2007a
**notify**

**Class:** qrandstream

Notify listeners of event

**Syntax**

```matlab
notify(h,'eventname')
notify(h,'eventname',data)
```

**Description**

`notify(h,'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a character vector.

`notify(h,'eventname',data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.eventdata` class.

**See Also**

`addlistener` | `event.EventData` | `events` | `qrandstream`
NonLinearModel class

Nonlinear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the predict or feval methods.

Construction

Create a NonLinearModel object using fitnlm.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates
numeric matrix

Covariance matrix of coefficient estimates, specified as a \( p \)-by-\( p \) matrix of numeric values. \( p \) is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names
cell array of character vectors

Coefficient names, specified as a cell array of character vectors containing a label for each coefficient.

Coefficients — Coefficient values
table

Coefficient values, specified as a table. Coefficients has one row for each coefficient and the following columns:
Estimate — Estimated coefficient value
SE — Standard error of the estimate
\textit{tStat} — t statistic for a test that the coefficient is zero
\textit{pValue} — p-value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in \texttt{mdl} the estimated coefficient vector is

\[
\texttt{beta} = \texttt{mdl.Coefficients.Estimate}
\]

Use \texttt{coefTest} to perform other tests on the coefficients.

\textbf{Diagnostics — Diagnostic information}

Diagnostics information for the model, specified as a table. Diagnostics can help identify outliers and influential observations. \texttt{Diagnostics} contains the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
<th>Utility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leverage</td>
<td>Diagonal elements of \texttt{HatMatrix}</td>
<td>Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with \textit{P} coefficients and \textit{N} observations, the average value of \textit{Leverage} is \textit{P}/\textit{N}. An observation with \textit{Leverage} larger than 2*\textit{P}/\textit{N} can be regarded as having high leverage.</td>
</tr>
<tr>
<td>CooksDistance</td>
<td>Cook's measure of scaled change in fitted values</td>
<td>\texttt{CooksDistance} is a measure of scaled change in fitted values. An observation with \texttt{CooksDistance} larger than three times the mean Cook's distance can be an outlier.</td>
</tr>
<tr>
<td>HatMatrix</td>
<td>Projection matrix to compute fitted from observed responses</td>
<td>\texttt{HatMatrix} is an \textit{N}-by-\textit{N} matrix such that \texttt{Fitted} = \texttt{HatMatrix}*\texttt{Y}, where \texttt{Y} is the response vector and \texttt{Fitted} is the vector of fitted response values.</td>
</tr>
</tbody>
</table>
DFE — Degrees of freedom for error
positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer value.

Fitted — Fitted response values based on input data
numeric vector

Fitted (predicted) values based on the input data, specified as a numeric vector. `fitnlm` attempts to make Fitted as close as possible to the response data.

Formula — Model information
LinearFormula object | NonLinearFormula object

Model information, specified as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

Iterative — Information about fitting process
structure

Information about the fitting process, specified as a structure with the following fields:

- InitialCoefs — Initial coefficient values (the `beta0` vector)
- IterOpts — Options included in the `Options` name-value pair argument for `fitnlm`

LogLikelihood — Log likelihood
numeric value

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison
structure

Criterion for model comparison, specified as a structure with the following fields:

- AIC — Akaike information criterion. $AIC = -2 \cdot \text{logL} + 2 \cdot m$, where $\text{logL}$ is the loglikelihood and $m$ is the number of estimated parameters.
• **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + \frac{(2m^2 + m)}{(n - m - 1)}$, where $n$ is the number of observations.

• **BIC** — Bayesian information criterion. $BIC = -2 \log L + m \log(n)$.

• **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \log L + m (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property by using dot notation. For example, in the model `mdl`, the AIC value `aic` is:

```matlab
aic = mdl.ModelCriterion.AIC
```

**MSE** — **Mean squared error**

`numeric value`

Mean squared error, specified as a numeric value. The mean squared error is an estimate of the variance of the error term in the model.

**NumCoefficients** — **Number of model coefficients**

`positive integer`

Number of coefficients in the fitted model, specified as a positive integer. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

**NumEstimatedCoefficients** — **Number of estimated coefficients**

`positive integer`

Number of estimated coefficients in the fitted model, specified as a positive integer. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

**NumPredictors** — **Number of predictor variables**

`positive integer`
Number of predictor variables used to fit the model, specified as a positive integer.

**NumVariables — Number of variables**
positive integer

Number of variables in the input data, specified as a positive integer. NumVariables is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

**ObservationInfo — Observation information**
table

Observation information, specified as a n-by-4 table, where n is equal to the number of rows of input data. The four columns of ObservationInfo contain the following:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weights</td>
<td>Observation weights. Default is all 1.</td>
</tr>
<tr>
<td>Excluded</td>
<td>Logical value, 1 indicates an observation that you excluded from the fit with the Exclude name-value pair.</td>
</tr>
<tr>
<td>Missing</td>
<td>Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.</td>
</tr>
<tr>
<td>Subset</td>
<td>Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.</td>
</tr>
</tbody>
</table>

**ObservationNames — Observation names**
cell array of character vectors

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, ObservationNames uses those names.
- Otherwise, ObservationNames is an empty cell array

**PredictorNames — Names of predictors used to fit the model**
cell array of character vectors

Names of predictors used to fit the model, specified as a cell array of character vectors.
**Residuals — Residuals for fitted model**

Residuals for fitted model, specified as a table that contains one row for each observation and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw</td>
<td>Observed minus fitted values.</td>
</tr>
<tr>
<td>Pearson</td>
<td>Raw residuals divided by RMSE.</td>
</tr>
<tr>
<td>Standardized</td>
<td>Raw residuals divided by their estimated standard deviation.</td>
</tr>
<tr>
<td>Studentized</td>
<td>Residual divided by an independent estimate of the residual standard deviation. The residual for observation ( i ) is divided by an estimate of the error standard deviation based on all observations except for observation ( i ).</td>
</tr>
</tbody>
</table>

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model \( mdl \), the ordinary raw residual vector \( r \) is:

\[
r = mdl.Residuals.Raw
\]

Rows not used in the fit because of missing values (in ObservationInfo.Missing) contain \( \text{NaN} \) values.

Rows not used in the fit because of excluded values (in ObservationInfo.Excluded) contain \( \text{NaN} \) values, with the following exceptions:

- \( \text{raw} \) contains the difference between the observed and predicted values.
- \( \text{standardized} \) is the residual, standardized in the usual way.
- \( \text{studentized} \) matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

**ResponseName — Response variable name**

character vector

Response variable name, specified as a character vector.

**RMSE — Root mean squared error**

numeric value
Root mean squared error, specified as a numeric value. The root mean squared error is an estimate of the standard deviation of the error term in the model.

**Robust — Robust fit information**

structure

Robust fit information, specified as a structure with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WgtFun</td>
<td>Robust weighting function, such as 'bisquare' (see robustfit)</td>
</tr>
<tr>
<td>Tune</td>
<td>Value specified for tuning parameter (can be [])</td>
</tr>
<tr>
<td>Weights</td>
<td>Vector of weights used in final iteration of robust fit</td>
</tr>
</tbody>
</table>

This structure is empty unless fitnlm constructed the model using robust regression.

**R_squared — R-squared value for the model**

structure

R-squared value for the model, specified as a structure.

For a linear or nonlinear model, Rsquared is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, Rsquared is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

\[ \text{R}^2 = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SST}}. \]
To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

\[ r_2 = mdl.Rsquared.Adjusted \]

**SSE — Sum of squared errors**
numeric value

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**SSR — Regression sum of squares**
numeric value

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**SST — Total sum of squares**
numeric value

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of response vector \( y \) from \( \text{mean}(y) \).

The Pythagorean theorem implies

\[ \text{SST} = \text{SSE} + \text{SSR}. \]

**VariableInfo — Information about input variables**
table

Information about input variables contained in `Variables`, specified as a table with one row for each model term and the following columns.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Character vector giving variable class, such as 'double'</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Range</td>
<td>Cell array giving variable range:</td>
</tr>
<tr>
<td></td>
<td>• Continuous variable — Two-element vector ([min, max]), the minimum and maximum values</td>
</tr>
<tr>
<td></td>
<td>• Categorical variable — Cell array of distinct variable values</td>
</tr>
<tr>
<td>InModel</td>
<td>Logical vector, where (\text{true}) indicates the variable is in the model</td>
</tr>
<tr>
<td>IsCategorical</td>
<td>Logical vector, where (\text{true}) indicates a categorical variable</td>
</tr>
</tbody>
</table>

**VariableNames — Names of variables used in fit**
cell array of character vectors

Names of variables used in fit, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

**Variables — Data used to fit the model**
table

Data used to fit the model, specified as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix \(X\) and response vector \(y\).
Methods

- **coefCI**: Confidence intervals of coefficient estimates of nonlinear regression model
- **coefTest**: Linear hypothesis test on nonlinear regression model coefficients
- **disp**: Display nonlinear regression model
- **feval**: Evaluate nonlinear regression model prediction
- **fit**: Fit nonlinear regression model
- **plotDiagnostics**: Plot diagnostics of nonlinear regression model
- **plotResiduals**: Plot residuals of nonlinear regression model
- **plotSlice**: Plot of slices through fitted nonlinear regression surface
- **predict**: Predict response of nonlinear regression model
- **random**: Simulate responses for nonlinear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

**Fit a Nonlinear Regression Model**

Fit a nonlinear regression model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the sample data. Create a matrix `X` containing the measurements for the horsepower (`Horsepower`) and weight (`Weight`) of each car. Create a vector `y` containing the response values in miles per gallon (`MPG`).

```matlab
load carbig
X = [Horsepower,Weight];
y = MPG;
```

Fit a nonlinear regression model.
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)

mdl =
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:
        Estimate      SE        tStat       pValue
    ______    _______    ________    ________
    b1     -49.383     119.97    -0.41164     0.68083
    b2      376.43     567.05     0.66384     0.50719
    b3    -0.78193    0.47168     -1.6578    0.098177
    b4      422.37     776.02     0.54428     0.58656
    b5    -0.24127    0.48325    -0.49926     0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

Find the predicted mileage of an average auto. Since the sample data contains some missing (NaN) observations, compute the mean using nanmean.

Xnew = nanmean(X)

Xnew = 1x2
10^3 x

0.1051  2.9794

MPGnew = predict(mdl,Xnew)

MPGnew = 21.8073
Definitions

Hat Matrix

The hat matrix $H$ is defined in terms of the data matrix $X$ and the Jacobian matrix $J$:

$$J_{i,j} = \frac{\partial f}{\partial \beta_j_{x_i,\beta}}$$

Here $f$ is the nonlinear model function, and $\beta$ is the vector of model coefficients.

The Hat Matrix $H$ is

$$H = J(J^TJ)^{-1}J^T.$$ 

The diagonal elements $H_{ii}$ satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where $n$ is the number of observations (rows of $X$), and $p$ is the number of coefficients in the regression model.

Leverage

The leverage of observation $i$ is the value of the $i$th diagonal term, $h_{ii}$, of the hat matrix $H$. Because the sum of the leverage values is $p$ (the number of coefficients in the regression model), an observation $i$ can be considered to be an outlier if its leverage substantially exceeds $p/n$, where $n$ is the number of observations.

Cook’s Distance

The Cook’s distance $D_i$ of observation $i$ is
Cook's distance is algebraically equivalent to the following expression:

\[ D_i = \frac{\sum_{j=1}^{n} (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}}, \]

where

- \( \hat{y}_j \) is the \( j \)th fitted response value.
- \( \hat{y}_{j(i)} \) is the \( j \)th fitted response value, where the fit does not include observation \( i \).
- MSE is the mean squared error.
- \( p \) is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

\[ D_i = \frac{n_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right), \]

where \( e_i \) is the \( i \)th residual.

“Nonlinear Regression Workflow” on page 13-15
“Nonlinear Regression” on page 13-2
normcdf

Normal cumulative distribution function

Syntax

\[
p = \text{normcdf}(x)
\]
\[
p = \text{normcdf}(x,\mu)
\]
\[
p = \text{normcdf}(x,\mu,\sigma)
\]
\[
[p,pLo,pUp] = \text{normcdf}(x,\mu,\sigma,p\text{Cov})
\]
\[
[p,pLo,pUp] = \text{normcdf}(x,\mu,\sigma,p\text{Cov},\alpha)
\]
\[
___ = \text{normcdf}(___,'upper')
\]

Description

\[
p = \text{normcdf}(x)\] returns the cumulative distribution function (cdf) of the standard normal distribution, evaluated at the values in \(x\).

\[
p = \text{normcdf}(x,\mu)\] returns the cdf of the normal distribution with mean \(\mu\) and unit standard deviation, evaluated at the values in \(x\).

\[
p = \text{normcdf}(x,\mu,\sigma)\] returns the cdf of the normal distribution with mean \(\mu\) and standard deviation \(\sigma\), evaluated at the values in \(x\).

\[
[p,pLo,pUp] = \text{normcdf}(x,\mu,\sigma,p\text{Cov})\] also returns the 95% confidence bounds \([p\text{Lo},p\text{Up}]\) of \(p\) when \(\mu\) and \(\sigma\) are estimates. \(p\text{Cov}\) is the covariance matrix of the estimated parameters.

\[
[p,pLo,pUp] = \text{normcdf}(x,\mu,\sigma,p\text{Cov},\alpha)\] specifies the confidence level for the confidence interval \([p\text{Lo},p\text{Up}]\) to be \(100(1-\alpha)\)%.

\[
___ = \text{normcdf}(___,'upper')\] returns the complement of the cdf, evaluated at the values in \(x\), using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow argument with any of the input arguments in the previous syntaxes.
Examples

Standard Normal Distribution cdf

Compute the probability that an observation from a standard normal distribution falls on the interval \([-1 \ 1]\).

\[
p = \text{normcdf}([-1 \ 1]);
p(2)-p(1)
\]

\[
\text{ans} = 0.6827
\]

About 68% of the observations from a normal distribution fall within one standard deviation of the mean 0.

Normal Distribution cdf

Compute the cdf values evaluated at the values in \(x\) for the normal distribution with mean \(mu\) and standard deviation \(sigma\).

\[
x = [-2,-1,0,1,2];
mu = 2;
sigma = 1;
p = \text{normcdf}(x,mu,sigma)
\]

\[
p = 1\times5
\]

\[
0.0000 \ 0.0013 \ 0.0228 \ 0.1587 \ 0.5000
\]

Compute the cdf values evaluated at zero for various normal distributions with different mean parameters.

\[
mu = [-2,-1,0,1,2];
sigma = 1;
p = \text{normcdf}(0,mu,sigma)
\]

\[
p = 1\times5
\]

\[
0.9772 \ 0.8413 \ 0.5000 \ 0.1587 \ 0.0228
\]
Confidence Interval of Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```matlab
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,n,1);
```

Estimate the distribution parameters mean and standard deviation by using `normfit`.

```matlab
[muHat,sigmaHat] = normfit(x)
muHat = 4.9347
sigmaHat = 1.9979
```

With no censoring, `muHat` is the sample mean and `sigmaHat` is the square root of the unbiased estimator of the variance. `muHat` is equal to the MLE of the mean parameter, but `sigmaHat` is not equal to the MLE of the standard deviation parameter. Transform `sigmaHat` into the MLE.

```matlab
sigmaHat = sqrt((n-1)/n)*sigmaHat
sigmaHat = 1.9969
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```matlab
[~,pCov] = normlike([muHat,sigmaHat],x)
pCov = 2x2
```

```
 0.0040   -0.0000
-0.0000    0.0020
```

Find the cdf value at zero and its 95% confidence interval.
[p,pLo,pUp] = normcdf(0,muHat,sigmaHat,pCov)
p = 0.0067
pLo = 0.0047
pUp = 0.0095

p is the cdf value using the normal distribution with the parameters muHat and sigmaHat. The interval [pLo,pUp] is the 95% confidence interval of the cdf evaluated at 0, considering the uncertainty of muHat and sigmaHat using pCov. The 95% confidence interval means that the probability that [pLo,pUp] contains the true cdf value is 0.95.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from a standard normal distribution will fall on the interval [10,Inf].

p1 = 1 - normcdf(10)
p1 = 0

normcdf(10) is nearly 1, so p1 becomes 0. Specify 'upper' so that normcdf computes the extreme upper-tail probabilities more accurately.

p2 = normcdf(10,'upper')
p2 = 7.6199e-24

You can use 'upper' to compute a right-tailed p-value.

Test for Normal Distribution Using Function Handle

Use the probability distribution function normcdf as a function handle in the chi-square goodness-of-fit test (chi2gof).

Test the null hypothesis that the sample data in the input vector x comes from a normal distribution with parameters \( \mu \) and \( \sigma \) equal to the mean (mean) and standard deviation (std) of the sample data, respectively.
rng('default') % For reproducibility
x = normrnd(50,5,100,1);
h = chi2gof(x,'cdf',{@normcdf,mean(x),std(x)})
h = 0

The returned result $h = 0$ indicates that chi2gof does not reject the null hypothesis at the default 5% significance level.

**Input Arguments**

$x$ — Values at which to evaluate cdf

 scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If you specify pCov to compute the confidence interval $[pLo,pUp]$, then $x$ must be a scalar value.

To evaluate the cdf at multiple values, specify $x$ using an array. To evaluate the cdfs of multiple normal distributions, specify $mu$ and $sigma$ using arrays. If one or more of the input arguments $x$, $mu$, and $sigma$ are arrays, then the array sizes must be the same. In this case, normcdf expands each scalar input into a constant array of the same size as the array inputs. Each element in $p$ is the cdf value of the normal distribution specified by the corresponding elements in $mu$ and $sigma$, evaluated at the corresponding element in $x$.

Example: $[-1,0,3,4]$

Data Types: single | double

$mu$ — Mean

 scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify pCov to compute the confidence interval $[pLo,pUp]$, then $mu$ must be a scalar value.

To evaluate the cdf at multiple values, specify $x$ using an array. To evaluate the cdfs of multiple normal distributions, specify $mu$ and $sigma$ using arrays. If one or more of the
input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the normal distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

**`sigma` — Standard deviation**

1 (default) | nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `p` is either 0 or 1. `p` is 0 if `x` is smaller than `mu`, or 1 otherwise.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `sigma` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple normal distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the normal distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

**`pCov` — Covariance of estimates**

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `x`, `mu`, and `sigma` each must be a scalar value.
You can estimate mu and sigma by using normfit and estimate the covariance of mu and sigma by using normlike. For an example, see “Confidence Interval of Normal cdf Value” on page 32-4423.

Data Types: single | double

**alpha — Confidence level**

0.05 (default) | scalar in the range (0,1)

Confidence level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where alpha is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

**Output Arguments**

**p — cdf values**

scalar value | array of scalar values

cdf values, evaluated at the values in x, returned as a scalar value or an array of scalar values. p is the same size as x, mu, and sigma after any necessary scalar expansion. Each element in p is the cdf value of the normal distribution specified by the corresponding elements in mu and sigma, evaluated at the corresponding element in x.

**pLo — Lower confidence bound for p**

scalar value | array of scalar values

Lower confidence bound for p, returned as a scalar value or an array of scalar values. pLo has the same size as p.

**pUp — Upper confidence bound for p**

scalar value | array of scalar values

Upper confidence bound for p, returned as a scalar value or an array of scalar values. pUp has the same size as p.
Definitions

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, \( \mu \), is the mean. The second parameter, \( \sigma \), is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal cdf is

\[
p = F(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{(t-\mu)^2}{2\sigma^2}} \, dt.
\]

\( p \) is the probability that a single observation from a normal distribution with parameters \( \mu \) and \( \sigma \) falls in the interval \((-\infty, x]\).

Algorithms

- The \texttt{normcdf} function uses the inverse complementary error function \texttt{erfc}. The relationship between \texttt{normcdf} and \texttt{erfc} is

\[
\text{normcdf}(x) = \frac{1}{2} \text{erfc}\left(\frac{-x}{\sqrt{2}}\right).
\]

The complementary error function \( \texttt{erfc}(x) \) is defined as

\[
\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-t^2} \, dt.
\]

- The \texttt{normcdf} function computes confidence bounds for \( p \) by using the delta method. \( \text{normcdf}(x, \mu, \sigma) \) is equivalent to \( \text{normcdf}(\frac{x-\mu}{\sigma}, 0, 1) \). Therefore, the \texttt{normcdf} function estimates the variance of \( \frac{x-\mu}{\sigma} \) using the covariance matrix of \( \mu \) and \( \sigma \) by the delta method, and finds the confidence bounds of \( \frac{x-\mu}{\sigma} \) using the estimates of this variance. Then, the function transforms the bounds to the scale of \( p \). The computed bounds give approximately the desired confidence level when you estimate \( \mu \), \( \sigma \), and \( p\text{Cov} \) from large samples.
Alternative Functionality

- `normcdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normcdf` is faster than the generic function `cdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics
“Normal Distribution” on page B-130

Introduced before R2006a
normfit

Normal parameter estimates

Syntax

[muHat,sigmaHat] = normfit(x)

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x)

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha)

[___] = normfit(x,alpha,censoring)

[___] = normfit(x,alpha,censoring,freq)

[___] = normfit(x,alpha,censoring,freq,options)

Description

[muHat,sigmaHat] = normfit(x) returns estimates of normal distribution parameters (the mean muHat and standard deviation sigmaHat), given the sample data in x. muHat is the sample mean, and sigmaHat is the square root of the unbiased estimator of the variance.

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x) also returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays muCI and sigmaCI, respectively.

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha) specifies the confidence level for the confidence intervals to be $100(1-\alpha)\%$.

[___] = normfit(x,alpha,censoring) specifies whether each value in x is right-censored or not. Use the logical vector censoring in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With censoring, muHat and sigmaHat are the maximum likelihood estimates (MLEs).

[___] = normfit(x,alpha,censoring,freq) specifies the frequency or weights of observation.
[___] = normfit(x,alpha,censoring,freq,options) specifies optimization options for the iterative algorithm normfit to use to compute MLEs with censoring. Create options by using the function statset.

You can pass in [] for alpha, censoring, and freq to use their default values.

**Examples**

**Estimate Parameters and Confidence Intervals**

Generate 1000 normal random numbers from the normal distribution with mean 3 and standard deviation 5.

```matlab
rng('default') % For reproducibility
x = normrnd(3,5,[1000,1]);
```

Find the parameter estimates and the 99% confidence intervals.

```matlab
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,0.01)
muHat = 2.8368
sigmaHat = 4.9948
muCI = 2×1
   2.4292
   3.2445
sigmaCI = 2×1
   4.7218
   5.2989
```

muHat is the sample mean, and sigmaHat is the square root of the unbiased estimator of the variance. muCI and sigmaCI are the 99% confidence intervals of the mean and standard deviation parameters. The first row is the lower bound, and the second row is the upper bound.
**Change Algorithm Options**

Find the MLEs of a data set with censoring by using `normfit`. Use `statset` to specify the iterative algorithm options that `normfit` uses to compute MLEs for censored data, and find the MLEs again.

Load the sample data.

```matlab
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```matlab
idx = find(lightbulb(:,2) == 0);
```

Assume that the lifetime follows the normal distribution, and find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```matlab
censoring = lightbulb(idx,3) == 1;
[muHat1,sigmaHat1] = normfit(lightbulb(idx,1),[],censoring)
```

```
muHat1 = 9.4966e+03
sigmaHat1 = 3.0640e+03
```

Display the default algorithm parameters that the function `normfit` uses to estimate the normal distribution parameters.

```matlab
statset('normfit')
```

```
ans = struct with fields:
  Display: 'off'
  MaxFunEvals: 200
  MaxIter: 100
  TolBnd: 1.0000e-06
```
Save the options under a different name. Change how the results will be displayed and the termination tolerance for the objective function, Display and TolFun.

```matlab
options = statset('normfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the function `statset`.

```matlab
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```matlab
[muHat2,sigmaHat2] = normfit(lightbulb(idx,1),[],censoring,[],options)
```

Successful convergence: Norm of gradient less than OPTIONS.TolFun

- muHat2 = 9.4966e+03
- sigmaHat2 = 3.0640e+03

`normfit` displays a report on the final iteration.
**Convert Unbiased Estimator to MLE**

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.

Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```matlab
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```matlab
[muHat,sigmaHat] = normfit(x)
muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```matlab
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat
sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large `n`.

Alternatively, you can find the MLEs by using the function `mle`.

```matlab
phat = mle(x)
phat = 1x2
     0.1231    1.1566
```

`phat(1)` and `phat(2)` are the MLEs of the mean and the standard deviation parameter, respectively.
Confirm that the log likelihood of the MLEs (muHat and sigmaHat_MLE) is greater than the log likelihood of the unbiased estimators (muHat and sigmaHat) by using the normlike function.

\[
\log L = -\text{normlike}([\muHat, \sigmaHat], x)
\]

\[
\log L = -156.4424
\]

\[
\log L_{\text{MLE}} = -\text{normlike}([\muHat, \sigmaHat_{\text{MLE}}], x)
\]

\[
\log L_{\text{MLE}} = -156.4399
\]

**Confidence Interval of Normal cdf Value**

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```matlab
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,n,1);
```

Estimate the distribution parameters mean and standard deviation by using `normfit`.

```matlab
[muHat,sigmaHat] = normfit(x)
```

```
muHat = 4.9347
sigmaHat = 1.9979
```

With no censoring, muHat is the sample mean and sigmaHat is the square root of the unbiased estimator of the variance. muHat is equal to the MLE of the mean parameter, but sigmaHat is not equal to the MLE of the standard deviation parameter. Transform sigmaHat into the MLE.

```matlab
sigmaHat = sqrt((n-1)/n)*sigmaHat
```

```
sigmaHat = 1.9969
```
Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```matlab
[~,pCov] = normlike([muHat,sigmaHat],x)
pCov = 2×2
  0.0040   -0.0000
  -0.0000    0.0020
```

Find the cdf value at zero and its 95% confidence interval.

```matlab
[p,pLo,pUp] = normcdf(0,muHat,sigmaHat,pCov)
p = 0.0067
pLo = 0.0047
pUp = 0.0095
```

`p` is the cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means that the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

**Input Arguments**

- `x` — **Sample data**
  vector | matrix
  Sample data, specified as a vector or matrix.
  If you specify `censoring` or `freq`, `x` must be a vector.
  Data Types: `single` | `double`

- `alpha` — **Confidence level**
  0.05 (default) | scalar in the range (0,1) | vector
  32-4437
Confidence level for the confidence interval, specified as a scalar or vector where each element is in the range (0,1). The confidence level is $100(1-\alpha)\%$. $\alpha$ is the probability that the confidence interval does not contain the true value.

If $\alpha$ is a vector of size $m$, then muCI and sigmaCI are matrices of size 2-by-$m$. The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Example: 0.01

Data Types: single | double

censoring — Indicator for censoring
array of 0s (default) | logical vector

Indicator for the censoring of each value in x, specified as a logical vector of the same size as x. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: logical

freq — Frequency or weights of observations
array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as x. The freq input argument typically contains nonnegative integer counts for the corresponding elements in x, but can contain any nonnegative values.

To obtain the weighted MLEs for the mean and standard deviation for a data set with censoring, specify weights of observations, normalized to the number of observations in x.

The default is an array of 1s, meaning one observation per element of x.

Data Types: single | double

options — Optimization options
statset('normfit') (default) | structure

Optimization options, specified as a structure. options determines the control parameters for the iterative algorithm that normfit uses to compute MLEs for censored data.
Create options by using the function `statset` or by creating a structure array containing the fields and values described in this table.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display</td>
<td>Amount of information displayed by the algorithm.</td>
<td>'off'</td>
</tr>
<tr>
<td></td>
<td>• 'off' — Displays no information.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 'final' — Displays the final output.</td>
<td></td>
</tr>
<tr>
<td>MaxFunEvals</td>
<td>Maximum number of objective function evaluations allowed, specified as a positive integer.</td>
<td>200</td>
</tr>
<tr>
<td>MaxIter</td>
<td>Maximum number of iterations allowed. Positive integer.</td>
<td>100</td>
</tr>
<tr>
<td>TolBnd</td>
<td>Lower bound of sigmaHat, specified as a positive scalar.</td>
<td>1e-6</td>
</tr>
<tr>
<td></td>
<td>The bounds for muHat and sigmaHat are [-Inf,Inf] and [TolBnd,Inf], respectively.</td>
<td></td>
</tr>
<tr>
<td>TolFun</td>
<td>Termination tolerance for the objective function value, specified as a positive scalar.</td>
<td>1e-8</td>
</tr>
<tr>
<td>TolX</td>
<td>Termination tolerance for the parameters, specified as a positive scalar.</td>
<td>1e-8</td>
</tr>
</tbody>
</table>

You can also enter `statset('normfit')` in the Command Window to see the names and default values of the fields that `normfit` accepts in the options structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and changes the maximum number of iterations allowed to 1000.

Data Types: `struct`
Output Arguments

\textbf{muHat — Estimate of mean}

\texttt{scalar | vector}

Estimate of the mean parameter of the normal distribution, returned as a scalar or vector.

- With no censoring, \texttt{muHat} is the sample mean.
- With censoring, \texttt{muHat} is the MLE. To compute the weighted MLE, specify the weights of observations by using \texttt{freq}.

\textbf{sigmaHat — Estimate of standard deviation}

\texttt{scalar | vector}

Estimate of the standard deviation parameter of the normal distribution, returned as a scalar or vector.

- With no censoring, \texttt{sigmaHat} is the square root of the unbiased estimator of the variance. To compute the MLE with no censoring, use the \texttt{mle} function.
- With censoring, \texttt{sigmaHat} is the MLE. To compute the weighted MLE, specify the weights of observations by using \texttt{freq}.

\textbf{muCI — Confidence interval for mean}

\texttt{2-by-1 column vector | 2-by-\textit{m} matrix}

Confidence interval for the mean parameter of the normal distribution, returned as a 2-by-1 column vector or 2-by-\textit{m} matrix containing the lower and upper bounds of the $100(1-\alpha)%$ confidence interval. \textit{m} is the number of values in \texttt{alpha}.

\textbf{sigmaCI — Confidence interval for standard deviation}

\texttt{2-by-1 column vector | 2-by-\textit{m} matrix}

Confidence interval for the standard deviation parameter of the normal distribution, returned as a 2-by-1 column vector or 2-by-\textit{m} matrix containing the lower and upper bounds of the $100(1-\alpha)%$ confidence interval. \textit{m} is the number of values in \texttt{alpha}. 
Algorithms

To compute the confidence intervals, `normfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on $t$ and chi-square distributions.

Alternative Functionality

`normfit` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the Distribution Fitter app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or custom density function.
- Create a `NormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the Distribution Fitter app. The object properties `mu` and `sigma` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Topics
“Normal Distribution” on page B-130

Introduced before R2006a
norminv

Normal inverse cumulative distribution function

**Syntax**

```matlab
x = norminv(p)
x = norminv(p,mu)
x = norminv(p,mu,sigma)

[x,xLo,xUp] = norminv(p,mu,sigma,pCov)
[x,xLo,xUp] = norminv(p,mu,sigma,pCov,alpha)
```

**Description**

$x = \text{norminv}(p)$ returns the inverse of the standard normal cumulative distribution function (cdf), evaluated at the probability values in $p$.

$x = \text{norminv}(p,mu)$ returns the inverse of the normal cdf with mean $mu$ and the unit standard deviation, evaluated at the probability values in $p$.

$x = \text{norminv}(p,mu,sigma)$ returns the inverse of the normal cdf with mean $mu$ and standard deviation $sigma$, evaluated at the probability values in $p$.

$[x,xLo,xUp] = \text{norminv}(p,mu,sigma,pCov)$ also returns the 95% confidence bounds $[xLo,xUp]$ of $x$ when $mu$ and $sigma$ are estimates. $pCov$ is the covariance matrix of the estimated parameters.

$[x,xLo,xUp] = \text{norminv}(p,mu,sigma,pCov,alpha)$ specifies the confidence level for the confidence interval $[pLo,pUp]$ to be $100(1-\alpha)\%$.

**Examples**
Inverse of Standard Normal cdf

Find an interval that contains 95% of the values from a standard normal distribution.

\[
x = \text{norminv}([0.025 \ 0.975])
\]

\[
x = 1\times2
\]

\[-1.9600 \quad 1.9600\]

Note that the interval \(x\) is not the only such interval, but it is the shortest. Find another interval.

\[
x_l = \text{norminv}([0.01 \ 0.96])
\]

\[
x_l = 1\times2
\]

\[-2.3263 \quad 1.7507\]

The interval \(x_l\) also contains 95% of the probability, but it is longer than \(x\).

Inverse of Normal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in \(p\) for the normal distribution with mean \(\mu\) and standard deviation \(\sigma\).

\[
p = 0:0.25:1;
\]

\[
\mu = 2;
\]

\[
\sigma = 1;
\]

\[
x = \text{norminv}(p,\mu,\sigma)
\]

\[
x = 1\times5
\]

\[-\text{Inf} \quad 1.3255 \quad 2.0000 \quad 2.6745 \quad \text{Inf}\]

Compute the inverse of cdf values evaluated at 0.5 for various normal distributions with different mean parameters.
mu = [-2,-1,0,1,2];
sigma = 1;
x = norminv(0.5,mu,sigma)

x = 1x5
    -2  -1   0   1   2

Confidence Interval of Inverse Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,[n,1]);

Estimate the distribution parameters mean and standard deviation by using normfit.

[muHat,sigmaHat] = normfit(x)

muHat = 4.9347
sigmaHat = 1.9979

With no censoring, muHat is the sample mean and sigmaHat is the square root of the unbiased estimator of the variance. muHat is equal to the MLE of the mean parameter, but sigmaHat is not equal to the MLE of the standard deviation parameter. Transform sigmaHat into the MLE.

sigmaHat = sqrt((n-1)/n)*sigmaHat

sigmaHat = 1.9969

Estimate the covariance of the distribution parameters by using normlike. The function normlike returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

[~,pCov] = normlike([muHat,sigmaHat],x)
pCov = 2×2

0.0040   -0.0000
-0.0000    0.0020

Find the inverse cdf value at 0.5 and its 99% confidence interval.

[x,xLo,xUp] = norminv(0.5,muHat,sigmaHat,pCov,0.01)

x = 4.9347

xLo = 4.7721

xUp = 5.0974

x is the inverse cdf value using the normal distribution with the parameters muHat and sigmaHat. The interval [xLo,xUp] is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of muHat and sigmaHat using pCov. The 99% confidence interval means that the probability that [xLo,xUp] contains the true inverse cdf value is 0.99.

**Input Arguments**

**p — Probability values at which to evaluate inverse of cdf**

scalar value in [0,1] | array of scalar values

Probability values at which to evaluate the inverse of the cdf, specified as a scalar value or an array of scalar values, where each element is in the range [0,1].

If you specify pCov to compute the confidence interval [xLo,xUp], then p must be a scalar value.

To evaluate the icdf at multiple values, specify x using an array. To evaluate the icdfs of multiple normal distributions, specify mu and sigma using arrays. If one or more of the input arguments p, mu, and sigma are arrays, then the array sizes must be the same. In this case, norminv expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the normal distribution specified by the corresponding elements in mu and sigma, evaluated at the corresponding element in p.

Example: [0.1,0.5,0.9]
Data Types: single | double

**mu — Mean**

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify pCov to compute the confidence interval \([xLo, xUp]\), then mu must be a scalar value.

To evaluate the icdf at multiple values, specify x using an array. To evaluate the icdfs of multiple normal distributions, specify mu and sigma using arrays. If one or more of the input arguments p, mu, and sigma are arrays, then the array sizes must be the same. In this case, norminv expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the normal distribution specified by the corresponding elements in mu and sigma, evaluated at the corresponding element in p.

Example: \([0 1 2; 0 1 2]\)

Data Types: single | double

**sigma — Standard deviation**

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify pCov to compute the confidence interval \([xLo, xUp]\), then sigma must be a scalar value.

To evaluate the icdf at multiple values, specify x using an array. To evaluate the icdfs of multiple normal distributions, specify mu and sigma using arrays. If one or more of the input arguments p, mu, and sigma are arrays, then the array sizes must be the same. In this case, norminv expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the normal distribution specified by the corresponding elements in mu and sigma, evaluated at the corresponding element in p.

Example: \([1 1 1; 2 2 2]\)

Data Types: single | double
**pCov — Covariance of estimates**
2-by-2 numeric matrix

Covariance of the estimates mu and sigma, specified as a 2-by-2 matrix.

If you specify pCov to compute the confidence interval \([x_{Lo}, x_{Up}]\), then \(p\), \(mu\), and \(sigma\) each must be a scalar value.

You can estimate \(mu\) and \(sigma\) by using `normfit` and estimate the covariance of \(mu\) and \(sigma\) by using `normlike`. For an example, see “Confidence Interval of Inverse Normal cdf Value” on page 32-4445.

Data Types: `single` | `double`

**alpha — Confidence level**
0.05 (default) | scalar in the range \((0,1)\)

Confidence level for the confidence interval, specified as a scalar in the range \((0,1)\). The confidence level is \(100(1-\alpha)\)%, where \(\alpha\) is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: `single` | `double`

### Output Arguments

**x — icdf values**
scalar value | array of scalar values

icdf values, evaluated at the probability values in \(p\), returned as a scalar value or an array of scalar values. \(x\) is the same size as \(p\), \(mu\), and \(sigma\) after any necessary scalar expansion. Each element in \(x\) is the icdf value of the normal distribution specified by the corresponding elements in \(mu\) and \(sigma\), evaluated at the corresponding element in \(p\).

**xLo — Lower confidence bound for x**
scalar value | array of scalar values

Lower confidence bound for \(x\), returned as a scalar value or an array of scalar values. \(x_{Lo}\) has the same size as \(x\).
**Definitions**

**Normal Distribution**

The normal distribution is a two-parameter family of curves. The first parameter, \( \mu \), is the mean. The second parameter, \( \sigma \), is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal inverse function is defined in terms of the normal cdf as

\[
x = F^{-1}(p \mid \mu, \sigma) = \{x : F(x \mid \mu, \sigma) = p\},
\]

where

\[
p = F(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \int_{-\infty}^{\frac{-(x-\mu)^2}{2\sigma^2}} dt.
\]

The result \( x \) is the solution of the integral equation where you supply the desired probability \( p \).

**Algorithms**

- The \texttt{norminv} function uses the inverse complementary error function \texttt{erfcinv}. The relationship between \texttt{norminv} and \texttt{erfcinv} is

\[
\texttt{norminv}(p) = -\sqrt{2} \texttt{erfcinv}(2p)
\]

The inverse complementary error function \texttt{erfcinv}(x) is defined as \texttt{erfcinv(\texttt{erfc}(x))=x}, and the complementary error function \texttt{erfc}(x) is defined as...
erfc(x) = 1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt.

- The norminv function computes confidence bounds for x by using the delta method. norminv(p,mu,sigma) is equivalent to mu+sigma*norminv(p,0,1). Therefore, the norminv function estimates the variance of mu+sigma*norminv(p,0,1) using the covariance matrix of mu and sigma by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give approximately the desired confidence level when you estimate mu, sigma, and pCov from large samples.

Alternative Functionality

norminv is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function icdf, which supports various probability distributions. To use icdf, create a NormalDistribution probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function norminv is faster than the generic function icdf.

NormalDistribution | erfcinv | icdf | normcdf | normfit | normlike | normspec

Topics
“Normal Distribution” on page B-130

Introduced before R2006a
**normlike**

Normal negative loglikelihood

**Syntax**

```matlab
nlogL = normlike(params,x)
nlogL = normlike(params,x,censoring)
nlogL = normlike(params,x,censoring,freq)
[nlogL,aVar] = normlike(___
```

**Description**

`nlogL = normlike(params,x)` returns the normal negative loglikelihood of the distribution parameters (`params`) given sample data (`x`). `params(1)` and `params(2)` correspond to the mean and standard deviation of the normal distribution, respectively.

`nlogL = normlike(params,x,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`nlogL = normlike(params,x,censoring,freq)` specifies the frequency or weights of observation. To specify `freq` without specifying `censoring`, you can pass `[]` for `censoring`.

`[nlogL,aVar] = normlike(___)` also returns the inverse of the Fisher information matrix `aVar`. If values in `params` are the maximum likelihood estimates (MLEs) of the parameters, `aVar` is an approximation to the asymptotic covariance matrix.

**Examples**
**Negative Log Likelihood of MLEs**

Find the MLEs of a data set with censoring by using `normfit`, and then find the negative log likelihood of the MLEs by using `normlike`.

Load the sample data.

```matlab
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```matlab
idx = find(lightbulb(:,2) == 0);
```

Find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```matlab
censoring = lightbulb(idx,3) == 1;
[muHat,sigmaHat] = normfit(lightbulb(idx,1),[],censoring)
```

- `muHat = 9.4966e+03`
- `sigmaHat = 3.0640e+03`

Find the negative log likelihood of the MLEs.

```matlab
nlogL = normlike([muHat,sigmaHat],lightbulb(idx,1),censoring)
nlogL = 376.2305
```

**Convert Unbiased Estimator to MLE**

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.
Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```matlab
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```matlab
[muHat,sigmaHat] = normfit(x)
muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```matlab
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat
sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large `n`.

Alternatively, you can find the MLEs by using the function `mle`.

```matlab
phat = mle(x)
phat = 1x2
     0.1231    1.1566
```

`phat(1)` and `phat(2)` are the MLEs of the mean and the standard deviation parameter, respectively.

Confirm that the log likelihood of the MLEs (`muHat` and `sigmaHat_MLE`) is greater than the log likelihood of the unbiased estimators (`muHat` and `sigmaHat`) by using the `normlike` function.

```matlab
logL = -normlike([muHat,sigmaHat],x)
logL = -156.4424
```
\[
\text{logL}_{\text{MLE}} = -\text{normlike}([\muHat, \sigmaHat_{\text{MLE}}], x)
\]
\[
\text{logL}_{\text{MLE}} = -156.4399
\]

**Confidence Interval of Inverse Normal cdf Value**

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

\[
\text{rng}('\text{default}') \quad \% \text{ For reproducibility}
\]
\[
n = 1000; \quad \% \text{ Number of samples}
\]
\[
x = \text{normrnd}(5, 2, [n, 1]);
\]

Estimate the distribution parameters mean and standard deviation by using `normfit`.

\[
[\muHat, \sigmaHat] = \text{normfit}(x)
\]
\[
\muHat = 4.9347
\]
\[
\sigmaHat = 1.9979
\]

With no censoring, \(\muHat\) is the sample mean and \(\sigmaHat\) is the square root of the unbiased estimator of the variance. \(\muHat\) is equal to the MLE of the mean parameter, but \(\sigmaHat\) is not equal to the MLE of the standard deviation parameter. Transform \(\sigmaHat\) into the MLE.

\[
\sigmaHat = \sqrt{\frac{(n-1)}{n}} \times \sigmaHat
\]
\[
\sigmaHat = 1.9969
\]

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

\[
[\sim, \text{pCov}] = \text{normlike}([\muHat, \sigmaHat], x)
\]
\[
\text{pCov} = 2 \times 2
\]
\[
\begin{bmatrix}
0.0040 & -0.0000 \\
\end{bmatrix}
\]
Find the inverse cdf value at 0.5 and its 99% confidence interval.

\[ [x, x_{\text{Lo}}, x_{\text{Up}}] = \text{norminv}(0.5, \mu_{\text{Hat}}, \sigma_{\text{Hat}}, \text{pCov}, 0.01) \]

\[ x = 4.9347 \]
\[ x_{\text{Lo}} = 4.7721 \]
\[ x_{\text{Up}} = 5.0974 \]

\( x \) is the inverse cdf value using the normal distribution with the parameters \( \mu_{\text{Hat}} \) and \( \sigma_{\text{Hat}} \). The interval \( [x_{\text{Lo}}, x_{\text{Up}}] \) is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of \( \mu_{\text{Hat}} \) and \( \sigma_{\text{Hat}} \) using \( \text{pCov} \). The 99% confidence interval means that the probability that \( [x_{\text{Lo}}, x_{\text{Up}}] \) contains the true inverse cdf value is 0.99.

### Input Arguments

**params — Normal distribution parameters**

vector of two numeric values

Normal distribution parameters consisting of the mean and standard deviation, specified as a vector of two numeric values. \( \text{params}(1) \) and \( \text{params}(2) \) correspond to the mean and standard deviation of the normal distribution, respectively. \( \text{params}(2) \) must be positive.

Example: \([0,1]\)

Data Types: single | double

**x — Sample data**

vector

Sample data, specified as a vector.

Data Types: single | double

**censoring — Indicator for censoring**

array of 0s (default) | logical vector
Indicator for the censoring of each value in \( x \), specified as a logical vector of the same size as \( x \). Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: logical

\textbf{freq — Frequency or weights of observations}

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as \( x \). The \text{freq} input argument typically contains nonnegative integer counts for the corresponding elements in \( x \), but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for the mean and standard deviation for a data set with censoring, specify weights of observations, normalized to the number of observations in \( x \).

The default is an array of 1s, meaning one observation per element of \( x \).

Data Types: single | double

\section*{Output Arguments}

\textbf{nlogL — Negative loglikelihood}

numeric value

Negative loglikelihood value of the distribution parameters (\text{params}) given sample data (\( x \)), returned as a numeric value.

\textbf{aVar — Inverse of Fisher information matrix}

numeric matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. \( \text{aVar} \) is based on the observed Fisher information given the observed data (\( x \)), not the expected information.

If values in \text{params} are the MLEs of the parameters, \( \text{aVar} \) is an approximation to the asymptotic variance-covariance matrix (also known as asymptotic covariance matrix). To find the MLEs, use \text{normfit} or \text{mle}. 
Alternative Functionality

`normlike` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mlecov`, `fitdist`, `negloglik`, and `proflik` and the Distribution Fitter app, which support various probability distributions.

- `mlecov` returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by the custom probability density function. For example, `mlecov(params,x,'pdf',@normpdf)` returns the asymptotic covariance matrix of the MLEs for the normal distribution.
- Create a NormalDistribution probability distribution object by fitting the distribution to data using the `fitdist` function or the Distribution Fitter app. The object property `ParameterCovariance` stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to `negloglik` and `proflik`, respectively.

Topics

“Negative Loglikelihood Functions” on page 5-30
“Normal Distribution” on page B-130

Introduced before R2006a
**normpdf**

Normal probability density function

**Syntax**

\[
y = \text{normpdf}(x) \\
y = \text{normpdf}(x, \mu) \\
y = \text{normpdf}(x, \mu, \sigma)
\]

**Description**

\( y = \text{normpdf}(x) \) returns the probability density function (pdf) of the standard normal distribution, evaluated at the values in \( x \).

\( y = \text{normpdf}(x, \mu) \) returns the pdf of the normal distribution with mean \( \mu \) and the unit standard deviation, evaluated at the values in \( x \).

\( y = \text{normpdf}(x, \mu, \sigma) \) returns the pdf of the normal distribution with mean \( \mu \) and standard deviation \( \sigma \), evaluated at the values in \( x \).

**Examples**

**Standard Normal Distribution pdf**

Compute the pdf values for the standard normal distribution at the values in \( x \).

\[
x = [-2, -1, 0, 1, 2]; \\
y = \text{normpdf}(x)
\]

\[
y = 1\times5 \\
   0.0540   0.2420   0.3989   0.2420   0.0540
\]
Normal Distribution pdf

Compute the pdf values evaluated at the values in x for the normal distribution with mean mu and standard deviation sigma.

```matlab
x = [-2,-1,0,1,2];
mu = 2;
sigma = 1;
y = normpdf(x,mu,sigma)
```

```
y = 1x5
     0.0001    0.0044    0.0540    0.2420    0.3989
```

Compute the pdf values evaluated at zero for various normal distributions with different mean parameters.

```matlab
mu = [-2,-1,0,1,2];
sigma = 1;
y = normpdf(0,mu,sigma)
```

```
y = 1x5
     0.0540    0.2420    0.3989    0.2420    0.0540
```

Input Arguments

- **x** — Values at which to evaluate pdf
  - scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify x using an array. To evaluate the pdfs of multiple normal distributions, specify mu and sigma using arrays. If one or more of the input arguments x, mu, and sigma are arrays, then the array sizes must be the same. In this case, normpdf expands each scalar input into a constant array of the same size as
the array inputs. Each element in \( y \) is the pdf value of the normal distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

Example: \([-1,0,3,4]\)

Data Types: `single` | `double`

**mu — Mean**

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify \( x \) using an array. To evaluate the pdfs of multiple normal distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( x \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \texttt{normpdf} expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the normal distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

Example: \([0 \ 1 \ 2; \ 0 \ 1 \ 2]\)

Data Types: `single` | `double`

**sigma — Standard deviation**

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify \( x \) using an array. To evaluate the pdfs of multiple normal distributions, specify \( \mu \) and \( \sigma \) using arrays. If one or more of the input arguments \( x \), \( \mu \), and \( \sigma \) are arrays, then the array sizes must be the same. In this case, \texttt{normpdf} expands each scalar input into a constant array of the same size as the array inputs. Each element in \( y \) is the pdf value of the normal distribution specified by the corresponding elements in \( \mu \) and \( \sigma \), evaluated at the corresponding element in \( x \).

Example: \([1 \ 1 \ 1; \ 2 \ 2 \ 2]\)

Data Types: `single` | `double`
Output Arguments

$y$ — pdf values  
scalar value | array of scalar values

pdf values, evaluated at the values in $x$, returned as a scalar value or an array of scalar values. $y$ is the same size as $x$, $\mu$, and $\sigma$ after any necessary scalar expansion. Each element in $y$ is the pdf value of the normal distribution specified by the corresponding elements in $\mu$ and $\sigma$, evaluated at the corresponding element in $x$.

Definitions

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, $\mu$, is the mean. The second parameter, $\sigma$, is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal pdf is

$$y = f(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$  

The likelihood function is the pdf viewed as a function of the parameters. Maximum likelihood estimates (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of $x$.

If $z$ is standard normal, then $\sigma z + \mu$ is also normal with mean $\mu$ and standard deviation $\sigma$. Conversely, if $x$ is normal with mean $\mu$ and standard deviation $\sigma$, then $z = (x - \mu) / \sigma$ is standard normal.

Alternative Functionality

- `normpdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability
distributions. To use pdf, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

**Topics**

“Normal Distribution” on page B-130

**Introduced before R2006a**
normplot

Normal probability plot

Syntax

normplot(x)
normplot(ax,x)
h = normplot(__)

Description

normplot(x) creates a normal probability plot comparing the distribution of the data in x to the normal distribution.

normplot plots each data point in x using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data. If the sample data has a normal distribution, then the data points appear along the reference line. A distribution other than normal introduces curvature in the data plot.

normplot(ax,x) adds a normal probability plot into the axes specified by ax.

h = normplot(__) returns graphics handles corresponding to the plotted lines, using any of the previous syntaxes.

Examples

Generate a Normal Probability Plot

Generate random sample data from a normal distribution with mu = 10 and sigma = 1.

rng default;  % For reproducibility
x = normrnd(10,1,25,1);
Create a normal probability plot of the sample data.

```
figure;
normplot(x)
```

The plot indicates that the data follows a normal distribution.

**Assess Normality Using a Normal Probability Plot**

Generate 50 random numbers from each of four different distributions: A standard normal distribution; a Student's-t distribution with five degrees of freedom (a "fat-tailed"
distribution); a set of Pearson random numbers with \( \mu \) equal to 0, \( \sigma \) equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution); and a set of Pearson random numbers with \( \mu \) equal to 0, \( \sigma \) equal to 1, skewness equal to -0.5, and kurtosis equal to 3 (a "left-skewed" distribution).

\[
\text{rng(11)} \quad \% \text{ For reproducibility}
\]
\x1 = \text{normrnd}(0,1,[50,1]);
\x2 = \text{trnd}(5,[50,1]);
\x3 = \text{pearsrnd}(0,1,0.5,3,[50,1]);
\x4 = \text{pearsrnd}(0,1,-0.5,3,[50,1]);

Plot four histograms on the same figure for a visual comparison of the pdf of each distribution.

\[
\text{figure}
\]
\text{subplot}(2,2,1)
\text{histogram(x1,10)}
\text{title('Normal')}
\text{axis([-4,4,0,15])}

\text{subplot}(2,2,2)
\text{histogram(x2,10)}
\text{title('Fat Tails')}
\text{axis([-4,4,0,15])}

\text{subplot}(2,2,3)
\text{histogram(x3,10)}
\text{title('Right-Skewed')}
\text{axis([-4,4,0,15])}

\text{subplot}(2,2,4)
\text{histogram(x4,10)}
\text{title('Left-Skewed')}
\text{axis([-4,4,0,15])}

32-4467
The histograms show how each sample differs from the normal distribution.

Create a normal probability plot for each sample.

```matlab
figure
subplot(2,2,1)
normplot(x1)
title('Normal')

subplot(2,2,2)
normplot(x2)
title('Fat Tails')

subplot(2,2,3)
normplot(x3)
title('Right-Skewed')

subplot(2,2,4)
normplot(x4)
title('Left-Skewed')
```
normplot(x3)
title('Right-Skewed')

subplot(2,2,4)
normplot(x4)
title('Left-Skewed')

Adjust Normal Probability Plot Line Properties

Create a 50-by-2 matrix containing 50 random numbers from each of two different distributions: A standard normal distribution in column 1, and a set of Pearson random
numbers with \( \mu \) equal to 0, \( \sigma \) equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution) in column 2.

```matlab
rng default  % For reproducibility
x = [normrnd(0,1,[50,1]) pearsrnd(0,1,0.5,3,[50,1])];
```

Create a normal probability plot for both samples on the same figure. Return the plot line graphic handles.

```matlab
figure
h = normplot(x)
```

```matlab
h =
    6x1 Line array:
    Line
    Line
    Line
    Line
    Line
    Line

legend({'Normal','Right-Skewed'},'Location','southeast')
```
The handles h(1) and h(2) correspond to the data points for the normal and skewed distributions, respectively. The handles h(3) and h(4) correspond to the second and third quartile line fit to the sample data. The handles h(5) and h(6) correspond to the extrapolated line that extends to the minimum and maximum of each set of sample data.

To illustrate, increase the line width of the second and third quartile line for the normally distributed data sample (represented by h(3)) to 2.

\[
\text{h(3).LineWidth} = 2; \\
\text{h(4).LineWidth} = 2;
\]
Input Arguments

x — Sample data
numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `normplot` displays each value in `x` using the symbol '+'.
If `x` is a matrix, then `normplot` displays a separate line for each column of `x`.

Data Types: `single` | `double`
**ax — Target axes**

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `normplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

**Output Arguments**

**h — Graphics handles for line objects**

vector of Line graphics handles

Graphics handles for line objects, returned as a vector of Line graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `normplot` returns three handles:

- The line representing the data points. `normplot` represents each data point in `x` using plus sign (`'+'`) markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

**Algorithms**

`normplot` matches the quantiles of sample data to the quantiles of a normal distribution. The sample data is sorted and plotted on the x-axis. The y-axis represents the quantiles of the normal distribution, converted into probability values. Therefore, the y-axis scaling is not linear.
Where the x-axis value is the \(i\)th sorted value from a sample of size \(N\), the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. The midpoint is equal to \(\frac{(i - 0.5)}{N}\).

`normplot` superimposes a reference line to assess the linearity of the plot. The line goes through the first and third quartiles of the data.

**Alternative Functionality**

You can use the `probpplot` function to create a probability plot. The `probpplot` function enables you to indicate censored data and specify the distribution for a probability plot.

**See Also**

`cdfplot` | `ecdf` | `probpplot` | `wblplot`

**Topics**

“Distribution Plots” on page 4-9

“Normal Distribution” on page B-130

**Introduced before R2006a**
normrnd

Normal random numbers

Syntax

\[ r = \text{normrnd}(\mu, \sigma) \]
\[ r = \text{normrnd}(\mu, \sigma, s_{z1}, \ldots, s_{zN}) \]
\[ r = \text{normrnd}(\mu, \sigma, [s_{z1}, \ldots, s_{zN}]) \]

Description

\( r = \text{normrnd}(\mu, \sigma) \) generates a random number from the normal distribution with mean parameter \( \mu \) and standard deviation parameter \( \sigma \).

\( r = \text{normrnd}(\mu, \sigma, s_{z1}, \ldots, s_{zN}) \) or \( r = \text{normrnd}(\mu, \sigma, [s_{z1}, \ldots, s_{zN}]) \) generates a \( s_{z1} \)-by-\( \cdots \)-by-\( s_{zN} \) array of normal random numbers.

Examples

Generate Normal Random Number

Generate a single random value from the standard normal distribution.

\[ \text{rng('default')} \quad \% \text{ For reproducibility} \]
\[ r = \text{normrnd}(0,1) \]
\[ r = 0.5377 \]
**Reset Random Number Generator**

Save the current state of the random number generator. Then create a 1-by-5 vector of normal random numbers from the normal distribution with mean 3 and standard deviation 10.

```matlab
s = rng;
r = normrnd(3,10,[1,5])
```

```
r = 1×5
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```matlab
rng(s);
r1 = normrnd(3,10,[1,5])
```

```
r1 = 1×5
```

**Clone Size from Existing Array**

Create a matrix of normally distributed random numbers with the same size as an existing array.

```matlab
A = [3 2; -2 1];
sz = size(A);
R = normrnd(0,1,sz)
```

```
R = 2×2
    0.5377   -2.2588
    1.8339    0.8622
```

You can combine the previous two lines of code into a single line.

```matlab
R = normrnd(1,0,size(A));
```
Input Arguments

**mu — Mean**

scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple normal distributions, specify **mu** and **sigma** using arrays. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either **mu** or **sigma** is a scalar, then **normrnd** expands the scalar argument into a constant array of the same size as the other argument. Each element in **r** is the random number generated from the normal distribution specified by the corresponding elements in **mu** and **sigma**.

Example: [0 1 2; 0 1 2]

Data Types: single | double

**sigma — Standard deviation**

nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If **sigma** is zero, then the output **r** is always equal to **mu**.

To generate random numbers from multiple normal distributions, specify **mu** and **sigma** using arrays. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either **mu** or **sigma** is a scalar, then **normrnd** expands the scalar argument into a constant array of the same size as the other argument. Each element in **r** is the random number generated from the normal distribution specified by the corresponding elements in **mu** and **sigma**.

Example: [1 1 1; 2 2 2]

Data Types: single | double

**sz1,...,szN — Size of each dimension**

integers | row vector of integers

Size of each dimension, specified as integers or a row vector of integers. For example, specifying 5,3,2 or [5,3,2] generates a 5-by-3-by-2 array of random numbers from the normal probability distribution.
If either mu or sigma is an array, then the specified dimensions sz1,...,szN must match the common dimensions of mu and sigma after any necessary scalar expansion. The default values of sz1,...,szN are the common dimensions.

- If you specify a single value sz1, then r is a square matrix of size sz1.
- If the size of any dimension is 0 or negative, then r is an empty array.
- Beyond the second dimension, normrnd ignores trailing dimensions with a size of 1. For example, normrnd(3,1,1,1) produces a 3-by-1 vector of random numbers.

Data Types: single | double

Output Arguments

r — Normal random numbers
scalar value | array of scalar values

Normal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by sz1,...,szN. Each element in r is the random number generated from the normal distribution specified by the corresponding elements in mu and sigma.

Alternative Functionality

- normrnd is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function random, which supports various probability distributions. To use random, create a NormalDistribution probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function normrnd is faster than the generic function random.
- Use randn to generate random numbers from the standard normal distribution.
- Use the random number generation user interface randtool to generate random numbers interactively.
References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a
**normspec**

Normal density plot shading between specifications

**Syntax**

\[
p = \text{normspec}([\text{specs}])
\]

\[
p = \text{normspec}([\text{specs},\mu,\sigma])
\]

\[
p = \text{normspec}([\text{specs},\mu,\sigma,\text{region}])
\]

\[
[p,h] = \text{normspec}([\_\_\_])
\]

**Description**

\[
p = \text{normspec}([\text{specs}])\] plots the standard normal density, shading the portion inside the specification limits given by the two-element vector specs, and returns the probability \( p \) of the shaded area. If spec has no lower limit, then set \( \text{specs}(1) \) to \(-\infty\); if spec has no upper limit, then set \( \text{specs}(2) \) to \( \infty \).

\[
p = \text{normspec}([\text{specs},\mu,\sigma])\] uses a normal density with parameters \( \mu \) and \( \sigma \).

\[
p = \text{normspec}([\text{specs},\mu,\sigma,\text{region}])\] specifies the shading region as either 'inside' or 'outside' the specification limits. The default is 'inside'.

\[
[p,h] = \text{normspec}([\_\_\_])\] also returns a column vector of chart line objects using any of the input arguments in the previous syntaxes. Use \( h \) to modify properties of a specific chart line after you create it. For a list of properties, see Line.

**Examples**

**Create Standard Normal Density Plot Shading Inside of Limits**

Create a standard normal density plot, shading the portion inside the specification limits \([-1,1]\).
Create Normal Density Plot Shading Outside of Limits

Create a normal density plot, shading the portion outside the specification limits.

For example, consider a production process that fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128 gallons). Create a normal density plot, shading the portion corresponding to the probability that the cans will be filled under specification by 3 or more ounces.
\[ p = \text{normspec}(\left[1-\frac{3}{128}, \infty\right], 1, \frac{2}{128}, 'outside') \]

\[ p = 0.0668 \]

### Input Arguments

**specs — Specification limits**

two-element numeric vector

Specification limits, specified as a two-element numeric vector. Set `specs(1)` to \(-\infty\) if there is no lower limit; set `specs(2)` to \(\infty\) if there is no upper limit.
Data Types: single | double

**mu — Mean**

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: single | double

**sigma — Standard deviation**

1 (default) | positive scalar value

Standard deviation of the normal distribution, specified as a positive scalar value.

Data Types: single | double

**region — Shading region**

'inside' (default) | 'outside'

Shading region, specified as either 'inside' or 'outside'. The function `normspec` shades the region either 'inside' or 'outside' the specification limits.

### Output Arguments

**p — Probability of shaded area**

nonnegative scalar value

Probability of the shaded area, returned as a nonnegative scalar value.

**h — One or more chart line objects**

scalar | vector

One or more chart line objects, returned as a scalar or vector. These objects are unique identifiers that you use to query and modify properties of a specific chart line. For a list of properties, see Chart Line.

Introduced before R2006a
normstat

Normal mean and variance

Syntax

\[ [m,v] = \text{normstat}(\mu,\sigma) \]

Description

\[ [m,v] = \text{normstat}(\mu,\sigma) \]
returns the mean and variance of the normal distribution with mean \( \mu \) and standard deviation \( \sigma \).

The mean of the normal distribution with parameters \( \mu \) and \( \sigma \) is \( \mu \), and the variance is \( \sigma^2 \).

Examples

Compute Mean and Variance

Compute the mean and variance of the normal distribution with parameters \( \mu \) and \( \sigma \).

\[
\mu = 1; \\
\sigma = 1:5; \\
[m,v] = \text{normstat}(\mu,\sigma)
\]

\[
m = 1\times5 \\
\begin{bmatrix}
1 & 1 & 1 & 1 & 1
\end{bmatrix}
\]

\[
v = 1\times5 \\
\begin{bmatrix}
1 & 4 & 9 & 16 & 25
\end{bmatrix}
\]
Input Arguments

**mu — Mean**  
Scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple normal distributions, specify distribution parameters using an array of scalar values. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either **mu** or **sigma** is a scalar, then **normstat** expands the scalar argument into a constant array of the same size as the other argument. Each element in m and v is the mean and variance of the normal distribution specified by the corresponding elements in **mu** and **sigma**.

Example: [0 1 2; 0 1 2]
Data Types: single | double

**sigma — Standard deviation**  
Positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To compute the means and variances of multiple normal distributions, specify distribution parameters using an array of scalar values. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either **mu** or **sigma** is a scalar, then **normstat** expands the scalar argument into a constant array of the same size as the other argument. Each element in m and v is the mean and variance of the normal distribution specified by the corresponding elements in **mu** and **sigma**.

Example: [1 1 1; 2 2 2]
Data Types: single | double

Output Arguments

**m — Mean**  
Scalar value | array of scalar values

Mean of the normal distribution, returned as a scalar value or an array of scalar values. m is the same size as **mu** and **sigma** after any necessary scalar expansion. Each element in m
is the mean of the normal distribution specified by the corresponding elements in mu and sigma.

\[ \mathbf{v} \] — Variance
scalar value | array of scalar values

Variance of the normal distribution, returned as a scalar value or an array of scalar values. \( \mathbf{v} \) is the same size as \( \mathbf{mu} \) and \( \mathbf{sigma} \) after any necessary scalar expansion. Each element in \( \mathbf{v} \) is the variance of the normal distribution specified by the corresponding elements in \( \mathbf{mu} \) and \( \mathbf{sigma} \).

Alternative Functionality

`normstat` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (`mean`), median (`median`), interquartile range (`iqr`), variance (`var`), and standard deviation (`std`), which support various probability distributions. To use these functions, create a `NormalDistribution` probability distribution object and pass the object as an input argument.

Topics
“Normal Distribution” on page B-130

Introduced before R2006a
nsegments

Number of segments in piecewise distribution

Syntax

\[ n = \text{nsegments}(pd) \]

Description

\[ n = \text{nsegments}(pd) \]
returns the number of segments in the piecewise distribution object \( pd \).

Examples

Number of Segments in \text{paretotails} Object

Generate a sample data set and fit a piecewise distribution with a Pareto tail to the data by using \text{paretotails}. Find the number of segments in the fitted distribution by using the object function \text{nsegments}.

Generate a sample data set containing 10% outliers in the right tail.

```matlab
rng('default'); % For reproducibility
right_tail = exprnd(5,100,1);
center = randn(900,1);
x = [center;right_tail];
```

Create a \text{paretotails} object by fitting a piecewise distribution to \( x \). Specify the boundaries of the tails using the lower and upper tail cumulative probabilities. Pass in 0 and 0.9 so that a fitted object does not contain a lower tail segment, and consists of the empirical distribution for the lower 90% of the data set and a generalized Pareto distribution (GPD) for the upper 10% of the data set.

```matlab
pd = paretotails(x,0,0.9)
```
pd =
Piecewise distribution with 2 segments
-Inf < x < 1.73931 (0 < p < 0.9): interpolated empirical cdf
  1.73931 < x < Inf (0.9 < p < 1): upper tail, GPD(0.643752,1.62246)

Return the number of segments in pd by using the nsegments function.

n = nsegments(pd)

n = 2

You can also get the number of segments by using the NumSegments property. Access the NumSegments property by using dot notation.

pd.NumSegments

ans = 2

Input Arguments

pd — Piecewise distribution with Pareto tails
paretotails object

Piecewise distribution with Pareto tails, specified as a paretotails object.

**numel**

**Class:** dataset

Number of elements in dataset array

**Note** The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB table documentation for more information.

**Syntax**

\[ n = \text{numel}(A) \]
\[ n = \text{numel}(A, \text{varargin}) \]

**Description**

\[ n = \text{numel}(A) \text{ returns 1. To find the number of elements, } n, \text{ in the dataset array } A, \text{ use } \text{prod(size(A)) or numel(A,'':'','')}. \]

\[ n = \text{numel}(A, \text{varargin}) \text{ returns the number of subscripted elements, } n, \text{ in } A(\text{index1, index2, ... indexn}), \text{ where varargin is a string array or cell array whose elements are index1, index2, ... indexn}. \]

**See Also**

`length` | `size`
numnodes

Class: classregtree

(Removed) Number of nodes

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

n = numnodes(t)

Description

n = numnodes(t) returns the number of nodes n in the tree t.

References

classregtree
NumTestSets property

Class: cvpartition

Number of test sets

Description

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.
Value is 1 in partitions of type 'holdout' and 'resubstitution'.
ObsNames property

Class: dataset

Cell array of nonempty, distinct character vectors giving names of observations in data set

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Description

A cell array of nonempty, distinct character vectors giving the names of the observations in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of observations.
optimalleaforder

Optimal leaf ordering for hierarchical clustering

Syntax

leafOrder = optimalleaforder(tree,D)  
leafOrder = optimalleaforder(tree,D,Name,Value)

Description

leafOrder = optimalleaforder(tree,D) returns an optimal leaf ordering for the hierarchical binary cluster tree, tree, using the distances, D. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

leafOrder = optimalleaforder(tree,D,Name,Value) returns the optimal leaf ordering using one or more name-value pair arguments.

Examples

Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using linkage. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

rng('default') % For reproducibility
X = rand(10,2);

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.
D = pdist(X);
tree = linkage(D,'average');
leafOrder = optimalleaforder(tree,D);

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

figure()
subplot(2,1,1)
dendrogram(tree)
title('Default Leaf Order')

subplot(2,1,2)
dendrogram(tree,'reorder',leafOrder)
title('Optimal Leaf Order')
The order of the leaves in the bottom figure corresponds to the elements in `leafOrder`.

```matlab
leafOrder
```

```
leafOrder = 1×10
1     4     9    10     2     5     8     3     7     6
```

**Optimal Leaf Order Using Inverse Distance Similarity**

Generate sample data.
rng('default') % For reproducibility
X = rand(10,2);

Create a distance vector and a hierarchical binary clustering tree.
D = pdist(X);
tree = linkage(D,'average');

Use the inverse distance similarity transformation to determine an optimal leaf order.
leafOrder = optimalleaforder(tree,D,'Transformation','inverse')
leafOrder = 1×10
       1     4     9    10     2     5     8     3     7     6

Input Arguments

tree — Hierarchical binary cluster tree
matrix returned by linkage

Hierarchical binary cluster tree, specified as an (M – 1)-by-3 matrix that you generate using linkage, where M is the number of leaves.

D — Distances
matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using pdist.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Criteria','group','Transformation','inverse' specifies that the sum of similarities be maximized between every leaf and all other leaves in adjacent clusters, using an inverse similarity transformation.
Criteria — Optimization criterion
'adjacent' (default) | 'group'

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of 'criteria' and one of these values:

'adjacent' Maximize the sum of similarities between adjacent leaves.
'group' Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

Example: 'Criteria','group'

Transformation — Method for transforming distances to similarities
'linear' (default) | 'inverse' | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of 'Transformation' and one of 'linear', 'inverse', or a function handle.

Let $d_{i,j}$ and $Sim_{i,j}$ denote the distance and similarity between leaves $i$ and $j$, respectively. The included similarity transformations are:

'linear' $Sim_{i,j} = \max_{i,j} (d_{i,j}) - d_{i,j}$
'inverse' $Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, $D$, and returns a matrix of similarities, $S$. The function should be monotonic decreasing in the range of distance values. $S$ must have the same size as $D$, with $S(i,j)$ being the similarity computed based on $D(i,j)$.

Example: 'Transformation', @myTransform

Output Arguments

leafOrder — Optimal leaf order
vector

Optimal leaf order, returned as a length-$M$ vector, where $M$ is the number of leaves. leafOrder is a permutation of the vector 1:M, giving an optimal leaf ordering based on the specified distances and similarity transformation.

dendrogram | linkage | pdist

Introduced in R2012b
**oobEdge**

Out-of-bag classification edge

**Syntax**

```matlab
edge = oobEdge(ens)
edge = oobEdge(ens,Name,Value)
```

**Description**

`edge = oobEdge(ens)` returns out-of-bag classification edge for `ens`.

`edge = oobEdge(ens,Name,Value)` computes classification edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Input Arguments**

`ens`

A classification bagged ensemble, constructed with `fitcensemble`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NumTrained`
mode

Character vector or string scalar representing the meaning of the output $L$:

- 'ensemble' — $L$ is a scalar value, the loss for the entire ensemble.
- 'individual' — $L$ is a vector with one element per trained learner.
- 'cumulative' — $L$ is a vector in which element $J$ is obtained by using learners $1:J$ from the input list of learners.

Default: 'ensemble'

Output Arguments

edge

Classification edge, a weighted average of the classification margin.

Examples

Estimate Out-of-Bag Edge

Load Fisher's iris data set.

load fisheriris

Train an ensemble of 100 bagged classification trees using the entire data set.

rng(1) % For reproducibility
Mdl = fitcensemble(meas,species,'Method','Bag');

Estimate the out-of-bag edge.

def = oobEdge(Mdl)
def = 0.8638
Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in \( \text{ens.Prior} \).

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix \( \text{ens.X} \).

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, \text{fitcensemble} generates many bootstrap replicas of the dataset and grows decision trees on these replicas. \text{fitcensemble} obtains each bootstrap replica by randomly selecting \( N \) observations out of \( N \) with replacement, where \( N \) is the dataset size. To find the predicted response of a trained ensemble, \text{predict} take an average over predictions from individual trees.

Drawing \( N \) out of \( N \) observations with replacement omits on average 37\% (\( 1/e \)) of observations for each decision tree. These are "out-of-bag" observations. For each observation, \text{oobLoss} estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

See Also

\text{oobLoss} | \text{oobMargin} | \text{oobPredict}
oobError

Class: TreeBagger

Out-of-bag error

Syntax

err = oobError(B)
err = oobError(B,'param1',val1,'param2',val2,...)

Description

err = oobError(B) computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger B. err is a vector of length NTrees, where NTrees is the number of trees in the ensemble.

err = oobError(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Mode'  Character vector or string scalar indicating how oobError computes errors. If set to 'cumulative' (default), the method computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.
Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.

Vector of tree weights. This vector must have the same length as the 'Trees' vector. oobError uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

Algorithms

oobError estimates the weighted ensemble error for out-of-bag observations. That is, oobError applies error to the training data stored in the input TreeBagger model B, and selects the out-of-bag observations for each tree to compose the ensemble error.

- B.X and B.Y are the training data predictors and responses, respectively.
- B.OOBIndices specifies which observations are out-of-bag for each tree in the ensemble.
- B.W specifies the observation weights.
- Optionally:
  - Using the 'Mode' name-value pair argument, you can specify to return the individual, weighted ensemble error for each tree, or the entire, weighted ensemble error. By default, oobError returns the cumulative, weighted ensemble error.
  - Using the 'Trees' name-value pair argument, you can choose which trees to use in the ensemble error calculations.
  - Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

oobError applies the algorithms described below. For more details, see error and predict.
For regression problems, `oobError` returns the weighted MSE.

1. `oobError` predicts responses for all out-of-bag observations.
2. The MSE estimate depends on the value of 'Mode'.

   - If you specify 'Mode','Individual', then `oobError` sets any in bag observations within a selected tree to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE for each selected tree.

   - If you specify 'Mode','Cumulative', then `oobError` returns a vector of cumulative, weighted MSEs, where MSE_t is the cumulative, weighted MSE for selected tree t. To compute MSE_t, for each observation that is out of bag for at least one tree through tree t, `oobError` computes the cumulative, weighted mean of the predicted responses through tree t. `oobError` sets observations that are in bag for all selected trees through tree t to the weighted sample average of the observed, training data responses. Then, `oobError` computes MSE_t.

   - If you specify 'Mode','Ensemble', then, for each observation that is out of bag for at least one tree, `oobError` computes the weighted mean over all selected trees. `oobError` sets observations that are in bag for all selected trees to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE, which is the same as the final, cumulative, weighted MSE.

In classification problems, `oobError` returns the weighted misclassification rate.

1. `oobError` predicts classes for all out-of-bag observations.
2. The weighted misclassification rate estimate depends on the value of 'Mode'.

   - If you specify 'Mode','Individual', then `oobError` sets any in bag observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `oobError` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes the weighted misclassification rate for each selected tree.

   - If you specify 'Mode','Cumulative', then `oobError` returns a vector of cumulative, weighted misclassification rates, where e_t^* is the cumulative, weighted misclassification rate for selected tree t. To compute e_t^*, for each observation that is out of bag for at least one tree through tree t, `oobError` finds the predicted, cumulative, weighted most popular class through tree t. `oobError` sets observations that are in bag for all selected trees through tree t to the weighted sample average of the observed, training data responses. Then, `oobError` computes MSE_t.
weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular. Then, oobError computes $e_t^*$.

- If you specify 'Mode','Ensemble', then, for each observation that is out of bag for at least one tree, oobError computes the weighted, most popular class over all selected trees. oobError sets observations that are in bag for all selected trees through tree $t$ to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular. Then, oobError computes the weighted misclassification rate, which is the same as the final, cumulative, weighted misclassification rate.

"Bootstrap Aggregation (Bagging) of Regression Trees" on page 18-139
"Bootstrap Aggregation (Bagging) of Classification Trees" on page 18-152
**oobLoss**

Out-of-bag classification error

**Syntax**

L = oobloss(ens)
L = oobloss(ens,Name,Value)

**Description**

L = oobloss(ens) returns the classification error for ens computed for out-of-bag data.

L = oobloss(ens,Name,Value) computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Input Arguments**

ens

A classification bagged ensemble, constructed with fitcensemble.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

learners

Indices of weak learners in the ensemble ranging from 1 to NumTrained. oobLoss uses only these learners for calculating loss.
Default: 1:NumTrained

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
</tr>
<tr>
<td>'classiferror'</td>
<td>Classification error</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
</tr>
<tr>
<td>'mincost'</td>
<td>Minimal expected misclassification cost (for classification scores that are posterior probabilities)</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
</tr>
</tbody>
</table>

'mincost' is appropriate for classification scores that are posterior probabilities. Bagged ensembles return posterior probabilities as classification scores by default.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (numel(ens.ClassNames), ens is the input model). Your function must have this signature

\[
\text{lossvalue} = \text{lossfun}(C,S,W,\text{Cost})
\]

where:

- The output argument lossvalue is a scalar.
- You choose the function name (lossfun).
- C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in ens.ClassNames.
Construct \( C \) by setting \( C(p,q) = 1 \) if observation \( p \) is in class \( q \), for each row. Set all other elements of row \( p \) to 0.

- \( S \) is an \( n \)-by-\( K \) numeric matrix of classification scores. The column order corresponds to the class order in \( \text{ens.ClassNames} \). \( S \) is a matrix of classification scores, similar to the output of \text{predict}.
- \( W \) is an \( n \)-by-1 numeric vector of observation weights. If you pass \( W \), the software normalizes them to sum to 1.
- \( \text{Cost} \) is a \( K \)-by-\( K \) numeric matrix of misclassification costs. For example, \( \text{Cost} = \text{ones}(K) - \text{eye}(K) \) specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using \'LossFun',@\text{lossfun}.'

For more details on loss functions, see "Classification Loss" on page 32-4513.

**Default:** \'classiferror'  

**mode**

Character vector or string scalar representing the meaning of the output \( L \):

- \'ensemble' — \( L \) is a scalar value, the loss for the entire ensemble.
- \'individual' — \( L \) is a vector with one element per trained learner.
- \'cumulative' — \( L \) is a vector in which element \( J \) is obtained by using learners 1:J from the input list of learners.

**Default:** \'ensemble'  

**Output Arguments**

\( L \)

Classification loss on page 32-4513 of the out-of-bag observations, a scalar. \( L \) can be a vector, or can represent a different quantity, depending on the name-value settings.

**Examples**
**Estimate Out-Of-Bag Error**

Load Fisher's iris data set.

```matlab
load fisheriris
```

Grow a bag of 100 classification trees.

```matlab
rng(1) % For reproducibility
ens = fitcensemble(meas,species,'Method','Bag');
```

Estimate the out-of-bag classification error.

```matlab
L = oobLoss(ens)
L = 0.0533
```

**Definitions**

**Out of Bag**

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitcensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitcensemble` obtains each bootstrap replica by randomly selecting \( N \) observations out of \( N \) with replacement, where \( N \) is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing \( N \) out of \( N \) observations with replacement omits on average 37% \((1/e)\) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.
Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- $L$ is the weighted average classification loss.
- $n$ is the sample size.
- For binary classification:
  - $y_j$ is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
  - $f(X_j)$ is the raw classification score for observation (row) $j$ of the predictor data $X$.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation $j$ into the class corresponding to $y_j$. Positive values of $m_j$ indicate correct classification and do not contribute much to the average loss. Negative values of $m_j$ indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - $y_j^*$ is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class $y_j$. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the ClassNames property of the input model.
  - $f(X_j)$ is the length $K$ vector of class scores for observation $j$ of the predictor data $X$. The order of the scores corresponds to the order of the classes in the ClassNames property of the input model.
  - $m_j = y_j^* f(X_j)$. Therefore, $m_j$ is the scalar classification score that the model predicts for the true, observed class.
  - The weight for observation $j$ is $w_j$. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

\[
\sum_{j=1}^{n} w_j = 1.
\]
Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

<table>
<thead>
<tr>
<th>Loss Function</th>
<th>Value of LossFun</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial deviance</td>
<td>'binodeviance'</td>
<td>[ L = \sum_{j=1}^{n} w_j \log \left[ 1 + \exp \left( -2m_j \right) \right]. ]</td>
</tr>
<tr>
<td>Exponential loss</td>
<td>'exponential'</td>
<td>[ L = \sum_{j=1}^{n} w_j \exp (-m_j). ]</td>
</tr>
<tr>
<td>Classification error</td>
<td>'classiferror'</td>
<td>[ L = \sum_{j=1}^{n} w_j I {\hat{y}_j \neq y_j}. ] It is the weighted fraction of misclassified observations where (\hat{y}_j) is the class label corresponding to the class with the maximal posterior probability. (I{x}) is the indicator function.</td>
</tr>
<tr>
<td>Hinge loss</td>
<td>'hinge'</td>
<td>[ L = \sum_{j=1}^{n} w_j \max {0,1- m_j}. ]</td>
</tr>
<tr>
<td>Logit loss</td>
<td>'logit'</td>
<td>[ L = \sum_{j=1}^{n} w_j \log \left( 1 + \exp (-m_j) \right). ]</td>
</tr>
<tr>
<td>Loss Function</td>
<td>Value of LossFun</td>
<td>Equation</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Minimal cost      | 'mincost'        | Minimal cost. The software computes the weighted minimal cost using this procedure for observations \( j = 1, \ldots, n \).

1. Estimate the 1-by-\( K \) vector of expected classification costs for observation \( j \):

\[
\gamma_j = f(X_j)C.
\]

\( f(X_j) \) is the column vector of class posterior probabilities for binary and multiclass classification. \( C \) is the cost matrix that the input model stores in the \text{Cost} property.

2. For observation \( j \), predict the class label corresponding to the minimum expected classification cost:

\[
\hat{y}_j = \min_{j=1,\ldots,K} (\gamma_j).
\]

3. Using \( C \), identify the cost incurred \( (c_j) \) for making the prediction.

The weighted, average, minimum cost loss is

\[
L = \frac{1}{\sum_{j=1}^{n} w_j c_j}.
\]

Quadratic loss     | 'quadratic'     | \[
L = \frac{1}{\sum_{j=1}^{n} w_j (1-m_j)^2}.
\]

This figure compares the loss functions (except 'mincost') for one observation over \( m \). Some functions are normalized to pass through [0,1].

**oobLoss**

Out-of-bag regression error

**Syntax**

\[
L = \text{oobLoss}(\text{ens}) \\
L = \text{oobLoss}(\text{ens},\text{Name},\text{Value})
\]

**Description**

\[
L = \text{oobLoss}(\text{ens})\text{ returns the mean squared error for }\text{ens} \text{ computed for out-of-bag data.}
\]

\[
L = \text{oobLoss}(\text{ens},\text{Name},\text{Value})\text{ computes error with additional options specified by one or more }\text{Name},\text{Value} \text{ pair arguments. You can specify several name-value pair arguments in any order as }\text{Name1},\text{Value1},...,\text{NameN},\text{ValueN}.
\]

**Input Arguments**

- **ens**
  
  A regression bagged ensemble, constructed with `fitrensemble`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

- **learners**
  
  Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.
Default: 1:NumTrained

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, oobLoss calls it as

FUN(Y,Yfit,W)

where Y, Yfit, and W are numeric vectors of the same length. Y is the observed response, Yfit is the predicted response, and W is the observation weights.

Default: 'mse'

mode

Character vector or string scalar representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Mean squared error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Examples

Find Out-of-Bag Regression Error

Compute the out-of-bag error for the carsmall data.

Load the carsmall data set and select engine displacement, horsepower, and vehicle weight as predictors.
load carsmall
X = [Displacement Horsepower Weight];

Train an ensemble of bagged regression trees.
ens = fitrensemble(X,MPG,'Method','Bag');

Find the out-of-bag error.
rng(10,'twister') % For reproducibility
L = oobLoss(ens)
L = 16.7197

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitrensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitrensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, predict takes an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% (1/e) of observations for each decision tree. These are "out-of-bag" observations. For each observation, oobLoss estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

oobMargin

Out-of-bag classification margins

Syntax

margin = oobMargin(ens)
margin = oobMargin(ens,Name,Value)

Description

margin = oobMargin(ens) returns out-of-bag classification margins.

margin = oobMargin(ens,Name,Value) calculates margins with additional options specified by one or more Name,Value pair arguments.

Input Arguments

ens
A classification bagged ensemble, constructed with fitcensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

learners
Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NumTrained
Output Arguments

margin

A numeric column vector of length size(ens.X,1).

Examples

Find Out-of-Bag Classification Margins

Find the out-of-bag margins for a bagged ensemble from the Fisher iris data.

Load the sample data set.

load fisheriris

Train an ensemble of bagged classification trees.

ens = fitensemble(meas,species,'Method','Bag');

Find the number of out-of-bag margins that are equal to 1.

rng(10,'twister') % For reproducibility
margin = oobMargin(ens);
sum(margin == 1)

ans = 105

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, fitensemble generates many bootstrap replicas of the dataset and grows decision trees on these replicas. fitensemble obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, predict takes an average over predictions from individual trees.
Drawing \( N \) out of \( N \) observations with replacement omits on average 37\% \((1/e)\) of observations for each decision tree. These are "out-of-bag" observations. For each observation, \texttt{oobLoss} estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix \texttt{ens.X}.

**See Also**

\texttt{margin|oobEdge|oobLoss|oobPredict}
oobMargin

Class: TreeBagger

Out-of-bag margins

Syntax

mar = oobMargin(B)
mar = oobMargin(B,'param1',val1,'param2',val2,...)

Description

mar = oobMargin(B) computes an Nobs-by-NTrees matrix of classification margins for out-of-bag observations in the training data, using the trained bagger B.

mar = oobMargin(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Mode' Character vector or string scalar indicating how oobMargin computes errors. If set to 'cumulative' (default), the method computes cumulative margins and mar is an Nobs-by-NTrees matrix, where the first column gives margins from trees(1), second column gives margins from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', mar is an Nobs-by-NTrees matrix, where each column gives margins from each tree in the ensemble. If set to 'ensemble', mar is a single column of length Nobs showing the cumulative margins for the entire ensemble.
'Trees' Vector of indices indicating what trees to include in this
calculation. By default, this argument is set to 'all' and the
method uses all trees. If 'Trees' is a numeric vector, the method
returns an Nobs-by-NTrees matrix for 'cumulative' and
'individual' modes, where NTrees is the number of elements
in the input vector, and a single column for 'ensemble' mode.
For example, in the 'cumulative' mode, the first column gives
margins from trees(1), the second column gives margins from
trees(1:2) etc.

'TreeWeights' Vector of tree weights. This vector must have the same length as
the 'Trees' vector. oobMargin uses these weights to combine
output from the specified trees by taking a weighted average
instead of the simple nonweighted majority vote. You cannot use
this argument in the 'individual' mode.

See Also
CompactTreeBagger.margin
**oobMeanMargin**

**Class:** TreeBagger

Out-of-bag mean margins

**Syntax**

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B,'param1',val1,'param2',val2,...)
```

**Description**

```
mar = oobMeanMargin(B) computes average classification margins for out-of-bag observations in the training data, using the trained bagger B. oobMeanMargin averages the margins over all out-of-bag observations. mar is a row-vector of length NTrees, where NTrees is the number of trees in the ensemble.

mar = oobMeanMargin(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Mode' Character vector or string scalar indicating how oobMeanMargin computes errors. If set to 'cumulative' (default), is a vector of length NTrees where the first element gives mean margin from trees(1), second column gives mean margins from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', mar is a vector of length NTrees, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', mar is a scalar showing the cumulative mean margin for the entire ensemble.
```
'Trees'  Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from trees(1), the second element gives mean margin from trees(1:2) etc.

'TreeWeights'  Vector of tree weights. This vector must have the same length as the 'Trees' vector. oobMeanMargin uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

See Also
CompactTreeBagger.meanMargin
Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees.

**Syntax**

\[
\text{Imp} = \text{oobPermutedPredictorImportance}(\text{Mdl}) \\
\text{Imp} = \text{oobPermutedPredictorImportance}(\text{Mdl}, \text{Name}, \text{Value})
\]

**Description**

\[
\text{Imp} = \text{oobPermutedPredictorImportance}(\text{Mdl}) \text{ returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-4534 using the random forest of classification trees } \text{Mdl}. \text{Mdl must be a ClassificationBaggedEnsemble model object.}
\]

\[
\text{Imp} = \text{oobPermutedPredictorImportance}(\text{Mdl}, \text{Name}, \text{Value}) \text{ uses additional options specified by one or more Name,Value pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.}
\]

**Input Arguments**

- **Mdl** — Random forest of classification trees  
  ClassificationBaggedEnsemble model object

Random forest of classification trees, specified as a ClassificationBaggedEnsemble model object created by fitcensemble.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Learners — Indices of learners to use in predictor importance estimation**

1:Mdl.NumTrained (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of 'Learners' and a numeric vector of positive integers. Values must be at most Mdl.NumTrained. When oobPermutedPredictorImportance estimates the predictor importance, it includes the learners in Mdl.Trained(learners) only, where learners is the value of 'Learners'.

Example: 'Learners', [1:2:Mdl.NumTrained]

**Options — Parallel computing options**

[ ] (default) | structure array returned by statset

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. 'Options' requires a Parallel Computing Toolbox license.

oobPermutedPredictorImportance uses the 'UseParallel' field only. statset('UseParallel',true) invokes a pool of workers.

Example: 'Options', statset('UseParallel',true)

**Output Arguments**

**Imp — Out-of-bag, predictor importance estimates by permutation**

numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-4534, returned as a 1-by-

p numeric vector. p is the number of predictor variables in the training data (size(Mdl.X,2)). Imp(j) is the predictor importance of the predictor Mdl.PredictorNames(j).

**Examples**
Estimate Importance of Predictors

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, martial status, race, sex, capital gain and loss, and number of working hours per week.

```matlab
load census1994
X = adultdata(:,{'age','workClass','education_num','marital_status','race',
                 'sex','capital_gain','capital_loss','hours_per_week','salary'});
rng('default'); % For reproducibility

Train a random forest of 50 classification trees using the entire data set.

```matlab
Mdl = fitcensemble(X,'salary','Method','bag','NumLearningCycles',50);
```matlab

Mdl is a ClassificationBaggedEnsemble model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```matlab
imp = oobPermutedPredictorImportance(Mdl);

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```
imp is a 1-by-9 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, marital_status is the most important predictor, followed by capital_gain.

**Unbiased Estimates of Predictor Importance Using Parallel Computing**

This example requires a Parallel Computing Toolbox™ license.

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, martial status, race, sex, capital gain and loss, and number of working hours per week.
load census1994
X = adultdata(:,{'age','workClass','education_num','marital_status','race',...
' sex','capital_gain','capital_loss','hours_per_week','salary'});
rng('default'); % For reproducibility

Display the number of categories represented in the categorical variables using summary.

min       1
median    40
max       99

salary: 32561×1 categorical
Values:
Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a random forest of 50 classification trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```matlab
t = templateTree('PredictorSelection','curvature','Surrogate','on');
Mdl = fitcensemble(X,'salary','Method','bag','NumLearningCycles',50,...
                   'Learners',t);
```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel. Compare the estimates using a bar graph.

```matlab
options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);
figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
```

```matlab
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```
In this case, capital_gain is the most important predictor, followed by martial_status. Compare these results to the results in “Estimate Importance of Predictors” on page 32-4528.

**Definitions**

**Out-of-Bag, Predictor Importance Estimates by Permutation**

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.
If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that \( R \) is a random forest of \( T \) learners and \( p \) is the number of predictors in the training data.

1. For tree \( t, t = 1,\ldots,T \):
   a. Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree \( t, s_t \subseteq \{1,\ldots,p\} \).
   b. Estimate the out-of-bag error \( \varepsilon_t \).
   c. For each predictor variable \( x_j, j \in s_t \):
      i. Randomly permute the observations of \( x_j \).
      ii. Estimate the model error, \( \varepsilon_{tj} \), using the out-of-bag observations containing the permuted values of \( x_j \).
      iii. Take the difference \( d_{tj} = \varepsilon_{tj} - \varepsilon_t \). Predictor variables not split when growing tree \( t \) are attributed a difference of 0.

2. For each predictor variable in the training data, compute the mean, \( \bar{d}_j \), and standard deviation, \( \sigma_j \), of the differences over the learners, \( j = 1,\ldots,p \).

3. The out-of-bag predictor importance by permutation for \( x_j \) is \( \frac{\bar{d}_j}{\sigma_j} \).

**Tips**

When growing a random forest using \texttt{fitcensemble}:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account
for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].

For more details, see templateTree.

ClassificationBaggedEnsemble | fitensemble | predictorImportance
Introduced in R2016b
**oobPermutedPredictorImportance**

Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees

**Syntax**

```matlab
Imp = oobPermutedPredictorImportance(Mdl)
Imp = oobPermutedPredictorImportance(Mdl,Name,Value)
```

**Description**

`Imp = oobPermutedPredictorImportance(Mdl)` returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-4544 using the random forest of regression trees `Mdl`. `Mdl` must be a `RegressionBaggedEnsemble` model object.

`Imp = oobPermutedPredictorImportance(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.

**Input Arguments**

`Mdl` — Random forest of regression trees

`RegressionBaggedEnsemble` model object

Random forest of regression trees, specified as a `RegressionBaggedEnsemble` model object created by `fitrensemble`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. 
Learners — Indices of learners to use in predictor importance estimation
1:Mdl.NumTrained (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of 'Learners' and a numeric vector of positive integers. Values must be at most Mdl.NumTrained. When oobPermutatedPredictorImportance estimates the predictor importance, it includes the learners in Mdl.Trained(learners) only, where learners is the value of 'Learners'.

Example: 'Learners',[1:2:Mdl.NumTrained]

Options — Parallel computing options
[] (default) | structure array returned by statset

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. 'Options' requires a Parallel Computing Toolbox license.

oobPermutatedPredictorImportance uses the 'UseParallel' field only. statset('UseParallel',true) invokes a pool of workers.

Example: 'Options',statset('UseParallel',true)

Output Arguments

Imp — Out-of-bag, predictor importance estimates by permutation
numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-4544, returned as a 1-by-p numeric vector. p is the number of predictor variables in the training data (size(Mdl.X,2)). Imp(j) is the predictor importance of the predictor Mdl.PredictorNames(j).

Examples

Estimate Importance of Predictors

Load the carsmall data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower,
manufacturer, model year, and weight. Consider Cylinders, Mfg, and Model-Year as categorical variables.

```matlab
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Train a random forest of 500 regression trees using the entire data set.

```matlab
Mdl = fitrensemble(X,'MPG','Method','bag','NumLearningCycles',500);
Mdl
```

Mdl is a `RegressionBaggedEnsemble` model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```matlab
imp = oobPermutedPredictorImportance(Mdl);
figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```
imp is a 1-by-7 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, Weight is the most important predictor, followed by Model_Year.

**Unbiased Estimates of Predictor Importance Using Parallel Computing**

This example requires a Parallel Computing Toolbox™ license.

Load the carsmall data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower,
manufacturer, model year, and weight. Consider Cylinders, Mfg, and Model_Year as categorical variables.

load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
rng('default'); % For reproducibility

Display the number of categories represented in the categorical variables.

numCylinders = numel(categories(Cylinders))
numMfg = numel(categories(Mfg))
numModelYear = numel(categories(Model_Year))

numCylinders =
    3

numMfg =
    28

numModelYear =
    3

Because there are 3 categories only in Cylinders and Model_Year, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

t = templateTree('PredictorSelection','curvature','Surrogate','on');
Mdl = fitrensemble(X,'MPG','Method','bag','NumLearningCycles',500,...
    'Learners',t);
Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel. Compare the estimates using a bar graph.

```matlab
options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);
figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
```

```matlab
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.
In this case, **Model Year** is the most important predictor, followed by **Cylinders**. Compare these results to the results in “Estimate Importance of Predictors” on page 32-4539.

### Definitions

**Out-of-Bag, Predictor Importance Estimates by Permutation**

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.
If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that $R$ is a random forest of $T$ learners and $p$ is the number of predictors in the training data.

1. For tree $t$, $t = 1, ..., T$:
   a. Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree $t$, $s_t \subseteq \{1, ..., p\}$.
   b. Estimate the out-of-bag error $\varepsilon_t$.
   c. For each predictor variable $x_j$, $j \in s_t$:
      i. Randomly permute the observations of $x_j$.
      ii. Estimate the model error, $\varepsilon_{tj}$, using the out-of-bag observations containing the permuted values of $x_j$.
      iii. Take the difference $d_{tj} = \varepsilon_{tj} - \varepsilon_t$. Predictor variables not split when growing tree $t$ are attributed a difference of 0.

2. For each predictor variable in the training data, compute the mean, $\bar{d}_j$, and standard deviation, $\sigma_j$, of the differences over the learners, $j = 1, ..., p$.

3. The out-of-bag predictor importance by permutation for $x_j$ is $\bar{d}_j / \sigma_j$.

**Tips**

When growing a random forest using `fitrensemble`:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.

- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account
for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].

RegressionBaggedEnsemble | fitrensemble | plotPartialDependence | predictorImportance
Introduced in R2016b
**oobPredict**

Predict out-of-bag response of ensemble

**Syntax**

\[
\text{[label, score]} = \text{oobPredict(ens)} \\
\text{[label, score]} = \text{oobPredict(ens, Name, Value)}
\]

**Description**

\[
\text{[label, score]} = \text{oobPredict(ens)} \text{ returns class labels and scores for ens for out-} \\
\text{of-bag data.}
\]

\[
\text{[label, score]} = \text{oobPredict(ens, Name, Value)} \text{ computes labels and scores with} \\
\text{additional options specified by one or more Name, Value pair arguments.}
\]

**Input Arguments**

- **ens**
  A classification bagged ensemble, constructed with `fitcensemble`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

- **learners**
  Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

  **Default:** `1:NumTrained`
Output Arguments

**label**

Classification labels of the same data type as the training data \( Y \). (The software treats string arrays as cell arrays of character vectors.) There are \( N \) elements or rows, where \( N \) is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in \texttt{ens.ClassNames}.

**score**

An \( N \)-by-\( K \) numeric matrix for \( N \) observations and \( K \) classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

Examples

**Find Out-of-Bag Response of Classification Ensemble**

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores with notable uncertainty in the resulting classifications.

Load the sample data set.

```matlab
load fisheriris
```

Train an ensemble of bagged classification trees.

```matlab
ens = fitcensemble(meas,species,'Method','Bag');
```

Find the out-of-bag predictions and scores.

```matlab
rng(10,'twister') % For reproducibility
[label,score] = oobPredict(ens);
```

Find the scores in the range (0.2,0.8). These scores have notable uncertainty in the resulting classifications.

```matlab
unsure = ((score > .2) & (score < .8));
sum(sum(unsure)) % Number of uncertain predictions
```

```matlab
ans = 18
```
Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitrensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitrensemble` obtains each bootstrap replica by randomly selecting \(N\) observations out of \(N\) with replacement, where \(N\) is the dataset size. To find the predicted response of a trained ensemble, `predict` takes an average over predictions from individual trees.

Drawing \(N\) out of \(N\) observations with replacement omits on average 37\% (\(1/e\)) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from \(\neg\infty\) to \(\infty\).
- Bag scores range from 0 to 1.

`oobEdge` | `oobLoss` | `oobMargin` | `predict`
**oobPredict**

Predict out-of-bag response of ensemble

**Syntax**

```matlab
Yfit = oobPredict(ens)
Yfit = oobPredict(ens,Name,Value)
```

**Description**

`Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

`ens`

A regression bagged ensemble, constructed with `fitrensemble`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

**Default**: `1:NumTrained`
Output Arguments

Yfit

A vector of predicted responses for out-of-bag data. Yfit has size(ens.X,1) elements.

You can find the indices of out-of-bag observations for weak learner L with the command
~ens.UseObsForLearner(:,L)

Examples

Find Out-of-Bag Response of Regression Ensemble

Compute the out-of-bag predictions for the carsmall data set. Display the first three terms of the fit.

Load the carsmall data set and select displacement, horsepower, and vehicle weight as predictors.

load carsmall
X = [Displacement Horsepower Weight];

Train an ensemble of bagged regression trees.
ens = fitrensemble(X,MPG,'Method','Bag');

Find the out-of-bag predictions, and display the first three terms of the fit.

rng(10,'twister') % For reproducibility
Yfit = oobPredict(ens);
Yfit(1:3) % First three terms

ans = 3×1

`oobLoss` | `predict`
**oobPredict**

**Class:** TreeBagger

Ensemble predictions for out-of-bag observations

**Syntax**

```plaintext
Y = oobPredict(B)
Y = oobPredict(B, Name, Value)
[Y, stdevs] = oobPredict(___)
[Y, scores] = oobPredict(___)
[Y, scores, stdevs] = oobPredict(__)
```

**Description**

`Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of character vectors for classification and a numeric array for regression.

`Y = oobPredict(B, Name, Value)` specifies additional options using one or both name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `all`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.

For regression, `[Y, stdevs] = oobPredict(__)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Y, scores] = oobPredict(__)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each out-of-bag observation and each class, the score generated by each tree is the probability of
the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `oobPredict` averages these scores over all trees in the ensemble.

\[ Y, \text{scores}, \text{stdevs} \] = `oobPredict(__)` also returns standard deviations of the computed scores for classification. \text{stdevs} is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

**Algorithms**

`oobPredict` and `predict` similarly predict classes and responses.

- In regression problems:
  - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean by selecting responses of trees in which the observation is out of bag. For this computation, the 'TreeWeights' name-value pair argument specifies the weights.
  - For each observation that is in bag for all trees, the predicted response is the weighted mean of all of the training responses. For this computation, the \text{W} property of the `TreeBagger` model (i.e., the observation weights) specify the weights.

- In classification problems:
  - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean of the class posterior probabilities by selecting the trees in which the observation is out of bag. Consequently, the predicted class is the class corresponding to the largest weighted mean. For this computation, the 'TreeWeights' name-value pair argument specifies the weights.
  - For each observation that is in bag for all trees, the predicted class is the weighted, most popular class over all training responses. For this computation, the \text{W} property of the `TreeBagger` model (i.e., the observation weights) specify the weights. If there are multiple most popular classes, `oobPredict` considers the one listed first in the \text{ClassNames} property of the `TreeBagger` model the most popular.

**oobQuantileError**

**Class:** TreeBagger

Out-of-bag quantile loss of bag of regression trees

**Syntax**

```matlab
err = quantileError(Mdl)
err = quantileError(Mdl,Name,Value)
```

**Description**

```matlab
err = quantileError(Mdl) returns half of the out-of-bag mean absolute deviation (MAD) from comparing the true responses in Mdl.Y to the predicted, out-of-bag medians at Mdl.X, the predictor data, and using the bag of regression trees Mdl. Mdl must be a TreeBagger model object.
```

```matlab
err = quantileError(Mdl,Name,Value) uses additional options specified by one or more Name,Value pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.
```

**Input Arguments**

`Mdl` — Bag of regression trees
TreeBagger model object (default)

Bag of regression trees, specified as a TreeBagger model object created by TreeBagger.

- The value of `Mdl.Method` must be `regression`.
- When you train `Mdl` using TreeBagger, you must specify the name-value pair `'OOBPrediction','on'`. Consequently, TreeBagger saves required out-of-bag observation index matrix in `Mdl.OOBIndices`.

32-4557
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Mode — Ensemble error type
'ensemble' (default) | 'cumulative' | 'individual'

Ensemble error type, specified as the comma-separated pair consisting of 'Mode' and a value in this table. Suppose tau is the value of Quantile.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cumulative'</td>
<td>err is a Mdl.NumTrees-by-numel(tau) numeric matrix of cumulative quantile regression errors. err(j,k) is the tau(k) quantile regression error using the learners in Mdl.Trees(1:j) only.</td>
</tr>
<tr>
<td>'ensemble'</td>
<td>err is a 1-by-numel(tau) numeric vector of cumulative quantile regression errors for the entire ensemble. err(k) is the tau(k) ensemble quantile regression error.</td>
</tr>
<tr>
<td>'individual'</td>
<td>err is a Mdl.NumTrees-by-numel(tau) numeric matrix of quantile regression errors from individual learners. err(j,k) is the tau(k) quantile regression error using the learner in Mdl.Trees(j) only.</td>
</tr>
</tbody>
</table>

For 'cumulative' and 'individual', if you choose to include fewer trees in quantile estimation using Trees, then this action affects the number of rows in err and corresponding row indices.

Example: 'Mode','cumulative'

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each observation (row) in Mdl.X, oobQuantileError estimates corresponding quantiles for all probabilities in Quantile.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double
Trees — Indices of trees to use in response estimation
'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of Mdl.Trees; each cell therein contains a tree in the ensemble. The maximum value of Trees must be less than or equal to the number of trees in the ensemble (Mdl.NumTrees).

For 'all', oobQuantileError uses all trees in the ensemble (that is, the indices 1:Mdl.NumTrees).

Values other than the default can affect the number of rows in err.

Example: 'Trees',[1 10 Mdl.NumTrees]
Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees
ones(Mdl.NumTrees,1) (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of numel(trees) nonnegative values. trees is the value of Trees.

If you specify 'Mode','individual', then oobQuantileError ignores TreeWeights.
Data Types: single | double

Output Arguments

err — Half of out-of-bag quantile regression error
numeric scalar | numeric matrix

Half of the out-of-bag quantile regression error on page 32-4563, returned as a numeric scalar or T-by-numel(tau) matrix. tau is the value of Quantile.

T depends on the values of Mode, Trees, and Quantile. Suppose that you specify 'Quantile',tau and 'Trees',trees.
• For 'Mode','cumulative', err is a numel(trees)-by-numel(tau) numeric matrix. err(j,k) is the tau(k) cumulative, out-of-bag quantile regression error using the learners in Mdl.Trees(trees(1:j)).

• For 'Mode','ensemble', err is a 1-by-numel(tau) numeric vector. err(k) is the tau(k) cumulative, out-of-bag quantile regression error using the learners in Mdl.Trees(trees).

• For 'Mode','individual', err is a numel(trees)-by-numel(tau) numeric matrix. err(j,k) is the tau(k) out-of-bag quantile regression error using the learner in Mdl.Trees(trees(j)).

Examples

Estimate Out-of-Bag Quantile Regression Error

Load the carsmall data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider Cylinders a categorical variable.

load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression','OOBPrediction','on');

Mdl is a TreeBagger ensemble.

Perform quantile regression, and out-of-bag estimate the MAD of the entire ensemble using the predicted conditional medians.

oobErr = oobQuantileError(Mdl)
oobErr = 1.5321

oobErr is an unbiased estimate of the quantile regression error for the entire ensemble.
Find Appropriate Ensemble Size Using Out-of-Bag Quantile Regression Error

Load the carsmall data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```matlab
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 250 weak learners and save the out-of-bag indices.

```matlab
rng('default'); % For reproducibility
Mdl = TreeBagger(250,X,'MPG','Method','regression',...
    'OOBPrediction','on');
```

Estimate the cumulative, out-of-bag, 0.25, 0.5, and 0.75 quantile regression errors.

```matlab
err = oobQuantileError(Mdl,'Quantile',[0.25 0.5 0.75],
    'Mode','cumulative');
```

`err` is an 250-by-3 matrix of cumulative, out-of-bag, quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees.

Plot the cumulative, out-of-bag, quantile errors on the same plot.

```matlab
figure;
plot(err);
legend('0.25 quantile error','0.5 quantile error','0.75 quantile error');
ylabel('Out-of-bag quantile error');
xlabel('Tree index');
title('Cumulative, Out-of-Bag, Quantile Regression Error')
```
All quantile error curves appear to level off after training about 50 trees. So, training 50 trees appears to be sufficient to achieve minimal quantile error for the three quantile probabilities.

**Definitions**

**Out-of-Bag**

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.
When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size $n$ for each learner, and then trains the learners using their respective bootstrap samples. Drawing $n$ out of $n$ observations with replacement omits on average about 37% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

**Quantile Regression Error**

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are $\tau$, the quantile probability. If the model over-predicts, then deviation weights are $1 - \tau$.

That is, the $\tau$ quantile regression error is

$$
L_{\tau} = \frac{\sum_{\{j: y_j \geq \hat{y}_{\tau,j}\}} w_j (y_j - \hat{y}_{\tau,j})}{\sum_{j=1}^{n} w_j} + (1 - \tau) \frac{\sum_{\{j: y_j < \hat{y}_{\tau,j}\}} w_j (\hat{y}_{\tau,j} - y_j)}{\sum_{j=1}^{n} w_j}.
$$

$y_j$ is true response $j$, $\hat{y}_{\tau,j}$ is the $\tau$ quantile that the model predicts, and $w_j$ is observation weight $j$.

**Tip**

The out-of-bag ensemble error estimator is unbiased for the true ensemble error. So, to tune parameters of a random forest, estimate the out-of-bag ensemble error instead of implementing cross-validation.

**Class:** TreeBagger

Quantile predictions for out-of-bag observations from bag of regression trees

**Syntax**

\[
\begin{align*}
YFit &= \text{oobQuantilePredict}(Mdl) \\
YFit &= \text{oobQuantilePredict}(Mdl, Name, Value) \\
[YFit, YW] &= \text{oobQuantilePredict}(\_\_) 
\end{align*}
\]

**Description**

\[
\begin{align*}
YFit &= \text{oobQuantilePredict}(Mdl) \text{ returns a vector of medians of the predicted responses at all out-of-bag observations in } Mdl.X, \text{ the predictor data, and using } Mdl, \text{ which is a bag of regression trees. } Mdl \text{ must be a } \text{TreeBagger} \text{ model object and } Mdl.OOBIndices \text{ must be nonempty.} \\
YFit &= \text{oobQuantilePredict}(Mdl, Name, Value) \text{ uses additional options specified by one or more } Name, Value \text{ pair arguments. For example, specify quantile probabilities or trees to include for quantile estimation.} \\
[YFit, YW] &= \text{oobQuantilePredict}(\_\_) \text{ also returns a sparse matrix of response weights on page } 32-4575 \text{ using any of the previous syntaxes.}
\end{align*}
\]

**Input Arguments**

- **Mdl — Bag of regression trees**
  - TreeBagger model object (default)

  Bag of regression trees, specified as a TreeBagger model object created by `TreeBagger`.

  - The value of `Mdl.Method` must be `regression`. 
• When you train Mdl using TreeBagger, you must specify the name-value pair 'OOBPrediction','on'. Consequently, TreeBagger saves required out-of-bag observation index matrix in Mdl.OOBIndices.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Quantile — Quantile probability**

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each observation (row) in Mdl.X, oobQuantilePredict estimates corresponding quantiles for all probabilities in Quantile.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double

**Trees — Indices of trees to use in response estimation**

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of Mdl.Trees; each cell therein contains a tree in the ensemble. The maximum value of Trees must be less than or equal to the number of trees in the ensemble (Mdl.NumTrees).

For 'all', oobQuantilePredict uses the indices 1:Mdl.NumTrees.

Example: 'Trees',[1 10 Mdl.NumTrees]

Data Types: char | string | single | double

**TreeWeights — Weights to attribute to responses from individual trees**

numeric vector of nonnegative values
Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of numel(trees) nonnegative values. trees is the value of the Trees name-value pair argument.

The default is ones(size(trees)).

Data Types: single | double

Output Arguments

YFit — Estimated quantiles
numeric matrix

Estimated quantiles for out-of-bag observations, returned as an n-by-numel(tau) numeric matrix. n is the number of observations in the training data (numel(Mdl.Y)) and tau is the value of the Quantile name-value pair argument. That is, YFit(j,k) is the estimated 100*tau(k) percentile of the response distribution given X(j,:) and using Mdl.

YW — Response weights
sparse matrix

Response weights on page 32-4575, returned as an n-by-n sparse matrix. n is the number of responses in the training data (numel(Mdl.Y)). YW(:,j) specifies the response weights for the observation in Mdl.X(j,:).

oobQuantilePredict predicts quantiles using linear interpolation of the empirical cumulative distribution function (cdf). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the cdf using kernel smoothing on page B-81.

Examples

Predict Out-of-Bag Medians Using Quantile Regression

Load the carsmall data set. Consider a model that predicts the fuel economy (in MPG) of a car given its engine displacement.

load carsmall
Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```matlab
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression','...
   'OOBPrediction','on');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression to predict the out-of-bag median fuel economy for all training observations.

```matlab
oobMedianMPG = oobQuantilePredict(Mdl);
```

`oobMedianMPG` is an `n`-by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in `Mdl.X`. `n` is the number of observations, `size(Mdl.X,1)`.

Sort the observations in ascending order. Plot the observations and the estimated medians on the same figure. Compare the out-of-bag median and mean responses.

```matlab
[sX,idx] = sort(Mdl.X);
oobMeanMPG = oobPredict(Mdl);

figure;
plot(Displacement,MPG,'k.'); hold on
plot(sX,oobMedianMPG(idx));
plot(sX,oobMeanMPG(idx),'r--');
ylabel('Fuel economy'); xlabel('Engine displacement');
legend('Data','Out-of-bag median','Out-of-bag mean'); hold off;
```
Estimate Out-of-Bag Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```matlab
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```matlab
Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.
```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',... 
    'OOBPrediction','on');

Perform quantile regression to predict the out-of-bag 2.5% and 97.5% percentiles.

oobQuantPredInts = oobQuantilePredict(Mdl,'Quantile',[0.025,0.975]);

oobQuantPredInts is an n-by-2 numeric matrix of prediction intervals corresponding to 
the out-of-bag observations in Mdl.X. n is number of observations, size(Mdl.X,1). The 
first column contains the 2.5% percentiles and the second column contains the 97.5% 
percentiles.

Plot the observations and the estimated medians on the same figure. Compare the 
percentile prediction intervals and the 95% prediction intervals, assuming the conditional 
distribution of MPG is Gaussian.

[oobMeanMPG,oobSTEMeanMPG] = oobPredict(Mdl);
STDNPredInts = oobMeanMPG + [-1 1]*norminv(0.975).*oobSTEMeanMPG;
[sX,idx] = sort(Mdl.X);

figure;
h1 = plot(Displacement,MPG,'k.');
hold on
h2 = plot(sX,oobQuantPredInts(idx,:),'b');
h3 = plot(sX,STDNPredInts(idx,:),'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend([h1,h2(1),h3(1)],{'Data','95% percentile prediction intervals',... 
    '95% Gaussian prediction intervals'});
hold off;
Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```matlab
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

```matlab
Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.
```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',
          'OOBPrediction','on');

Estimate the out-of-bag response weights.

[~,YW] = oobQuantilePredict(Mdl);

YW is an n-by-n sparse matrix containing the response weights. n is the number of training
observations, numel(Y). The response weights for the observation in Mdl.X(j,:) are in
YW(:,j). Response weights are independent of any specified quantile probabilities.

Estimate the out-of-bag, conditional cumulative distribution function (ccdf) of the
responses by:

1. Sorting the responses is ascending order, and then sorting the response weights
   using the indices induced by sorting the responses.

2. Computing the cumulative sums over each column of the sorted response weights.

[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);

ccdf(:,j) is the empirical out-of-bag ccdf of the response, given observation j.

Choose a random sample of four training observations. Plot the training sample and
identify the chosen observations.

[randX,idx] = datasample(Mdl.X,4);
figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(randX,Mdl.Y(idx),'*','MarkerSize',10);
text(randX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data','Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
Plot the out-of-bag ccdf for the four chosen responses in the same figure.

```matlab
figure;
plot(sortY,ccdf(:,idx));
legend('ccdf given obs. 1','ccdf given obs. 2','ccdf given obs. 3','ccdf given obs. 4','Location','SouthEast')
title('Out-of-Bag Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```
Definitions

Out-of-Bag

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.

When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size $n$ for each learner, and then trains the learners using their
respective bootstrap samples. Drawing \( n \) out of \( n \) observations with replacement omits on average about 37\% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

**Quantile Random Forest**

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95\% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval \([L, U]\) can be considered outliers:

\[
L = Q_1 - 1.5 \times IQR
\]

and

\[
U = Q_3 + 1.5 \times IQR,
\]

where:

- \( Q_1 \) is the 0.25 quantile.
- \( Q_3 \) is the 0.75 quantile.
- \( IQR = Q_3 - Q_1 \) (the interquartile range).

**Response Weights**

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.
Given the observation \( x \), the response weight for observation \( j \) in the training sample using tree \( t \) in the ensemble is

\[
w_{jt}(x) = \frac{I\{X_j \in S_t(x)\}}{\sum_{k=1}^{n_{\text{train}}} I\{X_k \in S_t(x)\}},
\]

where:

- \( I\{h\} \) is the indicator function.
- \( S_t(x) \) is the leaf of tree \( t \) containing \( x \).
- \( n_{\text{train}} \) is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

\[
w^*(x) = \frac{1}{T} \sum_{t=1}^{T} w_{jt}(x).
\]

**Algorithms**

\texttt{oobQuantilePredict} estimates out-of-bag quantiles by applying \texttt{quantilePredict} to all observations in the training data (\texttt{Mdl.X}). For each observation, the method uses only the trees for which the observation is out-of-bag.

For observations that are in-bag for all trees in the ensemble, \texttt{oobQuantilePredict} assigns the sample quantile of the response data. In other words, \texttt{oobQuantilePredict} does not use quantile regression for out-of-bag observations. Instead, it assigns \texttt{quantile(Mdl.Y, tau)}, where \( \tau \) is the value of the Quantile name-value pair argument.

“Conditional Quantile Estimation Using Kernel Smoothing” on page 18-174

Introduced in R2016b
optimizableVariable

Variable description for bayesopt or other optimizers

Description

Create variables for optimizers.

Creation

Syntax

variable = optimizableVariable(Name,Range)
variable = optimizableVariable(Name,Range,Name,Value)

Description

variable = optimizableVariable(Name,Range) creates a variable with the specified name and range of values.

variable = optimizableVariable(Name,Range,Name,Value) sets properties on page 32-4578 using name-value pair arguments. For example, optimizableVariable('xvar',[1 1000],'Type','integer') creates an integer variable from 1 to 1000. You can specify multiple name-value pair arguments. Enclose each property name in quotes.

Properties

Name — Variable name
character vector | string scalar

Variable name, specified as a character vector or string scalar. The name must be unique, meaning different from those of other variables in the optimization.
Note

- There are two names associated with an `optimizableVariable`:
  - The MATLAB workspace variable name
  - The name of the variable in the optimization

For example,

```matlab
xvar = optimizableVariable('spacevar',[1,100]);
```

`xvar` is the MATLAB workspace variable, and `spacevar` is the variable in the optimization.

Use these names as follows:

- Use `xvar` as an element in the vector of variables you pass to `bayesopt`. For example,
  ```matlab
  results = bayesopt(fun,[xvar,tvar])
  ```

- Use `'spacevar'` as the name of the variable in the optimization. For example, in an objective function,
  ```matlab
  function objective = mysvmfun(x,cdata,grp)
  SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...'
    'BoxConstraint',x.spacevar,...'
    'KernelScale',x.tvar);
  objective = kfoldLoss(crossval(SVMModel));
  ```

Example: 'X1'

Data Types: `char` | `string`

**Range — Variable range**

- 2-element increasing real vector | string array or cell array of names of categorical variables

Variable range, specified as a 2-element finite increasing real vector, or as a string array or cell array of names of categorical variables:

- For real or integer variables, `Range` gives the lower bound and upper bound of that variable.
• For categorical variables, Range gives the possible values.

Example: [-10,1]
Example: {'red','blue','black'}

Data Types: double | string | cell

**Type — Variable type**

'real' (default) | 'integer' | 'categorical'

Variable type, specified as 'real' (real variable), 'integer' (integer variable), or 'categorical' (categorical variable).

**Note** The MATLAB data type of both 'real' and 'integer' variables is the standard double-precision floating point number. The data type of 'categorical' variables is categorical. So, for example, to read a value of a categorical variable named 'colorv' in a table of variables named x, use the command char(x.colorv). For an example, see the objective function in “Custom Output Functions” on page 10-23.

Example: 'Type','categorical'

**Transform — Transform applied to variable**

'none' (default) | 'log'

Transform applied to variable, specified as 'none' (no transform) or 'log' (logarithmic transform).

For 'log', the variable must be 'real' or 'integer' and positive. The variable is searched and modeled on a log scale.

Example: 'Transform','log'

**Optimize — Indication to use variable in optimization**

true (default) | false

Indication to use variable in optimization, specified as true (use the variable) or false (do not use the variable).

Example: 'Optimize',false

Data Types: logical
**Note** You can use dot notation to change the following properties after creation.

- Range of real or integer variables. For example,
  ```
  xvar = optimizableVariable('x',[-10,10]);
  % Modify the range:
  xvar.Range = [1,5];
  ```
- Type between 'integer' and 'real'. For example,
  ```
  xvar.Type = 'integer';
  ```
- Transform of real or integer variables between 'log' and 'none'. For example,
  ```
  xvar.Transform = 'log';
  ```

You can use this flexibility, for example, to tweak an optimization that you want to continue. Update the range or transform using dot notation and then call `resume`.

**Object Functions**

bayesopt    Select optimal machine learning hyperparameters using Bayesian optimization

**Examples**

**Variables for Optimization Examples**

Real variable from 0 to 1:

```matlab
var1 = optimizableVariable('xvar',[0 1])
```

```matlab
var1 = optimizableVariable with properties:
    Name: 'xvar'
    Range: [0 1]
    Type: 'real'
    Transform: 'none'
    Optimize: 1
```

Integer variable from 1 to 1000 on a log scale:
var2 = optimizableVariable('ivar',[1 1000], 'Type','integer', 'Transform','log')

var2 =
    optimizableVariable with properties:

        Name: 'ivar'
        Range: [1 1000]
        Type: 'integer'
        Transform: 'log'
        Optimize: 1

Categorical variable of rainbow colors:

var3 = optimizableVariable('rvar',{'r' 'o' 'y' 'g' 'b' 'i' 'v'}, 'Type','categorical')

var3 =
    optimizableVariable with properties:

        Name: 'rvar'
        Range: {'r' 'o' 'y' 'g' 'b' 'i' 'v'}
        Type: 'categorical'
        Transform: 'none'
        Optimize: 1

Introduced in R2016b
ordinal

Arrays for ordinal data

**Note** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Description**

Ordinal data are discrete, nonnumeric values that have a natural ordering. `ordinal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `ordinal` arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use `ordinal` arrays as grouping variables when the elements indicate the group to which an observation belongs.

**Creation**

**Syntax**

```matlab
B = ordinal(X)
B = ordinal(X,labels)
B = ordinal(X,labels,levels)
B = ordinal(X,labels,[]),edges)
```

**Description**

`B = ordinal(X)` creates an ordinal array `B` from the array `X`. `ordinal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for the levels.

`B = ordinal(X,labels)` labels the levels in `B` according to `labels`. 
B = ordinal(X,labels,levels) creates an ordinal array with possible levels defined by levels.

B = ordinal(X,labels,[],edges) creates an ordinal array by binning the numeric array X with bin edges given by the numeric vector edges.

**Input Arguments**

**X — Input array**  
numeric | logical | character | string | categorical | cell array of character vectors  

Input array to convert to ordinal, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting ordinal array correspond to the sorted unique values in X.

**labels — Labels for discrete levels**  
character array | string array | cell array of character vectors  

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, ordinal assigns labels to the levels in B in order of the sorted unique values in X.

You can include duplicate labels in labels to merge multiple values in X into a single level in B.

Data Types: char | string | cell

**levels — Possible ordinal levels**  
vector  

Possible ordinal levels for the output ordinal array, specified as a vector whose values can be compared to those in X using the equality operator. ordinal assigns labels to each level from the corresponding elements of labels. If X contains any values not present in levels, the levels of the corresponding elements of B are undefined.

**edges — Bin edges**  
numeric vector  

Bin edges used to create the ordinal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. ordinal assigns labels to each level in the resulting ordinal array from the corresponding
elements of labels. When you specify the edges input argument, it must have one more element than labels.

**Output Arguments**

**B — Ordinal array**

ordinal array object

Ordinal array, returned as an ordinal array object.

By default, an element of B is undefined if the corresponding element of X is NaN (when X is numeric), an empty character vector (when X is a character), an empty or missing string (when X is a string), or undefined (when X is categorical). ordinal treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the levels input argument and include NaN, the empty character vector, the empty or missing string, or an undefined element.

**Properties**

**labels — Level labels**

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using getlabels.

Data Types: cell

**undeflabel — Label for undefined levels**

'〈undefined〉' (default)

This property is read-only.

Label for undefined levels, specified as '〈undefined〉'. You can find undefined elements in categorical arrays by using isundefined.
Object Functions
addlevels            Add levels to nominal or ordinal arrays
droplevels           Drop levels from a nominal or ordinal array
getlabels            Access nominal or ordinal array labels
getlevels            Access nominal or ordinal array levels
islevel              Determine if levels are in nominal or ordinal array
levelcounts          Element counts by level of a nominal or ordinal array
mergelevels          Merge levels of nominal or ordinal arrays
reorderlevels        Reorder levels of nominal or ordinal arrays
setlabels            Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with ordinal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.
double                Double-precision arrays
histogram             Histogram plot
isequal              Determine array equality
isundefined          Find undefined elements in categorical array
pie                  Pie chart
summary              Print summary of table, timetable, or categorical array
times                Element-wise multiplication

Examples

Create and Label Ordinal Arrays
Create an ordinal array from integer data, providing explicit labels.

quality = ordinal([1 2 3 3 2 1 2 1 3],...  
                 {'low' 'medium' 'high'})

quality = 1x9 ordinal array
Columns 1 through 7
     low    medium    high    high    medium    low    medium

Columns 8 through 9
     low    high
Show that the first element is less than the second element (low is less than medium).

\[ \text{quality}(1) < \text{quality}(2) \]

\[ \text{ans} = \text{logical} \]

Create an ordinal array by binning values between 0 and 1 into thirds with labels 'small', 'medium', and 'large'.

\[ X = \text{rand}(5,2) \]

\[ X = \begin{bmatrix} 0.8147 & 0.0975 \\ 0.9058 & 0.2785 \\ 0.1270 & 0.5469 \\ 0.9134 & 0.9575 \\ 0.6324 & 0.9649 \end{bmatrix} \]

\[ A = \text{ordinal}(X,\{'small', 'medium', 'large'\},[],[0 1/3 2/3 1]) \]

\[ A = \begin{bmatrix} \text{large} & \text{small} \\ \text{large} & \text{small} \\ \text{small} & \text{medium} \\ \text{large} & \text{large} \\ \text{medium} & \text{large} \end{bmatrix} \]

**Create and Manipulate Ordinal Arrays**

Create an ordinal array from integer data.

\[ \text{quality} = \text{ordinal}([1 2 3; 3 2 1; 2 1 3],\{'low', 'medium', 'high'\}) \]

\[ \text{quality} = \begin{bmatrix} \text{low} & \text{medium} & \text{high} \\ \text{high} & \text{medium} & \text{low} \\ \text{medium} & \text{low} & \text{high} \end{bmatrix} \]
Identify the elements in quality that are members of a level greater than or equal to 'medium'. A value of 1 in the resulting array indicates that the corresponding element of quality is a member of this level.

```matlab
quality >= 'medium'
ans = 3x3 logical array
     0   1   1
     1   1   0
     1   0   1
```

Identify the elements in quality that are members of either the level 'low' or 'high'.

```matlab
ismember(quality,{'low' 'high'})
ans = 3x3 logical array
     1   0   1
     1   0   1
     0   1   1
```

Merge the elements of the 'medium' and 'high' levels into a new level labeled 'ok'.

```matlab
quality = mergelevels(quality,{'medium','high'},'ok')
quality = 3x3 ordinal array
     low      ok      ok
     ok      ok      low
     ok      low      ok
```

Display the levels of quality.

```matlab
getlevels(quality)
ans = 1x2 ordinal array
     low      ok
```

Summarize the number of elements in each level. By default, summary returns counts for each column of the input array.

```matlab
summary(quality)
```

Introduced in R2007a
outlierMeasure

Class: CompactTreeBagger

Outlier measure for data

Syntax

out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)

Description

out = outlierMeasure(B,X) computes outlier measures for predictors X using trees in the ensemble B. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. outlierMeasure then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the 'Data' parameter.

out = outlierMeasure(B,X,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

'Data' Flag indicating how to treat the X input argument. If set to 'predictors' (default), the method assumes X is a matrix of predictors and uses it for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method. If you do not supply the proximity matrix, outlierMeasure computes it internally. If you use the proximity method to compute a proximity matrix, supplying it as input to outlierMeasure reduces computing time.
'Labels' Vector of true class labels. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in X.

proximity
**parallelcoords**

Parallel coordinates plot

**Syntax**

`parallelcoords(x)`  
`parallelcoords(x,Name,Value)`  
`parallelcoords(ax,___)`  
`h = parallelcoords(___)`

**Description**

`parallelcoords(x)` creates a parallel coordinates plot of the multivariate data in the matrix `x`. Use a parallel coordinates plot to visualize high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices.

`parallelcoords(x,Name,Value)` creates a parallel coordinates plot with additional options specified by one or more Name,Value pair arguments. For example, you can standardize the data in `x` or label the coordinate tick marks along the horizontal axis of the plot.

`parallelcoords(ax,___)` creates a parallel coordinates plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`h = parallelcoords(___)` returns a column vector of handles to the Line objects created by `parallelcoords`, with one handle for each row of `x`.

**Examples**
Parallel Coordinates Plot for Grouped Data

Load the Fisher iris sample data.

load fisheriris

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix meas contains all four measurements for each of 150 flowers. The cell array species contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

labels = {'Sepal Length','Sepal Width','Petal Length','Petal Width'};

Create a parallel coordinate plot using the measurement data in meas. Use a different color for each group as identified in species, and label the horizontal axis using the variable names.

parallelcoords(meas,'Group',species,'Labels',labels)
The resulting plot contains one line for each observation (flower). The color of each line indicates the flower species.

**Parallel Coordinates Plot with Quantile Values**

Load the Fisher iris sample data.

```matlab
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements.
for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```matlab
labels = {'Sepal Length','Sepal Width','Petal Length','Petal Width'};
```

Create a parallel coordinates plot using the measurement data in `meas`. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in `species`. Label the horizontal axis using the variable names.

```matlab
parallelcoords(meas,'group',species,'labels',labels,...
               'quantile',.25)
```
The plot shows the median values for each group as a solid line and the quartile values as dotted lines of the same color. For example, the solid blue line shows the median value measured for each variable on setosa irises. The dotted blue line below the solid blue line shows the 25th percentile of measurements for each variable on setosa irises. The dotted blue line above the solid blue line shows the 75th percentile of measurements for each variable on setosa irises.

Adjust Line Properties in Parallel Coordinates Plot

Load the Fisher iris sample data.

load fisheriris

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix meas contains all four measurements for each of 150 flowers. The cell array species contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

labels = {'Sepal Length','Sepal Width','Petal Length','Petal Width'};

Create a parallel coordinates plot using the measurement data in meas. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in species. Label the horizontal axis using the variable names. Set the line width to 2.

parallelcoords(meas,'group',species,'labels',labels,'quantile',.25,'LineWidth',2)
Specifying 'LineWidth' in this way sets the width of every line in the plot to 2.

Recreate the parallel coordinates plot, but this time, use handles to increase the width of only the line representing the median value for each measurement made on irises in the setosa group.

```matlab
h = parallelcoords(meas,'group',species,'labels',labels,...
    'quantile',.25)
```
h =
9x1 Line array:

Line (median)
Line (lower quantile)
Line (upper quantile)
Line (median)
Line (lower quantile)
Line (upper quantile)
Line (median)
Line (lower quantile)
Line (upper quantile)
The returned column vector `h` contains handles that correspond to each line object created by `parallelcoords`. For example, `h(1)` corresponds to the median line for the first grouping variable (setosa).

Use dot notation to increase the width of the line showing the median value for each measurement made on irises in the setosa group.

```matlab
h(1).LineWidth = 2;
```
Input Arguments

\( x \) — Multivariate input data
numeric matrix

Multivariate input data, specified as an \( n \)-by-\( p \) matrix of numeric values. \( n \) is the number of rows of \( x \), and each row corresponds to an observation in \( x \). \( p \) is the number of columns in \( x \), and each column corresponds to a variable in \( x \).

\texttt{parallelcoords} treats NaN values in \( x \) as missing values and does not plot those coordinate values.

Data Types: \texttt{single} | \texttt{double}

\( \text{ax} \) — Axes for plot
axes graphic object

Axes for plot, specified as an axes graphic object. If you do not specify \( \text{ax} \), then \texttt{parallelcoords} creates the plot using the current axis. For more information on creating an axes graphic object, see \texttt{axes} and \texttt{Axes}.

Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. \texttt{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

Example: \texttt{'}Group',species,'Quantile',.25\texttt{'} plots the median, 25 percent, and 75 percent quartile values for the input data, using a different color for each group identified in the variable \texttt{species}.

\textbf{Group} — Grouping variable for input data
numeric array | categorical variable | character matrix | string array | cell array

Grouping variable for input data, specified as the comma-separated pair consisting of \texttt{'}Group'} and a numeric array containing a group index for each observation. Alternatively, the array can be a categorical variable, character matrix, string array, or cell array containing a group name for each observation.

Data Types: \texttt{single} | \texttt{double} | \texttt{categorical} | \texttt{char} | \texttt{string} | \texttt{cell}
Labels — Horizontal axis labels
character array | string array | cell array

Horizontal axis labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, or cell array containing the label names.
Example: 'Labels',{'Sepal Width','Sepal Length'}
Data Types: char | string | cell

Quantile — Quantiles of input data to plot
numeric value in the range (0,1)

Quantiles of input data to plot, specified as the comma-separated pair consisting of 'Quantile' and a numeric value in the range (0,1). If you specify a value alpha for 'Quantile', then parallelcoords plots only the median, alpha, and 1 - alpha quantiles for each of the variables (columns) in x.

The quantile plot option provides a useful summary of the data when x contains many observations.
Example: 'Quantile',.25
Data Types: single | double

Standardize — Method to standardize input data
'on' | 'PCA' | 'PCAStd'

Method to standardize input data, specified as the comma-separated pair consisting of 'Standardize' and one of the following.

<table>
<thead>
<tr>
<th>'on'</th>
<th>Scale each column of x to have a mean equal to 0 and a standard deviation equal to 1 before plotting.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'PCA'</td>
<td>Create plot from the principal component scores of x, in order of decreasing eigenvalues. parallelcoords removes rows of x containing missing values (NaN) for PCA standardization.</td>
</tr>
<tr>
<td>'PCAStd'</td>
<td>Create plot using the standardized principal component scores.</td>
</tr>
</tbody>
</table>

Example: 'Standardize','on'
You can modify certain aspects of the plot lines by specifying a property name and value for any of the properties listed in Primitive Line. However, this approach applies the modification to all the lines in the plot. To modify only certain plot lines, use the syntax that returns graphics handles and use dot notation to adjust each line property individually. For an illustration, see “Adjust Line Properties in Parallel Coordinates Plot” on page 32-4596.

Output Arguments

h — Graphic handles for line objects
vector of Line graphic handles

Graphic handles for line objects, returned as a vector of Line graphic handles. Graphic handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

If you use the 'Quantile' name-value pair argument, then h contains one handle for each of the three lines objects created. If you use both the 'Quantile' and the 'Group' name-value pair arguments, then h contains three handles for each group.

Introduced before R2006a
paramci

Package: prob

Confidence intervals for probability distribution parameters

Syntax

ci = paramci(pd)
ci = paramci(pd,Name,Value)

Description

ci = paramci(pd) returns the array ci containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution pd.

ci = paramci(pd,Name,Value) returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

load examgrades
x = grades(:,1);

Fit a normal distribution object to the data.

pd = fitdist(x,'Normal')
pd =
    NormalDistribution

    Normal distribution
    mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

You can also obtain these intervals by using the function `paramci`.

```matlab
ci = paramci(pd)
ci = 2×2
     73.4321    7.7391
     76.5846    9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

### Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```matlab
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```matlab
pd = fitdist(x,'Normal')
pd =
    NormalDistribution

    Normal distribution
    mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```
Compute the 99% confidence interval for the distribution parameters.

\[ \text{ci} = \text{paramci}(\text{pd},'\text{Alpha}',.01) \]

\[ \text{ci} = \begin{bmatrix} 72.9245 & 7.4627 \\ 77.0922 & 10.4403 \end{bmatrix} \]

Column 1 of \text{ci} contains the lower and upper 99% confidence interval boundaries for the mu parameter, and column 2 contains the boundaries for the sigma parameter.

**Input Arguments**

- **pd** — Probability distribution
  
  Probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<table>
<thead>
<tr>
<th>Function or App</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makedist</td>
<td>Create a probability distribution object using specified parameter values.</td>
</tr>
<tr>
<td>fitdist</td>
<td>Fit a probability distribution object to sample data.</td>
</tr>
<tr>
<td><strong>Distribution Fitter</strong></td>
<td>Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.</td>
</tr>
</tbody>
</table>

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: 'Alpha',0.01 specifies a 99% confidence interval.
**Alpha — Confidence level**

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The confidence level of ci is \(100(1-\text{Alpha})\)%.

Example: 'Alpha',0.01

Data Types: single | double

**Parameter — Parameter list**

character vector | string array | cell array of character vectors

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of 'Parameter' and a character vector, string array, or cell array of character vectors containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: 'Parameter','mu'

Data Types: char | string | cell

**Type — Computation method**

'exact' | 'Wald' | 'lr'

Computation method for the confidence intervals, specified as the comma-separated pair consisting of 'Type' and 'exact', 'Wald', or 'lr'.

'exact' computes the confidence intervals using an exact method, and is available for the following distributions.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Computation Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binomial</td>
<td>Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.</td>
</tr>
<tr>
<td>Exponential</td>
<td>Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.</td>
</tr>
<tr>
<td>Distribution</td>
<td>Computation Method</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Normal</td>
<td>Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <em>paramci</em> uses the Wald method if <em>Type</em> is <em>exact</em>.</td>
</tr>
<tr>
<td>Lognormal</td>
<td>Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <em>paramci</em> uses the Wald method if <em>Type</em> is <em>exact</em>.</td>
</tr>
<tr>
<td>Poisson</td>
<td>Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.</td>
</tr>
<tr>
<td>Rayleigh</td>
<td>Computation method based on a chi-square distribution provides exact coverage probabilities.</td>
</tr>
</tbody>
</table>

*exact* is the default when it is available. Alternatively, you can specify *'Wald'* to compute the confidence intervals using the Wald method, or *'lr'* to compute the confidence intervals using the likelihood ratio method.

Example: *'Type','Wald'*

**LogFlag — Boolean flag for log scale**

*vector*

Boolean flag for the log scale, specified as the comma-separated pair consisting of *'LogFlag'* and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: *'LogFlag',[0,1]*

Data Types: *logical*
Output Arguments

**ci — Confidence interval array**

Confidence interval, returned as a $p$-by-2 array containing the lower and upper bounds of the $100(1-\text{Alpha})\%$ confidence interval for each distribution parameter. $p$ is the number of distribution parameters.

If you create pd by using `makedist` and specifying the distribution parameters, the lower and upper bounds are equal to the specified parameters.

**Introduced in R2013a**
parent

Class: classregtree

(Removed) Parent node

Note classregtree has been removed. Use fitctree, fitrtree, ClassificationTree, or RegressionTree instead.

Syntax

p = parent(t)
p = parent(t,nodes)

Description

p = parent(t) returns an n-element vector p containing the number of the parent node for each node in the tree t, where n is the number of nodes. The parent of the root node is 0.

p = parent(t,nodes) takes a vector nodes of node numbers and returns the parent nodes for the specified nodes.

paretotails

Piecewise distribution with Pareto tails

Description

A paretotails object is a piecewise distribution with generalized Pareto distributions (GPDs) in the tails.

A paretotails object consists of one or two GPDs in the tails and another distribution in the center. You can specify the distribution type for the center by using the cdffun argument of paretotails when you create an object. Valid values are 'ecdf', 'kernel', and a function handle.

paretotails fits a distribution of type cdffun to the observations (x) and finds the quantiles corresponding to the lower and upper tail cumulative probabilities (pl and pu, respectively). Then, paretotails fits two GPDs to the lower 100*pl percent of the observations and the upper 100*(1–pu) percent of the observations, respectively. If x does not have at least two distinct observations in a tail, then paretotails does not create the corresponding tail segment.

Use the object functions boundary, segment, upperparams, and lowerparams to find distribution characteristics. lowerparams and upperparams return the parameters of the GPDs in the tails. boundary returns the boundary points between piecewise distribution segments, segment returns the segment of a piecewise distribution containing input values, and nsegments returns the number of segments in an object.

Use the object functions cdf, icdf, pdf, and random to evaluate the distribution. These functions are wellsuited to copula and other Monte Carlo simulations. pdf returns the GPD density in the tails and the slope of the cumulative distribution function (cdf) in the center. These probability density function (pdf) values in the center are generally not good estimates of the underlying density of the original data.

Creation

Create a piecewise distribution object using paretotails.
Syntax

```matlab
pd = paretotails(x,pl,pu)
pd = paretotails(x,pl,pu,cdfun)
```

Description

`pd = paretotails(x,pl,pu)` returns the piecewise distribution object `pd`, which consists of the empirical distribution in the center and generalized Pareto distributions in the tails. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities `pl` and `pu`, respectively.

`pd = paretotails(x,pl,pu,cdfun)` specifies the type of center distribution segment using `cdfun`.

Input Arguments

`x` — Input data
numeric vector

Input data, specified as a numeric vector.
Data Types: double

`pl` — Lower tail cumulative probability
numeric scalar in the range [0,1]

Lower tail cumulative probability, specified as a numeric scalar in the range [0,1]. The quantile of `pl` is the boundary of the lower tail observations.

If `pl` is 0 or `x` does not have at least two distinct observations in the lower tail, then `paretotails` divides the input data in `x` into two groups, center and upper tail. In this case, the fitted piecewise distribution object `pd` consists of two segments: the empirical distribution in the center and GPD in the upper tail.

Example: 0.1
Data Types: single | double

`pu` — Upper tail cumulative probability
numeric scalar in the range [0,1]

...
Upper tail cumulative probability, specified as a numeric scalar in the range \([0, 1]\). The quantile of \(pu\) is the boundary of the upper tail observations.

If \(pu\) is 1 or \(x\) does not have at least two distinct observations in the upper tail, then \texttt{paretotails} divides the input data in \(x\) into two groups, center and lower tail. In this case, the fitted piecewise distribution object \(pd\) consists of two segments: the empirical distribution in the center and GPD in the lower tail.

Example: 0.9

Data Types: single | double

\textbf{\texttt{cdffun} — Type of center distribution segment}

Type of center distribution segment, specified as 'ecdf', 'kernel', or a function handle.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ecdf'</td>
<td>Interpolated empirical cdf. \texttt{paretotails} uses values in (x) as the midpoints in the vertical steps of the empirical cdf, and computes the estimates for the points between the values in (x) by linear interpolation. For details about how to find the interpolated empirical cdf, see A Piecewise Linear Nonparametric CDF Estimate.</td>
</tr>
<tr>
<td>'kernel'</td>
<td>Interpolated kernel smoothing estimate of the cdf. \texttt{paretotails} uses the \texttt{ksdensity} function to find cdf estimates for 100 points in the range of (x), and uses linear interpolation to compute the estimates for the points between the 100 points. 'kernel' is equivalent to specifying a function handle \texttt{fun = @(x)ksdensity(x,'function','cdf')};</td>
</tr>
</tbody>
</table>
Value | Description
-----|---------------------
function handle | Interpolated estimates using a specified function.

`paretotails` uses a handle to a function of the form `[p,xi] = fun(x)` that accepts the input data vector `x` and returns a vector `p` of cdf values and a vector `xi` of evaluation points. Values in `xi` must be sorted and distinct but do not have to equal the values in `x`. The `paretotails` function computes the cdf estimates for the points between the values in `xi` by linear interpolation.

`paretotails` uses `cdffun` to compute the quantiles corresponding to `pl` and `pu`.

Example: 'kernel'

**Properties**

**NumSegments — Number of segments**

```
3 | 2 | 1
```

This property is read-only.

Number of segments, including the center segment and tail segments in a `paretotail` object, specified as a scalar. `NumSegments` is 3, 2, or 1 if the number of the tail segments in the object is 2, 1, or 0, respectively.

Data Types: double

**LowerParameters — Lower tail GPD parameters**

```
numeric vector
```

This property is read-only.

Lower tail GPD parameters, fit to the lower extreme observations in `x`, specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the lower tail GPD is equal to the quantile of `pl`. Use the `boundary` function to return the location parameter. For example, run `[p,q] = boundary(pd)`, where `pd` is a `paretotails` object. `q(1)` is the location parameter.

Data Types: single | double
UpperParameters — Upper tail GPD parameters
numeric vector

This property is read-only.

Upper tail GPD parameters, fit to the upper extreme observations in x, specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the upper tail GPD is equal to the quantile of pu. Use the boundary function to return the location parameter. For example, run \([p,q] = \text{boundary}(pd)\), where pd is a paretotails object. q(2) is the location parameter.

Data Types: single | double

Object Functions

- boundary: Piecewise distribution boundaries
- cdf: Cumulative distribution function
- icdf: Inverse cumulative distribution function
- lowerparams: Lower Pareto tail parameters
- nsegments: Number of segments in piecewise distribution
- pdf: Probability density function
- random: Random numbers
- segment: Piecewise distribution segments containing input values
- upperparams: Upper Pareto tail parameters

Examples

Create paretotails with Empirical Distribution

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Specify an empirical distribution for the center by using paretotails with its default settings.

Generate a sample data set containing 100 random numbers from a \(t\) distribution with 3 degrees of freedom.

```matlab
rng('default');  % For reproducibility
t = trnd(3,100,1);
```
Create a `paretotails` object by fitting a piecewise distribution to `t`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```matlab
pd = paretotails(t,0.1,0.9)
```

```matlab
pd = 
  Piecewise distribution with 3 segments
  -Inf < x < -1.84875   (0 < p < 0.1): lower tail, GPD(0.183032,1.00347)
  -1.84875 < x < 2.07662  (0.1 < p < 0.9): interpolated empirical cdf
  2.07662 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.333239,1.19705)
```

Each line of the object display shows the summary of each segment, including the GPD parameters (shape and scale parameters) and the boundary values in the quantiles and cumulative probabilities. Use the object functions `boundary`, `lowerparams`, and `upperparams` to return these values.

You can use the `nsegments` function to return the number of segments and the `segment` function to return the segment that contains input values.

You can also use the distribution functions `cdf`, `icdf`, `pdf`, and `random` to evaluate the distribution and generate random samples.

Plot the cdf of the `t` distribution and the cdf of the `paretotails` object on the same figure.

```matlab
x = linspace(-5,5);
plot(x,tcdf(x,3),'r--')
hold on
plot(x,cdf(pd,x),'b-')
```

Find the boundary points between the segments of the `paretotails` object by using `boundary`, and mark the points on the figure.

```matlab
[p,q] = boundary(pd);
plot(q,p,'bo')
legend('t Distribution','Pareto Tails Object','Boundary Points','Location','best')
hold off
```
Create paretotails with Function Handle

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Fit a center segment by using paretotails with a function handle.

Generate a sample data set containing 20% outliers.

```matlab
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```
Define a function handle using ksdensity to specify a nondefault value of the bandwidth.

```matlab
myfun1 = @(x)ksdensity(x,'Bandwidth',.1,'Function','cdf');
```

Create a paretotails object by fitting a piecewise distribution with the specified kernel smoothing estimator to \( x \). Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the kernel estimator for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```matlab
pd1 = paretotails(x,0.1,0.9,myfun1)
```

```matlab
pd1 =
Piecewise distribution with 3 segments
-Inf < x < -1.35204    (0 < p < 0.1): lower tail, GPD(0.0104112,0.54947)
-1.35204 < x < 1.80824  (0.1 < p < 0.9): function: @(x)ksdensity(x,'Bandwidth',.1,'Function','cdf')
1.80824 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.227542,3.10586)
```

You can also use a parametric distribution for the center segment. Define a function that fits a normal distribution to data and returns the cdf values, and pass the function handle when you create a paretotails object.

```matlab
pd2 = paretotails(x,0.1,0.9,@myfun2)
```

```matlab
pd2 =
Piecewise distribution with 3 segments
-Inf < x < -2.70875    (0 < p < 0.1): lower tail, GPD(-0.358104,0.831855)
-2.70875 < x < 3.52195  (0.1 < p < 0.9): function: myfun2
3.52195 < x < Inf    (0.9 < p < 1): upper tail, GPD(-0.0661815,5.04694)
```

```matlab
function [p,xi] = myfun2(x)
    pd = fitdist(x,'Normal');
    xi = linspace(min(x),max(x),length(x)*2);
    p = cdf(pd,xi);
end
```

Introduced in R2007a
**partialcorr**

Linear or rank partial correlation coefficients

**Syntax**

```matlab
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr(___,Name,Value)
[rho,pval] = partialcorr(___)```

**Description**

`rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr(___,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr(___)` also returns a matrix `pval` of `p`-values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

**Examples**

32-4619
**Compute Partial Correlation Coefficients**

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```matlab
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```matlab
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient’s gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```matlab
rho = partialcorr(x)
rho = 4x4
```

```
1.0000  -0.0105   0.0273   0.9421
-0.0105   1.0000   0.0419   0.0369
 0.0273   0.0419   1.0000   0.0451
 0.9421   0.0369   0.0451   1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the $P$-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```matlab
rho = array2table(rho, ...
    'VariableNames',
    {'SexID','Age','Smoker','Weight'},...
    'RowNames',
    {'SexID','Age','Smoker','Weight'});
```

```matlab
disp('Partial Correlation Coefficients')
Partial Correlation Coefficients
```

```matlab
disp(rho)
```
Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the genders in hospital.Sex to numeric group identifiers.

```matlab
code
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```matlab
code
x = [hospital.Age hospital.BloodPressure];
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The x matrix contains the variables to test for partial correlation. The z matrix contains the variables to control for. The measurements for BloodPressure are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. partialcorr treats each column as a separate variable.

Test for partial correlation between pairs of variables in x, while controlling for the effects of the variables in z. Compute the correlation coefficients.

```matlab
code
[rho,pval] = partialcorr(x,z)
rho = 3x3
```

\[
\begin{array}{ccc}
1.0000 & 0.1300 & 0.0462 \\
0.1300 & 1.0000 & 0.0012 \\
0.0462 & 0.0012 & 1.0000 \\
\end{array}
\]
The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{'Age','BPTop','BPBottom'},...  
    'RowNames',{'Age','BPTop','BPBottom'});

pval = array2table(pval, ...  
    'VariableNames',{'Age','BPTop','BPBottom'},...  
    'RowNames',{'Age','BPTop','BPBottom'});

disp('Partial Correlation Coefficients')  

Partial Correlation Coefficients  

disp(rho)

```
```
   Age        BPTop      BPBottom
   ______    _________    _________
   Age                1         0.13     0.046202
   BPTop           0.13            1    0.0012475
   BPBottom    0.046202    0.0012475            1

```
```
disp('p-values')
p-values

disp(pval)
```
```
   Age       BPTop     BPBottom
   ______    _______    ________
   Age               0    0.20438    0.65316
   BPTop       0.20438          0    0.99032
   BPBottom    0.65316    0.99032          0
```
**Test for Paired Partial Correlation Coefficients**

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the genders in hospital.Sex to numeric group identifiers.

```matlab
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```matlab
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in x (the systolic and diastolic blood pressure measurements) and y (weight and age), while controlling for the variables in z (gender and smoking status). The measurements for BloodPressure are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in x and y, while controlling for the effects of the variables in z. Compute the correlation coefficients.

```matlab
[rho,pval] = partialcorr(x,y,z)
```

```
rho = 2×2
     -0.0257    0.1289
       0.0292    0.0472

pval = 2×2
       0.8018    0.2058
       0.7756    0.6442
```
The results in pval indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient’s blood pressure measurements and that patient’s weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```matlab
rho = array2table(rho, ...  'RowNames',{'BPTop','BPBottom'},...  'VariableNames',{'Weight','Age'});
pval = array2table(pval, ...  'RowNames',{'BPTop','BPBottom'},...  'VariableNames',{'Weight','Age'});
disp('Partial Correlation Coefficients')
Partial Correlation Coefficients
disp(rho)
    Weight  Age
   __________    ________
     BPTop  -0.02568     0.12893
     BPBottom 0.029168    0.047226
disp('p-values')
p-values
disp(pval)
    Weight  Age
   __________    _______
     BPTop      0.80182     0.2058
     BPBottom 0.77556    0.64424
```

**One-Tailed Partial Correlation Test**

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.
Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```matlab
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```matlab
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```matlab
[rho,pval] = partialcorr(x,y,z,'Tail','right')
```

```plaintext
rho = 2x2
     -0.0257  0.1289
      0.0292  0.0472

pval = 2x2
     0.5991  0.1029
     0.3878  0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```matlab
rho = array2table(rho,
     'RowNames',{'BPTop','BPBottom'},
     'VariableNames',{'Weight','Age'});
pval = array2table(pval, ...
    'RowNames',{'BPTop','BPBottom'},...
    'VariableNames',{'Weight','Age'});

**Input Arguments**

**x — Data matrix**
matrix

Data matrix, specified as an \( n \)-by-\( p_x \) matrix. The rows of \( x \) correspond to observations, and the columns correspond to variables.

Data Types: single | double

**y — Data matrix**
matrix

Data matrix, specified as an \( n \)-by-\( p_y \) matrix. The rows of \( y \) correspond to observations, and the columns correspond to variables.
Data Types: single | double

**z — Data matrix**

matrix

Data matrix, specified as an $n$-by-$p_z$ matrix. The rows of $z$ correspond to observations, and columns correspond to variables.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside quotes. You can specify several name and value pair arguments in any order as *Name1*,*Value1*,...,*NameN*,*ValueN*.

Example: *'Type','Spearman','Rows','complete'* computes Spearman partial correlations using only the data in rows that contain no missing values.

**Type — Type of partial correlations**

*Pearson* (default) | *Spearman*

Type of partial correlations to compute, specified as the comma-separated pair consisting of *'Type'* and one of the following.

- *'Pearson'* Compute Pearson (linear) partial correlations.
- *'Spearman'* Compute Spearman (rank) partial correlations.

Example: *'Type','Spearman'*

**Rows — Rows to use in computation**

*all* (default) | *complete* | *pairwise*

Rows to use in computation, specified as the comma-separated pair consisting of *'Rows'* and one of the following.

- *'all'* Use all rows of the input regardless of missing values (NaNs).
- *'complete'* Use only rows of the input with no missing values.
'pairwise'

Compute \( \rho(i,j) \) using rows with no missing values in column \( i \) or \( j \).

Example: 'Rows','complete'

**Tail — Alternative hypothesis**

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'
Test the alternative hypothesis that the correlation is not 0.

'right'
Test the alternative hypothesis that the correlation is greater than 0.

'left'
Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail','right'

**Output Arguments**

**rho — Sample linear partial correlation coefficients**

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an \( x \) matrix, \( \rho \) is a symmetric \( p_x \)-by-\( p_x \) matrix. The \((i,j)\)th entry is the sample linear partial correlation between the \( i \)-th and \( j \)-th columns in \( x \).
- If you input \( x \) and \( z \) matrices, \( \rho \) is a symmetric \( p_x \)-by-\( p_x \) matrix. The \((i,j)\)th entry is the sample linear partial correlation between the \( i \)-th and \( j \)-th columns in \( x \), controlled for the variables in \( z \).
- If you input \( x \), \( y \), and \( z \) matrices, \( \rho \) is a \( p_x \)-by-\( p_y \) matrix, where the \((i,j)\)th entry is the sample linear partial correlation between the \( i \)-th column in \( x \) and the \( j \)-th column in \( y \), controlled for the variables in \( z \).

If the covariance matrix of \([x,z]\) is

\[
S = \begin{pmatrix}
S_{xx} & S_{xz} \\
S_{xz}^T & S_{zz}
\end{pmatrix},
\]
then the partial correlation matrix of \( x \), controlling for \( z \), can be defined formally as a normalized version of the covariance matrix: \( S_{xx} - (S_{xz}S_{zz}^{-1}S_{zx}^T) \).

\[ pval \text{ — } p-values \]

\( p \)-values, returned as a matrix. Each element of \( pval \) is the \( p \)-value for the corresponding element of \( \rho \).

If \( pval(i,j) \) is small, then the corresponding partial correlation \( \rho(i,j) \) is statistically significantly different from 0.

\( \text{partialcorr} \) computes \( p \)-values for linear and rank partial correlations using a Student's \( t \) distribution for a transformation of the correlation. This is exact for linear partial correlation when \( x \) and \( z \) are normal, but is a large-sample approximation otherwise.

**See Also**

\( \text{corr} \mid \text{corrcoef} \mid \text{partialcorri} \mid \text{tiedrank} \)

**Introduced before R2006a**
**partialcorri**

Partial correlation coefficients adjusted for internal variables

**Syntax**

\[
\begin{align*}
\text{rho} &= \text{partialcorri}(y,x) \\
\text{rho} &= \text{partialcorri}(y,x,z) \\
\text{rho} &= \text{partialcorri}([\_\_],[\_\_,\_\_,\_\_]) \\
[\text{rho},pval] &= \text{partialcorri}(\_\_)
\end{align*}
\]

**Description**

\(\text{rho} = \text{partialcorri}(y,x)\) returns the sample linear partial correlation coefficients between pairs of variables in \(y\) and \(x\), adjusting for the remaining variables in \(x\).

\(\text{rho} = \text{partialcorri}(y,x,z)\) returns the sample linear partial correlation coefficients between pairs of variables in \(y\) and \(x\), adjusting for the remaining variables in \(x\), after first controlling both \(x\) and \(y\) for the variables in \(z\).

\(\text{rho} = \text{partialcorri}([\_\_],[\_\_,\_\_,\_\_,\_\_,\_\_,\_\_,\_\_])\) returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

\([\text{rho},pval] = \text{partialcorri}(\_\_}\) also returns a matrix \(pval\) of \(p\)-values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

**Examples**
Compute Partial Correlation Coefficients

Compute partial correlation coefficients for each pair of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x.

Load the sample data.

```matlab
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables.

```matlab
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```matlab
rho = partialcorri(y,x,'Rows','complete')
rho = 2×3
    -0.0537   -0.1520   -0.4856
    -0.3994   -0.4008    0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the p-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```matlab
rho = array2table(rho, ...
    'VariableNames',
    {'Displacement','Horsepower','Weight'}, ...
    'RowNames',
    {'MPG','Acceleration'});

disp('Partial Correlation Coefficients')
```
Partial Correlation Coefficients

disp(rho)

<table>
<thead>
<tr>
<th>Displacement</th>
<th>Horsepower</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPG</td>
<td>-0.053684</td>
<td>-0.15199</td>
</tr>
<tr>
<td>Acceleration</td>
<td>-0.39941</td>
<td>-0.40075</td>
</tr>
</tbody>
</table>

Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z.

Load the sample data.

load carsmall;

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Create a new variable Headwind, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

rng('default'); % For reproducibility
Headwind = (10:-0.2:-9.8)’ + 5*randn(100,1);

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
z = Headwind;
```
Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

[rho,pval] = partialcorri(y,x,z,'Rows','complete')

rho = 2×3

0.0572   -0.1055   -0.5736
-0.3845   -0.3966    0.4674

pval = 2×3

0.5923    0.3221    0.0000
0.0002    0.0001    0.0000

The small returned P-value of 0.001 in pval indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

rho = array2table(rho, ...  
  'VariableNames',{'Displacement','Horsepower','Weight'}, ...  
  'RowNames',{'MPG','Acceleration'});
pval = array2table(pval, ...  
  'VariableNames',{'Displacement','Horsepower','Weight'}, ...  
  'RowNames',{'MPG','Acceleration'});

**Input Arguments**

**x — Data matrix**

matrix

Data matrix, specified as an \(n\)-by-\(p_x\) matrix. The rows of \(x\) correspond to observations, and the columns correspond to variables.

Data Types: single | double

**y — Data matrix**

matrix

Data matrix, specified as an \(n\)-by-\(p_y\) matrix. The rows of \(y\) correspond to observations, and the columns correspond to variables.

Data Types: single | double

**z — Data matrix**

matrix

Data matrix, specified as an \(n\)-by-\(p_z\) matrix. The rows of \(z\) correspond to observations, and the columns correspond to variables.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.
Example: 'Type','Spearman','Rows','complete' computes Spearman partial
correlations using only the data in rows that contain no missing values.

**Type — Type of partial correlations**

| 'Pearson' (default) | 'Spearman' |

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and either 'Pearson' or 'Spearman'. *Pearson* computes the Pearson (linear) partial correlations. *Spearman* computes the Spearman (rank) partial correlations.

Example: 'Type','Spearman'

**Rows — Rows to use in computation**

| 'all' (default) | 'complete' | 'pairwise' |

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

- 'all': Use all rows regardless of missing (NaN) values.
- 'complete': Use only rows with no missing values.
- 'pairwise': Use all available values in each column of $y$ when computing the partial correlation coefficients and $p$-values corresponding to that column. For each column of $y$, rows will be dropped corresponding to missing values in $x$ (and/or $z$, if supplied). However, remaining rows with valid values in that column of $y$ are used, even if there are missing values in other columns of $y$.

Example: 'Rows','complete'

**Tail — Alternative hypothesis**

| 'both' (default) | 'right' | 'left' |

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'both': Test the alternative hypothesis that the correlation is not zero.
'right'  
Test the alternative hypothesis that the correlation is greater than 0.

'left'  
Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

Output Arguments

rho — Sample linear partial correlation coefficients
matrix

Sample linear partial correlation coefficients, returned as a \( p_y \)-by-\( p_x \) matrix.

- If you input \( x \) and \( y \) matrices, the \((i,j)\)th entry is the sample linear partial correlation between the \(i\)th column in \( y \) and the \(j\)th column in \( x \), controlled for all the columns of \( x \) except column \( j \).
- If you input \( x \), \( y \), and \( z \) matrices, the \((i,j)\)th entry is the sample linear partial correlation between the \(i\)th column in \( y \) and the \(j\)th column in \( x \), adjusted for all the columns of \( x \) except column \( j \), after first controlling both \( x \) and \( y \) for the variables in \( z \).

pval — \( p \)-values
matrix

\( p \)-values, returned as a matrix. Each element of \( pval \) is the \( p \)-value for the corresponding element of \( rho \). If \( pval(i,j) \) is small, then the corresponding partial correlation \( rho(i,j) \) is statistically significantly different from zero.

partialcorri computes \( p \)-values for linear and rank partial correlations using a Student's \( t \) distribution for a transformation of the correlation. This is exact for linear partial correlation when \( x \) and \( z \) are normal, but is a large-sample approximation otherwise.

Introduced in R2013b
**pca**

Principal component analysis of raw data

**Syntax**

```matlab
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca(__)
[coeff,score,latent,tsquared] = pca(__)
[coeff,score,latent,tsquared,explained,mu] = pca(__)
```

**Description**

`coeff = pca(X)` returns the principal component coefficients, also known as loadings, for the \( n \)-by-\( p \) data matrix \( X \). Rows of \( X \) correspond to observations and columns correspond to variables. The coefficient matrix is \( p \)-by-\( p \). Each column of \( coeff \) contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

```matlab
[coeff,score,latent] = pca(__) also returns the principal component scores in score and the principal component variances in latent. You can use any of the input arguments in the previous syntaxes.
```

Principal component scores are the representations of \( X \) in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of \( X \).
[coeff, score, latent, tsquared] = pca(___) also returns the Hotelling's T-squared statistic for each observation in X.

[coeff, score, latent, tsquared, explained, mu] = pca(___) also returns explained, the percentage of the total variance explained by each principal component and mu, the estimated mean of each variable in X.

Examples

Principal Components of a Data Set

Load the sample data set.

load hald

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

coeff = pca(ingredients)

coeff = 4×4

-0.0678   -0.6460    0.5673    0.5062
-0.6785   -0.0200   -0.5440    0.4933
 0.0290    0.7553    0.4036    0.5156
 0.7309   -0.1085   -0.4684    0.4844

The rows of coeff contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

PCA in the Presence of Missing Data

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

load imports-85
Data matrix $X$ has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.

```matlab
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the `'Rows','complete'` name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use `'pairwise'` to perform the principal component analysis.

```matlab
coeff = pca(X(:,3:15),'Rows','pairwise');
```

In this case, `pca` computes the $(i,j)$ element of the covariance matrix using the rows with no NaN values in the columns $i$ or $j$ of $X$. Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to `'eig'`. If you require `'svd'` as the algorithm, with the `'pairwise'` option, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues.

If you use the `'Rows','all'` name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```matlab
coeff = pca(X(:,3:15),'Rows','all');
```

Error using pca (line 180)
Raw data contains NaN missing value while 'Rows' option is set to 'all'. Consider using

**Weighted PCA**

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```matlab
load hald
```
Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```matlab
[wcoeff,~,latent,~,explained] = pca(ingredients,...
'VariableWeights','variance')
```

```
wcoeff = 4x4

-2.7998  2.9940  -3.9736   1.4180
-8.7743 -6.4411   4.8927  9.9863
 2.5240 -3.8749  -4.0845  1.7196
 9.1714  7.5529   3.2710 11.3273
```

```
latent = 4x1

2.2357
1.5761
0.1866
0.0016
```

```
explained = 4x1

55.8926
39.4017
 4.6652
 0.0406
```

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```matlab
coefforth = inv(diag(std(ingredients))) * wcoeff
```

```
coefforth = 4x4

-0.4760  0.5090  -0.6755   0.2411
-0.5639  -0.4139   0.3144  0.6418
 0.3941  -0.6050  -0.6377  0.2685
 0.5479   0.4512   0.1954  0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`. 
PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

load hald

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

[coeff, score, latent, tsquared, explained] = pca(ingredients);
coeff

coeff = 4×4

[-0.0678   -0.6460    0.5673    0.5062]
[-0.6785   -0.0200   -0.5440    0.4933]
[0.0290    0.7553    0.4036    0.5156]
[0.7309   -0.1085   -0.4684    0.4844]

Introduce missing values randomly.

y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```matlab
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
    'algorithm','als');
coeff1
```

```
coeff1 = 4×4
        -0.0362    0.8215   -0.5252    0.2190
     -0.6831   -0.0998    0.1828    0.6999
        0.0169    0.5575    0.8215   -0.1185
        0.7292   -0.0657    0.1261    0.6694
```

Display the estimated mean.

```matlab
mu1
```

```
mu1 = 1×4
         8.9956    47.9088    9.0451    28.5515
```

Reconstruct the observed data.

```matlab
t = score1*coeff1' + repmat(mu1,13,1)
```
The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```matlab
subspace(coeff,coeff1)
ans = 3.9965e-16
```

This is a small value. It indicates that the results if you use `pca` with 'Rows','complete' name-value pair argument when there is no missing data and if you use `pca` with 'algorithm','als' name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using 'Rows','complete' name-value pair argument and display the component coefficients.

```matlab
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
coeff2 = 4×3
-0.2054 0.8587 0.0492
-0.6694 -0.3720 0.5510
0.1474 -0.3513 -0.5187
0.6986 -0.0298 0.6518
```
In this case, pca removes the rows with missing values, and y has only four rows with no missing values. pca returns only three principal components. You cannot use the 'Rows','pairwise' option because the covariance matrix is not positive semidefinite and pca returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when 'Rows','complete').

\[
\text{subspace(coeff(:,1:3),coeff2)}
\]

\[
\text{ans} = 0.3576
\]

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

\[
\text{mu2}
\]

\[
\text{mu2} = 1\times4
\]

\[
\begin{array}{cccc}
7.8889 & 46.9091 & 9.8750 & 29.6000 \\
\end{array}
\]

In this case, the mean is just the sample mean of y.

Reconstruct the observed data.

\[
\text{score2*coeff2}'
\]

\[
\text{ans} = 13\times4
\]

\[
\begin{array}{cccc}
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
-7.5162 & -18.3545 & 4.0968 & 22.0056 \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
-0.5644 & 5.3213 & -3.3432 & 3.6040 \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
\text{NaN} & \text{NaN} & \text{NaN} & \text{NaN} \\
12.8315 & -0.1076 & -6.3333 & -3.7758 \\
\end{array}
\]
This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

**Principal Component Coefficients, Scores, and Variances**

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```matlab
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```matlab
[coeff,score,latent] = pca(ingredients)
```

```matlab
coeff = 4×4

-0.0678   -0.6460    0.5673    0.5062
-0.6785   -0.0200   -0.5440    0.4933
 0.0290    0.7553    0.4036    0.5156
 0.7309   -0.1085   -0.4684    0.4844

score = 13×4

36.8218   -6.8709   -4.5909    0.3967
29.6073    4.6109   -2.2476   -0.3958
-12.9818   -4.2049    0.9022   -1.1261
23.7147   -6.6341    1.8547   -0.3786
-0.5532   -4.4617   -6.0874    0.1424
-10.8125   -3.6466    0.9130   -0.1350
-32.5882    8.9798   -1.6063    0.0818
22.6064   10.7259    3.2365    0.3243
-9.2626    8.9854   -0.0169   -0.5437
-3.2840   -14.1573    7.0465    0.3405
```

```matlab
latent = 4×1

pca 32-4645
```
Each column of \texttt{score} corresponds to one principal component. The vector, \texttt{latent}, stores the variances of the four principal components.

Reconstruct the centered ingredients data.

\texttt{Xcentered} = \texttt{score*coeff'}

\texttt{Xcentered} = 13\times4

\begin{verbatim}
-0.4615  -22.1538  -5.7692  30.0000
-6.4615  -19.1538   3.2308  22.0000
 3.5385   7.8462  -3.7692 -10.0000
 3.5385  -17.1538  -3.7692  17.0000
-0.4615   3.8462  -5.7692   3.0000
 3.5385   6.8462  -2.7692  -8.0000
-4.4615  22.8462   5.2308 -24.0000
-6.4615  -17.1538  10.2308  14.0000
-5.4615   5.8462   6.2308   8.0000
13.5385  -1.1538  -7.7692  -4.0000
\vdots
\end{verbatim}

The new data in \texttt{Xcentered} is the original ingredients data centered by subtracting the column means from corresponding columns.

Visualize both the orthonormal principal component coefficients for each variable and the principal component scores for each observation in a single plot.

\texttt{biplot(coeff(:,1:2),'scores',score(:,1:2),'varlabels',
{'v_1','v_2','v_3','v_4'})};
All four variables are represented in this biplot by a vector, and the direction and length of the vector indicate how each variable contributes to the two principal components in the plot. For example, the first principal component, which is on the horizontal axis, has positive coefficients for the third and fourth variables. Therefore, vectors $v_3$ and $v_4$ are directed into the right half of the plot. The largest coefficient in the first principal component is the fourth, corresponding to the variable $v_4$.

The second principal component, which is on the vertical axis, has negative coefficients for the variables $v_1$, $v_2$, and $v_4$, and a positive coefficient for the variable $v_3$. 
This 2-D biplot also includes a point for each of the 13 observations, with coordinates indicating the score of each observation for the two principal components in the plot. For example, points near the left edge of the plot have the lowest scores for the first principal component. The points are scaled with respect to the maximum score value and maximum coefficient length, so only their relative locations can be determined from the plot.

**T-Squared Statistic**

Find the Hotelling’s T-squared statistic values.

Load the sample data set.

```matlab
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```matlab
[coeff,score,latent,tsquared] = pca(ingredients);
tsquared
```

```
tsquared = 13×1
    5.6803
    3.0758
    6.0002
    2.6198
    3.3681

    3.4818
    3.9794
    2.6086
    7.4818
    ⋮
```

Request only the first two principal components and compute the T-squared values in the reduced space of requested principal components.

```matlab
[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);
tsquared
```
tsquared = 13×1

5.6803
3.0758
6.0002
2.6198
3.3681
0.5668
3.4818
3.9794
2.6086
7.4818

:  

Note that even when you specify a reduced component space, pca computes the T-squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.

tsquared = mahal(score,score)

tsqreduced = 13×1

3.179
2.0079
0.5874
1.7382
0.2955
0.4228
3.2457
2.6914
1.3619
2.9903

:  

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.

tsqdiscarded = tsquared - tsqreduced

tsqdiscarded = 13×1
Percent Variability Explained by Principal Components

Find the percent variability explained by the principal components. Show the data representation in the principal components space.

Load the sample data set.

```
load imports-85
```

Data matrix $X$ has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff, score, latent, tsquared, explained] = pca(X(:,3:15));
```

```
explained
```

```
explained = 13x1

64.3429
35.4484
0.1550
0.0379
0.0078
0.0048
0.0013
0.0011
```
The first three components explain 99.95% of all variability.

Visualize the data representation in the space of the first three principal components.

```matlab
scatter3(score(:,1),score(:,2),score(:,3))
axis equal
xlabel('1st Principal Component')
ylabel('2nd Principal Component')
zlabel('3rd Principal Component')
```
The data shows the largest variability along the first principal component axis. This is the largest possible variance among all possible choices of the first axis. The variability along the second principal component axis is the largest among all possible remaining choices of the second axis. The third principal component axis has the third largest variability, which is significantly smaller than the variability along the second principal component axis. The fourth through thirteenth principal component axes are not worth inspecting, because they explain only 0.05% of all variability in the data.

To skip any of the outputs, you can use ~ instead in the corresponding element. For example, if you don’t want to get the T-squared values, specify

```matlab
[coeff, score, latent, ~, explained] = pca(X(:,3:15));
```

### Input Arguments

**X — Input data**

matrix

Input data for which to compute the principal components, specified as an \( n \)-by-\( p \) matrix. Rows of \( X \) correspond to observations and columns to variables.

Data Types: `single` | `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```matlab
'Algorithm','eig','Centered',false,'Rows','all','NumComponents',3
```

specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

**Algorithm — Principal component algorithm**

'svd' (default) | 'eig' | 'als'
Principal component algorithm that pca uses to perform the principal component analysis, specified as the comma-separated pair consisting of 'Algorithm' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'svd'</td>
<td>Default. Singular value decomposition (SVD) of X.</td>
</tr>
<tr>
<td>'eig'</td>
<td>Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, n, exceeds the number of variables, p, but is less accurate because the condition number of the covariance is the square of the condition number of X.</td>
</tr>
<tr>
<td>'als'</td>
<td>Alternating least squares (ALS) algorithm. This algorithm finds the best rank-k approximation by factoring X into a n-by-k left factor matrix, L, and a p-by-k right factor matrix, R, where k is the number of principal components. The factorization uses an iterative method starting with random initial values. ALS is designed to better handle missing values. It is preferable to pairwise deletion ('Rows', 'pairwise') and deals with missing values without listwise deletion ('Rows', 'complete'). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.</td>
</tr>
</tbody>
</table>

Example: 'Algorithm','eig'

**Centered — Indicator for centering columns**

true (default) | false

Indicator for centering the columns, specified as the comma-separated pair consisting of 'Centered' and one of these logical expressions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Default. pca centers X by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If X contains NaN missing values, nanmean is used to find the mean with any available data. You can reconstruct the centered data using score*coeff'.</td>
</tr>
<tr>
<td>false</td>
<td>In this case pca does not center the data. You can reconstruct the original data using score*coeff'.</td>
</tr>
</tbody>
</table>

Example: 'Centered',false
**Data Types:** logical

**Economy — Indicator for economy size output**

- true (default) | false

Indicator for the economy size output when the degrees of freedom, \( d \), is smaller than the number of variables, \( p \), specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Default. ( \text{pca} ) returns only the first ( d ) elements of ( \text{latent} ) and the corresponding columns of ( \text{coeff} ) and ( \text{score} ). This option can be significantly faster when the number of variables ( p ) is much larger than ( d ).</td>
</tr>
<tr>
<td>false</td>
<td>( \text{pca} ) returns all elements of ( \text{latent} ). The columns of ( \text{coeff} ) and ( \text{score} ) corresponding to zero elements in ( \text{latent} ) are zeros.</td>
</tr>
</tbody>
</table>

Note that when \( d < p \), \( \text{score}(::,d+1:p) \) and \( \text{latent}(d+1:p) \) are necessarily zero, and the columns of \( \text{coeff}(::,d+1:p) \) define directions that are orthogonal to \( X \).

Example: 'Economy',false

**Data Types:** logical

**NumComponents — Number of components requested**

- number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer \( k \) satisfying \( 0 < k \leq p \), where \( p \) is the number of original variables in \( X \). When specified, \( \text{pca} \) returns the first \( k \) columns of \( \text{coeff} \) and \( \text{score} \).

Example: 'NumComponents',3

**Data Types:** single | double

**Rows — Action to take for NaN values**

- 'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix \( X \), specified as the comma-separated pair consisting of 'Rows' and one of the following.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'complete'</td>
<td>Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into score and tsquared at the corresponding locations.</td>
</tr>
<tr>
<td>'pairwise'</td>
<td>This option only applies when the algorithm is 'eig'. If you don’t specify the algorithm along with 'pairwise', then pca sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows','pairwise', then pca returns a warning message, sets the algorithm to 'eig' and continues. When you specify the 'Rows','pairwise' option, pca computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of X. Note that the resulting covariance matrix might not be positive definite. In that case, pca terminates with an error message.</td>
</tr>
<tr>
<td>'all'</td>
<td>X is expected to have no missing values. pca uses all of the data and terminates if any NaN value is found.</td>
</tr>
</tbody>
</table>

Example: 'Rows','pairwise'

**Weights — Observation weights**

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n containing all positive elements.

Data Types: single | double

**VariableWeights — Variable weights**

row vector | 'variance'

Variable weights on page 32-4659, specified as the comma-separated pair consisting of 'VariableWeights' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row vector</td>
<td>Vector of length p containing all positive elements.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'variance'</td>
<td>The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights', then the variable weights become the inverse of weighted sample variance. If 'Centered' is set to true at the same time, the data matrix X is centered and standardized. In this case, pca returns the principal components based on the correlation matrix.</td>
</tr>
</tbody>
</table>

Example: 'VariableWeights','variance'

Data Types: single | double | char | string

**Coeff0 — Initial value for coefficients**

matrix of random values (default) | p-by-k matrix

Initial value for the coefficient matrix coeff, specified as the comma-separated pair consisting of 'Coeff0' and a p-by-k matrix, where p is the number of variables, and k is the number of principal components requested.

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

**Score0 — Initial value for scores**

matrix of random values (default) | k-by-m matrix

Initial value for scores matrix score, specified as a comma-separated pair consisting of 'Score0' and an n-by-k matrix, where n is the number of observations and k is the number of principal components requested.

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

**Options — Options for iterations**

structure
Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Display'</td>
<td>Level of display output. Choices are 'off', 'final', and 'iter'.</td>
</tr>
<tr>
<td>'MaxIter'</td>
<td>Maximum number steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.</td>
</tr>
<tr>
<td>'TolFun'</td>
<td>Positive number giving the termination tolerance for the cost function. The default is 1e-6.</td>
</tr>
<tr>
<td>'TolX'</td>
<td>Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.</td>
</tr>
</tbody>
</table>

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

Example: `opt = statset('pca'); opt.MaxIter = 2000; coeff = pca(X,'Options',opt);`

Data Types: `struct`

**Output Arguments**

**coeff** — Principal component coefficients
matrix

Principal component coefficients, returned as a p-by-p matrix. Each column of coeff contains coefficients for one principal component. The columns are in the order of descending component variance, `latent`.

**score** — Principal component scores
matrix
Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

`latent — Principal component variances`

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of X, returned as a column vector.

`tSquared — Hotelling’s T-squared statistic`

column vector

“Hotelling’s T-Squared Statistic” on page 32-4658, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

`explained — Percentage of total variance explained`

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

`mu — Estimated means`

row vector

Estimated means of the variables in X, returned as a row vector when `Centered` is set to `true`. When `Centered` is `false`, the software does not compute the means and returns a vector of zeros.

**Definitions**

**Hotelling’s T-Squared Statistic**

Hotelling’s T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic (computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:
• For the T-squared statistic in the reduced space, use mahal(score, score).
• For the T-squared statistic in the discarded space, first compute the T-squared statistic using
  \[\text{[coeff, score, latent, tsquared]} = \text{pca}(X, 'NumComponents', k, ...),\]
  compute the T-squared statistic in the reduced space using
  \[\text{tsqreduced} = \text{mahal}(\text{score}, \text{score}),\]
  and then take the difference: \(\text{tsquared} - \text{tsqreduced}\).

**Degrees of Freedom**

The degrees of freedom, \(d\), is equal to \(n - 1\), if data is centered and \(n\) otherwise, where:

• \(n\) is the number of rows without any NaNs if you use 'Rows', 'complete'.
• \(n\) is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use 'Rows', 'pairwise'.

**Variable Weights**

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called \(\text{varwei}\), and the principal component coefficients vector \(\text{pca}\) returned is \(\text{wcoeff}\). You can then calculate the orthonormal coefficients using the transformation

\[\text{diag}(\sqrt{\text{varwei}}) \ast \text{wcoeff}.\]

**References**

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- pca works directly with tall arrays by computing the covariance matrix and using the in-memory pcacov function to compute the principle components.
- Supported syntaxes are:
  - coeff = pca(X)
  - [coeff, score, latent] = pca(X)
  - [coeff, score, latent, explained] = pca(X)
  - [coeff, score, latent, tsquared] = pca(X)
  - [coeff, score, latent, tsquared, explained] = pca(X)
- Name-value pair arguments are not supported.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
- When 'Algorithm' is 'als', the 'Display' value for 'Options' is ignored.
- If supplied, 'Weights' and 'VariableWeights' must be real.
- The generated code always returns the fifth output explained as a column vector.
- The generated code always returns the sixth output mu as a row vector.
- If mu is empty, pca returns mu as a 1-by-0 array. pca does not convert mu to a 0-by-0 empty array.
- The generated code does not treat an input matrix X that has all NaN values as a special case. The output dimensions are commensurate with corresponding finite inputs.

Introduced in R2012b
pcacov

Principal component analysis on covariance matrix

Syntax

COEFF = pcacov(V)
[COEFF,latent] = pcacov(V)
[COEFF,latent,explained] = pcacov(V)

Description

COEFF = pcacov(V) performs principal components analysis on the p-by-p covariance matrix V and returns the principal component coefficients, also known as loadings. COEFF is a p-by-p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

pcacov does not standardize V to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix $R = V ./ (SD * SD')$, where $SD = \sqrt{\text{diag}(V)}$, in place of V. To perform principal components analysis directly on the data matrix, use pca.

[COEFF,latent] = pcacov(V) returns latent, a vector containing the principal component variances, that is, the eigenvalues of V.

[COEFF,latent,explained] = pcacov(V) returns explained, a vector containing the percentage of the total variance explained by each principal component.

Examples

load hald
covx = cov(ingredients);
[COEFF,latent,explained] = pcacov(covx)
COEFF =
  0.0678 -0.6460  0.5673 -0.5062
  0.6785 -0.0200 -0.5440 -0.4933
-0.0290  0.7553  0.4036 -0.5156
-0.7309 -0.1085 -0.4684 -0.4844

latent =
  517.7969
  67.4964
  12.4054
  0.2372

explained =

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

pcacov and factoran do not work directly on tall arrays. Instead, use C = gather(cov(X)) to compute the covariance matrix of a tall array. Then, you can use pcacov or factoran on the in-memory covariance matrix. Alternatively, you can use pca directly on a tall array.
For more information, see “Tall Arrays” (MATLAB).

pcares

Residuals from principal component analysis

Syntax

residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)

Description

residuals = pcares(X,ndim) returns the residuals obtained by retaining ndim principal components of the n-by-p matrix X. Rows of X correspond to observations, columns to variables. ndim is a scalar and must be less than or equal to p. residuals is a matrix of the same size as X. Use the data matrix, not the covariance matrix, with this function.

pcares does not normalize the columns of X. To perform the principal components analysis based on standardized variables, that is, based on correlations, use pcares(zscore(X), ndim). You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using pcacov.

[residuals,reconstructed] = pcares(X,ndim) returns the reconstructed observations; that is, the approximation to X obtained by retaining its first ndim principal components.

Examples

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);
\( r_{11} = r_1(1,:) \)
\[
\begin{bmatrix}
2.0350 & 2.8304 & -6.8378 & 3.0879
\end{bmatrix}
\]

\( r_{21} = r_2(1,:) \)
\[
\begin{bmatrix}
-2.4037 & 2.6930 & -1.6482 & 2.3425
\end{bmatrix}
\]

\( r_{31} = r_3(1,:) \)
\[
\begin{bmatrix}
0.2008 & 0.1957 & 0.2045 & 0.1921
\end{bmatrix}
\]

**Introduced before R2006a**
ppca

Probabilistic principal component analysis

Syntax

[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca(__)
[coeff,score,pcvar,mu,v,S] = ppca(__)

Description

[coeff,score,pcvar] = ppca(Y,K) returns the principal component coefficients for the n-by-p data matrix Y based on a probabilistic principal component analysis on page 32-4676 (PPCA). It also returns the principal component scores, which are the representations of Y in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of Y, in pcvar.

Each column of coeff contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of score correspond to observations, and columns correspond to components. Rows of Y correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

[coeff,score,pcvar] = ppca(Y,K,Name,Value) returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more Name,Value pair arguments.

For example, you can introduce initial values for the residual variance, v, or change the termination criteria.
[coeff,score,pcvar,mu] = ppca(__) also returns the estimated mean of each variable in Y. You can use any of the input arguments in the previous syntaxes.

[coeff,score,pcvar,mu,v,S] = ppca(__) also returns the isotropic residual variance in v and the final results at convergence in structure S.

Examples

Perform Probabilistic Principal Component Analysis

Load the sample data.

load fisheriris

The double matrix meas consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;

Now, approximately 20% of the data is missing, indicated by NaN.

Perform probabilistic principal component analysis and request the component coefficients and variances.

[coeff,score,pcvar,mu] = ppca(y,3);
coeff

coeff = 4x3

0.3562 0.6709 -0.5518
-0.0765 0.7120 0.6332
0.8592 -0.1597 0.0596
0.3592 -0.1318 0.5395

pcvar
pcvar = 3×1
    4.0914
    0.2125
    0.0617

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',... 'NumComponents',3);
coeff2
coeff2 = 4×3
    0.3376    0.4952    0.7406
   -0.0731    0.8609   -0.4476
    0.8657   -0.1168   -0.1233
    0.3623   -0.0086   -0.4857

pcvar2
pcvar2 = 3×1
    4.0733
    0.2652
    0.1222

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

subspace(coeff,coeff2)
ans = 0.0884

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.
Change the Termination Criteria for Probabilistic Principal Component Analysis

Load the sample data set.

load imports-85

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

[coeff,score,pcvar] = ppca(X(:,3:15),3);

Warning: Maximum number of iterations 1000 reached.

Change the termination tolerance for the cost function to 0.01.

opt = statset('ppca');
opt.TolFun = 0.01;

Perform probabilistic principal component analysis.

[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);

Warning: Maximum number of iterations 1000 reached.

ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

Reconstruct Observations

Load the sample data.

load hald
y = ingredients;

The ingredients data has 13 observations for 4 variables.
Introduce missing values to the data.

\[ y(2:16:end) = \text{NaN}; \]

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

\[
[\text{coeff}, \text{score}, \text{pcvar}, \text{mu}, v, S] = \text{ppca}(y, 3);
\]

Warning: Maximum number of iterations 1000 reached.

S.Recon

\[
\begin{array}{cccc}
6.8536 & 25.8700 & 5.8389 & 59.8730 \\
1.0433 & 28.9710 & 14.9654 & 51.9738 \\
11.5770 & 56.5067 & 8.6352 & 20.5076 \\
11.0835 & 31.0722 & 8.0920 & 47.0748 \\
7.0679 & 52.2556 & 6.0748 & 33.0598 \\
11.0486 & 55.0430 & 9.0534 & 22.0423 \\
2.8493 & 70.8691 & 16.8339 & 5.8656 \\
1.0333 & 31.0281 & 19.6907 & 44.0306 \\
2.0400 & 54.0354 & 18.0440 & 22.0349 \\
20.7822 & 46.8091 & 3.7603 & 25.8081 \\
\end{array}
\]

\[ \vdots \]

You can also reconstruct the observations using the principal components and the estimated mean.

\[ t = \text{score} \ast \text{coeff'} + \text{repmat(mu,13,1)}; \]

**Results at Convergence**

Load the data.

load hald

Here, ingredients is a real-valued matrix of predictor variables.
Perform the probabilistic principal components analysis and display coefficients.

```matlab
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
```

Warning: Maximum number of iterations 1000 reached.

coeff

coeff = 4x3

```
-0.0693  -0.6459   0.5673
-0.6786  -0.0184  -0.5440
 0.0308   0.7552   0.4036
 0.7306  -0.1102  -0.4684
```

Display the algorithm results at convergence of the PPCA.

S

```matlab
S = struct with fields:
    W: [4x3 double]
    Xexp: [13x3 double]
    Recon: [13x4 double]
    v: 0.2372
    NumIter: 1000
    RMSResid: 0.2340
    nloglk: 149.3388
```

Display the matrix W.

S.W

```matlab
ans = 4x3
```

```
 0.5624   2.0279   5.4075
 4.8320  -10.3894  5.9202
-3.7521  -3.0555  -4.1552
-1.5144  11.7122  -7.2564
```

Orthogonalizing W recovers the coefficients.

```matlab
orth(S.W)
```
ans = 4×3
   -0.0693    0.6459    0.5673
   -0.6786    0.0184   -0.5440
    0.0308   -0.7552    0.4036
    0.7306    0.1102   -0.4684

**Input Arguments**

**Y — Input data**

*n-by*-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of *Y* correspond to observations and columns correspond to variables.

Data Types: single | double

**K — Number of principal components**

Positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is min(*n*,*p*), where *n* is the number of observations and *p* is the number of variables. However, if the data is correlated, the rank might be smaller than min(*n*,*p*).

**ppca** orders the components based on their variance.

If K is min(*n*,*p*), **ppca** sets *K* equal to min(*n*,*p*) - 1, and 'W0' is truncated to min(*p*,*n*) - 1 columns if you specify a *p*-by-*p* W0 matrix.

For example, you can request only the first three components, based on the component variance as follows.

Example: `coeff = ppca(Y,3)`

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes.
You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'W0',init,'Options',opt specifies that the initial values for 'W0' are in matrix init and pPCA uses the options defined by opt.

**W0 — Initial value of W**
matrix of random values (default) | p-by-k matrix

Initial value of W in the probabilistic principal component analysis on page 32-4676 algorithm, specified as a comma-separated pair consisting of 'W0' and a p-by-k matrix.

Data Types: single | double

**v0 — Initial value of residual variance**
random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of 'v0' and a positive scalar value.

Data Types: single | double

**Options — Options for iterations**
structure

Options for the iterations, specified as a comma-separated pair 'Options' and a structure created by the statset function. pPCA uses the following fields in the options structure.

<table>
<thead>
<tr>
<th>'Display'</th>
<th>Level of display output. Choices are 'off', 'final', and 'iter'.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'MaxIter'</td>
<td>Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.</td>
</tr>
<tr>
<td>'TolFun'</td>
<td>Positive integer stating the termination tolerance for the cost function. The default is 1e-6.</td>
</tr>
<tr>
<td>'TolX'</td>
<td>Positive integer stating the convergence threshold for the relative change in the elements of W. The default is 1e-6.</td>
</tr>
</tbody>
</table>

You can change the values of these fields and specify the new structure in pPCA using the 'Options' name-value pair argument.
Example: `opt = statset('ppca'); opt.MaxIter = 2000; coeff = pPCA(Y, 3,'Options',opt);`

Data Types: `struct`

### Output Arguments

- **coeff** — **Principal component coefficients**
  
  `p`-by-`k` matrix

  Principal component coefficients, returned as a `p`-by-`k` matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `pcvar`.

- **score** — **Principal component scores**
  
  `n`-by-`k` matrix

  Principal component scores, returned as an `n`-by-`k` matrix. Rows of `score` correspond to observations, and columns correspond to components.

- **pcvar** — **Principal component variances**
  
  column vector

  Principal component variances, which are the eigenvalues of the covariance matrix of `Y`, returned as a column vector.

- **mu** — **Estimated mean**
  
  row vector

  Estimated mean of each variable in `Y`, returned as a row vector.

- **v** — **Isotropic residual variance**
  
  scalar value

  Isotropic residual variance, returned as a scalar value.

- **S** — **Final results at convergence**
  
  structure

  Final results at convergence, returned as a structure containing the following fields.
\( W \)  |  \( W \) at convergence.
---|---
Xexp | Conditional expectation of the estimated latent variable \( x \).
Recon | Reconstructed observations using \( k \) principal components. This is a low dimension approximation of the input data \( Y \), and is equal to \( \mu + \text{score} \times \text{coeff}' \).
\( \nu \) | Residual variance.
RMSResid | Root mean square of residuals.
NumIter | Number of iteration counts.
nloglk | Negative loglikelihood function value.

### Definitions

#### Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a \( p \)-dimensional observation vector \( y \) to a corresponding \( k \)-dimensional vector of latent (or unobserved) variable \( x \), which is normal with mean zero and covariance \( I(k) \). The relationship is

\[
y^T = W \times x^T + \mu + \varepsilon,
\]

where \( y \) is the row vector of observed variable, \( x \) is the row vector of latent variables, and \( \varepsilon \) is the isotropic error term. \( \varepsilon \) is Gaussian with mean zero and covariance of \( \nu \times I(k) \), where \( \nu \) is the residual variance. Here, \( k \) needs to be smaller than the rank for the residual variance to be greater than 0 (\( \nu > 0 \)). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, \( y \), are conditionally independent given the values of the latent variables, \( x \). So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular \( y \). The \( p \)-by-\( k \) matrix \( W \) relates the latent and observation variables, and the vector \( \mu \) permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.
Under this model,

\[ y \sim N(\mu, W^T W + \nu I(k)) \]

There is no closed-form analytical solution for \( W \) and \( \nu \), so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of \( W \) spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of \( W \).

**Introduced in R2013a**
pdf

Package: prob

Probability density function

Syntax

\[ y = pdf('name',x,A) \]
\[ y = pdf('name',x,A,B) \]
\[ y = pdf('name',x,A,B,C) \]
\[ y = pdf('name',x,A,B,C,D) \]
\[ y = pdf(pd,x) \]

Description

\[ y = pdf('name',x,A) \] returns the probability density function (pdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the values in \( x \).

\[ y = pdf('name',x,A,B) \] returns the pdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the values in \( x \).

\[ y = pdf('name',x,A,B,C) \] returns the pdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in \( x \).

\[ y = pdf('name',x,A,B,C,D) \] returns the pdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the values in \( x \).

\[ y = pdf(pd,x) \] returns the pdf of the probability distribution object pd, evaluated at the values in \( x \).
Examples

Compute the Normal Distribution pdf

Create a standard normal distribution object with the mean $\mu$ equal to 0 and the standard deviation $\sigma$ equal to 1.

```matlab
mu = 0;
sigma = 1;
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector $x$ to contain the values at which to calculate the pdf.

```matlab
x = [-2 -1 0 1 2];
```

Compute the pdf values for the standard normal distribution at the values in $x$.

```matlab
y = pdf(pd,x)
y = 1x5
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Each value in $y$ corresponds to a value in the input vector $x$. For example, at the value $x$ equal to 1, the corresponding pdf value $y$ is equal to 0.2420.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a standard normal distribution using the same parameter values for $\mu$ and $\sigma$.

```matlab
y2 = pdf('Normal',x,mu,sigma)
y2 = 1x5
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The pdf values are the same as those computed using the probability distribution object.
Compute the Poisson Distribution pdf

Create a Poisson distribution object with the rate parameter, $\lambda$, equal to 2.

```matlab
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector `x` to contain the values at which to calculate the pdf.

```matlab
x = [0 1 2 3 4];
```

Compute the pdf values for the Poisson distribution at the values in `x`.

```matlab
y = pdf(pd,x)
y = 1x5
    0.1353    0.2707    0.2707    0.1804    0.0902
```

Each value in `y` corresponds to a value in the input vector `x`. For example, at the value `x` equal to 3, the corresponding pdf value in `y` is equal to 0.1804.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a Poisson distribution using the same value for the rate parameter, $\lambda$.

```matlab
y2 = pdf('Poisson',x,lambda)
y2 = 1x5
    0.1353    0.2707    0.2707    0.1804    0.0902
```

The pdf values are the same as those computed using the probability distribution object.

Plot the pdf of a Standard Normal Distribution

Create a standard normal distribution object.

```matlab
pd = makedist('Normal')
```
pd =
    NormalDistribution

    Normal distribution
    mu = 0
    sigma = 1

Specify the x values and compute the pdf.

x = -3:.1:3;
pdf_normal = pdf(pd,x);

Plot the pdf.

plot(x,pdf_normal,'LineWidth',2)
Plot the pdf of a Weibull Distribution

Create a Weibull probability distribution object.

```matlab
pd = makedist('Weibull','a',5,'b',2)

pd =
    WeibullDistribution

    Weibull distribution
      A = 5
      B = 2
```
Specify the x values and compute the pdf.

```matlab
x = 0:.1:15;
y = pdf(pd,x);

Plot the pdf.

plot(x,y,'LineWidth',2)
```
# Input Arguments

'\textit{name}' — Probability distribution name  
character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

Example: 'Normal'

**x — Values at which to evaluate pdf**

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value, or an array of scalar values.

If one or more of the input arguments x, A, B, C, and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs.

Example: [-1, 0, 3, 4]

Data Types: single | double

**A — First probability distribution parameter**

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x, A, B, C, and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs.
Data Types: single | double

**B — Second probability distribution parameter**
scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments $x$, $A$, $B$, $C$, and $D$ are arrays, then the array sizes must be the same. In this case, $pdf$ expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**C — Third probability distribution parameter**
scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments $x$, $A$, $B$, $C$, and $D$ are arrays, then the array sizes must be the same. In this case, $pdf$ expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**D — Fourth probability distribution parameter**
scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments $x$, $A$, $B$, $C$, and $D$ are arrays, then the array sizes must be the same. In this case, $pdf$ expands each scalar input into a constant array of the same size as the array inputs.

Data Types: single | double

**pd — Probability distribution**
probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.
<table>

</tr>
</tbody>
</table>

Output Arguments

\( y \) — pdf values

scalar value | array of scalar values

pdf values, returned as a scalar value or an array of scalar values. \( y \) is the same size as \( x \) after any necessary scalar expansion. Each element in \( y \) is the pdf value of the distribution, specified by the corresponding elements in the distribution parameters (A, B, C, and D) or specified by the probability distribution object (pd), evaluated at the corresponding element in \( x \).

Alternative Functionality

- pdf is a generic function that accepts either a distribution by its name 'name' or a probability distribution object pd. It is faster to use a distribution-specific function, such as normpdf for the normal distribution and binopdf for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-16.
- Use the Probability Distribution Function app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.
Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include coder.Constant('Normal') in the -args value of codegen.
- Code generation does not support the probability distribution object (pd) input argument.

Introduced before R2006a
**pdf**

Probability density function for Gaussian mixture distribution

**Syntax**

```matlab
y = pdf(gm,X)
```

**Description**

$y = \text{pdf}(gm,X)$ returns the probability density function (pdf) of the Gaussian mixture distribution $gm$, evaluated at the values in $X$.

**Examples**

**Compute pdf Values**

Create a `gmdistribution` object and compute its pdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```matlab
mu = [1 2; -3 -5];
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```matlab
gm = gmdistribution(mu,sigma)
gm =
```

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean: 1 2
Component 2:
Mixing proportion: 0.500000
Mean:  -3   -5

Compute the pdf values of gm.

\[
X = \begin{bmatrix} 0 & 0; 1 & 2; 3 & 3; 5 & 3 \end{bmatrix};
\]

\[
\text{pdf(gm,X)}
\]

\[
\begin{array}{c}
0.0065 \\
0.0796 \\
0.0065 \\
0.0000
\end{array}
\]

**Plot pdf**

Create a `gmdistribution` object and plot its pdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

\[
p = \begin{bmatrix} 0.4 & 0.6 \end{bmatrix}; \quad \% \text{ Mixing proportions}
\]
\[
\text{mu} = \begin{bmatrix} 1 & 2; -3 & -5 \end{bmatrix}; \quad \% \text{ Means}
\]
\[
\text{sigma} = \text{cat}(3,[2 \ 0.5],[1 \ 1]) \quad \% \text{ Covariances 1-by-2-by-2 array}
\]

\[
sigma =
\begin{array}{c}
sigma(:,:,1) = \\
2.0000 0.5000
\end{array}
\]

\[
sigma(:,:,2) =
\begin{array}{c}
1 1
\end{array}
\]

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,:)` contains the diagonal elements of the covariance matrix of component i.
Create a gmdistribution object by using the gmdistribution function.

```matlab
gm = gmdistribution(mu,sigma)
```

```
gm =
Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean: 1 2

Component 2:
Mixing proportion: 0.500000
Mean: -3 -5

Plot the pdf of the Gaussian mixture distribution by using ezsurf.

```matlab
ezsurf(@(x,y)pdf(gm,[x y]),[-10 10],[-10 10])
```
Input Arguments

**gm — Gaussian mixture distribution**

*gm* is a `gmdistribution` object.

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the...
distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

**X — Values at which to evaluate pdf**

*n*-by-*m* numeric matrix

Values at which to evaluate the pdf, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

Data Types: `single` | `double`

### Output Arguments

**y — pdf values**

*n*-by-1 numeric vector

Pdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

The `pdf` function computes the pdf values by using the likelihood of each component given each observation and the component probabilities.

\[
y(i) = \sum_{j=1}^{k} L(C_j \mid O_i) P(C_j),
\]

where \( L(C_j \mid O_i) \) is the likelihood of component \( j \) given observation \( i \), and \( P(C_j) \) is the probability of component \( j \). The `pdf` function computes the likelihood term by using the multivariate normal pdf of the \( j \)th Gaussian mixture component evaluated at observation \( i \). The component probabilities are the mixing proportions of mixture components, the `ComponentProportion` property of `gm`.

Introduced in R2007b
pdist

Pairwise distance between pairs of observations

Syntax

D = pdist(X)
D = pdist(X,Distance)
D = pdist(X,Distance,DistParameter)

Description

D = pdist(X) returns the Euclidean distance between pairs of observations in X.

D = pdist(X,Distance) returns the distance by using the method specified by Distance.

D = pdist(X,Distance,DistParameter) returns the distance by using the method specified by Distance and DistParameter. You can specify DistParameter only when Distance is 'seuclidean', 'minkowski', or 'mahalanobis'.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using squareform.

Create a matrix with three observations and two variables.

rng('default') % For reproducibility
X = rand(3,2);

Compute the Euclidean distance.

D = pdist(X)
D = 1×3
    0.2954  1.0670  0.9448

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations i and j by using squareform.

Z = squareform(D)
Z = 3×3
    0   0.2954  1.0670
    0.2954   0   0.9448
    1.0670  0.9448   0

squareform returns a symmetric matrix where Z(i,j) corresponds to the pairwise distance between observations i and j. For example, you can find the distance between observations 2 and 3.

Z(2,3)
ans = 0.9448

Pass Z to the squareform function to reproduce the output of the pdist function.

y = squareform(Z)
y = 1×3
    0.2954  1.0670  0.9448

The outputs y from squareform and D from pdist are the same.

**Compute Minkowski Distance**

Create a matrix with three observations and two variables.

rng('default') % For reproducibility
X = rand(3,2);
Compute the Minkowski distance with the default exponent 2.

\[ D1 = \text{pdist}(X,'\text{minkowski}') \]

\[
D1 = 1\times3 \\
0.2954 \quad 1.0670 \quad 0.9448 
\]

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.

\[ D2 = \text{pdist}(X,'\text{minkowski}',1) \]

\[
D2 = 1\times3 \\
0.3721 \quad 1.5036 \quad 1.3136 
\]

\[ D3 = \text{pdist}(X,'\text{cityblock}') \]

\[
D3 = 1\times3 \\
0.3721 \quad 1.5036 \quad 1.3136 
\]

**Compute Pairwise Distance with Missing Elements Using a Custom Distance Function**

Define a custom distance function that ignores coordinates with \texttt{NaN} values, and compute pairwise distance by using the custom distance function.

Create a matrix with three observations and two variables.

\[
\text{rng('default')} \quad \% \ \text{For reproducibility} \\
X = \text{rand}(3,2); 
\]

Assume that the first element of the first observation is missing.

\[ X(1,1) = \text{NaN}; \]

Compute the Euclidean distance.
D1 = pdist(X)

D1 =

    NaN    NaN    0.9448

If observation i or j contains NaN values, the function pdist returns NaN for the pairwise distance between i and j. Therefore, D1(1) and D1(2), the pairwise distances (2,1) and (3,1), are NaN values.

Define a custom distance function naneucdist that ignores coordinates with NaN values and returns the Euclidean distance.

```matlab
function D2 = naneucdist(XI,XJ)
    %NANEUCDIST Euclidean distance ignoring coordinates with NaNs
    n = size(XI,2);
    sqdx = (XI-XJ).^2;
    nstar = sum(~isnan(sqdx),2); % Number of pairs that do not contain NaNs
    nstar(nstar == 0) = NaN; % To return NaN if all pairs include NaNs
    D2squared = nansum(sqdx,2).*n./nstar; % Correction for missing coordinates
    D2 = sqrt(D2squared);
end
```

Compute the distance with naneucdist by passing the function handle as an input argument of pdist.

D2 = pdist(X,@naneucdist)

D2 =

    0.3974    1.1538    0.9448

Input Arguments

X — Input data
numeric matrix
Input data, specified as a numeric matrix of size $m$-by-$n$. Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

**Distance — Distance metric**  
character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance (default).</td>
</tr>
<tr>
<td>'squaredeuclidean'</td>
<td>Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use DistParameter to specify another value for $S$.</td>
</tr>

| @distfun | Custom distance function handle. A distance function has the form  

```matlab
function D2 = distfun(ZI,ZJ)
    % calculation of distance
    ...
end
```

where  

- ZI is a 1-by-n vector containing a single observation.  
- ZJ is an m2-by-n matrix containing multiple observations. distfun must accept a matrix ZJ with an arbitrary number of observations.  
- D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).  

If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For definitions, see “Distance Metrics” on page 32-4703.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument DistParameter to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of DistParameter.

Example: 'minkowski'

**DistParameter — Distance metric parameter values**

<table>
<thead>
<tr>
<th>positive scalar</th>
<th>numeric vector</th>
<th>numeric matrix</th>
</tr>
</thead>
</table>

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify Distance as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If Distance is 'seuclidean', DistParameter is a vector of scaling factors for each dimension, specified as a positive vector. The default value is nanstd(X).
• If Distance is 'minkowski', DistParameter is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.
• If Distance is 'mahalanobis', DistParameter is a covariance matrix, specified as a numeric matrix. The default value is nan cov(X). DistParameter must be symmetric and positive definite.

Example: 'minkowski', 3

Data Types: single | double

Output Arguments

D — Pairwise distances
numeric row vector

Pairwise distances, returned as a numeric row vector of length \(m(m-1)/2\), corresponding to pairs of observations, where \(m\) is the number of observations in \(X\).

The distances are arranged in the order \((2,1), (3,1), \ldots, (m,1), (3,2), \ldots, (m,2), \ldots, (m,m-1)\), i.e., the lower-left triangle of the \(m\)-by-\(m\) distance matrix in column order. The pairwise distance between observations \(i\) and \(j\) is in \(D((i-1)*(m-i/2)+j-i)\) for \(i\leq j\).

You can convert \(D\) into a symmetric matrix by using the squareform function. \(Z =\) squareform\(D\) returns an \(m\)-by-\(m\) matrix where \(Z(i,j)\) corresponds to the pairwise distance between observations \(i\) and \(j\).

If observation \(i\) or \(j\) contains NaNs, then the corresponding value in \(D\) is NaN for the built-in distance functions.

\(D\) is commonly used as a dissimilarity matrix in clustering or multidimensional scaling. For details, see “Hierarchical Clustering” on page 16-4 and the function reference pages for cmdscale, cophenet, linkage, mdscale, and optimalleaforder. These functions take \(D\) as an input argument.

Definitions

Distance Metrics

A distance metric is a function that defines a distance between two observations. pdist supports various distance metrics: Euclidean distance, standardized Euclidean distance,
Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an $m$-by-$n$ data matrix $X$, which is treated as $m$ (1-by-$n$) row vectors $x_1, x_2, ..., x_m$, the various distances between the vector $x_s$ and $x_t$ are defined as follows:

- **Euclidean distance**
  \[ d_{st}^2 = (x_s - x_t)(x_s - x_t)' \]
  The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- **Standardized Euclidean distance**
  \[ d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)' \]
  where $V$ is the $n$-by-$n$ diagonal matrix whose $j$th diagonal element is $(S(j))^2$, where $S$ is a vector of scaling factors for each dimension.

- **Mahalanobis distance**
  \[ d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)' \]
  where $C$ is the covariance matrix.

- **City block distance**
  \[ d_{st} = \sum_{j=1}^{n} |x_{sj} - x_{tj}| \]
  The city block distance is a special case of the Minkowski distance, where $p = 1$.

- **Minkowski distance**
  \[ d_{st} = \left( \sum_{j=1}^{n} |x_{sj} - x_{tj}|^p \right)^{\frac{1}{p}} \]
For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- **Chebychev distance**
  
  $$d_{st} = \max_j \left\{ |x_{sj} - x_{tj}| \right\}.$$  

  The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- **Cosine distance**
  
  $$d_{st} = 1 - \frac{x_s x'_t}{\sqrt{(x_s x'_s)(x_t x'_t)}}.$$  

- **Correlation distance**
  
  $$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'(x_t - \bar{x}_t)(x_t - \bar{x}_t)'}},$$  

  where

  $$\bar{x}_s = \frac{1}{n} \sum x_{sj} \quad \text{and} \quad \bar{x}_t = \frac{1}{n} \sum x_{tj}.$$  

- **Hamming distance**

  $$d_{st} = \frac{\#(x_{sj} \neq x_{tj})}{n}.$$  

- **Jaccard distance**
  
  $$d_{st} = \frac{\# \left[ (x_{sj} \neq x_{tj}) \cap \left( (x_{sj} \neq 0) \cup (x_{tj} \neq 0) \right) \right]}{\# \left[ (x_{sj} \neq 0) \cup (x_{tj} \neq 0) \right]}.$$  

- **Spearman distance**
\[ d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}} \]

where

- \( r_{sj} \) is the rank of \( x_{sj} \) taken over \( x_{1j}, x_{2j}, \ldots, x_{mj} \), as computed by \texttt{tiedrank}.
- \( r_s \) and \( r_t \) are the coordinate-wise rank vectors of \( x_s \) and \( x_t \), i.e., \( r_s = (r_{s1}, r_{s2}, \ldots, r_{sn}) \).
- 
\[
\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}.
\]
- 
\[
\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}.
\]

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The distance input argument value (\texttt{Distance}) must be a compile-time constant. For example, to use the Minkowski distance, include \texttt{coder.Constant('Minkowski')} in the \texttt{-args} value of \texttt{codegen}.
- The distance input argument value (\texttt{Distance}) cannot be a custom distance function.
- For code generation, \texttt{pdist} uses \texttt{parfor} (by default) to create loops that run in parallel on supported shared-memory multicore platforms. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the \texttt{parfor}-loops as \texttt{for}-loops. To find supported compilers, see \url{https://www.mathworks.com/support/compilers/current_release/}. To disable OpenMP library, specify the \texttt{EnableOpenMP} property of the \texttt{codegen} configuration object as \texttt{false}. For details, see \texttt{coder.CodeConfig}.
GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

• The Distance argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“Introduction to Cluster Analysis” on page 16-2
“Hierarchical Clustering” on page 16-4

Introduced before R2006a
pdist2

Pairwise distance between two sets of observations

Syntax

D = pdist2(X,Y,Distance)

D = pdist2(X,Y,Distance,DistParameter)

D = pdist2(___,Name,Value)

[D,I] = pdist2(___,Name,Value)

Description

D = pdist2(X,Y,Distance) returns the distance between each pair of observations in X and Y using the metric specified by Distance.

D = pdist2(X,Y,Distance,DistParameter) returns the distance using the metric specified by Distance and DistParameter. You can specify DistParameter only when Distance is 'seuclidean', 'minkowski', or 'mahalanobis'.

D = pdist2(___,Name,Value) specifies an additional option using one of the name-value pair arguments 'Smallest' or 'Largest' in addition to any of the arguments in the previous syntaxes.

For example,

- D = pdist2(X,Y,Distance,'Smallest',K) computes the distance using the metric specified by Distance and returns the K smallest pairwise distances to observations in X for each observation in Y in ascending order.
- D = pdist2(X,Y,Distance,DistParameter,'Largest',K) computes the distance using the metric specified by Distance and DistParameter and returns the K largest pairwise distances in descending order.
[D,I] = pdist2(___,Name,Value) also returns the matrix I using any of the arguments in the previous syntaxes. The matrix I contains the indices of the observations in X corresponding to the distances in D.

Examples

Compute Euclidean Distance

Create two matrices with three observations and two variables.

rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);

Compute the Euclidean distance. The default value of the input argument Distance is 'euclidean'. When computing the Euclidean distance without using a name-value pair argument, you do not need to specify Distance.

D = pdist2(X,Y)
D = 3×3

0.5387    0.8018    0.1538
0.7100    0.5951    0.3422
0.8805    0.4242    1.2050

D(i,j) corresponds to the pairwise distance between observation i in X and observation j in Y.

Compute Minkowski Distance

Create two matrices with three observations and two variables.

rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);

Compute the Minkowski distance with the default exponent 2.
D1 = pdist2(X,Y,'minkowski')
D1 = 3×3
    0.5387    0.8018    0.1538
    0.7100    0.5951    0.3422
    0.8805    0.4242    1.2050

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.
D2 = pdist2(X,Y,'minkowski',1)
D2 = 3×3
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036

D3 = pdist2(X,Y,'cityblock')
D3 = 3×3
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036

Find the Two Smallest Pairwise Distances
Create two matrices with three observations and two variables.

rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);

Find the two smallest pairwise Euclidean distances to observations in X for each observation in Y.

[D,I] = pdist2(X,Y,'euclidean','Smallest',2)
D = 2×3

0.5387  0.4242  0.1538
0.7100  0.5951  0.3422

I = 2×3

1     3     1
2     2     2

For each observation in Y, pdist2 finds the two smallest distances by computing and comparing the distance values to all the observations in X. The function then sorts the distances in each column of D in ascending order. I contains the indices of the observations in X corresponding to the distances in D.

**Compute Pairwise Distance with Missing Elements Using a Custom Distance Function**

Define a custom distance function that ignores coordinates with NaN values, and compute pairwise distance by using the custom distance function.

Create two matrices with three observations and three variables.

```matlab
rng('default') % For reproducibility
X = rand(3,3)
Y = [X(:,1:2) rand(3,1)]
```

X =

```
0.8147    0.9134    0.2785
0.9058    0.6324    0.5469
0.1270    0.0975    0.9575
```

Y =

```
0.8147    0.9134    0.9649
0.9058    0.6324    0.1576
```
The first two columns of X and Y are identical. Assume that X(1,1) is missing.

\[ X(1,1) = \text{NaN} \]

\[
X = \begin{bmatrix}
\text{NaN} & 0.9134 & 0.2785 \\
0.9058 & 0.6324 & 0.5469 \\
0.1270 & 0.0975 & 0.9575
\end{bmatrix}
\]

Compute the Hamming distance.

\[ D1 = \text{pdist2}(X,Y,'\text{hamming}') \]

\[
D1 = \begin{bmatrix}
\text{NaN} & \text{NaN} & \text{NaN} \\
1.0000 & 0.3333 & 1.0000 \\
1.0000 & 1.0000 & 0.3333
\end{bmatrix}
\]

If observation \( i \) in \( X \) or observation \( j \) in \( Y \) contains \text{NaN} values, the function \text{pdist2} returns \text{NaN} for the pairwise distance between \( i \) and \( j \). Therefore, \( D1(1,1) \), \( D1(1,2) \), and \( D1(1,3) \) are \text{NaN} values.

Define a custom distance function \text{nanhamdist} that ignores coordinates with \text{NaN} values and computes the Hamming distance. When working with a large number of observations, you can compute the distance more quickly by looping over coordinates of the data.

```matlab
function D2 = nanhamdist(XI,XJ)
%NANHAMDIST Hamming distance ignoring coordinates with NaNs
[m,p] = size(XJ);
nesum = zeros(m,1);
pstar = zeros(m,1);
for q = 1:p
    notnan = ~(isnan(XI(q)) | isnan(XJ(:,q)));
    nesum = nesum + ((XI(q) ~= XJ(:,q)) & notnan);
    pstar = pstar + notnan;
end
D2 = nesum / pstar;
```

32-4712
end
D2 = nesum./pstar;

Compute the distance with `nanhamdist` by passing the function handle as an input argument of `pdist2`.

D2 = pdist2(X,Y,@nanhamdist)

D2 =

0.5000   1.0000   1.0000
1.0000   0.3333   1.0000
1.0000   1.0000   0.3333

**Input Arguments**

**X, Y — Input data**

numeric matrix

Input data, specified as a numeric matrix. `X` is an `mx`-by-`n` matrix and `Y` is an `my`-by-`n` matrix. Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

**Distance — Distance metric**

character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'euclidean'</td>

| @distfun | Custom distance function handle. A distance function has the form  

```matlab
function D2 = distfun(ZI,ZJ)  
% calculation of distance  
...
```

where  

- ZI is a 1-by-n vector containing a single observation.
- ZJ is an m2-by-n matrix containing multiple observations.  
  distfun must accept a matrix ZJ with an arbitrary number of observations.
- D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:).

If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For definitions, see “Distance Metrics” on page 32-4717.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument DistParameter to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of DistParameter.

Example: 'minkowski'

**DistParameter — Distance metric parameter values**

```matlab
positive scalar | numeric vector | numeric matrix
```

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify Distance as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If Distance is 'seuclidean', DistParameter is a vector of scaling factors for each dimension, specified as a positive vector. The default value is nanstd(X).
- If Distance is 'minkowski', DistParameter is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.
• If Distance is 'mahalanobis', DistParameter is a covariance matrix, specified as a numeric matrix. The default value is \( \text{nancov}(X) \). DistParameter must be symmetric and positive definite.

Example: 'minkowski',3
Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name, Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: Either 'Smallest',K or 'Largest',K. You cannot use both 'Smallest' and 'Largest'.

**Smallest — Number of smallest distances to find**

positive integer

Number of smallest distances to find, specified as the comma-separated pair consisting of 'Smallest' and a positive integer. If you specify 'Smallest', then pdist2 sorts the distances in each column of D in ascending order.

Example: 'Smallest',3
Data Types: single | double

**Largest — Number of largest distances to find**

positive integer

Number of largest distances to find, specified as the comma-separated pair consisting of 'Largest' and a positive integer. If you specify 'Largest', then pdist2 sorts the distances in each column of D in descending order.

Example: 'Largest',3
Data Types: single | double
Output Arguments

D — Pairwise distances
numeric matrix

Pairwise distances, returned as a numeric matrix.

If you do not specify either 'Smallest' or 'Largest', then D is an mx-by-my matrix, where mx and my are the number of observations in X and Y, respectively. D(i, j) is the distance between observation i in X and observation j in Y. If observation i in X or observation j in Y contains NaN, then D(i, j) is NaN for the built-in distance functions.

If you specify either 'Smallest' or 'Largest' as K, then D is a K-by-my matrix. D contains either the K smallest or K largest pairwise distances to observations in X for each observation in Y. For each observation in Y, pdist2 finds the K smallest or largest distances by computing and comparing the distance values to all the observations in X. If K is greater than mx, pdist2 returns an mx-by-my matrix.

I — Sort index
positive integer matrix

Sort index, returned as a positive integer matrix. I is the same size as D. I contains the indices of the observations in X corresponding to the distances in D.

Definitions

Distance Metrics

A distance metric is a function that defines a distance between two observations. pdist2 supports various distance metrics: Euclidean distance, standardized Euclidean distance, Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an mx-by-n data matrix X, which is treated as mx (1-by-n) row vectors x₁, x₂, ..., xₘₓ, and an my-by-n data matrix Y, which is treated as my (1-by-n) row vectors y₁, y₂, ..., yₘᵧ, the various distances between the vector xₛ and yᵣ are defined as follows:

- Euclidean distance
\[ d_{st}^2 = (x_s - y_t)(x_s - y_t)' . \]

The Euclidean distance is a special case of the Minkowski distance, where \( p = 2 \).

- **Standardized Euclidean distance**
  \[ d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)' , \]
  where \( V \) is the \( n \)-by-\( n \) diagonal matrix whose \( j \)th diagonal element is \((S(j))^2\), where \( S \) is a vector of scaling factors for each dimension.

- **Mahalanobis distance**
  \[ d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)' , \]
  where \( C \) is the covariance matrix.

- **City block distance**
  \[ d_{st}^2 = \sum_{j=1}^{n} |x_{sj} - y_{tj}| . \]
  The city block distance is a special case of the Minkowski distance, where \( p = 1 \).

- **Minkowski distance**
  \[ d_{st} = \sqrt[p]{\sum_{j=1}^{n} |x_{sj} - y_{tj}|^p} . \]
  For the special case of \( p = 1 \), the Minkowski distance gives the city block distance. For the special case of \( p = 2 \), the Minkowski distance gives the Euclidean distance. For the special case of \( p = \infty \), the Minkowski distance gives the Chebychev distance.

- **Chebychev distance**
  \[ d_{st} = \max_j \{|x_{sj} - y_{tj}|\} . \]
  The Chebychev distance is a special case of the Minkowski distance, where \( p = \infty \).
• Cosine distance
\[ d_{st} = 1 - \frac{x_s y'_t}{\sqrt{(x_s x'_s)(y_t y'_t)}}. \]

• Correlation distance
\[ d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'}\sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}. \]

where
\[ \bar{x}_s = \frac{1}{n} \sum_{j} x_{sj} \]
and
\[ \bar{y}_t = \frac{1}{n} \sum_{j} y_{tj}. \]

• Hamming distance
\[ d_{st} = \frac{\#(x_{sj} \neq y_{tj})}{n}. \]

• Jaccard distance
\[ d_{st} = \frac{\#[(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}. \]

• Spearman distance
\[ d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}. \]

where
• $r_{sj}$ is the rank of $x_{sj}$ taken over $x_{1j}, x_{2j}, \ldots x_{mj}$, as computed by `tiedrank`.
• $r_{tj}$ is the rank of $y_{tj}$ taken over $y_{1j}, y_{2j}, \ldots y_{mj}$, as computed by `tiedrank`.
• $r_s$ and $r_t$ are the coordinate-wise rank vectors of $x_s$ and $y_t$, i.e., $r_s = (r_{s1}, r_{s2}, \ldots r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \ldots r_{tn})$.

$$
\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n + 1)}{2}.
$$

$$
\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n + 1)}{2}.
$$

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• The distance input argument value (Distance) must be a compile-time constant. For example, to use the Minkowski distance, include `coder.Constant('Minkowski')` in the -args value of codegen.
• The distance input argument value (Distance) cannot be a custom distance function.
• Names in name-value pair arguments must be compile-time constants. For example, to use the 'Smallest' name-value pair argument in the generated code, include `{coder.Constant('Smallest'),0}` in the -args value of codegen.
• The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
• For code generation, `pdist2` uses `parfor` (by default) to create loops that run in parallel on supported shared-memory multicore platforms. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, specify the `EnableOpenMP` property of the `codegen` configuration object as `false`. For details, see `coder.CodeConfig`. 

32-4720
GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The Distance argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2010a
pearsrnd

Pearson system random numbers

Syntax

\[
\begin{align*}
r &= \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, m, n) \\
r &= \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}) \\
r &= \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, m, n, \ldots) \\
r &= \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, [m, n, \ldots]) \\
[r, \text{type}] &= \text{pearsrnd}(\ldots) \\
[r, \text{type}, \text{coefs}] &= \text{pearsrnd}(\ldots)
\end{align*}
\]

Description

\[
r = \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, m, n)
\]
returns an \(m\)-by-\(n\) matrix of random numbers drawn from the distribution in the Pearson system with mean \(\mu\), standard deviation \(\sigma\), skewness \(\text{skew}\), and kurtosis \(\text{kurt}\). The parameters \(\mu\), \(\sigma\), \(\text{skew}\), and \(\text{kurt}\) must be scalars.

**Note** Because \(r\) is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

pearsrnd uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The pearsrnd function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

\[
r = \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt})
\]
returns a scalar value.

\[
r = \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, m, n, \ldots) \text{ or } r = \text{pearsrnd}(\mu, \sigma, \text{skew}, \text{kurt}, [m, n, \ldots])
\]
returns an \(m\)-by-\(n\)-by-\(\ldots\) array.
[r,type] = pearsrnd(...) returns the type of the specified distribution within the Pearson system. type is a scalar integer from 0 to 7. Set m and n to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal on page B-130 distribution
- 1 — Four-parameter beta on page B-4 distribution
- 2 — Symmetric four-parameter beta on page B-4 distribution
- 3 — Three-parameter gamma on page B-45 distribution
- 4 — Not related to any standard distribution. The density is proportional to:
  
  \[
  (1 + ((x - a)/b)^2)^c \exp(-d \arctan((x - a)/b)).
  \]
  
- 5 — Inverse gamma on page B-45 location-scale distribution
- 6 — F on page B-42 location-scale distribution
- 7 — Student's t location-scale on page B-166 distribution

[r,type,coefs] = pearsrnd(...) returns the coefficients coefs of the quadratic polynomial that defines the distribution via the differential equation

\[
\frac{d}{dx} \log(p(x)) = \frac{-(a + x)}{c(0) + c(1)x + c(2)x^2}.
\]

**Examples**

Generate random values from the standard normal distribution:

\[ r = \text{pearsrnd}(0,1,0,3,100,1); \quad \text{% Equivalent to randn(100,1)} \]

Determine the distribution type:

\[ [r,\text{type}] = \text{pearsrnd}(0,1,1,4,0,0); \]
\[ r = \]
\[ [] \]
\[ \text{type} = \]
\[ 1 \]
References

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:
The generated code matches MATLAB only when generated output \( r \) is scalar.

Introduced in R2006a
perfcurve

Receiver operating characteristic (ROC) curve or other performance curve for classifier output

Syntax

[X,Y] = perfcurve(labels,scores,posclass)
[X,Y,T] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass)
[___] = perfcurve(labels,scores,posclass,Name,Value)

Description

[X,Y] = perfcurve(labels,scores,posclass) returns the X and Y coordinates of an ROC curve for a vector of classifier predictions, scores, given true class labels, labels, and the positive class label, posclass. You can visualize the performance curve using plot(X,Y).

[X,Y,T] = perfcurve(labels,scores,posclass) returns an array of thresholds on classifier scores for the computed values of X and Y.

[X,Y,T,AUC] = perfcurve(labels,scores,posclass) returns the area under the curve for the computed values of X and Y.

[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass) returns the optimal operating point of the ROC curve.

[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass) returns the Y values for negative subclasses.

[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,posclass) returns the negative class names.
[___] = perfcurve(labels,scores,posclass,Name,Value) returns the coordinates of a ROC curve and any other output argument from the previous syntaxes, with additional options specified by one or more Name,Value pair arguments.

For example, you can provide a list of negative classes, change the X or Y criterion, compute pointwise confidence bounds on page 32-4755 using cross validation or bootstrap, specify the misclassification cost, or compute the confidence bounds in parallel.

Examples

Plot ROC Curve for Classification by Logistic Regression

Load the sample data.

load fisheriris

Use only the first two features as predictor variables. Define a binary classification problem by using only the measurements that correspond to the species versicolor and virginica.

pred = meas(51:end,1:2);

Define the binary response variable.

resp = (1:100)'>50;  % Versicolor = 0, virginica = 1

Fit a logistic regression model.

mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');

Compute the ROC curve. Use the probability estimates from the logistic regression model as scores.

scores = mdl.Fitted.Probability;
[X,Y,T,AUC] = perfcurve(species(51:end,:),scores,'virginica');

perfcurve stores the threshold values in the array T.

Display the area under the curve.

AUC
AUC = 0.7918

The area under the curve is 0.7918. The maximum AUC is 1, which corresponds to a perfect classifier. Larger AUC values indicate better classifier performance.

Plot the ROC curve.

plot(X,Y)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC for Classification by Logistic Regression')
Compare Classification Methods Using ROC Curve

Load the sample data.

```matlab
load ionosphere
```

X is a 351x34 real-valued matrix of predictors. Y is a character array of class labels: 'b' for bad radar returns and 'g' for good radar returns.

Reformat the response to fit a logistic regression. Use the predictor variables 3 through 34.

```matlab
resp = strcmp(Y,'b'); % resp = 1, if Y = 'b', or 0 if Y = 'g'
pred = X(:,3:34);
```

Fit a logistic regression model to estimate the posterior probabilities for a radar return to be a bad one.

```matlab
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
score_log = mdl.Fitted.Probability; % Probability estimates
```

Compute the standard ROC curve using the probabilities for scores.

```matlab
[Xlog,Ylog,Tlog,AUClog] = perfcurve(resp,score_log,'true');
```

Train an SVM classifier on the same sample data. Standardize the data.

```matlab
mdlSVM = fitcsvm(pred,resp,'Standardize',true);
```

Compute the posterior probabilities (scores).

```matlab
mdlSVM = fitPosterior(mdlSVM);
[~,score_svm] = resubPredict(mdlSVM);
```

The second column of `score_svm` contains the posterior probabilities of bad radar returns.

Compute the standard ROC curve using the scores from the SVM model.

```matlab
[Xsvm,Ysvm,Tsvm,AUCsvm] = perfcurve(resp,score_svm(:,mdlSVM.ClassNames),'true');
```

Fit a naive Bayes classifier on the same sample data.

```matlab
mdlNB = fitcnb(pred,resp);
```

Compute the posterior probabilities (scores).
[~,score_nb] = resubPredict(mdlNB);

Compute the standard ROC curve using the scores from the naive Bayes classification.

[Xnb,Ynb,Tnb,AUCnb] = perfcurve(resp,score_nb(:,mdlNB.ClassNames),'true');

Plot the ROC curves on the same graph.

plot(Xlog,Ylog)
hold on
plot(Xsvm,Ysvm)
plot(Xnb,Ynb)
legend('Logistic Regression','Support Vector Machines','Naive Bayes','Location','Best')
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC Curves for Logistic Regression, SVM, and Naive Bayes Classification')
hold off
Although SVM produces better ROC values for higher thresholds, logistic regression is usually better at distinguishing the bad radar returns from the good ones. The ROC curve for naive Bayes is generally lower than the other two ROC curves, which indicates worse in-sample performance than the other two classifier methods.

Compare the area under the curve for all three classifiers.

\[
\text{AUC}_{\text{log}} = 0.9659
\]

\[
\text{AUC}_{\text{svm}} = 0.9488
\]
AUCnb

AUCnb = 0.9393

Logistic regression has the highest AUC measure for classification and naive Bayes has the lowest. This result suggests that logistic regression has better in-sample average performance for this sample data.

**Determine the Parameter Value for Custom Kernel Function**

This example shows how to determine the better parameter value for a custom kernel function in a classifier using the ROC curves.

Generate a random set of points within the unit circle.

```matlab
rng(1); % For reproducibility
n = 100; % Number of points per quadrant

r1 = sqrt(rand(2*n,1)); % Random radii
r2 = sqrt(rand(2*n,1));

t1 = [pi/2*rand(n,1); (pi/2*rand(n,1)+pi)]; % Random angles for Q1 and Q3

X1 = [r1.*cos(t1) r1.*sin(t1)]; % Polar-to-Cartesian conversion

% Random angles for Q2 and Q4

X2 = [r2.*cos(t2) r2.*sin(t2)];

r2 = sqrt(rand(2*n,1));

t2 = [pi/2*rand(n,1)+pi/2; (pi/2*rand(n,1)-pi/2)]; % Random angles for Q2 and Q4

X2 = [r2.*cos(t2) r2.*sin(t2)];

Define the predictor variables. Label points in the first and third quadrants as belonging to the positive class, and those in the second and fourth quadrants in the negative class.

```matlab
pred = [X1; X2];
resp = ones(4*n,1);
resp(2*n + 1:end) = -1; % Labels
```

Create the function `mysigmoid.m`, which accepts two matrices in the feature space as inputs, and transforms them into a Gram matrix using the sigmoid kernel.

```matlab
function G = mysigmoid(U,V)
% Sigmoid kernel function with slope gamma and intercept c

\[ G = \tanh(\gamma U'V + c) \]
```
Train an SVM classifier using the sigmoid kernel function. It is good practice to standardize the data.

```matlab
SVMMModel1 = fitcsvm(pred,resp,'KernelFunction','mysigmoid',...
    'Standardize',true);
SVMMModel1 = fitPosterior(SVMMModel1);
[~,scores1] = resubPredict(SVMMModel1);
```

Set `gamma = 0.5` within `mysigmoid.m` and save as `mysigmoid2.m`. And, train an SVM classifier using the adjusted sigmoid kernel.

```matlab
function G = mysigmoid2(U,V)
    % Sigmoid kernel function with slope gamma and intercept c
    gamma = 0.5;
    c = -1;
    G = tanh(gamma*U*V' + c);
end
```

```matlab
SVMMModel2 = fitcsvm(pred,resp,'KernelFunction','mysigmoid2',...
    'Standardize',true);
SVMMModel2 = fitPosterior(SVMMModel2);
[~,scores2] = resubPredict(SVMMModel2);
```

Compute the ROC curves and the area under the curve (AUC) for both models.

```matlab
[x1,y1,~,auc1] = perfcurve(resp,scores1(:,2),1);
[x2,y2,~,auc2] = perfcurve(resp,scores2(:,2),1);
```

Plot the ROC curves.

```matlab
plot(x1,y1)
hold on
plot(x2,y2)
hold off
legend('gamma = 1','gamma = 0.5','Location','SE');
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC for classification by SVM');
The kernel function with the gamma parameter set to 0.5 gives better in-sample results.

Compare the AUC measures.

\[
\text{auc1} \\
\text{auc2}
\]

\[
\text{auc1} = 0.9518
\]

\[
\text{auc2} =
\]
The area under the curve for gamma set to 0.5 is higher than that for gamma set to 1. This also confirms that gamma parameter value of 0.5 produces better results. For visual comparison of the classification performance with these two gamma parameter values, see “Train SVM Classifier Using Custom Kernel” on page 18-196.

**Plot ROC Curve for Classification Tree**

Load the sample data.

```matlab
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Train a classification tree using the sepal length and width as the predictor variables. It is a good practice to specify the class names.

```matlab
Model = fitctree(meas(:,1:2),species,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Predict the class labels and scores for the species based on the tree `Model`.

```matlab
[~,score] = resubPredict(Model);
```

The scores are the posterior probabilities that an observation (a row in the data matrix) belongs to a class. The columns of `score` correspond to the classes specified by 'ClassNames'. So, the first column corresponds to setosa, the second corresponds to versicolor, and the third column corresponds to virginica.

Compute the ROC curve for the predictions that an observation belongs to versicolor, given the true class labels `species`. Also compute the optimal operating point and y values for negative subclasses. Return the names of the negative classes.

Because this is a multiclass problem, you cannot merely supply `score(:,2)` as input to `perfcurve`. Doing so would not give `perfcurve` enough information about the scores
for the two negative classes (setosa and virginica). This problem is unlike a binary classification problem, where knowing the scores of one class is enough to determine the scores of the other class. Therefore, you must supply `perfcurve` with a function that factors in the scores of the two negative classes. One such function is

$$score(:,2) - \max(score(:,1),score(:,3)).$$

diffscore = score(:,2) - max(score(:,1),score(:,3));
[X,Y,T,~,OPTROCPT,suby,subnames] = perfcurve(species,diffscore,'versicolor');

$X$, by default, is the false positive rate (fallout or 1-specificity) and $Y$, by default, is the true positive rate (recall or sensitivity). The positive class label is `versicolor`. Because a negative class is not defined, `perfcurve` assumes that the observations that do not belong to the positive class are in one class. The function accepts it as the negative class.

**OPTROCPT**

OPTROCPT = 1x2

0.1000 0.8000

**suby**

suby = 12x2

0 0
0.1800 0.1800
0.4800 0.4800
0.5800 0.5800
0.6200 0.6200
0.8000 0.8000
0.8800 0.8800
0.9200 0.9200
0.9600 0.9600
0.9800 0.9800

**subnames**

subnames = 1x2 cell array

{`setosa`}  {`virginica`}

Plot the ROC curve and the optimal operating point on the ROC curve.
Find the threshold that corresponds to the optimal operating point.

\[ T((X==\text{OPTROCPT}(1)) \& (Y==\text{OPTROCPT}(2))) \]

\[ \text{ans} = 0.2857 \]
Specify *virginica* as the negative class and compute and plot the ROC curve for *versicolor*.

Again, you must supply `perfcurve` with a function that factors in the scores of the negative class. An example of a function to use is $score(:,2) - score(:,3)$.

```matlab
diffscore = score(:,2) - score(:,3);
[X,Y,~,~,OPTROCPT] = perfcurve(species,diffscore,'versicolor', ... 
    'negClass','virginica');

OPTROCPT

OPTROCPT = 1×2
    0.1800    0.8200
```

```matlab
figure, plot(X,Y)
hold on
plot(OPTROCPT(1),OPTROCPT(2),'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off
```
Compute Pointwise Confidence Intervals for ROC Curve

Load the sample data.

load fisheriris

The column vector species consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix meas consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.
Use only the first two features as predictor variables. Define a binary problem by using only the measurements that correspond to the versicolor and virginica species.

```matlab
pred = meas(51:end,1:2);
```

Define the binary response variable.

```matlab
resp = (1:100)'>50;  % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```matlab
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

Compute the pointwise confidence intervals on the true positive rate (TPR) by vertical averaging (VA) and sampling using bootstrap.

```matlab
[X,Y,T] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000,'XVals',[0:0.05:1]);
```

'NBoot',1000 sets the number of bootstrap replicas to 1000. 'XVals','All' prompts `perfcurve` to return X, Y, and T values for all scores, and average the Y values (true positive rate) at all X values (false positive rate) using vertical averaging. If you do not specify XVals, then `perfcurve` computes the confidence bounds using threshold averaging by default.

Plot the pointwise confidence intervals.

```matlab
errorbar(X,Y(:,1),Y(:,1)-Y(:,2),Y(:,3)-Y(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwVA','Location','Best')
```
It might not always be possible to control the false positive rate (FPR, the X value in this example). So you might want to compute the pointwise confidence intervals on true positive rates (TPR) by threshold averaging.

```matlab
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,... 'virginica','NBoot',1000);
```

If you set 'TVals' to 'All', or if you do not specify 'TVals' or 'Xvals', then `perfcurve` returns `X`, `Y`, and `T` values for all scores and computes pointwise confidence bounds for `X` and `Y` using threshold averaging.

Plot the confidence bounds.
Specify the threshold values to fix and compute the ROC curve. Then plot the curve.

```matlab
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000,'TVals',0:0.05:1);
figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```

![ROC Curve with Pointwise Confidence Bounds](image)

32-4741
Input Arguments

labels — True class labels
numeric vector | logical vector | character matrix | string array | cell array of character vectors | categorical array
True class labels, specified as a numeric vector, logical vector, character matrix, string array, cell array of character vectors, or categorical array. For more information, see “Grouping Variables” on page 2-57.

Example: {'hi','mid','hi','low',...,'mid'}
Example: [ 'H','M','H','L',...,'M' ]

Data Types: single | double | logical | char | string | cell | categorical

**scores — Scores returned by a classifier**

vector of floating points

Scores returned by a classifier for some sample data, specified as a vector of floating points. `scores` must have the same number of elements as `labels`.

Data Types: single | double

**posclass — Positive class label**

numeric scalar | logical scalar | character vector | string scalar | cell containing a character vector | categorical scalar

Positive class label, specified as a numeric scalar, logical scalar, character vector, string scalar, cell containing a character vector, or categorical scalar. The positive class must be a member of the input labels. The value of `posclass` that you can specify depends on the value of `labels`.

<table>
<thead>
<tr>
<th>Labels value</th>
<th>posclass value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric vector</td>
<td>Numeric scalar</td>
</tr>
<tr>
<td>Logical vector</td>
<td>Logical scalar</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Character vector</td>
</tr>
<tr>

<td>String scalar</td>
</tr>
<tr>
<td>Cell array of character vectors</td>
<td>Character vector or cell containing character vector</td>
</tr>
<tr>
<td>Categorical vector</td>
<td>Categorical scalar</td>
</tr>
</tbody>
</table>

For example, in a cancer diagnosis problem, if a malignant tumor is the positive class, then specify `posclass` as 'malignant'.

Data Types: single | double | logical | char | string | cell | categorical
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'NegClass', 'versicolor', 'XCrit', 'fn', 'NBoot', 1000, 'BootType', 'per' specifies the species versicolor as the negative class, the criterion for the X-coordinate as false negative, the number of bootstrap samples as 1000. It also specifies that the pointwise confidence bounds are computed using the percentile method.

NegClass — List of negative classes

'Selection of negative classes

'all' (default) | numeric array | categorical array | string array | cell array of character vectors

List of negative classes, specified as the comma-separated pair consisting of 'NegClass', and a numeric array, a categorical array, a string array, or a cell array of character vectors. By default, perfcurve sets NegClass to 'all' and considers all nonpositive classes found in the input array of labels to be negative.

If NegClass is a subset of the classes found in the input array of labels, then perfcurve discards the instances with labels that do not belong to either positive or negative classes.

Example: 'NegClass', {'versicolor', 'setosa'}

Data Types: single | double | categorical | char | string | cell

XCrit — Criterion to compute for X

'fpr' (default) | 'fnr' | 'tnr' | 'ppv' | 'ecost' | ...

Criterion to compute for X, specified as the comma-separated pair consisting of 'XCrit' and one of the following.

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tp</td>
<td>Number of true positive instances</td>
</tr>
<tr>
<td>fn</td>
<td>Number of false negative instances.</td>

<td>Sum of true positive and false positive instances.</td>
</tr>
<tr>
<td>rpp</td>
<td>Rate of positive predictions.</td>
</tr>
<tr>
<td>rnn</td>
<td>Rate of negative predictions.</td>
</tr>
<tr>
<td>accu</td>
<td>Accuracy.</td>
</tr>
<tr>
<td>tpr, or sens, or reca</td>
<td>True positive rate, or sensitivity, or recall.</td>
</tr>
<tr>
<td>fnr, or miss</td>
<td>False negative rate, or miss.</td>
</tr>
<tr>
<td>fpr, or fall</td>
<td>False positive rate, or fallout, or 1 - specificity.</td>
</tr>
<tr>
<td>tnr, or spec</td>
<td>True negative rate, or specificity.</td>
</tr>
<tr>
<td>ppv, or prec</td>
<td>Positive predictive value, or precision.</td>
</tr>
<tr>
<td>npv</td>
<td>Negative predictive value.</td>
</tr>
<tr>
<td>ecost</td>
<td>Expected cost.</td>
</tr>
<tr>
<td>Custom criterion</td>
<td>A custom-defined function with the input arguments ((C, scale, cost)), where (C) is a 2-by-2 confusion matrix, (scale) is a 2-by-1 array of class scales, and (cost) is a 2-by-2 misclassification cost matrix.</td>
</tr>
</tbody>
</table>

**Caution** Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

Example: 'XCrit', 'ecost'
**YCrit — Criterion to compute for Y**
'tpr' (default) | same criteria options for X

Criterion to compute for Y, specified as the comma-separated pair consisting of 'YCrit' and one of the same criteria options as for X. This criterion does not have to be a monotone function of the positive class score.

Example: 'YCrit','ecost'

**XVals — Values for the X criterion**
'all' (default) | numeric array

Values for the X criterion, specified as the comma-separated pair consisting of 'XVals' and a numeric array.

- If you specify XVals, then perfcurve computes X and Y and the pointwise confidence bounds on page 32-4755 for Y (when applicable) only for the specified XVals.
- If you do not specify XVals, then perfcurve, computes X and Y and the values for all scores by default.

**Note** You cannot set XVals and TVals at the same time.

Example: 'XVals',[0:0.05:1]

Data Types: single | double | char | string

**TVals — Thresholds for the positive class score**
'all' (default) | numeric array

Thresholds for the positive class score, specified as the comma-separated pair consisting of 'TVals' and either 'all' or a numeric array.

- If TVals is set to 'all' or not specified, and XVals is not specified, then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds on page 32-4755 for X and Y using threshold averaging.
- If TVals is set to a numeric array, then perfcurve returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for X and Y at these thresholds using threshold averaging.

**Note** You cannot set XVals and TVals at the same time.
Example: 'TVals', [0:0.05:1]

Data Types: single | double | char | string

UseNearest — Indicator to use the nearest values in the data

'on' (default) | 'off'

Indicator to use the nearest values in the data instead of the specified numeric XVals or TVals, specified as the comma-separated pair consisting of 'UseNearest' and either 'on' or 'off'.

- If you specify numeric XVals and set UseNearest to 'on', then perfcurve returns the nearest unique X values found in the data, and it returns the corresponding values of Y and T.
- If you specify numeric XVals and set UseNearest to 'off', then perfcurve returns the sorted XVals.
- If you compute confidence bounds by cross validation or bootstrap, then this parameter is always 'off'.

Example: 'UseNearest', 'off'

ProcessNaN — perfcurve method for processing NaN scores

'ignore' (default) | 'addtofalse'

Perfcurve method for processing NaN scores, specified as the comma-separated pair consisting of 'ProcessNaN' and 'ignore' or 'addtofalse'.

- If ProcessNaN is 'ignore', then perfcurve removes observations with NaN scores from the data.
- If ProcessNaN is 'addtofalse', then perfcurve adds instances with NaN scores to false classification counts in the respective class. That is, perfcurve always counts instances from the positive class as false negative (FN), and it always counts instances from the negative class as false positive (FP).

Example: 'ProcessNaN', 'addtofalse'

Prior — Prior probabilities for positive and negative classes

'empirical' (default) | 'uniform' | array with two elements

Prior probabilities for positive and negative classes, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', or an array with two elements.
If \texttt{Prior} is 'empirical', then \texttt{perfcurve} derives prior probabilities from class frequencies.

If \texttt{Prior} is 'uniform', then \texttt{perfcurve} sets all prior probabilities to be equal.

Example: \texttt{'Prior',[0.3,0.7]}

Data Types: \texttt{single} | \texttt{double} | \texttt{char} | \texttt{string}

\textbf{Cost — Misclassification costs}

\begin{align*}
[0; 0.5; 0.5; 0] \text{ (default)} | 2\text{-by-2 matrix}
\end{align*}

Misclassification costs, specified as the comma-separated pair consisting of \texttt{'Cost'} and a 2-by-2 matrix, containing \([\text{Cost}(P|P), \text{Cost}(N|P); \text{Cost}(P|N), \text{Cost}(N|N)]\).

\text{Cost}(N|P) \text{ is the cost of misclassifying a positive class as a negative class. } \text{Cost}(P|N) \text{ is the cost of misclassifying a negative class as a positive class. Usually, } \text{Cost}(P|P) = 0 \text{ and } \text{Cost}(N|N) = 0, \text{ but } \texttt{perfcurve} \text{ allows you to specify nonzero costs for correct classification as well.}

Example: \texttt{'Cost',[0 0.7;0.3 0]}

Data Types: \texttt{single} | \texttt{double}

\textbf{Alpha — Confidence level}

\begin{align*}
0.05 \text{ (default)} | \text{ scalar value in the range 0 through 1}
\end{align*}

Confidence level for the confidence bounds, specified as the comma-separated pair consisting of \texttt{'Alpha'} and a scalar value in the range 0 through 1. \texttt{perfcurve} computes 100*(1 - \alpha) percent pointwise confidence bounds on page 32-4755 for \(X, Y, T,\) and AUC for a confidence level of \(\alpha\).

Example: \texttt{'Alpha',0.01} specifies 99% confidence bounds

Data Types: \texttt{single} | \texttt{double}

\textbf{Weights — Observation weights}

\begin{align*}
\text{vector of nonnegative scalar values} | \text{ cell array of vectors of nonnegative scalar values}
\end{align*}

Observation weights, specified as the comma-separated pair consisting of \texttt{'Weights'} and a vector of nonnegative scalar values. This vector must have as many elements as \texttt{scores} or \texttt{labels} do.

If \texttt{scores} and \texttt{labels} are in cell arrays and you need to supply \texttt{Weights}, the weights must be in a cell array as well. In this case, every element in \texttt{Weights} must be a numeric
vector with as many elements as the corresponding element in \textit{scores}. For example, \texttt{numel(weights{1}) == numel(scores{1})}.

When \texttt{perfcurve} computes the \textit{X}, \textit{Y} and \textit{T} or confidence bounds using cross-validation, it uses these observation weights instead of observation counts.

When \texttt{perfcurve} computes confidence bounds using bootstrap, it samples \textit{N} out of \textit{N} observations with replacement, using these weights as multinomial sampling probabilities.

The default is a vector of 1s or a cell array in which each element is a vector of 1s.

\textbf{Data Types:} \texttt{single} \textbar{} \texttt{double} \textbar{} \texttt{cell}

\textbf{NBoot — Number of bootstrap replicas}

\texttt{0} (default) \textbar{} \texttt{positive integer}

Number of bootstrap replicas for computation of confidence bounds, specified as the comma-separated pair consisting of \texttt{'NBoot'} and a positive integer. The default value 0 means the confidence bounds are not computed.

If \texttt{labels} and \texttt{scores} are cell arrays, this parameter must be 0 because \texttt{perfcurve} can use either cross-validation or bootstrap to compute confidence bounds.

Example: \texttt{'NBoot',500}

\textbf{Data Types:} \texttt{single} \textbar{} \texttt{double}

\textbf{BootType — Confidence interval type for bootci}

\texttt{'bca'} (default) \textbar{} \texttt{'norm'} \textbar{} \texttt{'per'} \textbar{} \texttt{'cper'} \textbar{} \texttt{'stud'}

Confidence interval type for \texttt{bootci} to use to compute confidence bounds, specified as the comma-separated pair consisting of \texttt{'BootType'} and one of the following:

- \texttt{'bca'} — Bias corrected and accelerated percentile method
- \texttt{'norm'} or \texttt{'normal'} — Normal approximated interval with bootstrapped bias and standard error
- \texttt{'per'} or \texttt{'percentile'} — Percentile method
- \texttt{'cper'} or \texttt{'corrected percentile'} — Bias corrected percentile method
- \texttt{'stud'} or \texttt{'student'} — Studentized confidence interval

Example: \texttt{'BootType','cper'}
**BootArg — Optional input arguments for bootci**

[] (default) | {'Nbootstd',nbootstd} | {'Stderr',stderr}

Optional input arguments for bootci to compute confidence bounds, specified as the comma-separated pair consisting of 'BootArg' and {'Nbootstd',nbootstd} or {'Stderr',stderr}, name-value pair arguments of bootci.

When you compute the studentized bootstrap confidence intervals ('BootType' is 'student'), you can additionally specify 'Nbootstd' or 'Stderr', name-value pair arguments of bootci, by using 'BootArg'.

- 'BootArg', {'Nbootstd',nbootstd} estimates the standard error of the bootstrap statistics using bootstrap with nbootstd data samples. nbootstd is a positive integer and its default is 100.
- 'BootArg', {'Stderr',stderr} evaluates the standard error of the bootstrap statistics by a user-defined function stderr that takes [1:numel(scores)]' as an input argument. stderr is a function handle.

Example: 'BootArg', {'Nbootstd',nbootstd}

Data Types: cell

**Options — Options for controlling the computation of confidence intervals**

[] (default) | structure array returned by statset

Options for controlling the computation of confidence intervals, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. These options require Parallel Computing Toolbox. perfcurve uses this argument for computing pointwise confidence bounds only. To compute these bounds, you must pass cell arrays for labels and scores or set NBoot to a positive integer.

This table summarizes the available options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UseParallel'</td>
<td>• false — Serial computation (default).</td>
</tr>
<tr>
<td></td>
<td>• true — Parallel computation. You need Parallel Computing Toolbox for this option to work.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 'UseSubstreams' | • false — Do not use a separate substream for each iteration (default).  
• true — Use a separate substream for each iteration to compute in parallel in a reproducible fashion. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. |
| 'Streams'      | A RandStream object, or a cell array of such objects. If you specify Streams, use a single object, except when:  
• You have an open parallel pool.  
• UseParallel is true.  
• UseSubstreams is false.  
In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then Streams must supply a single random number stream. |

If 'UseParallel' is true and 'UseSubstreams' is false, then the length of 'Streams' must equal the number of workers used by perfcurve. If a parallel pool is already open, then the length of 'Streams' is the size of the parallel pool. If a parallel pool is not already open, then MATLAB might open a pool for you, depending on your installation and preferences. To ensure more predictable results, use parpool and explicitly create a parallel pool before invoking perfcurve and setting 'Options', statset('UseParallel',true).

Example: 'Options', statset('UseParallel',true)

Data Types: struct

**Output Arguments**

**X — x-coordinates for the performance curve**

vector, fpr (default) | m-by-3 matrix
x-coordinates for the performance curve, returned as a vector or an m-by-3 matrix. By default, X values are the false positive rate, FPR (fallout or 1 – specificity). To change X, use the XCrit name-value pair argument.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4755, or if it computes them using vertical averaging, then X is a vector.
- If perfcurve computes the confidence bounds using threshold averaging, then X is an m-by-3 matrix, where m is the number of fixed threshold values. The first column of X contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

Y — y-coordinates for the performance curve
vector, tpr (default) | m-by-3 matrix

y-coordinates for the performance curve, returned as a vector or an m-by-3 matrix. By default, Y values are the true positive rate, TPR (recall or sensitivity). To change Y, use YCrit name-value pair argument.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4755, then Y is a vector.
- If perfcurve computes the confidence bounds, then Y is an m-by-3 matrix, where m is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

T — Thresholds on classifier scores
vector | m-by-3 matrix

Thresholds on classifier scores for the computed values of X and Y, returned as a vector or m-by-3 matrix.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4755, or computes them using threshold averaging, then T is a vector.
- If perfcurve computes the confidence bounds using vertical averaging, T is an m-by-3 matrix, where m is the number of fixed X values. The first column of T contains the mean value. The second and third columns contain the lower bound, and the upper bound, respectively, of the pointwise confidence bounds.

For each threshold, TP is the count of true positive observations with scores greater than or equal to this threshold, and FP is the count of false positive observations with scores greater than or equal to this threshold. perfcurve defines negative counts, TN and FN, in
a similar way. The function then sorts the thresholds in the descending order that corresponds to the ascending order of positive counts.

For the $m$ distinct thresholds found in the array of scores, perfcurve returns the $X$, $Y$ and $T$ arrays with $m + 1$ rows. perfcurve sets elements $T(2:m+1)$ to the distinct thresholds, and $T(1)$ replicates $T(2)$. By convention, $T(1)$ represents the highest 'reject all' threshold, and perfcurve computes the corresponding values of $X$ and $Y$ for $TP = 0$ and $FP = 0$. The $T(end)$ value is the lowest 'accept all' threshold for which $TN = 0$ and $FN = 0$.

**AUC — Area under the curve**

*scalar value | 3-by-1 vector*

Area under the curve (AUC) for the computed values of $X$ and $Y$, returned as a scalar value or a 3-by-1 vector.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4755, AUC is a scalar value.
- If perfcurve computes the confidence bounds using vertical averaging, AUC is a 3-by-1 vector. The first column of AUC contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the confidence bound.

For a perfect classifier, AUC = 1. For a classifier that randomly assigns observations to classes, AUC = 0.5.

If you set XVals to 'all' (default), then perfcurve computes AUC using the returned $X$ and $Y$ values.

If XVals is a numeric array, then perfcurve computes AUC using $X$ and $Y$ values from all distinct scores in the interval, which are specified by the smallest and largest elements of XVals. More precisely, perfcurve finds $X$ values for all distinct thresholds as if XVals were set to 'all', and then uses a subset of these (with corresponding $Y$ values) between $\min(XVals)$ and $\max(XVals)$ to compute AUC.

perfcure uses trapezoidal approximation to estimate the area. If the first or last value of $X$ or $Y$ are NaNs, then perfcurve removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).
**OPTROCPT — Optimal operating point of the ROC curve**

1-by-2 array

Optimal operating point of the ROC curve, returned as a 1-by-2 array with false positive rate (FPR) and true positive rate (TPR) values for the optimal ROC operating point.

`perfcurve` computes `OPTROCPT` for the standard ROC curve only, and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, `perfcurve` first finds the slope, $S$, using

$$S = \frac{\text{Cost}(P \mid N) - \text{Cost}(N \mid N) \cdot N}{\text{Cost}(N \mid P) - \text{Cost}(P \mid P) \cdot P}$$

- Cost($N\mid P$) is the cost of misclassifying a positive class as a negative class. Cost($P\mid N$) is the cost of misclassifying a negative class as a positive class.
- $P = TP + FN$ and $N = TN + FP$. They are the total instance counts in the positive and negative class, respectively.

`perfcurve` then finds the optimal operating point by moving the straight line with slope $S$ from the upper left corner of the ROC plot (FPR = 0, TPR = 1) down and to the right, until it intersects the ROC curve.

**SUBY — Values for negative subclasses**

array

Values for negative subclasses, returned as an array.

- If you specify only one negative class, then `SUBY` is identical to `Y`.
- If you specify $k$ negative classes, then `SUBY` is a matrix of size $m$-by-$k$, where $m$ is the number of returned values for `X` and `Y`, and $k$ is the number of negative classes.

`perfcurve` computes `Y` values by summing counts over all negative classes.

`SUBY` gives values of the `Y` criterion for each negative class separately. For each negative class, `perfcurve` places a new column in `SUBY` and fills it with `Y` values for true negative (TN) and false positive (FP) counted just for this class.

**SUBYNAMES — Negative class names**

cell array

Negative class names, returned as a cell array.
• If you provide an input array of negative class names, \texttt{NegClass}, then \texttt{perfcurve} copies names into \texttt{SUBYNAMES}.

• If you do not provide \texttt{NegClass}, then \texttt{perfcurve} extracts \texttt{SUBYNAMES} from the input labels. The order of \texttt{SUBYNAMES} is the same as the order of columns in \texttt{SUBY}. That is, \texttt{SUBY(:,1)} is for negative class \texttt{SUBYNAMES{1}}, \texttt{SUBY(:,2)} is for negative class \texttt{SUBYNAMES{2}}, and so on.

\textbf{Algorithms}

\textbf{Pointwise Confidence Bounds}

If you supply cell arrays for \texttt{labels} and \texttt{scores}, or if you set \texttt{NBoot} to a positive integer, then \texttt{perfcurve} returns pointwise confidence bounds for \texttt{X}, \texttt{Y}, \texttt{T}, and \texttt{AUC}. You cannot supply cell arrays for \texttt{labels} and \texttt{scores} and set \texttt{NBoot} to a positive integer at the same time.

\texttt{perfcurve} resamples data to compute confidence bounds using either cross validation or bootstrap.

• Cross-validation — If you supply cell arrays for \texttt{labels} and \texttt{scores}, then \texttt{perfcurve} uses cross-validation and treats elements in the cell arrays as cross-validation folds. \texttt{labels} can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of character vectors, or categorical vectors. All elements in \texttt{labels} must have the same type. \texttt{scores} can be a cell array of numeric vectors. The cell arrays for \texttt{labels} and \texttt{scores} must have the same number of elements. The number of labels in cell \texttt{j} of \texttt{labels} must be equal to the number of scores in cell \texttt{j} of \texttt{scores} for any \texttt{j} in the range from 1 to the number of elements in \texttt{scores}.

• Bootstrap — If you set \texttt{NBoot} to a positive integer \texttt{n}, \texttt{perfcurve} generates \texttt{n} bootstrap replicas to compute pointwise confidence bounds. If you use \texttt{XCrit} or \texttt{YCrit} to set the criterion for \texttt{X} or \texttt{Y} to an anonymous function, \texttt{perfcurve} can compute confidence bounds only using bootstrap.

\texttt{perfcurve} estimates the confidence bounds using one of two methods:

• Vertical averaging (VA) — \texttt{perfcurve} estimates confidence bounds on \texttt{Y} and \texttt{T} at fixed values of \texttt{X}. That is, \texttt{perfcurve} takes samples of the ROC curves for fixed \texttt{X} values, averages the corresponding \texttt{Y} and \texttt{T} values, and computes the standard errors. You can use the \texttt{XVals} name-value pair argument to fix the \texttt{X} values for computing
confidence bounds. If you do not specify XVals, then perfcurve computes the confidence bounds at all X values.

- Threshold averaging (TA) — perfcurve takes samples of the ROC curves at fixed thresholds T for the positive class score, averages the corresponding X and Y values, and estimates the confidence bounds. You can use the TVals name-value pair argument to use this method for computing confidence bounds. If you set TVals to 'all' or do not specify TVals or XVals, then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging.

When you compute the confidence bounds, Y is an m-by-3 array, where m is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds. AUC is a row vector with three elements, following the same convention. If perfcurve computes the confidence bounds using VA, then T is an m-by-3 matrix, and X is a column vector. If perfcurve uses TA, then X is an m-by-3 matrix and T is a column-vector.

perfcurve returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

“Performance Curves” on page 17-3

Introduced in R2009a
plot

**Class:** clustering.evaluation.ClusterCriterion  
**Package:** clustering.evaluation

Plot clustering evaluation object criterion values

**Syntax**

```matlab
plot(eva)
h = plot(eva)
```

**Description**

`plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object `eva`.

`h = plot(eva)` returns a handle to the plot line.

**Input Arguments**

- `eva` — **Clustering evaluation data**
  - clustering evaluation object
  - Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

**Output Arguments**

- `h` — **Handle to plot line**
  - scalar value
  - Handle to the plot line, returned as a scalar value.
Examples

Plot the Clustering Evaluation Criterion Values

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```matlab
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```matlab
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```matlab
figure;
plot(eva);
```
The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

plot

Class: LinearModel

Scatter plot or added variable plot of linear model

Syntax

    plot(mdl)
    h = plot(mdl)

Description

    plot(mdl) creates a plot of the full, fitted linear model, mdl. The plot type depends on
    the number of predictor variables.

    • If there is just one predictor variable, plot creates a scatter plot of the data along
      with a fitted curve and confidence bounds.
    • If there are multiple predictor variables, plot creates an added variable plot.
    • If there are no predictors, plot creates a histogram of the residuals.

    h = plot(mdl) returns handles to the lines in the plot.

Input Arguments

    mdl — Full, fitted linear regression model
    LinearModel object

    Full, fitted linear regression model, specified as a LinearModel object constructed using
    fitlm or stepwiselm.
Output Arguments

h — Graphics handles
vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.

Examples

Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the carsmall data.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');

Create an added variable plot.

plot(mdl)
```
The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

**Definitions**

**Added Variable Plot and Adjust Response**

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting
direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

**Alternatives**

Use `plotAdded` to select particular predictors for an added variable plot.

“Linear Regression” on page 11-11
plot

**Class:** RepeatedMeasuresModel

Plot data with optional grouping

**Syntax**

```matlab
plot(rm)
plot(rm,Name,Value)
H = plot(__)
```

**Description**

`plot(rm)` plots the measurements in the repeated measures model `rm` for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through `r` as the time values, where `r` is the number of repeated measurements.

`plot(rm,Name,Value)` also plots the measurements in the repeated measures model `rm`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

```matlab
H = plot(__) returns handles, H, to the plotted lines.
```

**Input Arguments**

- `rm` — **Repeated measures model**
  - `RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`. 
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Group — Name of between-subject factor or factors

character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of 'Group' and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: 'Group', {'Drug', 'Sex'}

Data Types: char | string | cell

Marker — Marker to use for each group

string array | cell array of character vectors

Marker to use for each group, specified as the comma-separated pair consisting of 'Marker' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify o as the marker for the groups of drug and x as the marker for the groups of sex as follows.

Example: 'Marker', {'o','o','x','x'}

Data Types: string | cell

Color — Color for each group

character vector | string array | cell array of character vectors | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a character vector, string array, cell array of character vectors, or rows of a three-column RGB matrix.
For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: 'Color','rrbb'

Data Types: single | double | char | string | cell

**LineStyle — Line style for each group**

string array | cell array of character vectors

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: 'LineStyle',{'-' ':' '-' ':'}

Data Types: string | cell

**Output Arguments**

H — Handle to plotted lines
handle

Handle to plotted lines, returned as a handle.

**Examples**

**Plot Data by Group**

Load the sample data.

load fisheriris

The column vector *species* consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix *meas* consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.
Store the data in a table array.

t = table(species, meas(:,1), meas(:,2), meas(:,3), meas(:,4), ...
'VariableNames', {'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]', 'VarNames', {'Measurements'});

Fit a repeated measures model, where the measurements are the responses and the
species is the predictor variable.

rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);

Plot data grouped by the factor species.

plot(rm, 'group', 'species')
Change the line style for each group.

```matlab
plot(rm,'group','species','LineStyle',{'-','--',':'})
```

---

**Plot Data Grouped by Two Factors**

Load the sample data.

```matlab
load repeatedmeas
```
The table between includes the between-subject variables age, IQ, group, gender, and eight repeated measures y1 through y8 as responses. The table within includes the within-subject variables w1 and w2. This is simulated data.

Fit a repeated measures model, where the repeated measures y1 through y8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```matlab
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Plot data with Group coded by color and Gender coded by line type.

```matlab
plot(rm,'group',{'Group' 'Gender'},'Color','rrbbgg',...
     'LineStyle',{'-' ':' '-' ':' '-' ':'},'Marker','.'
)
```

**plotAdded**

**Class:** LinearModel

Added variable plot or leverage plot for linear model

**Syntax**

plotAdded(mdl)
plotAdded(mdl,coef)
h = plotAdded(mdl,___)
h = plotAdded(mdl,coef,Name,Value)

**Description**

plotAdded(mdl) produces a generalized added variable plot for all terms in the full, fitted regression model mdl, except the constant term.

plotAdded(mdl,coef) produces an added variable plot for the coef terms in mdl, after adjusting for all other terms.

h = plotAdded(mdl,___) returns handles to the lines in the plot, using any of the previous syntaxes.

h = plotAdded(mdl,coef,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

mdl — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a LinearModel object constructed using fitlm or stepwiselm.
coef — Coefficients in regression model
character vector | string scalar | vector of coefficient numbers

Coefficients in regression model mdl, specified as one of the following:
- Character vector or string scalar giving a single coefficient name
- Vector of coefficient numbers in the mdl.CoefficientNames property.

Data Types: char | string | single | double

Name-Value Pair Arguments
Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** The plot property name-value pairs apply to the first returned handle h(1).

Color — Color of line or marker
ColorSpec specification

Color of the line or marker, specified as the comma-separated pair consisting of 'Color' and a ColorSpec specification. For details, see linespec.

LineStyle — Line style
Chart Line Properties specification

Line style, specified as the comma-separated pair consisting of 'LineStyle' and a Chart Line specification. For details, see linespec.

LineWidth — Width of line or edges
0.5 (default) | positive numeric value

Width of the line or edges of filled area, in points, specified as the comma-separated pair consisting of 'LineWidth' and a positive numeric value. One point is equal to 1/72 inch.

MarkerEdgeColor — Color of marker or edge
ColorSpec specification
Color of the marker or edge color for filled markers, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a ColorSpec specification. For details, see linespec.

**MarkerFaceColor — Color of marker face**
ColorSpec specification

Color of the marker face for filled markers, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a ColorSpec specification. For details, see linespec.

**MarkerSize — Size of marker**
positive numeric value

Size of the marker in points, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric value. One point is 1/72 inch.

### Output Arguments

**h** — Graphics handles
vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.

### Examples

#### Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the carsmall data.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```
Create an added variable plot.

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

**Create an Added Variable Plot for Particular Variables**

Create a model of car mileage as a function of weight and model year. Then create a plot to see the effect of the weight terms (`Weight` and `Weight^2`).
Create a linear model of mileage from the carsmall data.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to the Weight and Weight^2.

```matlab
mdl.CoefficientNames
```

```matlab
ans = 1x5 cell array
    {'(Intercept)'}    {'Weight'}    {'Year_76'}    {'Year_82'}    {'Weight^2'}
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```matlab
coef = [2 5];
plotAdded(mdl,coef)
```
The plot illustrates that the weight terms are significant because a horizontal line does not fit between the confidence bounds.

**Definitions**

**Added Variable Plot and Adjusted Response**

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting
direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the $x$ and $y$ values for any data point, along with the observation name or number.

**See Also**

`LinearModel | plot`

plotAdjustedResponse

**Class:** LinearModel

Adjusted response plot for linear regression model

**Syntax**

```matlab
plotAdjustedResponse(mdl,var)
h = plotAdjustedResponse(mdl,var)
h = plotAdjustedResponse(mdl,var,Name,Value)
```

**Description**

`plotAdjustedResponse(mdl,var)` gives an adjusted response plot for the variable `var` in the `mdl` regression model.

`h = plotAdjustedResponse(mdl,var)` returns handles to the lines in the plot.

`h = plotAdjustedResponse(mdl,var,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

`mdl` — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a `LinearModel` object constructed using `fitlm` or `stepwiselm`.

`var` — Variable for adjusted response plot
variable name | integer value

Variable for adjusted response plot, specified as a variable name or an integer value representing the index of a variable in `mdl.CoefficientNames`. 

32-4779
Data Types: char | string | single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** The plot property name-value pairs apply to the first returned handle h(1).

**Color — Color of line or marker**

ColorSpec specification

Color of the line or marker, specified as the comma-separated pair consisting of 'Color' and a ColorSpec specification. For details, see linespec.

**LineStyle — Line style**

Chart Line Properties specification

Line style, specified as the comma-separated pair consisting of 'LineStyle' and a Chart Line specification. For details, see linespec.

**LineWidth — Width of line or edges**

0.5 (default) | positive numeric value

Width of the line or edges of filled area, in points, specified as the comma-separated pair consisting of 'LineWidth' and a positive numeric value. One point is equal to 1/72 inch.

**MarkerEdgeColor — Color of marker or edge**

ColorSpec specification

Color of the marker or edge color for filled markers, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a ColorSpec specification. For details, see linespec.

**MarkerFaceColor — Color of marker face**

ColorSpec specification
Color of the marker face for filled markers, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a ColorSpec specification. For details, see linespec.

**MarkerSize — Size of marker**

positive numeric value

Size of the marker in points, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric value. One point is 1/72 inch.

### Output Arguments

**h — Graphics handles**

vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.

### Examples

#### Plot Adjusted Responses

Plot the adjusted responses of a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the effect of 'Weight' averaged over Year values.

```matlab
plotAdjustedResponse(mdl,'Weight')
```
Plot the effect of Year averaged over 'Weight' values. Include the h output.

```matlab
h = plotAdjustedResponse(mdl,'Year');
```
Change the adjusted data to black x instead of red o.

```matlab
h(1).Marker = 'x';
h(1).Color = 'k';
```
Definitions

Adjusted Response Plot

The adjusted response plot shows the fitted response as a function of \( \text{var} \), with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.
**Tips**

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

plot

Plot Bayesian optimization results

Syntax

plot(results,'all')
plot(results,plotFcn1,plotFcn2,...)

Description

plot(results,'all') calls all predefined plot functions on results.
plot(results,plotFcn1,plotFcn2,...) calls the listed plot functions on results.

Examples

Plot After Optimization

This example shows how to plot the error model and the best objective trace after the optimization has finished. The objective function for this example throws an error for points with norm larger than 2.

```matlab
function f = makeanerror(x)
f = x.x1 - x.x2 - sqrt(4-x.x1^2-x.x2^2);

fun = @makeanerror;
Create the variables for optimization.
var1 = optimizableVariable('x1',[-5,5]);
var2 = optimizableVariable('x2',[-5,5]);
vars = [var1,var2];
```
Run the optimization without any plots. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function. Optimize for 60 iterations so the error model becomes well-trained.

```matlab
rng default
results = bayesopt(fun,vars,'MaxObjectiveEvaluations',60,...
    'AcquisitionFunctionName','expected-improvement-plus',...  
    'PlotFcn',[],'Verbose',0);
```

Plot the error model and the best objective trace.

```matlab
plot(results,@plotConstraintModels,@plotMinObjective)
```
Probability of feasibility
Error model
Input Arguments

results — Bayesian optimization results
BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

plotFcn — Plot function
function handle

Plot function, specified as a function handle.
There are several built-in plot functions:

<table>
<thead>
<tr>
<th>Model Plots — Apply When D ≤ 2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@plotAcquisitionFunction</td>
<td>Plot the acquisition function surface.</td>
</tr>
</tbody>
</table>
| @plotConstraintModels           | Plot each constraint model surface. Negative values indicate feasible points.  

Also plot a \( P(\text{feasible}) \) surface.  

Also plot the error model, if it exists, which ranges from –1 to 1. Negative values mean that the model probably does not error; positive values mean that it probably does error. The model is:  

Plotted error = 2*Probability(error) - 1. |
| @plotObjectiveEvaluation        | Plot the objective function evaluation time model surface. |
| TimeModel                       | Plot the \( \text{fun} \) model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean. |
| @plotObjectiveModel             | |

<table>
<thead>
<tr>
<th>Trace Plots — Apply to All D</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@plotObjective</td>
<td>Plot each observed function value versus the number of function evaluations.</td>
</tr>
<tr>
<td>@plotObjectiveEvaluation</td>
<td>Plot each observed function evaluation run time versus the number of function evaluations.</td>
</tr>
<tr>
<td>Time</td>
<td></td>
</tr>
<tr>
<td>@plotMinObjective</td>
<td>Plot the minimum observed and estimated function values versus the number of function evaluations.</td>
</tr>
<tr>
<td>@plotElapsedTime</td>
<td>Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.</td>
</tr>
</tbody>
</table>
You can include a handle to your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-14.

Example: @plotObjective

Data Types: function_handle

**Alternative Functionality**

You can specify plot functions in the `bayesopt` `PlotFcn` name-value pair. This allows you to monitor the progress of the optimization.

**See Also**

BayesianOptimization | bayesopt

*Introduced in R2016b*
plotDiagnostics

**Class:** GeneralizedLinearModel

Plot diagnostics of generalized linear regression model

**Syntax**

```matlab
plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
[h] = plotDiagnostics(...)
[h] = plotDiagnostics(mdl,plottype,Name,Value)
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`[h] = plotDiagnostics(...)` returns handles to the lines in the plot.

`[h] = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

- **mdl**
  Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

- **plottype**
  Character vector or string scalar specifying the type of plot:
### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

**Color**

Color of the line or marker, a `ColorSpec` specification. For details, see `linespec`.

**LineStyle**

Type of line, a Chart Line specification. For details, see `linespec`.

**LineWidth**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default**: 0.5

**MarkerEdgeColor**

Color of the marker or edge color for filled markers, a `ColorSpec` specification. For details, see `linespec`.

**MarkerFaceColor**

Color of the marker face for filled markers, a `ColorSpec` specification. For details, see `linespec`. 

### Table

<table>
<thead>
<tr>
<th>Contour</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'contour'</td>
<td>Residual vs. leverage with overlayed Cook's contours</td>
</tr>
<tr>
<td>'cookd'</td>
<td>Cook's distance</td>
</tr>
<tr>
<td>'leverage'</td>
<td>Leverage (diagonal of Hat matrix)</td>
</tr>
</tbody>
</table>

**Default**: 'leverage'
MarkerSize
Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h
Vector of handles to lines or patches in the plot.

Examples

Diagnostic Plots for Generalized Linear Models
Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```matlab
rng default % for reproducibility
rndvars = randn(100,2);
X = [2+ rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.
```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a leverage plot.
```
plotDiagnostics(mdl)
```
Create a contour plot with Cook's distance.

plotDiagnostics(mdl,'contour')
Definitions

Hat Matrix

The hat matrix $H$ is defined in terms of the data matrix $X$ and a diagonal weight matrix $W$:

$$H = X(X^T WX)^{-1} X^T W^T.$$  

$W$ has diagonal elements $w_i$:  

32-4797
\[ w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}}, \]

where

- \( g \) is the link function mapping \( y_i \) to \( x_i b \).
- \( g' \) is the derivative of the link function \( g \).
- \( V \) is the variance function.
- \( \mu_i \) is the \( i \)th mean.

The diagonal elements \( H_{ii} \) satisfy

\[
0 \leq h_{ii} \leq 1
\]

\[
\sum_{i=1}^{n} h_{ii} = p,
\]

where \( n \) is the number of observations (rows of \( X \)), and \( p \) is the number of coefficients in the regression model.

**Leverage**

The leverage of observation \( i \) is the value of the \( i \)th diagonal term, \( h_{ii} \), of the hat matrix \( H \). Because the sum of the leverage values is \( p \) (the number of coefficients in the regression model), an observation \( i \) can be considered to be an outlier if its leverage substantially exceeds \( p/n \), where \( n \) is the number of observations.

**Cook’s Distance**

The Cook’s distance \( D_i \) of observation \( i \) is

\[
D_i = w_i \frac{e_i^2}{p \Phi} \frac{h_{ii}}{(1 - h_{ii})^2},
\]

where

\[ w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}}, \]
• \( \hat{\phi} \) is the dispersion parameter (estimated or theoretical).
• \( e_i \) is the linear predictor residual, \( g(y_i) - x_i \hat{\beta} \), where
  • \( g \) is the link function.
  • \( y_i \) is the observed response.
  • \( x_i \) is the observation.
  • \( \hat{\beta} \) is the estimated coefficient vector.
• \( p \) is the number of coefficients in the regression model.
• \( h_{ii} \) is the 1\(^{\text{st}} \) diagonal element of the Hat Matrix on page 32-2744 \( H \).

**Tips**

• For many plots, the Data Cursor tool in the figure window displays the \( x \) and \( y \) values for any data point, along with the observation name or number.

plotDiagnostics

Class: LinearModel

Plot diagnostics of linear regression model

Syntax

plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
h = plotDiagnostics(__)
h = plotDiagnostics(mdl,plottype,Name,Value)

Description

plotDiagnostics(mdl) plots diagnostics from the mdl linear model using the leverage values.

plotDiagnostics(mdl,plottype) plots diagnostics in a plot of type plottype.

h = plotDiagnostics(__) returns handles to the lines in the plot, using any of the previous syntaxes.

h = plotDiagnostics(mdl,plottype,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.

Input Arguments

mdl — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a LinearModel object constructed using fitlm or stepwiselm.
**plotDiagnostics**

**plottype — Type of plot**
'leverage' (default) | 'contour' | 'cookd' | 'covratio' | 'dfbetas' | 'dffits' | 's2_i'

Type of plot, specified as one of the following:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'contour'</td>
<td>Residual vs. leverage with overlayed Cook's contours</td>
</tr>
<tr>
<td>'cookd'</td>
<td>Cook's distance</td>
</tr>
<tr>
<td>'covratio'</td>
<td>Delete-1 ratio of determinant of covariance</td>
</tr>
<tr>
<td>'dfbetas'</td>
<td>Scaled delete-1 coefficient estimates</td>
</tr>
<tr>
<td>'dffits'</td>
<td>Scaled delete-1 fitted values</td>
</tr>
<tr>
<td>'leverage'</td>
<td>Leverage</td>
</tr>
<tr>
<td>'s2_i'</td>
<td>Delete-1 variance estimate</td>
</tr>
</tbody>
</table>

Delete-1 means compute a new model without the current observation. If the delete-1 calculation differs significantly from the model using all observations, then the observation is influential.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** The plot property name-value pairs apply to the first returned handle h(1).

**Color — Color of line or marker**
ColorSpec specification

Color of the line or marker, specified as the comma-separated pair consisting of 'Color' and a ColorSpec specification. For details, see linespec.

**LineStyle — Line style**
Chart Line Properties specification
Line style, specified as the comma-separated pair consisting of 'LineStyle' and a Chart Line specification. For details, see linespec.

**LineWidth — Width of line or edges**
0.5 (default) | positive numeric value

Width of the line or edges of filled area, in points, specified as the comma-separated pair consisting of 'LineWidth' and a positive numeric value. One point is equal to 1/72 inch.

**MarkerEdgeColor — Color of marker or edge**
ColorSpec specification

Color of the marker or edge color for filled markers, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a ColorSpec specification. For details, see linespec.

**MarkerFaceColor — Color of marker face**
ColorSpec specification

Color of the marker face for filled markers, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a ColorSpec specification. For details, see linespec.

**MarkerSize — Size of marker**
positive numeric value

Size of the marker in points, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric value. One point is 1/72 inch.

### Output Arguments

**h — Graphics handles**
vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.

### Examples
**Leverage Plot of Linear Model**

Plot the leverage values of observations in a fitted model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```matlab
plotDiagnostics(mdl)
```
Plot the Cook's distance.

```matlab
plotDiagnostics(mdl, 'cookd')
```

The two diagnostic plots give different results.

**Definitions**

**Hat Matrix**

The hat matrix $H$ is defined in terms of the data matrix $X$: 
\( H = X(X^TX)^{-1}X^T. \)

The diagonal elements \( h_{ii} \) satisfy

\[
0 \leq h_{ii} \leq 1
\]

\[
\sum_{i=1}^{n} h_{ii} = p,
\]

where \( n \) is the number of observations (rows of \( X \)), and \( p \) is the number of coefficients in the regression model.

**Leverage**

The leverage of observation \( i \) is the value of the \( i \)th diagonal term, \( h_{ii} \), of the hat matrix \( H \). Because the sum of the leverage values is \( p \) (the number of coefficients in the regression model), an observation \( i \) can be considered to be an outlier if its leverage substantially exceeds \( p/n \), where \( n \) is the number of observations.

**Cook’s Distance**

Cook’s distance is the scaled change in fitted values. Each element in \( \text{CooksDistance} \) is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook’s distance, \( D_i \), of observation \( i \) is

\[
D_i = \frac{\sum_{j=1}^{n} (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{ MSE}},
\]

where

- \( \hat{y}_j \) is the \( j \)th fitted response value.
- \( \hat{y}_{j(i)} \) is the \( j \)th fitted response value, where the fit does not include observation \( i \).
- MSE is the mean squared error.
- \( p \) is the number of coefficients in the regression model.

Cook’s distance is algebraically equivalent to the following expression:
\[ D_i = \frac{r_i^2}{p \text{MSE} \left( \frac{h_{ii}}{1-h_{ii}} \right)^2}, \]

where \( r_i \) is the \( i \)th residual, and \( h_{ii} \) is the \( i \)th leverage value.

CooksDistance is an \( n \)-by-1 column vector in the Diagnostics table of the LinearModel object.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the \( x \) and \( y \) values for any data point, along with the observation name or number.

**Alternatives**

The mdl.Diagnostics property contains the information that plotDiagnostics uses to create plots.

LinearModel

**Topics**

“Diagnostic Plots” on page 11-22
“Linear Regression” on page 11-11
plotDiagnostics

Class: NonLinearModel

Plot diagnostics of nonlinear regression model

Syntax

plotDiagnostics(mdl)
plotDiagnostics(mdl,plottype)
h = plotDiagnostics(...)
h = plotDiagnostics(mdl,plottype,Name,Value)

Description

plotDiagnostics(mdl) plots diagnostics from the mdl linear model using leverage as the plot type.

plotDiagnostics(mdl,plottype) plots diagnostics in a plot of type plottype.

h = plotDiagnostics(...) returns handles to the lines in the plot.

h = plotDiagnostics(mdl,plottype,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.

Input Arguments

mdl

Nonlinear regression model, constructed by fitnlm.

plottype

Character vector or string scalar specifying the type of plot:
| 'contour' | Residual vs. leverage with overlayed Cook's contours |
| 'cookd' | Cook's distance |
| 'leverage' | Leverage (diagonal of Hat matrix) |

**Default:** 'leverage'

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

**Color**

Color of the line or marker, a **ColorSpec** specification. For details, see `linespec`.

**LineStyle**

Type of line, a Chart Line specification. For details, see `linespec`.

**LineWidth**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

**MarkerEdgeColor**

Color of the marker or edge color for filled markers, a **ColorSpec** specification. For details, see `linespec`.

**MarkerFaceColor**

Color of the marker face for filled markers, a **ColorSpec** specification. For details, see `linespec`. 
MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```matlab
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a leverage plot of the fitted model.

```matlab
plotDiagnostics(mdl)
```
Use data tips to examine the observation with high leverage. A data tip appears when you hover over a data point.
Alternatively, find the high-leverage observation at the command line.

```plaintext
find(mdl.Diagnostics.Leverage > 0.8)
```
Definitions

Hat Matrix

The hat matrix $H$ is defined in terms of the data matrix $X$ and the Jacobian matrix $J$:

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here $f$ is the nonlinear model function, and $\beta$ is the vector of model coefficients.

The Hat Matrix $H$ is

$$H = J(J^TJ)^{-1}J^T.$$  

The diagonal elements $H_{ii}$ satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where $n$ is the number of observations (rows of $X$), and $p$ is the number of coefficients in the regression model.

Leverage

The leverage of observation $i$ is the value of the $i$th diagonal term, $h_{ii}$, of the hat matrix $H$. Because the sum of the leverage values is $p$ (the number of coefficients in the regression model), an observation $i$ can be considered to be an outlier if its leverage substantially exceeds $p/n$, where $n$ is the number of observations.
Cook’s Distance

The Cook’s distance $D_i$ of observation $i$ is

$$D_i = \frac{\sum_{j=1}^{n} (\hat{y}_j - \hat{y}_{j(i)})^2}{p \cdot MSE},$$

where

- $\hat{y}_j$ is the $j$th fitted response value.
- $\hat{y}_{j(i)}$ is the $j$th fitted response value, where the fit does not include observation $i$.
- $MSE$ is the mean squared error.
- $p$ is the number of coefficients in the regression model.

Cook’s distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \cdot MSE} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where $e_i$ is the $i$th residual.

Tips

- For many plots, the Data Cursor tool in the figure window displays the $x$ and $y$ values for any data point, along with the observation name or number.

“Nonlinear Regression” on page 13-2
plotEffects

Class: CompactLinearModel

Plot main effects of each predictor in linear regression model

Syntax

plotEffects(mdl)

h = plotEffects(mdl)

Description

plotEffects(mdl) produces an effects plot for the predictors in the mdl regression model. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. plotEffects chooses values to produce a relatively large effect on the response.

h = plotEffects(mdl) returns handles to the lines in the plot.

Input Arguments

mdl — Linear model object
LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using fitlm or stepwiselm, or a compacted CompactLinearModel object constructed using compact.

Output Arguments

h — Graphics handles
vector of graphics handles
Graphics handles to lines or patches in plot, returned as a vector of graphics handles. 
\( h(1) \) is a handle to the circles that represent the main effect estimates. 
\( h(j+1) \) is a handle to the line that defines the confidence interval for the effect of predictor \( j \).

**Examples**

**Effects Plot for Fitted Linear Regression Model**

Plot the effects of two predictors in a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an effects plot.

```matlab
plotEffects(mdl)
```
The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.
Alternatives

Use plotInteraction for an effects plot of the interactions of two specified variables.

CompactLinearModel | LinearModel | plotAdjustedResponse | plotInteraction

Topics
“Plots to Understand Predictor Effects” on page 11-29
“Linear Regression” on page 11-11
**plotInteraction**

**Class:** CompactLinearModel

Plot interaction effects of two predictors in linear regression model

**Syntax**

```
plotInteraction(mdl,var1,var2)
pplotInteraction(mdl,var1,var2,ptype)
h = plotInteraction(__)
```

**Description**

`plotInteraction(mdl,var1,var2)` creates a plot of the interaction effects of the predictors `var1` and `var2` in `mdl`. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. `plotInteraction` chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.

`plotInteraction(mdl,var1,var2,ptype)` returns a plot of the type specified in `ptype`.

```
h = plotInteraction(__)```
returns handles to the lines in the plot, using any of the previous syntaxes.

**Input Arguments**

- **mdl** — Linear model object
  
  Linear model object, specified as a full `LinearModel` object constructed using `fitlm` or `stepwiselm`, or a compacted `CompactLinearModel` object constructed using `compact`.
var1 — First variable for plot
variable name

First variable for plot, specified as a variable name. plotInteraction chooses values of var1 to create relatively large changes in the response. If you set ptype equal to 'predictions', then the plot shows curves as a function of var2 with various fixed values of var1.

Data Types: char | string

var2 — Second variable for plot
variable name

Second variable for plot, specified as a variable name. plotInteraction chooses values of var2 to create relatively large changes in the response. If you set ptype equal to 'predictions', then the plot shows curves as a function of var2 with various fixed values of var1.

Data Types: char | string

ptype — Plot type
'effects' (default) | 'predictions'

Plot type, specified as one of the following.

• 'effects' — The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. plotInteraction computes the effect values from the adjusted response curve, as shown by the plotAdjustedResponse function.
• 'predictions' — The plot shows the adjusted response curve as a function of var2, with var1 fixed at certain values.

Output Arguments

h — Graphics handles
vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.
Examples

Interaction Plot for Linear Regression Model

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(tbl,'MPG ~ Year * Weight^2');

Create an interaction plot.
plotInteraction(mdl,var1,var2)
```
The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

**Prediction Curve Interaction Plot for Linear Model**

Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(tbl,'MPG ~ Year * Weight^2');

Create an interaction plot with type 'predictions'.

plotInteraction(mdl,var1,var2,'predictions')

The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.
Tips

• For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

Alternatives

Use plotEffects for an effects plot showing separate effects for all predictors.

plotprofile

Class: RepeatedMeasuresModel
Plot expected marginal means with optional grouping

Syntax

plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile(__)

Description

plotprofile(rm,X) plots the expected marginal means computed from the repeated measures model rm as a function of the variable X.

plotprofile(rm,Name,Value) plots the expected marginal means computed from the repeated measures model rm with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the factors to group by or change the line colors.

H = plotprofile(__) returns handles, H, to the plotted lines.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object
Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

X — Name of between-subjects or within-subjects factor
count scalar
Name of a between-subjects or within-subjects factor, specified as a character vector or string scalar.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable drug, you can specify it as follows.

Example: 'Drug'

Data Types: char | string

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Group — Name of between-subject factor or factors
character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of 'Group' and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: 'Group', {'Drug', 'Sex'}

Data Types: char | string | cell

Marker — Marker to use for each group
string array | cell array of character vectors

Marker to use for each group, specified as the comma-separated pair consisting of 'Marker' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify o as the marker for the groups of drug and x as the marker for the groups of sex as follows.

Example: 'Marker', {'o', 'o', 'x', 'x'}

Data Types: string | cell
Color — Color for each group
character vector | string array | cell array of character vectors | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a character vector, string array, cell array of character vectors, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: 'Color','rrbb'

Data Types: single | double | char | string | cell

LineStyle — Line style for each group
string array | cell array of character vectors

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: 'LineStyle',{-' ':' '-' ':'}

Data Types: string | cell

Output Arguments

H — Handle to plotted lines
handle

Handle to plotted lines, returned as a handle.

Examples
Plot Expected Marginal Means

Load the sample data.

load fisheriris

The column vector species consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix meas consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{"species","meas1","meas2","meas3","meas4"});
Meas = dataset([1 2 3 4],{'VarNames',{"Measurements"}});

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);

Perform data grouped by the factor species.

plotprofile(rm,'species')
The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

**Plot Marginal Means for Two Groups**

Load the sample data.

```
load repeatedmeas
```
The table between includes the between-subject variables age, IQ, group, gender, and eight repeated measures y1 through y8 as responses. The table within includes the within-subject variables w1 and w2. This is simulated data.

Fit a repeated measures model, where the repeated measures y1 through y8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```matlab
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot the estimated marginal means based on the factors Group and Gender.

```matlab
ax1 = subplot(1,2,1);
plotprofile(rm, 'Group')
ax2 = subplot(1,2,2);
plotprofile(rm, 'Gender')
linkaxes([ax1 ax2], 'y')
```
Plot the estimated marginal means based on the factor Group and grouped by Gender.

```matlab
figure()
plotprofile(rm, 'Group', 'Group', 'Gender')
```

fitrm | margmean | plot
plotResiduals

**Class:** GeneralizedLinearModel

Plot residuals of generalized linear regression model

**Syntax**

plotResiduals(mdl)
plotResiduals(mdl,plottype)

h = plotResiduals(...)

h = plotResiduals(mdl,plottype,Name,Value)

**Description**

plotResiduals(mdl) gives a histogram plot of the residuals of the mdl nonlinear model.

plotResiduals(mdl,plottype) plots residuals in a plot of type plottype.

h = plotResiduals(...) returns handles to the lines in the plot.

h = plotResiduals(mdl,plottype,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.

**Input Arguments**

**mdl**

Generalized linear model, as constructed by fitglm or stepwiseglm.

**plottype**

Character vector or string scalar specifying the type of plot:
<table>
<thead>
<tr>
<th>'caseorder'</th>
<th>Residuals vs. case (row) order</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fitted'</td>
<td>Residuals vs. fitted values</td>
</tr>
<tr>
<td>'histogram'</td>
<td>Histogram</td>
</tr>
<tr>
<td>'lagged'</td>
<td>Residuals vs. lagged residual (r(t) vs. r(t-1))</td>
</tr>
<tr>
<td>'probability'</td>
<td>Normal probability plot</td>
</tr>
<tr>
<td>'symmetry'</td>
<td>Symmetry plot</td>
</tr>
</tbody>
</table>

**Default:** 'histogram'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**Note** The plot property name-value pairs apply to the first returned handle h(1).

**Color**

Color of the line or marker, a ColorSpec specification. For details, see linespec.

**LineStyle**

Type of line, a Chart Line specification. For details, see linespec.

**LineWidth**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

**MarkerEdgeColor**

Color of the marker or edge color for filled markers, a ColorSpec specification. For details, see linespec.
**MarkerFaceColor**

Color of the marker face for filled markers, a ColorSpec specification. For details, see `linespec`.

**MarkerSize**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

**ResidualType**

Type of residual used in the plot.

<table>
<thead>
<tr>
<th>ResidualType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Raw'</td>
<td>Observed minus fitted values</td>
</tr>
<tr>
<td>'LinearPredictor'</td>
<td>Residuals on the linear predictor scale, equal to the adjusted response</td>
</tr>
<tr>
<td></td>
<td>value minus the fitted linear combination of the predictors</td>
</tr>
<tr>
<td>'Pearson'</td>
<td>Raw residuals divided by RMSE</td>
</tr>
<tr>
<td>'Anscombe'</td>
<td>Residuals defined on transformed data with the transformation chosen to</td>
</tr>
<tr>
<td></td>
<td>remove skewness</td>
</tr>
<tr>
<td>'Deviance'</td>
<td>Residuals based on the contribution of each observation to the deviance</td>
</tr>
</tbody>
</table>

**Default:** 'Raw'

**Output Arguments**

**h**

Vector of handles to lines or patches in the plot.

**Examples**

**Residual Plots for Generalized Linear Models**

Create residual plots of a fitted generalized linear model.
Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```matlab
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```matlab
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a default residuals plot.

```matlab
plotResiduals(mdl)
```
Create a probability plot. The residuals do not match a normal distribution in the tails because they are more spread out.

plotResiduals(mdl,'probability')
Create a plot of the fitted residuals of Anscombe type.

plotResiduals(mdl,'fitted','ResidualType','Anscombe')
Definitions

Deviance

Deviance is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.
**Tips**

- For many plots, the Data Cursor tool in the figure window displays the \(x\) and \(y\) values for any data point, along with the observation name or number.

“Residuals — Model Quality for Training Data” on page 12-27
“Generalized Linear Models” on page 12-12
plotResiduals

Class: GeneralizedLinearMixedModel
Plot residuals of generalized linear mixed-effects model

Syntax

plotResiduals(glme,plottype)
plotResiduals(glme,plottype,Name,Value)

h = plotResiduals(___)

Description

plotResiduals(glme,plottype) plots the raw conditional residuals of the
generalized linear mixed-effects model glme in a plot of the type specified by plottype.

plotResiduals(glme,plottype,Name,Value) plots the conditional residuals of
glm in a plot using additional options specified by one or more Name,Value pair arguments. For
example, you can specify to plot the Pearson residuals.

h = plotResiduals(___ ) returns a handle, h, to the lines or patches in the plot of
residuals.

Input Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel
object. For properties and methods of this object, see GeneralizedLinearMixedModel.

plottype — Type of residual plot
'histogram' (default)| 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'
Type of residual plot, specified as one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'histogram'</td>
<td>Histogram of residuals</td>
</tr>
<tr>
<td>'caseorder'</td>
<td>Residuals versus case order. Case order is the same as the row order used in the input data tbl when fitting the model using fitglme.</td>
</tr>
<tr>
<td>'fitted'</td>
<td>Residuals versus fitted values</td>
</tr>
<tr>
<td>'lagged'</td>
<td>Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)</td>
</tr>
<tr>
<td>'probability'</td>
<td>Normal probability plot</td>
</tr>
<tr>
<td>'symmetry'</td>
<td>Symmetry plot</td>
</tr>
</tbody>
</table>

Example: plotResiduals(glme,'lagged')

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**ResidualType — Residual type**

'raw' (default) | 'Pearson'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

<table>
<thead>
<tr>
<th>Residual Type</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'raw'</td>
<td>$r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{\delta})$</td>
</tr>
<tr>
<td>'Pearson'</td>
<td>$r_{ci}^{\text{Pearson}} = \frac{r_{ci}}{\sqrt{\frac{\hat{\sigma}^2}{w_i} \left[ \nu_i \left( \mu_i \left( \hat{\beta}, \hat{\delta} \right) \right) \right]}}$</td>
</tr>
</tbody>
</table>
In each of these equations:

- \( y_i \) is the \( i \)th element of the \( n \)-by-1 response vector, \( y \), where \( i = 1, \ldots, n \).
- \( g^{-1} \) is the inverse link function for the model.
- \( x_i^T \) is the \( i \)th row of the fixed-effects design matrix \( X \).
- \( z_i^T \) is the \( i \)th row of the random-effects design matrix \( Z \).
- \( \delta_i \) is the \( i \)th offset value.
- \( \sigma^2 \) is the dispersion parameter.
- \( w_i \) is the \( i \)th observation weight.
- \( \nu_i \) is the variance term for the \( i \)th observation.
- \( \mu_i \) is the mean of the response for the \( i \)th observation.
- \( \hat{\beta} \) and \( \hat{b} \) are estimated values of \( \beta \) and \( b \).

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

### Output Arguments

**h** — Handle to residual plot

*graphics object*

Handle to the residual plot, returned as a graphics object. You can use dot notation to change certain property values of the object, including face color for a histogram, and marker style and color for a scatterplot. For more information, see “Access Property Values” (MATLAB).

### Examples

#### Create Plots of Residuals

Load the sample data.
This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[ \log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_{\text{dev},ij} + \beta_3 \text{temp}_{\text{dev},ij} + \beta_4 \text{supplier}_{C,ij} + \beta_5 \text{supplier}_{B,ij} + b_i, \]

where
• \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).

• \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1,2,\ldots,20 \)) during batch \( j \) (where \( j = 1,2,\ldots,5 \)).

• newprocess\(_{ij} \), time_dev\(_{ij} \), and temp_dev\(_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, newprocess\(_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.

• supplier\(_{Cij} \) and supplier\(_{Bij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).

• \( b_i \sim N(0,\sigma^2_b) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

\[
\text{glme} = \text{fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects')}
\]

Create diagnostic plots using Pearson residuals to test the model assumptions.

Plot a histogram to visually confirm that the mean of the Pearson residuals is equal to 0. If the model is correct, we expect the Pearson residuals to be centered at 0.

\[
\text{plotResiduals(glme,'histogram','ResidualType','Pearson')}
\]
The histogram shows that the Pearson residuals are centered at 0.

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity). We expect the conditional Pearson residuals to have a constant variance. Therefore, a plot of conditional Pearson residuals versus conditional fitted values should not reveal any systematic dependence on the conditional fitted values.

plotResiduals(glme,'fitted','ResidualType','Pearson')
The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

Plot the Pearson residuals versus lagged residuals, to check for correlation among the residuals. The conditional independence assumption in GLME implies that the conditional Pearson residuals are approximately uncorrelated.

plotResiduals(glme,'lagged','ResidualType','Pearson')
There is no pattern to the plot, so there are no signs of correlation among the residuals.

GeneralizedLinearMixedModel | fitglme | fitted | plot | residuals
plotResiduals

Class: LinearModel
Plot residuals of linear regression model

Syntax

plotResiduals(mdl)
plotResiduals(mdl,plottype)
h = plotResiduals(__)
h = plotResiduals(mdl,plottype,Name,Value)

Description

plotResiduals(mdl) gives a histogram plot of the residuals of the mdl linear model.

plotResiduals(mdl,plottype) plots residuals in a plot of type plottype.

h = plotResiduals(__) returns handles to the lines in the plot, using any of the previous syntaxes.

h = plotResiduals(mdl,plottype,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.

Input Arguments

mdl — Full, fitted linear regression model
LinearModel object

Full, fitted linear regression model, specified as a LinearModel object constructed using fitlm or stepwiselm.

plottype — Plot type
'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'
Plot type, specified as one of the following:

<table>
<thead>
<tr>
<th>Plot Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'caseorder'</td>
<td>Residuals vs. case (row) order</td>
</tr>
<tr>
<td>'fitted'</td>
<td>Residuals vs. fitted values</td>
</tr>
<tr>
<td>'histogram'</td>
<td>Histogram</td>
</tr>
<tr>
<td>'lagged'</td>
<td>Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)</td>
</tr>
<tr>
<td>'probability'</td>
<td>Normal probability plot</td>
</tr>
<tr>
<td>'symmetry'</td>
<td>Symmetry plot</td>
</tr>
</tbody>
</table>

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

#### Color — Color of line or marker

ColorSpec specification

Color of the line or marker, specified as the comma-separated pair consisting of 'Color' and a ColorSpec specification. For details, see `linespec`.

#### LineStyle — Line style

Chart Line Properties specification

Line style, specified as the comma-separated pair consisting of 'LineStyle' and a Chart Line specification. For details, see `linespec`.

####LineWidth — Width of line or edges

0.5 (default) | positive numeric value

Width of the line or edges of filled area, in points, specified as the comma-separated pair consisting of 'LineWidth' and a positive numeric value. One point is equal to 1/72 inch.

#### MarkerEdgeColor — Color of marker or edge

ColorSpec specification
Color of the marker or edge color for filled markers, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a ColorSpec specification. For details, see linespec.

**MarkerFaceColor — Color of marker face**

ColorSpec specification

Color of the marker face for filled markers, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a ColorSpec specification. For details, see linespec.

**MarkerSize — Size of marker**

positive numeric value

Size of the marker in points, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric value. One point is 1/72 inch.

**ResidualType — Residual type**

'raw' (default) | 'pearson' | 'standardized' | 'studentized'

Type of residual used in the plot, specified as the comma-separated pair consisting of 'ResidualType' and one of the following:

<table>
<thead>
<tr>
<th>ResidualType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'raw'</td>
<td>Observed minus fitted values</td>
</tr>
<tr>
<td>'pearson'</td>
<td>Raw residuals divided by RMSE</td>
</tr>
<tr>
<td>'standardized'</td>
<td>Raw residuals divided by their estimated standard deviation</td>
</tr>
<tr>
<td>'studentized'</td>
<td>Raw residuals divided by an independent (delete-1) estimate of their standard deviation</td>
</tr>
</tbody>
</table>

**Output Arguments**

**h — Graphics handles**

vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.
Examples

Histogram of Linear Model Residuals

Plot a histogram of the residuals of a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');

Plot the raw residuals.

plotResiduals(mdl)
```
Normal Probability Plot of Linear Model Residuals

Create a normal probability plot of the residuals of a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```
Create a normal probability plot of the residuals of the fitted model.

```matlab
plotResiduals(mdl,'probability')
```

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.
Alternatives

The mdl.Residuals table contains the information in residual plots.

plotResiduals

Class: LinearMixedModel

Plot residuals of linear mixed-effects model

Syntax

plotResiduals(lme,plottype)
plotResiduals(lme,plottype,Name,Value)

h = plotResiduals(__)

Description

plotResiduals(lme,plottype) plots the raw conditional residuals of the linear mixed-effects model lme in a plot of the type specified by plottype.

plotResiduals(lme,plottype,Name,Value) also plots the residuals of the linear mixed-effects model lme with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

plotResiduals also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see plot.

h = plotResiduals(__) returns a handle, h, to the lines or patches in the plot of residuals.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.
plotResiduals — Type of residual plot

| 'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry' |

Type of residual plot, specified as one of the following.

- `'histogram'`: Default. Histogram of residuals
- `'caseorder'`: Residuals versus case (row) order
- `'fitted'`: Residuals versus fitted values
- `'lagged'`: Residuals versus lagged residual ($r(t)$ versus $r(t-1)$)
- `'probability'`: Normal probability plot
- `'symmetry'`: Symmetry plot

Example: `plotResiduals(lme,'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

ResidualType — Residual type

| 'Raw' (default) | 'Pearson' | 'Standardized' |

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

<table>
<thead>
<tr>
<th>Residual Type</th>
<th>Conditional</th>
<th>Marginal</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Raw'</td>
<td>$r_i^C = \left[ y - X\hat{\beta} - Zb \right]_i$</td>
<td>$r_i^M = \left[ y - X\hat{\beta} \right]_i$</td>
</tr>
<tr>
<td>'Pearson'</td>
<td>$pr_i^C = \frac{r_i^C}{\sqrt{\text{Var}_{y,b} \left( y - X\beta - Zb \right)_i}}$</td>
<td>$pr_i^M = \frac{r_i^M}{\sqrt{\text{Var}_{y} \left( y - X\beta \right)_i}}$</td>
</tr>
</tbody>
</table>
Residual Type | Conditional | Marginal
---|---|---
'Standardized' | $s_{t}^{C} = \frac{r_{i}^{C}}{\sqrt{\text{Var}(r^{C})_{ii}}}$ | $s_{t}^{M} = \frac{r_{i}^{M}}{\sqrt{\text{Var}(r^{M})_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see Definitions at the end of this page.

Example: 'ResidualType','Standardized'

### Output Arguments

**h — Handle to residual plot**

`handle`

Handle to the residual plot, returned as a handle.

### Examples

#### Examine Residuals

Load the sample data.

```matlab
load(fullfile(matlabroot,'examples','stats','weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');

Plot the histogram of the raw residuals.
plotResiduals(lme)

Plot the residuals versus the fitted values.
figure();
plotResiduals(lme,'fitted')
There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```plaintext
figure();
plotResiduals(lme,'probability')
```
Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```matlab
find(residuals(lme)>0.25)
```

```matlab
ans =
    101
```

Create a box plot of the raw, Pearson, and standardized residuals.

32-4861
\[ r = \text{residuals(lme)}; \]
\[ \text{pr} = \text{residuals(lme,'ResidualType','Pearson')}; \]
\[ \text{st} = \text{residuals(lme,'ResidualType','Standardized')}; \]
\[ X = [r \ \text{pr} \ \text{st}]; \]
\[ \text{boxplot}(X,'labels',\{'\text{Raw}',\'\text{Pearson}',\'\text{Standardized}'\}); \]

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point out a second possible outlier on the left tail. Find the corresponding observation number.

\[ \text{find(pr<-2)} \]

\[ \text{ans =} \]

[32-4862]
Plot the raw residuals versus lagged residuals.

```matlab
plotResiduals(lme, 'lagged')
```

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

**See Also**

`LinearMixedModel`, `fitted`, `residuals`
**plotResiduals**

**Class:** NonLinearModel

Plot residuals of nonlinear regression model

**Syntax**

```matlab
plotResiduals(mdl)
plotResiduals(mdl,plottype)
```

```
h = plotResiduals(...)  
h = plotResiduals(mdl,plottype,Name,Value)
```

**Description**

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

```
h = plotResiduals(...)  returns handles to the lines in the plot.
```

```
h = plotResiduals(mdl,plottype,Name,Value) plots with additional options specified by one or more Name,Value pair arguments.
```

**Input Arguments**

- **mdl**
  Nonlinear regression model, constructed by `fitnlm`.

- **plottype**
  Character vector or string scalar specifying the type of plot:
<table>
<thead>
<tr>
<th>Case</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'caseorder'</td>
<td>Residuals vs. case (row) order</td>
</tr>
<tr>
<td>'fitted'</td>
<td>Residuals vs. fitted values</td>
</tr>
<tr>
<td>'histogram'</td>
<td>Histogram</td>
</tr>
<tr>
<td>'lagged'</td>
<td>Residuals vs. lagged residual (rt vs. r(t-1))</td>
</tr>
<tr>
<td>'probability'</td>
<td>Normal probability plot</td>
</tr>
<tr>
<td>'symmetry'</td>
<td>Symmetry plot</td>
</tr>
</tbody>
</table>

**Default:** 'histogram'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

**Color**

Color of the line or marker, a `ColorSpec` specification. For details, see `linespec`.

**LineStyle**

Type of line, a Chart Line specification. For details, see `linespec`.

**LineWidth**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

**MarkerEdgeColor**

Color of the marker or edge color for filled markers, a `ColorSpec` specification. For details, see `linespec`. 
MarkerFaceColor

Color of the marker face for filled markers, a ColorSpec specification. For details, see linespec.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

ResidualType

Type of residual used in the plot:

<table>
<thead>
<tr>
<th>ResidualType</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Raw'</td>
<td>Observed minus fitted values</td>
</tr>
<tr>
<td>'Pearson'</td>
<td>Raw residuals divided by RMSE</td>
</tr>
<tr>
<td>'Standardized'</td>
<td>Raw residuals divided by their estimated standard deviation</td>
</tr>
<tr>
<td>'Studentized'</td>
<td>Raw residuals divided by an independent (delete-1) estimate of their standard deviation</td>
</tr>
</tbody>
</table>

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Residual Plot

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
Plot the residuals of the fitted model.

```matlab
plotResiduals(mdl)
```

**Residual Probability Plot**

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the `reaction` data and fit a model of the reaction rate as a function of reactants.

```matlab
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```
Create a normal probability plot of the residuals of the fitted model.

```matlab
plotResiduals(mdl,'probability')
```

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the x and y values for any data point, along with the observation name or number.

“Nonlinear Regression” on page 13-2
plotSlice

Plot of slices through fitted generalized linear regression surface

Syntax

plotSlice(mdl)

h = plotSlice(mdl)

Description

plotSlice(mdl) creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by mdl. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

h = plotSlice(mdl) returns handles to the lines in the plot.

Input Arguments

mdl

Generalized linear model, specified as a full GeneralizedLinearModel object constructed using fitglm or stepwiseglm, or a compacted CompactGeneralizedLinearModel object constructed using compact.

Output Arguments

h

Vector of handles to lines or patches in the plot.
Examples

Slice Plot of Generalized Linear Regression Model

Create a slice plot of a Poisson generalized linear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```matlab
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```matlab
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create the slice plot.

```matlab
plotSlice(mdl)
```

Drag the $x_1$ prediction line to the right and view the changes in the prediction and the response curve for the $x_2$ predictor.
Tips

- If there are more than eight predictors, plotSlice selects the first five for plotting. Use the Predictors menu to control which predictors are plotted.
- The Bounds menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

plotSlice

Class: CompactLinearModel

Plot of slices through fitted linear regression surface

Syntax

plotSlice(mdl)
h = plotSlice(mdl)

Description

plotSlice(mdl) creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by mdl. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

h = plotSlice(mdl) returns handles to the lines in the plot.

Input Arguments

mdl — Linear model object
LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using fitlm or stepwiselm, or a compacted CompactLinearModel object constructed using compact.

Output Arguments

h — Graphics handles
vector of graphics handle objects

Graphics handles, returned as a vector of graphics handles corresponding to the lines or patches in the plot.
Examples

Slice Plot for Linear Regression Model

Plot the slices through a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```matlab
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');

Create a slice plot.

plotSlice(mdl)
```

Drag the Weight prediction line to the right and observe the change in the predicted MPG and the response curve for Year.
Tips

• If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
• The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

plotSlice

Class: NonLinearModel

Plot of slices through fitted nonlinear regression surface

Syntax

plotSlice(mdl)

h = plotSlice(mdl)

Description

plotSlice(mdl) creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by mdl. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

h = plotSlice(mdl) returns handles to the lines in the plot.

Input Arguments

mdl

Nonlinear regression model, constructed by fitnlm.

Output Arguments

h

Vector of handles to lines or patches in the plot.
Examples

Slice Plot

Plot slices of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```matlab
load reaction
mdl = fitnlm(reactants,...
    rate,@hougen,[1 .05 .02 .1 2]);
```

Create a slice plot

```matlab
plotSlice(mdl)
```

Drag the X1 prediction line to the right, and observe the change in the predicted response y and in the predicted response curves to X2 and X3.
Tips

- If there are more than eight predictors, plotSlice selects the first five for plotting. Use the Predictors menu to control which predictors are plotted.
- The Bounds menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

**plsregress**

Partial least-squares regression

**Syntax**

```matlab
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = plsregress(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,
param1,val1,param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = plsregress(X,Y,ncomp,...)
```

**Description**

[XL,YL] = plsregress(X,Y,ncomp) computes a partial least-squares (PLS) regression of Y on X, using ncomp PLS components, and returns the predictor and response loadings in XL and YL, respectively. X is an n-by-p matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an n-by-m response matrix. XL is a p-by-ncomp matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. YL is an m-by-ncomp matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

[XL,YL,XS] = plsregress(X,Y,ncomp) returns the predictor scores XS, that is, the PLS components that are linear combinations of the variables in X. XS is an n-by-ncomp orthonormal matrix with rows corresponding to observations and columns to components.

[XL,YL,XS,YS] = plsregress(X,Y,ncomp) returns the response scores YS, that is, the linear combinations of the responses with which the PLS components XS have maximum covariance. YS is an n-by-ncomp matrix with rows corresponding to observations and columns to components. YS is neither orthogonal nor normalized.
The `plsregress` function uses the SIMPLS algorithm, first centering X and Y by subtracting off column means to get centered variables $X_0$ and $Y_0$. However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize X and Y.

If `ncomp` is omitted, its default value is $\min(\text{size}(X,1)-1,\text{size}(X,2))$.

The relationships between the scores, loadings, and centered variables $X_0$ and $Y_0$ are:

$$XL = (XS'X_0)' = X_0'*XS,$$

$$YL = (XS'Y_0)' = Y_0'*XS,$$

$XL$ and $YL$ are the coefficients from regressing $X_0$ and $Y_0$ on $XS$, and $XS*XL'$ and $XS*YL'$ are the PLS approximations to $X_0$ and $Y_0$.

`plsregress` initially computes $YS$ as:

$$YS = Y_0*YL = Y_0*Y_0'*XS,$$

By convention, however, `plsregress` then orthogonalizes each column of $YS$ with respect to preceding columns of $XS$, so that $XS'*YS$ is lower triangular.

$$[XL,YL,XS,YS,BETA] = plsregress(X,Y,ncomp,...)$$

returns the PLS regression coefficients $BETA$. $BETA$ is a $(p+1)$-by-$m$ matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n,1),X]*BETA + Y\text{residuals},$$

$$Y_0 = X_0*BETA(2:end,:)+Y\text{residuals}.$$ Here $Y\text{residuals}$ is the vector of response residuals.

$$[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)$$

returns a 2-by-$ncomp$ matrix $PCTVAR$ containing the percentage of variance explained by the model. The first row of $PCTVAR$ contains the percentage of variance explained in $X$ by each PLS component, and the second row contains the percentage of variance explained in $Y$.

$$[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)$$

returns a 2-by-($ncomp+1$) matrix $MSE$ containing estimated mean-squared errors for PLS models with $0:ncomp$ components. The first row of $MSE$ contains mean-squared errors for the predictor variables in $X$, and the second row contains mean-squared errors for the response variable(s) in $Y$. 
[XL, YL, XS, YS, BETA, PCTVAR, MSE] = 
plsregress(..., param1, val1, param2, val2, ...) specifies optional parameter name/value pairs from the following table to control the calculation of MSE.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cv'</td>
<td>The method used to compute MSE.</td>
</tr>
<tr>
<td></td>
<td>• When the value is a positive integer k, plsregress uses k-fold cross-validation.</td>
</tr>
<tr>
<td></td>
<td>• When the value is an object of the cvpartition on page 32-1169 class, other forms of cross-validation can be specified.</td>
</tr>
<tr>
<td></td>
<td>• When the value is 'resubstitution', plsregress uses X and Y both to fit the model and to estimate the mean-squared errors, without cross-validation.</td>
</tr>
<tr>
<td></td>
<td>The default is 'resubstitution'.</td>
</tr>
<tr>
<td>'mcreps'</td>
<td>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution'.</td>
</tr>
<tr>
<td>options</td>
<td>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with statset. Option fields:</td>
</tr>
<tr>
<td></td>
<td>• UseParallel — Set to true to compute in parallel. Default is false.</td>
</tr>
<tr>
<td></td>
<td>• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
<tr>
<td></td>
<td>• Streams — A RandStream object or cell array consisting of one such object. If you do not specify Streams, plsregress uses the default stream.</td>
</tr>
</tbody>
</table>

To compute in parallel, you need Parallel Computing Toolbox.

[XL, YL, XS, YS, BETA, PCTVAR, MSE, stats] = plsregress(X, Y, ncomp, ...) returns a structure stats with the following fields:

- W — A p-by-ncomp matrix of PLS weights so that XS = X0*W.
- T2 — The $T^2$ statistic for each point in XS.
- Xresiduals — The predictor residuals, that is, $X0 - XS * XL'$.
- Yresiduals — The response residuals, that is, $Y0 - XS * YL'$.
Examples

Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

```matlab
load spectra
X = NIR;
y = octane;

Perform PLS regression with ten components.

[XL,yl,XS,YS,beta,PCTVAR] = plsregress(X,y,10);

Plot the percent of variance explained in the response variable as a function of the number of components.

plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');
```
Compute the fitted response and display the residuals.

```matlab
yfit = [ones(size(X,1),1) X]*beta;
residuals = y - yfit;
stem(residuals)
xlabel('Observation');
ylabel('Residual');
```
References

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

regress | sequentialfs

Introduced in R2008a
**PointOrder property**

**Class:** sobolset

Point generation method

**Description**

The `PointOrder` property contains a character vector that specifies the order in which the Sobol sequence points are produced. The property value must be one of 'standard' or 'graycode'. When set to 'standard' the points produced match the original Sobol sequence implementation. When set to 'graycode', the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

You can specify `PointOrder` as a character vector or string scalar using dot notation: `P.PointOrder = newPointOrder`. 
PointSet property

Class: qrandstream

Point set from which stream is drawn

Description

The PointSet property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

Examples

Q = qrandstream('sobol', 5, 'Skip', 8);
% Create a new stream based on the same sequence as that in Q
Q2 = qrandstream(Q.PointSet);
u1 = qrand(Q, 10)
u2 = qrand(Q2, 10) % contains exactly the same values as u1
poisscdf

Poisson cumulative distribution function

Syntax

\[ p = \text{poisscdf}(x, \lambda) \]
\[ p = \text{poisscdf}(x, \lambda, '\text{upper}') \]

Description

\[ p = \text{poisscdf}(x, \lambda) \] returns the Poisson cdf at each value in \( x \) using the corresponding mean parameters in \( \lambda \). \( x \) and \( \lambda \) can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in \( \lambda \) must be positive.

\[ p = \text{poisscdf}(x, \lambda, '\text{upper}') \] returns the complement of the Poisson cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

The Poisson cdf is

\[ p = F(x \mid \lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!} \]

Examples

Compute Poisson Distribution cdf

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an
inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors (\( \lambda \)) is two?

\[
\text{probability} = 1 - \text{poisscdf}(4, 2)
\]

\[
\text{probability} = 0.0527
\]

About 5% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

Suppose the average number of flaws (\( \lambda \)) increases to four. What is the probability of finding fewer than five flaws on a hard drive?

\[
\text{probability} = \text{poisscdf}(4, 4)
\]

\[
\text{probability} = 0.6288
\]

This means that this faulty manufacturing process continues to operate after this first inspection almost 63% of the time.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“Poisson Distribution” on page B-137

Introduced before R2006a
poissfit

Poisson parameter estimates

Syntax

\[
\text{lambdahat} = \text{poissfit(data)} \\
[\text{lambdahat, lambdaci}] = \text{poissfit(data)} \\
[\text{lambdahat, lambdaci}] = \text{poissfit(data, alpha)}
\]

Description

\[
\text{lambdahat} = \text{poissfit(data)} \text{ returns the maximum likelihood estimate (MLE) of the} \\
\text{parameter of the Poisson distribution, } \lambda, \text{ given the data } \text{data}.
\]

\[
[\text{lambdahat, lambdaci}] = \text{poissfit(data)} \text{ also gives 95\% confidence intervals in} \\
\text{lambdaci}.
\]

\[
[\text{lambdahat, lambdaci}] = \text{poissfit(data, alpha)} \text{ gives } 100(1 - \alpha)\% \\
\text{confidence intervals. For example } \alpha = 0.001 \text{ yields 99.9\% confidence intervals}.
\]

The sample mean is the MLE of \( \lambda \).

\[
\hat{\lambda} = \frac{1}{n} \sum_{i=1}^{n} x_i
\]

Examples

\[
r = \text{poissrnd}(5,10,2); \\
[l, lci] = \text{poissfit(r)}
\]

\[
l =
\begin{array}{cc}
7.4000 & 6.3000 \\
\end{array}
\]

\[
lci =
\begin{array}{cc}
5.8000 & 4.8000 \\
9.1000 & 7.9000 \\
\end{array}
\]

"Poisson Distribution" on page B-137

Introduced before R2006a
poissinv

Poisson inverse cumulative distribution function

Syntax

X = poissinv(P,lambda)

Description

X = poissinv(P,lambda) returns the smallest value X such that the Poisson cdf evaluated at X equals or exceeds P, using mean parameters in lambda. P and lambda can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

Examples

If the average number of defects (λ) is two, what is the 95th percentile of the number of defects?

```matlab
poissinv(0.95,2)
an5 =
  5
```

What is the median number of defects?

```matlab
median_defects = poissinv(0.50,2)
median_defects =
  2
```
Extended Capabilities

“Poisson Distribution” on page B-137

Introduced before R2006a
poisspdf

Poisson probability density function

Syntax

Y = poisspdf(X,lambda)

Description

Y = poisspdf(X,lambda) computes the Poisson pdf at each of the values in X using mean parameters in lambda. X and lambda can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in lambda must all be positive.

The Poisson pdf is

\[ f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \ldots, \infty. \]

The density function is zero unless x is an integer.

Examples

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem, \( \lambda = 2 \) and \( x = 0 \).

\[
\begin{align*}
p &= \text{poisspdf}(0,2) \\
p &= 0.1353
\end{align*}
\]
Extended Capabilities

Topics
“Poisson Distribution” on page B-137

Introduced before R2006a
**poissrnd**

Poisson random numbers

**Syntax**

\[
R = \text{poissrnd}(\lambda)
R = \text{poissrnd}(\lambda,m,n,...)
R = \text{poissrnd}(\lambda,[m,n,...])
\]

**Description**

\( R = \text{poissrnd}(\lambda) \) generates random numbers from the Poisson distribution with mean parameter \( \lambda \). \( \lambda \) can be a vector, a matrix, or a multidimensional array. The size of \( R \) is the size of \( \lambda \).

\( R = \text{poissrnd}(\lambda,m,n,...) \) or \( R = \text{poissrnd}(\lambda,[m,n,...]) \) generates an \( m \)-by-\( n \)-by-\( ... \) array. The \( \lambda \) parameter can be a scalar or an array of the same size as \( R \).

**Examples**

Generate a random sample of 10 pseudo-observations from a Poisson distribution with \( \lambda = 2 \).

\[
\text{lambda} = 2;
\]

\[
\text{random_sample1} = \text{poissrnd}(
\text{lambda},1,10)
\]
\[
\text{random_sample1} =
\begin{bmatrix}
1 & 0 & 1 & 2 & 1 & 3 & 4 & 2 & 0 & 0
\end{bmatrix}
\]

\[
\text{random_sample2} = \text{poissrnd}(\text{lambda},[1 10])
\]
\[
\text{random_sample2} =
\begin{bmatrix}
1 & 1 & 1 & 5 & 0 & 3 & 2 & 2 & 3 & 4
\end{bmatrix}
\]

\[
\text{random_sample3} = \text{poissrnd}(\text{lambda(ones(1,10)))}
\]
random_sample3 =
3 2 1 1 0 0 4 0 2 0

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

“Poisson Distribution” on page B-137

Introduced before R2006a
poisstat

Poisson mean and variance

Syntax

M = poisstat(lambda)
[M,V] = poisstat(lambda)

Description

M = poisstat(lambda) returns the mean of the Poisson distribution using mean parameters in lambda. The size of M is the size of lambda.

[M,V] = poisstat(lambda) also returns the variance V of the Poisson distribution.

For the Poisson distribution with parameter \( \lambda \), both the mean and variance are equal to \( \lambda \).

Examples

Find the mean and variance for the Poisson distribution with \( \lambda = 2 \).

\[
[M,V] = poisstat([1 2; 3 4])
\]

\[
M =
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]

\[
V =
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]
Extended Capabilities

Topics
“Poisson Distribution” on page B-137

Introduced before R2006a
polyconf

Polynomial confidence intervals

Syntax

Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)

Description

Y = polyconf(p,X) evaluates the polynomial p at the values in X. p is a vector of coefficients in descending powers.

[Y,DELTA] = polyconf(p,X,S) takes outputs p and S from polyfit and generates 95% prediction intervals Y ± DELTA for new observations at the values in X.

[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...) specifies optional parameter name/value pairs chosen from the following list.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'alpha'</td>
<td>A value between 0 and 1 specifying a confidence level of 100*(1-alpha)%. The default is 0.05.</td>
</tr>
<tr>
<td>'mu'</td>
<td>A two-element vector containing centering and scaling parameters. With this option, polyconf uses (X-mu(1))/mu(2) in place of X.</td>
</tr>
<tr>
<td>'predopt'</td>
<td>Either 'observation' (the default) to compute prediction intervals for new observations at the values in X, or 'curve' to compute confidence intervals for the fit evaluated at the values in X. See below.</td>
</tr>
<tr>
<td>'simopt'</td>
<td>Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.</td>
</tr>
</tbody>
</table>

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:
- \( p(x) \) — the unknown mean function estimated by the fit
- \( l(x) \) — the lower confidence bound
- \( u(x) \) — the upper confidence bound

Suppose you make a new observation \( y_{n+1} \) at \( x_{n+1} \), so that

\[
y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}
\]

By default, the interval \([l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]\) is a 95% confidence bound on \( y_{n+1}(x_{n+1}) \).

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

<table>
<thead>
<tr>
<th>'simopt'</th>
<th>'predopt'</th>
<th>Bounded Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>'off'</td>
<td>'observation'</td>
<td>( y_{n+1}(x_{n+1}) ) (default)</td>
</tr>
<tr>
<td>'off'</td>
<td>'curve'</td>
<td>( p(x_{n+1}) )</td>
</tr>
<tr>
<td>'on'</td>
<td>'observation'</td>
<td>( y_{n+1}(x) ), for all ( x )</td>
</tr>
<tr>
<td>'on'</td>
<td>'curve'</td>
<td>( p(x) ), for all ( x )</td>
</tr>
</tbody>
</table>

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors \( x \).
Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into text for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

**Note** Statistics and Machine Learning Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder.
Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```matlab
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));
degree = 2;       % Degree of the fit
alpha = 0.05;    % Significance level

% Compute the fit and return the structure used by % POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the % data.
r = roots(p)';                                           % Roots as a row vector.
real_r = r(imag(r) == 0);                                 % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
        'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
```
hroots = plot(real_r,zeros(size(real_r)),...
    'bo','MarkerSize',5,...
    'LineWidth',2,...
    'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100;  % Round for display.
htitle = title(['\bf Fit:  ',
    texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100;  % Round for display.
hxlabel = xlabel(['\bf Real Roots:     ',
    num2str(approx_real_r)]);
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
    'Data','Fit','Real Roots of Fit',...
    '95% Prediction Intervals')

polyfit | polytool | polyval

Introduced before R2006a
polytool

Interactive polynomial fitting

Syntax

polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)  

Description

polytool(x,y) fits a line to the vectors x and y and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

polytool(x,y,n) initially fits a polynomial of degree n. The default is 1, which produces a linear fit.

polytool(x,y,n,alpha) initially plots 100(1 - alpha)% confidence intervals on the predicted values. The default is 0.05 which results in 95% confidence intervals.

polytool(x,y,n,alpha,xname,yname) labels the x and y values on the graphical interface using xname and yname. Specify n and alpha as [] to use their default values.

h = polytool(...) outputs a vector of handles, h, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

Examples

Interactive polynomial fitting

This example shows how to start an interactive fitting session with polytool.
Generate data from a quadratic curve with added noise.

```matlab
generating('default') % for reproducibility
x = -5:5;
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with \(0.90\) confidence intervals.

```matlab
n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)
```

invpred | polyconf | polyfit | polyval

**Introduced before R2006a**
posterior

Posterior probability of Gaussian mixture component

Syntax

\[ P = \text{posterior}(gm, X) \]
\[ [P, n\text{logL}] = \text{posterior}(gm, X) \]

Description

\( P = \text{posterior}(gm, X) \) returns the posterior probability of each Gaussian mixture component in \( gm \) given each observation in \( X \).

\[ [P, n\text{logL}] = \text{posterior}(gm, X) \] also returns the negative loglikelihood of the Gaussian mixture model \( gm \) given the data \( X \).

Examples

Compute Posterior Probabilities

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the \text{mvnrnd} function. Fit a Gaussian mixture model (GMM) to the generated data by using the \text{fitgmdist} function, and then compute the posterior probabilities of the mixture components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

\[
\begin{align*}
\text{mu1} &= [2 \ 2]; & \% \text{Mean of the 1st component} \\
\text{sigma1} &= [2 \ 0; \ 0 \ 1]; & \% \text{Covariance of the 1st component} \\
\text{mu2} &= [-2 \ -1]; & \% \text{Mean of the 2nd component} \\
\text{sigma2} &= [1 \ 0; \ 0 \ 1]; & \% \text{Covariance of the 2nd component}
\end{align*}
\]
Generate an equal number of random variates from each component, and combine the
two sets of random variates.

```matlab
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set \( X \) contains random variates following a mixture of two bivariate
Gaussian distributions.

Fit a two-component GMM to \( X \).

```matlab
gm = fitgmdist(X,2)
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500765
Mean:  -1.9675   -0.9654

Component 2:
Mixing proportion: 0.499235
Mean:   1.9657    2.0342
```

Plot \( X \) by using `scatter`. Visualize the fitted model \( gm \) by using `pdf` and `ezcontour`.

```matlab
figure
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
ezcontour(@(x,y)pdf(gm,[x y]),[-6 8],[-4 6])
c1 = colorbar;
ylabel(c1,'Probability Density Function')
```
Compute the posterior probabilities of the components.

\[ P = \text{posterior}(gm,X); \]

\[ P(i,j) \] is the posterior probability of the \( j \)th Gaussian mixture component given observation \( i \).

Plot the posterior probabilities of Component 1 by using the `scatter` function. Use the circle colors to visualize the posterior probability values.

```matlab
figure
scatter(X(:,1),X(:,2),10,P(:,1))
c2 = colorbar;
ylabel(c2,'Posterior Probability of Component 1')
```
Plot the posterior probabilities of Component 2.

```matlab
figure
scatter(X(:,1),X(:,2),10,P(:,2))
c3 = colorbar;
ylabel(c3,'Posterior Probability of Component 2')
```
## Input Arguments

**gm — Gaussian mixture distribution**

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the
distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

**X — Data**
n-by-m numeric matrix

Data, specified as an n-by-m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

If a row of X contains NaNs, then posterior excludes the row from the computation. The corresponding value in P is NaN.

Data Types: `single` | `double`

### Output Arguments

**P — Posterior probability**
n-by-k numeric vector

Posterior probability of each Gaussian mixture component in gm given each observation in X, returned as an n-by-k numeric vector, where n is the number of observations in X and k is the number of mixture components in gm.

P(i,j) is the posterior probability of the jth Gaussian mixture component given observation i, `Probability(component j | observation i)`.

**nlogL — Negative loglikelihood**
numeric value

Negative loglikelihood value of the Gaussian mixture model gm given the data X, returned as a numeric value.

“Cluster Gaussian Mixture Data Using Soft Clustering” on page 16-48

Introduced in R2007b
**postFitStatistics**

**Class:** RegressionGP

Compute post-fit statistics for the exact Gaussian process regression model

**Syntax**

```matlab
loores = postFitStatistics(gprMdl)
[loores,neff] = postFitStatistics(gprMdl)
```

**Description**

`loores = postFitStatistics(gprMdl)` returns the leave-one-out residuals, `loores`, for the trained Gaussian process regression (GPR) model.

`[loores,neff] = postFitStatistics(gprMdl)` also returns the number of effective parameters, `neff`.

**Input Arguments**

`gprMdl` — Gaussian process regression model
RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

**Output Arguments**

`loores` — Leave-one-out residuals
n-by-1 matrix

Leave-one-out residuals, returned as an n-by-1 matrix, where n is the number of observations in the training data.
**neff — Number of effective parameters**

*n*-by-1 matrix

Number of effective parameters, returned as an *n*-by-1 matrix, where *n* is the number of observations in the training data.

## Examples

### Compute Post-Fit Statistics

Generate sample data.

```matlab
rng(0,'twister'); % For reproducibility
n = 1500;
x = linspace(-10,10,n);
y = sin(3*x).*cos(3*x) + sin(2*x).*cos(2*x) + sin(x) + cos(x) + 0.2*randn(n,1);
```

Fit a GPR model using the exact method for fitting and prediction.

```matlab
gprMdl = fitrgp(x,y,'Basis','linear','FitMethod','exact',
'PredictMethod','exact','KernelFunction','matern52');
```

Compute the leave-one-out residuals and the effective number of parameters in the trained model.

```matlab
[loores,neff] = postFitStatistics(gprMdl);
```

Predict the responses using the trained model.

```matlab
ypred = resubPredict(gprMdl);
```

Plot the true and predicted responses, and display effective number of parameters in the fit.

```matlab
figure()
plot(x,y,'r.');
hold on;
plot(x,ypred,'b');
xlabel('x');
ylabel('y');
legend('Data','GPR prediction','Location','Best');
```
effective number of parameters = 94.7514

Plot leave-one-out residuals.

figure()
plot(x,loores,'r.-');
xlabel('x');
ylabel('leave-one-out residuals');
**Tips**

- You can only compute the post-fit statistics when `PredictMethod` is 'exact'.
- If `FitMethod` is 'exact', then `postFitStatistics` accounts for the fact that the fixed basis function coefficients are estimated from the data.
- If `FitMethod` is different than 'exact', then `postFitStatistics` treats the fixed basis function coefficients as known.
- For all `PredictMethod` and `FitMethod` options, `postFitStatistics` treats the estimated kernel parameters and noise standard deviation as known.

RegressionGP | fitrgp

Introduced in R2015b
prctile

Percentiles of a data set

Syntax

Y = prctile(X,p)
Y = prctile(X,p,'all')
Y = prctile(X,p,dim)
Y = prctile(X,p,vecdim)
Y = prctile(___, 'Method', method)

Description

Y = prctile(X,p) returns percentiles of the elements in a data vector or array X for
the percentages p in the interval [0,100].

• If X is a vector, then Y is a scalar or a vector with the same length as the number of
  percentiles requested (length(p)). Y(i) contains the p(i) percentile.
• If X is a matrix, then Y is a row vector or a matrix, where the number of rows of Y is
equal to the number of percentiles requested (length(p)). The ith row of Y contains
  the p(i) percentiles of each column of X.
• For multidimensional arrays on page 32-4932, prctile operates along the first
  nonsingleton dimension on page 32-4933 of X.

Y = prctile(X,p,'all') returns percentiles of all the elements of X.

Y = prctile(X,p,dim) returns percentiles along the operating dimension dim.

Y = prctile(X,p,vecdim) returns percentiles over the dimensions specified in the
vector vecdim. For example, if X is a matrix, then prctile(X,50,[1 2]) returns the
50th percentile of all the elements of X because every element of a matrix is contained in
the array slice defined by dimensions 1 and 2.

Y = prctile(___, 'Method', method) returns either exact or approximate
percentiles based on the value of method, using any of the input argument combinations
in the previous syntaxes.
Examples

Percentiles of a Data Vector

Generate a data set of size 10.

```matlab
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x = 1×10
6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328    5.6852   12.1568   10.5389
```

Calculate the 42nd percentile.

```matlab
Y = prctile(x,42)
```

```
Y = 5.6709
```

Percentiles of All Values

Find the percentiles of all the values in an array.

Create a 3-by-5-by-2 array `X`.

```matlab
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =
     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15
X(:,:,2) =
    16    19    22    25    28
    17    20    23    26    29
```
Find the 40th and 60th percentiles of the elements of $X$.

$Y = \text{prctile}(X,[40\ 60], 'all')$

$Y = \begin{bmatrix} 12.5000 \\ 18.5000 \end{bmatrix}$

$Y(1)$ is the 40th percentile of $X$, and $Y(2)$ is the 60th percentile of $X$.

**Percentiles of a Data Matrix**

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

$X = (1:5)'*(2:6)$

$X = \begin{bmatrix} 2 & 3 & 4 & 5 & 6 \\ 4 & 6 & 8 & 10 & 12 \\ 6 & 9 & 12 & 15 & 18 \\ 8 & 12 & 16 & 20 & 24 \\ 10 & 15 & 20 & 25 & 30 \end{bmatrix}$

Calculate the 25th, 50th, and 75th percentiles along the columns of $X$.

$Y = \text{prctile}(X,[25\ 50\ 75],1)$

The rows of \( Y \) correspond to the percentiles of columns of \( X \). For example, the 25th, 50th, and 75th percentiles of the third column of \( X \) with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. \( Y = \text{prctile}(X, [25 \ 50 \ 75]) \) returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of \( X \).

\[
Y = \text{prctile}(X, [25 \ 50 \ 75], 2)
\]

\[
Y = \begin{bmatrix}
2.7500 & 4.0000 & 5.2500 \\
5.5000 & 8.0000 & 10.5000 \\
8.2500 & 12.0000 & 15.7500 \\
11.0000 & 16.0000 & 21.0000 \\
13.7500 & 20.0000 & 26.2500
\end{bmatrix}
\]

The rows of \( Y \) correspond to the percentiles of rows of \( X \). For example, the 25th, 50th, and 75th percentiles of the first row of \( X \) with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

**Percentiles of Multidimensional Array**

Find the percentiles of a multidimensional array along multiple dimensions simultaneously.

Create a 3-by-5-by-2 array \( X \).

\[
X = \text{reshape}(1:30, [3 \ 5 \ 2])
\]

\[
X = \begin{bmatrix}
1 & 4 & 7 & 10 & 13 \\
2 & 5 & 8 & 11 & 14 \\
3 & 6 & 9 & 12 & 15 \\
16 & 19 & 22 & 25 & 28 \\
17 & 20 & 23 & 26 & 29
\end{bmatrix}
\]
Calculate the 40th and 60th percentiles for each page of X by specifying dimensions 1 and 2 as the operating dimensions.

\[
Y_{\text{page}} = \text{prctile}(X, [40 \ 60], [1 \ 2])
\]

\[
Y_{\text{page}} =
\]

\[
Y_{\text{page}}(:,:,1) =
\]

\[
\begin{array}{c}
6.5000 \\
9.5000
\end{array}
\]

\[
Y_{\text{page}}(:,:,2) =
\]

\[
\begin{array}{c}
21.5000 \\
24.5000
\end{array}
\]

For example, \(Y_{\text{page}}(1,1,1)\) is the 40th percentile of the first page of \(X\), and \(Y_{\text{page}}(2,1,1)\) is the 60th percentile of the first page of \(X\).

Calculate the 40th and 60th percentiles of the elements in each \(X(:,i,:)\) slice by specifying dimensions 1 and 3 as the operating dimensions.

\[
Y_{\text{col}} = \text{prctile}(X, [40 \ 60], [1 \ 3])
\]

\[
Y_{\text{col}} = 2\times5
\]

\[
\begin{array}{c}
2.9000 \\
16.1000 \\
5.9000 \\
19.1000 \\
8.9000 \\
22.1000 \\
11.9000 \\
25.1000 \\
14.9000 \\
28.1000
\end{array}
\]

For example, \(Y_{\text{col}}(1,4)\) is the 40th percentile of the elements in \(X(:,4,:)\), and \(Y_{\text{col}}(2,4)\) is the 60th percentile of the elements in \(X(:,4,:)\).

**Percentiles of Tall Vector for Given Percentage**

Calculate exact and approximate percentiles of a tall column vector for a given percentage.
Create a datastore for the airlinesmall data set. Treat 'NA' values as missing data so that datastore replaces them with NaN values. Specify to work with the ArrTime variable.

```matlab
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',... 'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```matlab
t = tall(ds) % Tall table
Starting parallel pool (parpool) using the 'local' profile ... connected to 6 workers.

t =

M×1 tall table

    ArrTime
     _______
        735
       1124
       2218
       1431
       746
      1547
      1052
      1134
      :   
      :

x = t{:,:} % Tall vector

x =

M×1 tall double column vector

    735
   1124
  2218
  1431
  746
 1547
Calculate the exact 50th percentile of \( x \). Because \( x \) is a tall column vector and \( p \) is a scalar, `prctile` returns the exact percentile value by default.

\[
p = 50;
y_{\text{Exact}} = \text{prctile}(x,p)
\]

\[
y_{\text{Exact}} = \begin{bmatrix}
? & ? & ? & \ldots \\
? & ? & ? & \ldots \\
? & ? & ? & \ldots \\
\vdots & \vdots & \vdots & \ddots
\end{bmatrix}
\]

Calculate the approximate 50th percentile of \( x \). Specify `'Method','approximate'` to use an approximation algorithm based on “T-Digest” on page 32-4933 for computing the percentile.

\[
y_{\text{Approx}} = \text{prctile}(x,p,'\text{Method}','\text{approximate}')
\]

\[
y_{\text{Approx}} = \begin{bmatrix}
? & ? & ? & \ldots \\
? & ? & ? & \ldots \\
? & ? & ? & \ldots \\
\vdots & \vdots & \vdots & \ddots
\end{bmatrix}
\]

Evaluate the tall arrays and bring the results into memory by using `gather`.

\[
[y_{\text{Exact}},y_{\text{Approx}}] = \text{gather}(y_{\text{Exact}},y_{\text{Approx}})
\]
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 4: Completed in 9.7 sec
- Pass 2 of 4: Completed in 0.7 sec
- Pass 3 of 4: Completed in 1.8 sec
- Pass 4 of 4: Completed in 1 sec
Evaluation completed in 16 sec

yExact = 1522

yApprox = 1.5220e+03

The values of the approximate percentile and the exact percentile are the same to the four digits shown.

**Percentiles of Tall Matrix Along Different Dimensions**

Calculate exact and approximate percentiles of a tall matrix for specified percentages along different dimensions.

Create a tall matrix X containing a subset of variables from the airlinesmall data set. See “Percentiles of Tall Vector for Given Percentage” on page 32-4925 for details about the steps to extract data from a tall array.

```matlab
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',... 'SelectedVariableNames',varnames); % Datastore
t = tall(ds); % Tall table
X = t{:,varnames} % Tall matrix
X =

   8.0000    735.0000    642.0000     53.0000
   8.0000   1124.0000   1021.0000     63.0000
  21.0000   2218.0000   2055.0000     83.0000
  13.0000   1431.0000   1332.0000     59.0000
   4.0000    746.0000    629.0000     77.0000
  59.0000   1547.0000   1446.0000     61.0000
   3.0000   1052.0000    928.0000     84.0000
  11.0000   1134.0000    859.0000    155.0000
```
When operating along a dimension that is not 1, the `prctile` function calculates the exact percentiles only, so that it can perform the computation efficiently using a sorting-based algorithm (see “Algorithms” on page 32-4936) instead of an approximation algorithm based on “T-Digest” on page 32-4933.

Calculate the exact 25th, 50th, and 75th percentiles of \( X \) along the second dimension.

\[
p = [25 \ 50 \ 75]; \quad \text{% Vector of percentages}
\]

\[
Y_{\text{exact}} = \text{prctile}(X,p,2)
\]

\[
Y_{\text{exact}} = \\
\text{M}\times\text{N}\times\ldots \text{ tall double array} \\
\text{? \ ? \ ? \ ...} \\
\text{? \ ? \ ? \ ...} \\
\text{? \ ? \ ? \ ...} \\
: \ : \ : \\
: \ : \ :
\]

Preview deferred. Learn more.

When the function operates along the first dimension and \( p \) is a vector of percentages, you must use the approximation algorithm based on t-digest to compute the percentiles. Using the sorting-based algorithm to find the percentiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate 25th, 50th, and 75th percentiles of \( X \) along the first dimension. Because the default dimension is 1, you do not need to specify a value for \( \text{dim} \).

\[
Y_{\text{approx}} = \text{prctile}(X,p,'\text{Method}', '\text{approximate}')
\]

\[
Y_{\text{approx}} = \\
\text{M}\times\text{N}\times\ldots \text{ tall double array} \\
\text{? \ ? \ ? \ ...} \\
\text{? \ ? \ ? \ ...} \\
\text{? \ ? \ ? \ ...} \\
: \ : \ : \\
: \ : \ :
\]

32-4929
Evaluate the tall arrays and bring the results into memory by using `gather`.

\[ \text{[Yexact,Yapprox] = gather(Yexact,Yapprox);} \]

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.3 sec
Evaluation completed in 6.5 sec

Show the first five rows of the exact 25th, 50th, and 75th percentiles along the second dimension of \( X \).

\[ \text{Yexact(1:5,:)} \]

\[
\begin{array}{ccc}
10^3 & \\
0.0305 & 0.3475 & 0.6885 \\
0.0355 & 0.5420 & 1.0725 \\
0.0520 & 1.0690 & 2.1365 \\
0.0360 & 0.6955 & 1.3815 \\
0.0405 & 0.3530 & 0.6875 \\
\end{array}
\]

Each row of the matrix \( \text{Yexact} \) contains the three percentiles of the corresponding row in \( X \). For example, \( 30.5, 347.5, \) and \( 688.5 \) are the 25th, 50th, and 75th percentiles, respectively, of the first row in \( X \).

Show the approximate 25th, 50th, and 75th percentiles of \( X \) along the first dimension.

\[ \text{Yapprox} \]

\[
\begin{array}{cccc}
10^3 & \\
-0.0070 & 1.1149 & 0.9322 & 0.0700 \\
0 & 1.5220 & 1.3350 & 0.1020 \\
0.0110 & 1.9180 & 1.7400 & 0.1510 \\
\end{array}
\]

Each column of the matrix \( \text{Yapprox} \) corresponds to the three percentiles for each column of the matrix \( X \). For example, the first column of \( \text{Yapprox} \) with elements \((-7, 0, 11)\) contains the percentiles for the first column of \( X \).
**Input Arguments**

**X — Input data**  
vector | array  
Input data, specified as a vector or array.  
Data Types: double | single

**p — Percentages**  
scalar | vector  
Percentages for which to compute percentiles, specified as a scalar or vector of scalars from 0 to 100.  
Example: 25  
Example: [25, 50, 75]  
Data Types: double | single

**dim — Dimension**  
positive integer  
Dimension along which the percentiles of X are requested, specified as a positive integer. For example, for a matrix X, when dim = 1, prctile returns the percentile(s) of the columns of X; when dim = 2, prctile returns the percentile(s) of the rows of X. For a multidimensional array X, the length of the dimth dimension of Y is equal to the length of p.  
Data Types: double | single

**vecdim — Vector of dimensions**  
positive integer vector  
Vector of dimensions, specified as a positive integer vector. Each element of vecdim represents a dimension of the input array X. The output Y has length length(p) in the smallest specified operating dimension (that is, dimension min(vecdim)) and has length 1 in each of the remaining operating dimensions. The other dimension lengths are the same for X and Y.
For example, consider a 2-by-3-by-3 array X with p = [20 40 60 80]. In this case, `prctile(X,p,[1 2])` returns an array, where each page of the array contains the 20th, 40th, 60th, and 80th percentiles of the elements of the corresponding page of X. Because 1 and 2 are the operating dimensions, with min([1 2]) = 1 and length(p) = 4, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`

**method — Method for calculating percentiles**

'exact' (default) | 'approximate'

Method for calculating percentiles, specified as 'exact' or 'approximate'. By default, `prctile` returns the exact percentiles by implementing an algorithm on page 32-4936 that uses sorting. You can specify 'method', 'approximate' for `prctile` to return approximate percentiles by implementing an algorithm that uses T-Digest on page 32-4933.

Data Types: `char` | `string`

### Output Arguments

**Y — Percentiles**

scalar | array

Percentiles of a data vector or array, returned as a scalar or array for one or more percentage values.

- If X is a vector, then Y is a scalar or a vector with the same length as the number of percentiles requested (length(p)). Y(i) contains the p(i)th percentile.
- If X is an array of dimension d, then Y is an array with the length of the smallest operating dimension equal to the number of percentiles requested (length(p)).

### Definitions

**Multidimensional Array**

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.
Nonsingleton Dimension

A first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X.

Linear Interpolation

Linear interpolation uses linear polynomials to find \( y_i = f(x_i) \), the values of the underlying function \( Y = f(X) \) at the points in the vector or array \( x \). Given the data points \( (x_1, y_1) \) and \( (x_2, y_2) \), where \( y_1 = f(x_1) \) and \( y_2 = f(x_2) \), linear interpolation finds \( y = f(x) \) for a given \( x \) between \( x_1 \) and \( x_2 \) as follows:

\[
y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).
\]

Similarly, if the \( 100(1.5/n) \)th percentile is \( y_{1.5/n} \) and the \( 100(2.5/n) \)th percentile is \( y_{2.5/n} \), then linear interpolation finds the \( 100(2.3/n) \)th percentile, \( y_{2.3/n} \) as:

\[
y_{2.3/n} = y_{1.5/n} + \frac{2.3}{n} \frac{1.5}{n} \left( y_{2.5/n} - y_{1.5/n} \right).
\]

T-Digest

T-digest\[2\] on page 32-4936 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation \( (q(1-q) \) for the \( q \)th quantile). For these reasons, t-digest is practical for working with tall arrays.
To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near \( q = 0.5 \) and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near \( q = 0 \) or \( q = 1 \).

T-digest controls the cluster size by using a scaling function that maps a quantile \( q \) to an index \( k \) with a compression parameter \( \delta \). That is,

\[
k(q, \delta) = \delta \cdot \left( \frac{\sin^{-1}(2q-1)}{\pi} + \frac{1}{2} \right),
\]

where the mapping \( k \) is monotonic with minimum value \( k(0, \delta) = 0 \) and maximum value \( k(1, \delta) = \delta \).
Scaling Function for $\delta = 10$

The scaling function translates the quantile $q$ to the scaling factor $k$ in order to give variable size steps in $q$. As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.
You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the endpoints (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

**Algorithms**

For an \( n \)-element vector \( X \), \texttt{prctile} returns percentiles by using a sorting-based algorithm as follows:

1. The sorted elements in \( X \) are taken as the \( 100(0.5/n) \)th, \( 100(1.5/n) \)th, ..., \( 100([n - 0.5]/n) \)th percentiles. For example:
   - For a data vector of five elements such as \{6, 3, 2, 10, 1\}, the sorted elements \{1, 2, 3, 6, 10\} respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
   - For a data vector of six elements such as \{6, 3, 2, 10, 8, 1\}, the sorted elements \{1, 2, 3, 6, 8, 10\} respectively correspond to the \((50/6)\)th, \((150/6)\)th, \((250/6)\)th, \((350/6)\)th, \((450/6)\)th, and \((550/6)\)th percentiles.

2. \texttt{prctile} uses linear interpolation on page 32-4933 to compute percentiles for percentages between \( 100(0.5/n) \) and \( 100([n - 0.5]/n) \).

3. \texttt{prctile} assigns the minimum or maximum values of the elements in \( X \) to the percentiles corresponding to the percentages outside that range.

\texttt{prctile} treats NaNs as missing values and removes them.

**References**

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- The following syntaxes are not supported.
  - \( Y = \text{prctile}(X,p,'all') \)
  - \( Y = \text{prctile}(X,p,\text{vecdim}) \)
  - \( Y = \text{prctile}(X,p) \) returns the exact percentiles (using a sorting-based algorithm on page 32-4936) under these conditions.
    - \( X \) is a tall column vector and \( p \) is a scalar. In this case, \( \text{dim} = 1 \).
    - \( X \) is a tall matrix and \( \text{dim} \) is not 1.
  - If \( p \) is a vector and \( \text{dim} \) is 1, then you must specify 'Method','approximate' to use an approximation algorithm based on T-Digest on page 32-4933 for computing the percentiles.

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The following syntaxes do not support code generation.
  - \( Y = \text{prctile}(X,p,'all') \)
  - \( Y = \text{prctile}(X,p,\text{vecdim}) \)
  - See “Automatic dimension restriction” (MATLAB Coder).
