To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: ` 'KFold',5`

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `Leaveout` and `on` or `off`. If you specify `Leaveout`, `'on'`, then, for each of the $n$ observations (where $n$ is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
2. Store the $n$ compact, trained models in the cells of an $n$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: ` 'Leaveout','on'`

**Output Arguments**

**CVMdl** — Cross-validated SVM regression model

`RegressionPartitionedSVM` model

Cross-validated SVM regression model, returned as a `RegressionPartitionedSVM` model.
Examples

Train Cross-Validated SVM Regression Model Using crossval

This example shows how to train a cross-validated SVM regression model using \texttt{crossval}.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name 'abalone.data'. Read the data into a table.

\begin{verbatim}
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility
\end{verbatim}

The sample data contains 4177 observations. All the predictor variables are continuous except for \texttt{sex}, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

\begin{verbatim}
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 2.2, 'Standardize', true);
\end{verbatim}

\texttt{mdl} is a trained \texttt{RegressionSVM} regression model.

Cross validate the model using 10-fold cross validation.

\begin{verbatim}
CVMdl = crossval(mdl)
\end{verbatim}

\texttt{CVMdl} is a \texttt{RegressionPartitionedSVM} cross-validated regression model. The software:

1. Randomly partitions the data into 10 equally sized sets.
2. Trains an SVM regression model on nine of the 10 sets.
3. Repeats steps 1 and 2 \( k \) = 10 times. It leaves out one of the partitions each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

Calculate the resubstitution loss for the cross-validated model.

\begin{verbatim}
loss = kfoldLoss(CVMdl)
\end{verbatim}
Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name 'abalone.data'. Read the data into a table.

tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility

The sample data contains 4177 observations. All the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true);

mdl is a trained RegressionSVM regression model.

Cross validate the regression model by specifying a 10% holdout sample.

CVMdl = crossval(mdl,'Holdout',0.1)

CVMdl is a RegressionPartitionedSVM model object.

Calculate the resubstitution loss for the cross-validated model.

loss = kfoldLoss(CVMdl)
loss = 
5.2499

**Alternatives**

Instead of training an SVM regression model and then cross-validating it, you can create a cross-validated model directly by using `fitrsvm` and specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

**Introduced in R2015b**
crossval

Class: RegressionTree
Cross-validated decision tree

Syntax

cvmodel = crossval(model)
cvmodel = crossval(model,Name,Value)

Description

cvmodel = crossval(model) creates a partitioned model from model, a fitted regression tree. By default, crossval uses 10-fold cross validation on the training data to create cvmodel.

cvmodel = crossval(model,Name,Value) creates a partitioned model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

model
A regression model, produced using fitrtree.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

CVPartition
Object of class cvpartition, created by the cvpartition function. crossval splits the data into subsets with cvpartition.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: []

Holdout
Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

KFold
Number of folds to use in a cross-validated tree, a positive integer value greater than 1.
Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Default:** 10

**Leaveout**

Set to 'on' for leave-one-out cross-validation.

### Output Arguments

**cvmodel**

A partitioned model of class `RegressionPartitionedModel`.

### Examples

**Cross-Validate Regression Tree**

Load the `carsmall` data set. Consider Acceleration, Displacement, Horsepower, and Weight as predictor variables.

```matlab
load carsmall
X = [Acceleration Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```matlab
Mdl = fitrtree(X,MPG);
```

`Mdl` is a `RegressionTree` model.

Cross-validate the regression tree using 10-fold cross-validation.

```matlab
CVMdl = crossval(Mdl);
```

`CVMdl` is a `RegressionPartitionedModel` cross-validated model. `crossval` stores the ten trained, compact regression trees in the `Trained` property of `CVMdl`.

Display the compact regression tree that `crossval` trained using all observations except those in the first fold.

```matlab
CVMdl.Trained{1}
```

ans =
```
classreg.learning.regr.CompactRegressionTree
PredictorNames: {'x1'  'x2'  'x3'  'x4'}
ResponseName: 'Y'
CategoricalPredictors: []
ResponseTransform: 'none'
```

Properties, Methods
Estimate the generalization error of Mdl by computing the 10-fold cross-validated mean-squared error.

L = kfoldLoss(CVMdl)

L = 25.6450

**Tips**

- Assess the predictive performance of model on cross-validated data using the “kfold” methods and properties of cvmodel, such as kfoldLoss.

**Alternatives**

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in fitrtree: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**See Also**
crossval | fitrtree
cvloss

Class: ClassificationTree

Classification error by cross validation

Syntax

E = cvloss(tree)
[E,SE] = cvloss(tree)
[E,SE,Nleaf] = cvloss(tree)
[E,SE,Nleaf,BestLevel] = cvloss(tree)
[___] = cvloss(tree,Name,Value)

Description

E = cvloss(tree) returns the cross-validated classification error (loss) for tree, a classification tree. The cvloss method uses stratified partitioning to create cross-validated sets. That is, for each fold, each partition of the data has roughly the same class proportions as in the data used to train tree.

[E,SE] = cvloss(tree) returns the standard error of E.

[E,SE,Nleaf] = cvloss(tree) returns the number of leaves of tree.

[E,SE,Nleaf,BestLevel] = cvloss(tree) returns the optimal pruning level for tree.

[___] = cvloss(tree,Name,Value) cross validates with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

tree — Trained classification tree
ClassificationTree model object

Trained classification tree, specified as a ClassificationTree model object produced by fitctree.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Subtrees — Pruning level
0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.
If you specify a vector, then all elements must be at least 0 and at most \( \max(tree.PruneList) \). 0 indicates the full, unpruned tree and \( \max(tree.PruneList) \) indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then cvloss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using 0:max(tree.PruneList).

cvloss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune','on', or by pruning tree using prune.

Example: 'Subtrees','all'

Data Types: single | double | char | string

TreeSize — Tree size
'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- 'se' — cvloss uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — cvloss uses the minimal cost tree.

Example: 'TreeSize','min'

KFold — Number of cross-validation samples
10 (default) | positive integer value greater than 1

Number of cross-validation samples, specified as the comma-separated pair consisting of KFold and a positive integer value greater than 1.

Example: 'KFold',8

Output Arguments

E — Cross-validation classification error
numeric vector | scalar value

Cross-validation classification error (loss), returned as a vector or scalar depending on the setting of the Subtrees name-value pair.

SE — Standard error
numeric vector | scalar value

Standard error of E, returned as a vector or scalar depending on the setting of the Subtrees name-value pair.

Nleaf — Number of leaf nodes
numeric vector | scalar value

Number of leaf nodes in tree, returned as a vector or scalar depending on the setting of the Subtrees name-value pair. Leaf nodes are terminal nodes, which give classifications, not splits.
**BestLevel — Best pruning level**

scalar value

Best pruning level, returned as a scalar value. By default, a scalar representing the largest pruning level that achieves a value of $E$ within $SE$ of the minimum error. If you set `TreeSize` to `'min'`, `BestLevel` is the smallest value in `Subtrees`.

**Examples**

**Compute the Cross-Validation Error**

Compute the cross-validation error for a default classification tree.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Grow a classification tree using the entire data set.

```matlab
Mdl = fitctree(X,Y);
```

Compute the cross-validation error.

```matlab
rng(1); % For reproducibility
E = cvloss(Mdl)
```

```matlab
E = 0.1111
```

$E$ is the 10-fold misclassification error.

**Find the Best Pruning Level Using Cross Validation**

Apply $k$-fold cross validation to find the best level to prune a classification tree for all of its subtrees.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Grow a classification tree using the entire data set. View the resulting tree.

```matlab
Mdl = fitctree(X,Y);
view(Mdl,'Mode','graph')
```
Compute the 5-fold cross-validation error for each subtree except for the highest pruning level. Specify to return the best pruning level over all subtrees.

rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1
m = 7
[E,~,~,bestLevel] = cvloss(Mdl,'SubTrees',0:m,'KFold',5)
E = 8×1
0.1368
0.1339
0.1311
0.1339
0.1339
0.1254
0.0997
0.1738

bestLevel = 6
Of the 7 pruning levels, the best pruning level is 6.

Prune the tree to the best level. View the resulting tree.

```matlab
MdlPrune = prune(Mdl,'Level',bestLevel);
view(MdlPrune,'Mode','graph')
```

**Alternatives**

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`. `kfoldLoss` also does not allow you to examine any error other than the classification error.

**See Also**

**cvloss**

**Class:** RegressionTree

Regression error by cross validation

**Syntax**

\[
E = \text{cvloss}(\text{tree})
\]

\[
[E, SE] = \text{cvloss}(\text{tree})
\]

\[
[E, SE, Nleaf] = \text{cvloss}(\text{tree})
\]

\[
[E, SE, Nleaf, \text{BestLevel}] = \text{cvloss}(\text{tree})
\]

\[
[E, \ldots] = \text{cvloss}(\text{tree}, \text{Name, Value})
\]

**Description**

\[
E = \text{cvloss}(\text{tree})\text{ returns the cross-validated regression error (loss) for } \text{tree}, \text{ a regression tree.}
\]

\[
[E, SE] = \text{cvloss}(\text{tree})\text{ returns the standard error of } E.
\]

\[
[E, SE, Nleaf] = \text{cvloss}(\text{tree})\text{ returns the number of leaves (terminal nodes) in } \text{tree}.
\]

\[
[E, SE, Nleaf, \text{BestLevel}] = \text{cvloss}(\text{tree})\text{ returns the optimal pruning level for } \text{tree}.
\]

\[
[E, \ldots] = \text{cvloss}(\text{tree}, \text{Name, Value})\text{ cross validates with additional options specified by one or more } \text{Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, \ldots, NameN, ValueN.}
\]

**Input Arguments**

**tree — Trained regression tree**

RegressionTree object

Trained regression tree, specified as a RegressionTree object constructed using fitrtree.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Subtrees — Pruning level**

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).
If you specify 'all', then cvloss operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using $0: \text{max} (\text{tree.PruneList})$.

cvloss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune', 'on', or by pruning tree using prune.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

**TreeSize — Tree size**

'\text{se}' (default) | '\text{min}'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following:

- 'se' — cvloss uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — cvloss uses the minimal cost tree.

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

Example: 'KFold', 8

**Output Arguments**

**E** — Mean squared error

scalar value | numeric vector

Cross-validation mean squared error (loss), returned as a vector or scalar depending on the setting of the Subtrees name-value pair.

**SE** — Standard error

scalar value | numeric vector

Standard error of E, returned as vector or scalar depending on the setting of the Subtrees name-value pair.

**NLeaf** — Number of leaf nodes

vector of integer values

Number of leaf nodes in tree, returned as a vector or scalar depending on the setting of the Subtrees name-value pair. Leaf nodes are terminal nodes, which give responses, not splits.

**BestLevel** — Best pruning level

scalar value

Best pruning level as defined in the TreeSize name-value pair; returned as a scalar whose value depends on TreeSize:
• If TreeSize is 'se', then BestLevel is the largest pruning level that achieves a value of $E$ within SE of the minimum error.
• If TreeSize is 'min', then BestLevel is the smallest value in Subtrees.

**Examples**

**Compute the Cross-Validation Error**

Compute the cross-validation error for a default regression tree.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```matlab
Mdl = fitrtree(X,MPG);
```

Compute the cross-validation error.

```matlab
rng(1); % For reproducibility
E = cvloss(Mdl)
E = 27.6976
```

$E$ is the 10-fold weighted, average MSE (weighted by number of test observations in the folds).

**Find the Best Pruning Level Using Cross Validation**

Apply k-fold cross validation to find the best level to prune a regression tree for all of its subtrees.

Load the carsmall data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set. View the resulting tree.

```matlab
Mdl = fitrtree(X,MPG);
view(Mdl,'Mode','graph')
```
Compute the 5-fold cross-validation error for each subtree except for the first two lowest and highest pruning level. Specify to return the best pruning level over all subtrees.

```matlab
rng(1); % For reproducibility
m = max(Mdl.PruneList) - 1
m = 15
[~,~,~,bestLevel] = cvloss(Mdl,'SubTrees',2:m,'KFold',5)
bestLevel = 14

Of the 15 pruning levels, the best pruning level is 14.

Prune the tree to the best level. View the resulting tree.

MdlPrune = prune(Mdl,'Level',bestLevel);
view(MdlPrune,'Mode','graph')
Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvloss`. If you are going to examine the cross-validated tree more than once, then the alternative can save time.

However, unlike `cvloss`, `kfoldLoss` does not return SE, Nleaf, or BestLevel.

crossval | fitrtree | kfoldLoss | loss
cvpartition class

Data partitions for cross validation

Description

An object of the cvpartition class defines a random partition on a set of data of a specified size. Use this partition to define test and training sets for validating a statistical model using cross validation.

Construction

cvpartition Create cross-validation partition for data

Methods

disp Display cvpartition object
display Display cvpartition object
repartition Repartition data for cross-validation
test Test indices for cross-validation
training Training indices for cross-validation

Properties

NumObservations Number of observations (including observations with missing group values)
NumTestSets Number of test sets
TestSize Size of each test set
TrainSize Size of each training set
Type Type of partition

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes (MATLAB) in the MATLAB Object-Oriented Programming documentation.

Examples

Use a 10-fold stratified cross validation to compute the misclassification error for classify on iris data.

```matlab
load('fisheriris');
CVO = cvpartition(species,'k',10);
err = zeros(CVO.NumTestSets,1);
for i = 1:CVO.NumTestSets
```

32-983
trIdx = CVO.training(i);
testIdx = CVO.test(i);
ytest = classify(meas(testIdx,:), meas(trIdx,:),
              species(trIdx,:));
    err(i) = sum(~strcmp(ytest, species(testIdx)));
end

cvErr = sum(err)/sum(CVO.TestSize);

See Also
crossval

Topics
"Grouping Variables" on page 2-45
**cvpartition**

**Class:** cvpartition

Create cross-validation partition for data

**Syntax**

```matlab
c = cvpartition(n,'KFold',k)
c = cvpartition(n,'HoldOut',p)
c = cvpartition(group,'KFold',k)
c = cvpartition(group,'KFold',k,'Stratify',stratifyOption)
c = cvpartition(group,'HoldOut',p)
c = cvpartition(group,'HoldOut',p,'Stratify',stratifyOption)
c = cvpartition(n,'LeaveOut')
c = cvpartition(n,'resubstitution')
```

**Description**

- `c = cvpartition(n,'KFold',k)` constructs an object `c` of the `cvpartition` class defining a random nonstratified partition for k-fold cross-validation on `n` observations. The partition divides the observations into `k` disjoint subsamples (or folds), chosen randomly but with roughly equal size. The default value of `k` is 10.

- `c = cvpartition(n,'HoldOut',p)` creates a random nonstratified partition for holdout validation on `n` observations. This partition divides the observations into a training set and a test (or holdout) set. The parameter `p` must be a scalar. When `0 < p < 1`, `cvpartition` randomly selects approximately `p*n` observations for the test set. When `p` is an integer, `cvpartition` randomly selects `p` observations for the test set. The default value of `p` is 1/10.

- `c = cvpartition(group,'KFold',k)` creates a random partition for a stratified k-fold cross-validation. `group` is a numeric vector, categorical array, character array, string array, or cell array of character vectors indicating the class of each observation. Each subsample has roughly equal size and roughly the same class proportions as in `group`.

When you supply `group` as the first input argument to `cvpartition`, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in `group`.

- `c = cvpartition(group,'KFold',k,'Stratify',stratifyOption)` returns an object `c` defining a random partition for k-fold cross-validation. When you supply `group` as the first input argument to `cvpartition`, then the function implements stratification by default. If you also specify `'Stratify',false`, then the function creates nonstratified random partitions.

You can specify `'Stratify',true` only if the first input argument to `cvpartition` is `group`.

- `c = cvpartition(group,'HoldOut',p)` randomly partitions observations into a training set and a holdout (or test) set with stratification, using the class information in `group`. Both the training and test sets have roughly the same class proportions as in `group`. 

c = cvpartition(group,'HoldOut',p,'Stratify',stratifyOption) returns an object c defining a random partition into a training set and a holdout (or test) set. When you supply group as the first input argument to cvpartition, then the function implements stratification by default. If you also specify 'Stratify',false, then the function creates nonstratified random partitions.

c = cvpartition(n,'LeaveOut') creates a random partition for leave-one-out cross-validation on n observations. Leave-one-out is a special case of 'KFold' in which the number of folds equals the number of observations.

c = cvpartition(n,'resubstitution') creates an object c that does not partition the data. Both the training set and the test set contain all of the original n observations.

Examples

Find Misclassification Rate for K-Fold Cross-Validation

Use stratified 10-fold cross-validation to compute misclassification rate.

Load Fisher's iris data set.

load fisheriris;
y = species;
X = meas;

Create a random partition for a stratified 10-fold cross-validation.

c = cvpartition(y,'KFold',10);

Create a function that computes the number of misclassified test samples.

fun = @(xTrain,yTrain,xTest,yTest)(sum(~strcmp(yTest,...
classify(xTest,xTrain,yTrain))));

Return the estimated misclassification rate using cross-validation.

rate = sum(crossval(fun,X,y,'partition',c))...
/sum(c.TestSize)

rate = 0.0200

Create Nonstratified Partition

Find the proportion of each class in a 5-fold nonstratified partition of the fisheriris data.

Load Fisher's iris data set.

load fisheriris;

Find the number of instances of each class in the data.

[C,,-,idx] = unique(species);
C % Unique classes
C = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

n = accumarray(idx(:),1) % Number of instances for each class in species
n = 3x1
    50
    50
    50

The three classes occur in equal proportion.

Create a random, nonstratified 5-fold partition.

cv = cvpartition(species,'KFold',5,'Stratify',false)
cv =
    K-fold cross validation partition
    NumObservations: 150
    NumTestSets: 5
        TrainSize: 120  120  120  120  120
        TestSize: 30  30  30  30  30

Show that the three classes do not occur in equal proportion for each fold of the data set.

for i = 1:cv.NumTestSets
    disp(['Fold ',num2str(i)])
    testClasses = species(cv.test(i));
    [C,~,idx] = unique(testClasses);
    C % Unique classes
    nCount = accumarray(idx(:),1) % Number of instances for each class in a fold
end

Fold 1
C = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

nCount = 3x1
    8
    13
    9

Fold 2
C = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
Because `cv` is a random nonstratified partition of the `fisheriris` data, the class proportions in each of the five folds are not guaranteed to be equal to the class proportions in `species`. That is, the classes do not occur equally in each fold, as they do in `species`. Cross-validation produces randomness in the results, so your number of instances for each class in a fold can vary from those shown.
Create Nonstratified Holdout Set for Tall Array

Compare the number of instances for each class in a nonstratified holdout set with a stratified holdout set of a tall array.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the mapreducer function.

Create a numeric vector of two classes, where class 1 and class 2 occur in the ratio 1:10.

group = [ones(20,1);2*ones(200,1)]
group = 220×1

   :

Holdout is the only cvpartition option that is supported for tall arrays. Create a random, nonstratified holdout partition.

CV0 = cvpartition(tgroup,'Holdout',1/4,'Stratify',false)

CV0 =
Hold-out cross validation partition
Return the result of CV0.test to memory by using the gather function.

testIdx0 = gather(CV0.test);

Find the number of times each class occurs in the holdout set.

accumarray(group(testIdx0),1) % Number of instances for each class in the holdout set

ans = 2x1

5
52

cvpartition produces randomness in the results, so your number of instances for each class can vary from those shown.

Because CV0 is a nonstratified partition, class 1 and class 2 in the holdout set are not guaranteed to occur in the same ratio that they do in tgroup. However, because of the inherent randomness in cvpartition, you can sometimes obtain a holdout set for which the classes occur in the same ratio that they do in tgroup even though you specify 'Stratify',false. A similar result can be illustrated for the training set.

Return the result of CV0.training to memory.

trainIdx0 = gather(CV0.training);

Find the number of times each class occurs in the training set.

accumarray(group(trainIdx0),1) % Number of instances for each class in the training set

ans = 2x1

15
148

The classes in the nonstratified training set are not guaranteed to occur in the same ratio that they do in tgroup.

Create a random, stratified holdout partition.

CV1 = cvpartition(tgroup,'Holdout',1/4)
NumObservations: [1x1 tall]
NumTestSets: 1
TrainSize: [1x1 tall]
TestSize: [1x1 tall]

Return the result of `CV1.test` to memory.

testIdx1 = gather(CV1.test);

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.4 sec
Evaluation completed in 2.5 sec

Find the number of times each class occurs in the holdout set.

`accumarray(group(testIdx1),1) % Number of instances for each class in the holdout set`

ans = 2x1

5
49

In the case of the stratified holdout partition, the class ratio in the holdout set and the class ratio in `tgroup` are the same (1:10).

**Algorithms**

- If you supply `group` as the first input argument to `cvpartition`, the function creates cross-validation partitions that do not include rows of observations corresponding to missing values in `group`.
- When you supply `group` as the first input argument to `cvpartition`, then the function implements stratification by default. You can specify `{'Stratify','false'}` to create nonstratified random partitions.
- You can specify `{'Stratify','true'}` only if the first input argument to `cvpartition` is `group`.

**Extended Capabilities**

**Tall Arrays**
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- When you use `cvpartition` with tall arrays, the first input argument must be a grouping variable, `tGroup`. If you specify a tall scalar as the first input argument, `cvpartition` gives an error.
- `cvpartition` supports only `Holdout` cross-validation for tall arrays; for example, `c = cvpartition(tGroup,'HoldOut',p)`. By default, `cvpartition` randomly partitions observations into a training set and a test set with stratification, using the class information in `tGroup`. The parameter `p` is a scalar such that `0 < p < 1`.
- To create nonstratified `Holdout` partitions, specify the value of the `{'Stratify','false'}` name-value pair argument as `false`; for example, `c = cvpartition(tGroup,'HoldOut',p,'Stratify','false')`. 

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

cvshrink

Class: ClassificationDiscriminant

Cross-validate regularization of linear discriminant

Syntax

e = cvshrink(obj)
[err, gamma] = cvshrink(obj)
[err, gamma, delta] = cvshrink(obj)
[err, gamma, delta, numpred] = cvshrink(obj)
[err, ...] = cvshrink(obj, Name, Value)

Description

e = cvshrink(obj) returns a vector of cross-validated classification error values for differing values of the regularization parameter Gamma.

[err, gamma] = cvshrink(obj) also returns the vector of Gamma values.

[err, gamma, delta] = cvshrink(obj) also returns the vector of Delta values.

[err, gamma, delta, numpred] = cvshrink(obj) returns the vector of number of nonzero predictors for each setting of the parameters Gamma and Delta.

[err, ...] = cvshrink(obj, Name, Value) cross validates with additional options specified by one or more Name, Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using fitcdiscr.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

delta

- Scalar delta — cvshrink uses this value of delta with every value of gamma for regularization.
- Row vector delta — For each i and j, cvshrink uses delta(j) with gamma(i) for regularization.
- Matrix delta — The number of rows of delta must equal the number of elements in gamma. For each i and j, cvshrink uses delta(i, j) with gamma(i) for regularization.

Default: 0
gamma

Vector of Gamma values for cross-validation.

**Default:** 0:0.1:1

**NumDelta**

Number of Delta intervals for cross-validation. For every value of Gamma, `cvshrink` cross-validates the discriminant using `NumDelta + 1` values of Delta, uniformly spaced from zero to the maximal Delta at which all predictors are eliminated for this value of Gamma. If you set `delta`, `cvshrink` ignores `NumDelta`.

**Default:** 0

**NumGamma**

Number of Gamma intervals for cross-validation. `cvshrink` cross-validates the discriminant using `NumGamma + 1` values of Gamma, uniformly spaced from `MinGamma` to 1. If you set `gamma`, `cvshrink` ignores `NumGamma`.

**Default:** 10

**verbose**

Verbosity level, an integer from 0 to 2. Higher values give more progress messages.

**Default:** 0

**Output Arguments**

**err**

Numeric vector or matrix of errors. `err` is the misclassification error rate, meaning the average fraction of misclassified data over all folds.

- If `delta` is a scalar (default), `err(i)` is the misclassification error rate for `obj` regularized with `gamma(i)`.
- If `delta` is a vector, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(i,j)`.

**gamma**

Vector of Gamma values used for regularization. See “Gamma and Delta” on page 32-996.

**delta**

Vector or matrix of Delta values used for regularization. See “Gamma and Delta” on page 32-996.

- If you give a scalar for the `delta` name-value pair, the output `delta` is a row vector the same size as `gamma`, with entries equal to the input scalar.
• If you give a row vector for the \texttt{delta} name-value pair, the output \texttt{delta} is a matrix with the same number of columns as the row vector, and with the number of rows equal to the number of elements of \texttt{gamma}. The output \texttt{delta}(i,j) is equal to the input \texttt{delta}(j).

• If you give a matrix for the \texttt{delta} name-value pair, the output \texttt{delta} is the same as the input matrix. The number of rows of \texttt{delta} must equal the number of elements in \texttt{gamma}.

\texttt{numpred}

Numeric vector or matrix containing the number of predictors in the model at various regularizations. \texttt{numpred} has the same size as \texttt{err}.

• If \texttt{delta} is a scalar (default), \texttt{numpred}(i) is the number of predictors for \texttt{obj} regularized with \texttt{gamma}(i) and \texttt{delta}.

• If \texttt{delta} is a vector, \texttt{numpred}(i,j) is the number of predictors for \texttt{obj} regularized with \texttt{gamma}(i) and \texttt{delta}(j).

• If \texttt{delta} is a matrix, \texttt{numpred}(i,j) is the number of predictors for \texttt{obj} regularized with \texttt{gamma}(i) and \texttt{delta}(i,j).

\textbf{Examples}

\textbf{Regularize Data with Many Predictors}

Regularize a discriminant analysis classifier, and view the tradeoff between the number of predictors in the model and the classification accuracy.

Create a linear discriminant analysis classifier for the \texttt{ovariancancer} data. Set the \texttt{SaveMemory} and \texttt{FillCoeffs} options to keep the resulting model reasonably small.

```matlab
load ovariancancer
obj = fitcdiscr(obs,grp,...
    'SaveMemory','on','FillCoeffs','off');
```

Use 10 levels of Gamma and 10 levels of Delta to search for good parameters. This search is time-consuming. Set \texttt{Verbose} to 1 to view the progress.

```matlab
rng('default') % for reproducibility
[err,gamma,delta,numpred] = cvshrink(obj,...
    'NumGamma',9,'NumDelta',9,'Verbose',1);
```

Done building cross-validated model.
Processing Gamma step 1 out of 10.
Processing Gamma step 2 out of 10.
Processing Gamma step 3 out of 10.
Processing Gamma step 4 out of 10.
Processing Gamma step 5 out of 10.
Processing Gamma step 6 out of 10.
Processing Gamma step 7 out of 10.
Processing Gamma step 8 out of 10.
Processing Gamma step 9 out of 10.
Processing Gamma step 10 out of 10.

Plot the classification error rate against the number of predictors.
More About

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$, that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let $\Sigma$ represent the covariance matrix of the data $X$, and let $\bar{X}$ be the centered data (the data $X$ minus the mean by class). Define

$$D = \text{diag}(\bar{X}^T \cdot \bar{X}).$$

The regularized covariance matrix $\bar{\Sigma}$ is

$$\bar{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\bar{\Sigma}$ is nonsingular.
Let $\mu_k$ be the mean vector for those elements of $X$ in class $k$, and let $\mu_0$ be the global mean vector (the mean of the rows of $X$). Let $C$ be the correlation matrix of the data $X$, and let $\tilde{C}$ be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where $I$ is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point $x$ is

$$(x - \mu_0)^T \Sigma^{-1} (\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2} \right] \left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter $\delta$ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$ is set to zero if it is smaller in magnitude than the threshold $\delta$. Therefore, for class $k$, if component $j$ is thresholded to zero, component $j$ of $x$ does not enter into the evaluation of the posterior probability.

The DeltaPredictor property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes $k$ have

$$\left|\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor $i$.

**Tips**

- Examine the `err` and `numpred` outputs to see the tradeoff between cross-validated error and number of predictors. When you find a satisfactory point, set the corresponding `gamma` and `delta` properties in the model using dot notation. For example, if $(i,j)$ is the location of the satisfactory point, set

  ```matlab
  obj.Gamma = gamma(i);
  obj.Delta = delta(i,j);
  ```

cvshrink

Cross validate shrinking (pruning) ensemble

Syntax

vals = cvshrink(ens)
[vals,nlearn] = cvshrink(ens)
[vals,nlearn] = cvshrink(ens,Name,Value)

Description

vals = cvshrink(ens) returns an L-by-T matrix with cross-validated values of the mean squared error. L is the number of lambda values in the ens.Regularization structure. T is the number of threshold values on weak learner weights. If ens does not have a Regularization property filled in by the regularize method, pass a lambda name-value pair:

[vals,nlearn] = cvshrink(ens) returns an L-by-T matrix of the mean number of learners in the cross-validated ensemble.

[vals,nlearn] = cvshrink(ens,Name,Value) cross validates with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

ens

A regression ensemble, created with fitrensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

cvpartition

A partition created with cvpartition to use in a cross-validated tree. You can only use one of these four options at a time: 'kfold','holdout','leaveout', or 'cvpartition'.

holdout

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'kfold','holdout','leaveout', or 'cvpartition'.

kfold

Number of folds to use in a cross-validated tree, a positive integer. If you do not supply a cross-validation method, cvshrink uses 10-fold cross validation. You can only use one of these four options at a time: 'kfold','holdout','leaveout', or 'cvpartition'.

32-998
**Default:** 10

**lambda**

Vector of nonnegative regularization parameter values for lasso. If empty, cvshrink does not perform cross validation.

**Default:** []

**leaveout**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**threshold**

Numeric vector with lower cutoffs on weights for weak learners. cvshrink discards learners with weights below threshold in its cross-validation calculation.

**Default:** 0

**Output Arguments**

**vals**

L-by-T matrix with cross-validated values of the mean squared error. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

**nlearn**

L-by-T matrix with cross-validated values of the mean number of learners in the cross-validated ensemble. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

**Examples**

**Cross-Validate Regression Ensemble**

Create a regression ensemble for predicting mileage from the carsmall data. Cross-validate the ensemble.

Load the carsmall data set and select displacement, horsepower, and vehicle weight as predictors.

```matlab
load carsmall
X = [Displacement Horsepower Weight];
```

You can train an ensemble of bagged regression trees.

```matlab
ens = fitrensemble(X,Y,'Method','Bag')
```

fircensemble uses a default template tree object templateTree() as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible',true when you create a tree template object, and then use the object as a weak learner.
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibility of random predictor selections
ens = fitrensemble(X,MPG,'Method','Bag','Learners',t);

Specify values for lambda and threshold. Use these values to cross-validate the ensemble.

[val,nlearn] = cvshrink(ens,'lambda',[.01 .1 1],'threshold',[0 .01 .1])

vals = 3×3
    18.1135   18.4634  115.5087
    18.1140   18.4630  115.4477
    18.0823   18.3565  124.1655

nlearn = 3×3
     13.8000   11.5000    3.5000
    13.7000   11.4000    3.5000
    13.8000   11.3000    3.3000

Clearly, setting a threshold of 0.1 leads to unacceptable errors, while a threshold of 0.01 gives similar errors to a threshold of 0. The mean number of learners with a threshold of 0.01 is about 11.4, whereas the mean number is about 13.8 when the threshold is 0.

datasample

Randomly sample from data, with or without replacement

Syntax

\[ y = \text{datasample}(\text{data},k) \]
\[ y = \text{datasample}(\text{data},k,\text{dim}) \]
\[ y = \text{datasample}(\_,\text{Name},\text{Value}) \]
\[ y = \text{datasample}(\text{s},\_) \]
\[ [y,\text{idx}] = \text{datasample}(\_) \]

Description

\[ y = \text{datasample}(\text{data},k) \] returns \( k \) observations sampled uniformly at random, with replacement, from the data in \( \text{data} \).

\[ y = \text{datasample}(\text{data},k,\text{dim}) \] returns a sample taken along dimension \( \text{dim} \) of \( \text{data} \).

\[ y = \text{datasample}(\_,\text{Name},\text{Value}) \] returns a sample for any of the input arguments in the previous syntaxes, with additional options specified by one or more name-value pair arguments. For example, 'Replace',false specifies sampling without replacement.

\[ y = \text{datasample}(\text{s},\_) \] uses the random number stream \( \text{s} \) to generate random numbers. The option \( \text{s} \) can precede any of the input arguments in the previous syntaxes.

\[ [y,\text{idx}] = \text{datasample}(\_) \] also returns an index vector indicating which values \( \text{datasample} \) sampled from \( \text{data} \) using any of the input arguments in the previous syntaxes.

Examples

Sample Unique Values from Vector

Create the random number stream for reproducibility.

\[ s = \text{RandStream}('\text{mlfg6331}_64'); \]

Draw five unique values from the integers 1 to 10.

\[ y = \text{datasample}(s,1:10,5,'\text{Replace}',\text{false}) \]

\[ y = 1\times5 \]

\[
\begin{array}{cccccc}
9 & 8 & 3 & 6 & 2 \\
\end{array}
\]

Generate Random Characters for Specified Probabilities

Create the random number stream for reproducibility.
s = RandStream('mlfg6331_64');

Generate 48 random characters from the sequence ACGT per specified probabilities.

seq = datasample(s,'ACGT',48,'Weights',[0.15 0.35 0.35 0.15])

seq = 'GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG'

**Select Random Subset of Matrix Columns**

Set the random seed for reproducibility of the results.

rng(10,'twister')

Generate a matrix with 10 rows and 1000 columns.

X = randn(10,1000);

Create the random number stream for reproducibility within datasample.

s = RandStream('mlfg6331_64');

Randomly select five unique columns from X.

Y = datasample(s,X,5,2,'Replace',false)

Y = 10×5

**Create a Bootstrap Replicate Data Set**

Resample observations from a dataset array to create a bootstrap replicate data set. See “Bootstrap Resampling” on page 3-14 for more information about bootstrapping.

Load the sample data set.

load hospital

Create a data set that has the same size as the hospital data set and contains random samples chosen with replacement from the hospital data set.

y = datasample(hospital,size(hospital,1));
Sample in Parallel from Two Data Vectors

Select samples from data based on indices of a sample chosen from another vector.

Generate two random vectors.

```matlab
x1 = randn(100,1); x2 = randn(100,1);
```

Select a sample of 10 elements from vector `x1`, and return the indices of the sample in vector `idx`.

```matlab
[y1,idx] = datasample(x1,10);
```

Select a sample of 10 elements from vector `x2` using the indices in vector `idx`.

```matlab
y2 = x2(idx);
```

Input Arguments

data — Input data
vector | matrix | multidimensional array | table | dataset array

Input data from which to sample, specified as a vector, matrix, multidimensional array, table, or dataset array. By default, `datasample` samples from the first nonsingleton dimension of `data`. For example, if `data` is a matrix, then `datasample` samples from the rows. Change this behavior with the `dim` input argument.

Data Types: `single` | `double` | `logical` | `char` | `string` | `table`

k — Number of samples
positive integer

Number of samples, specified as a positive integer.

Example: `datasample(data,100)` returns 100 observations sampled uniformly and at random from the data in `data`.

Data Types: `single` | `double`

dim — Dimension to sample
1 (default) | positive integer

Dimension to sample, specified as a positive integer. For example, if `data` is a matrix and `dim` is 2, `y` contains a selection of columns in `data`. If `data` is a table or dataset array and `dim` is 2, `y` contains a selection of variables in `data`. Use `dim` to ensure sampling along a specific dimension regardless of whether `data` is a vector, matrix, or N-dimensional array.

Data Types: `single` | `double`

s — Random number stream
`global stream` (default) | `RandStream`

Random number stream, specified as the global stream or `RandStream`. For example, `s = RandStream('mlfg6331_64')` creates a random number stream that uses the multiplicative lagged
Fibonacci generator algorithm. For details, see “Creating and Controlling a Random Number Stream” (MATLAB).

The `rng` function provides a simple way to control the global stream. For example, `rng(seed)` seeds the random number generator using the nonnegative integer seed. For details, see “Managing the Global Stream” (MATLAB).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Replace`,false,'Weights',ones(datasize,1) samples without replacement and with probability proportional to the elements of `Weights`, where `datasize` is the size of the dimension being sampled.

**Replace** — Indicator for sampling with replacement

true (default) | false

Indicator for sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and either `true` or `false`.

Sample with replacement if `'Replace'` is `true`, or without replacement if `'Replace'` is `false`. If `'Replace'` is `false`, then `k` must not be larger than the size of the dimension being sampled. For example, if `data = [1 3 Inf; 2 4 5]` and `y = datasample(data,k,'Replace',false)`, then `k` cannot be larger than 2.

Data Types: `logical`

**Weights** — Sampling weights

ones(datasize,1) (default) | vector of nonnegative numeric values

Sampling weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of nonnegative numeric values. The vector is of size `datasize`, where `datasize` is the size of the dimension being sampled. The vector must have at least one positive value and cannot contain `NaN` values. The `datasample` function samples with probability proportional to the elements of `'Weights'`.

Example: `'Weights'`,[0.1 0.5 0.35 0.46]

Data Types: `single` | `double`

**Output Arguments**

**y** — Sample

vector | matrix | multidimensional array | table | dataset array

Sample, returned as a vector, matrix, multidimensional array, table, or dataset array.

- If `data` is a vector, then `y` is a vector containing `k` elements selected from `data`.
- If `data` is a matrix and `dim = 1`, then `y` is a matrix containing `k` rows selected from `data`. Or, if `dim = 2`, then `y` is a matrix containing `k` columns selected from `data`.  

32-1004
• If \( \text{data} \) is an \( N \)-dimensional array and \( \text{dim} = 1 \), then \( y \) is an \( N \)-dimensional array of samples taken along the first nonsingleton dimension of \( \text{data} \). Or, if you specify a value for the \text{dim} name-value pair argument, \text{datasample} samples along the dimension \( \text{dim} \).
• If \( \text{data} \) is a table and \( \text{dim} = 1 \), then \( y \) is a table containing \( k \) rows selected from \( \text{data} \). Or, if \( \text{dim} = 2 \), then \( y \) is a table containing \( k \) variables selected from \( \text{data} \).
• If \( \text{data} \) is a dataset array and \( \text{dim} = 1 \), then \( y \) is a dataset array containing \( k \) rows selected from \( \text{data} \). Or, if \( \text{dim} = 2 \), then \( y \) is a dataset array containing \( k \) variables selected from \( \text{data} \).

If the input \( \text{data} \) contains missing observations that are represented as \( \text{NaN} \) values, \text{datasample} samples from the entire input, including the \( \text{NaN} \) values. For example, \( y = \text{datasample}([[\text{NaN} 6 14],2]) \) can return \( y = \text{NaN} 14 \).

When the sample is taken with replacement (default), \( y \) can contain repeated observations from \( \text{data} \). Set the \text{Replace} name-value pair argument to \text{false} to sample without replacement.

\( \text{idx} \) — Indices
vector

Indices, returned as a vector indicating which elements \text{datasample} chooses from \( \text{data} \) to create \( y \). For example:
• If \( \text{data} \) is a vector, then \( y = \text{data(\text{idx})} \).
• If \( \text{data} \) is a matrix and \( \text{dim} = 1 \), then \( y = \text{data(\text{idx},:)} \).
• If \( \text{data} \) is a matrix and \( \text{dim} = 2 \), then \( y = \text{data(:,\text{idx})} \).

Tips
• To sample random integers with replacement from a range, use \text{randi}.
• To sample random integers without replacement, use \text{randperm} or \text{datasample}.
• To randomly sample from \( \text{data} \), with or without replacement, use \text{datasample}.

Algorithms
\text{datasample} uses \text{randperm}, \text{rand}, or \text{randi} to generate random values. Therefore, \text{datasample} changes the state of the MATLAB global random number generator. Control the random number generator using \text{rng}.

For selecting weighted samples without replacement, \text{datasample} uses the algorithm of Wong and Easton [1].

Alternative Functionality
You can use \text{randi} or \text{randperm} to generate indices for random sampling with or without replacement, respectively. However, \text{datasample} can be more convenient to use because it samples directly from your data. \text{datasample} also allows weighted sampling.

References
Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• `datasample` is useful as a precursor to plotting and fitting a random subset of a large data set. Sampling a large data set preserves trends in the data without requiring the use of all the data points. If the sample is small enough to fit in memory, then you can apply plotting and fitting functions that do not directly support tall arrays.

• `datasample` supports sampling only along the first dimension of the data.

• For tall arrays, `datasample` does not support sampling with replacement. You must specify `‘Replace’,false`, for example, `datasample(data,k,‘Replace’,false)`.

• The value of `‘Weights’` must be a numeric tall array of the same height as `data`.

• For the syntax `[Y,idx] = datasample(___)`, the output `idx` is a tall logical vector of the same height as `data`. The vector indicates whether each data point is included in the sample.

• If you specify a random number stream, then the underlying generator must support multiple streams and substreams. If you do not specify a random number stream, then `datasample` uses the stream controlled by `tallrng`.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Introduced in R2011b
dataset class

(Not Recommended) Arrays for statistical data

**Note** The **dataset** data type is not recommended. To work with heterogeneous data, use the **MATLAB** table data type instead. See MATLAB table documentation for more information.

**Description**

Dataset arrays are used to collect heterogeneous data and metadata including variable and observation names into a single container variable. Dataset arrays are suitable for storing column-oriented or tabular data that are often stored as columns in a text file or in a spreadsheet, and can accommodate variables of different types, sizes, units, etc.

Dataset arrays can contain different kinds of variables, including numeric, logical, character, string, categorical, and cell. However, a dataset array is a different class than the variables that it contains. For example, even a dataset array that contains only variables that are double arrays cannot be operated on as if it were itself a double array. However, using dot subscripting, you can operate on variable in a dataset array as if it were a workspace variable.

You can subscript dataset arrays using parentheses much like ordinary numeric arrays, but in addition to numeric and logical indices, you can use variable and observation names as indices.

**Construction**

Use the **dataset** constructor to create a dataset array from variables in the MATLAB workspace. You can also create a dataset array by reading data from a text or spreadsheet file. You can access each variable in a dataset array much like fields in a structure, using dot subscripting. See the following section for a list of operations available for dataset arrays.

**dataset** (Not Recommended) Construct dataset array
Methods

cat  (Not Recommended) Concatenate dataset arrays
cellstr (Not Recommended) Create cell array of character vectors from dataset array
dataset2cell (Not Recommended) Convert dataset array to cell array
dataset2struct (Not Recommended) Convert dataset array to structure
datasetfun (Not Recommended) Apply function to dataset array variables
disp (Not Recommended) Display dataset array
display (Not Recommended) Display dataset array
double (Not Recommended) Convert dataset variables to double array
disp (Not Recommended) Last index in indexing expression for dataset array
display (Not Recommended) Write dataset array to file
get (Not Recommended) Access dataset array properties
horzcat (Not Recommended) Horizontal concatenation for dataset arrays
intersect (Not Recommended) Set intersection for dataset array observations
isempty (Not Recommended) True for empty dataset array
ismember (Not Recommended) Dataset array elements that are members of set
ismissing (Not Recommended) Find dataset array elements with missing values
join (Not Recommended) Merge observations
length (Not Recommended) Length of dataset array
ndims (Not Recommended) Number of dimensions of dataset array
numel (Not Recommended) Number of elements in dataset array
replacedata (Not Recommended) Replace dataset variables
replaceWithMissing (Not Recommended) Insert missing data indicators into a dataset array
set (Not Recommended) Set and display properties
setdiff (Not Recommended) Set difference for dataset array observations
setxor (Not Recommended) Set exclusive or for dataset array observations
single (Not Recommended) Convert dataset variables to single array
size (Not Recommended) Size of dataset array
sortrows (Not Recommended) Sort rows of dataset array
stack (Not Recommended) Stack data from multiple variables into single variable
subsasgn (Not Recommended) Subscripted assignment to dataset array
subsref (Not Recommended) Subscripted reference for dataset array
summary (Not Recommended) Print summary of dataset array
union (Not Recommended) Set union for dataset array observations
unique (Not Recommended) Unique observations in dataset array
unstack (Not Recommended) Unstack data from single variable into multiple variables
vertcat (Not Recommended) Vertical concatenation for dataset arrays
Properties

A dataset array D has properties that store metadata (information about your data). Access or assign to a property using \( P = D.Properties.PropName \) or \( D.Properties.PropName = P \), where PropName is one of the following:

- **Description**  (Not Recommended) Character vector describing data set
- **DimNames**   (Not Recommended) Two-element cell array of character vectors giving names of dimensions of data set
- **ObsNames**   (Not Recommended) Cell array of nonempty, distinct character vectors giving names of observations in data set
- **Units**      (Not Recommended) Units of variables in data set
- **UserData**   (Not Recommended) Variable containing additional information associated with data set
- **VarDescription** (Not Recommended) Cell array of character vectors giving descriptions of variables in data set
- **VarNames**   (Not Recommended) Cell array giving names of variables in data set

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes (MATLAB) in the MATLAB Object-Oriented Programming documentation.

Examples

Load a dataset array from a .mat file and create some simple subsets:

```matlab
load hospital
h1 = hospital(1:10,:)
h2 = hospital(:,{'LastName' 'Age' 'Sex' 'Smoker'})

% Access and modify metadata
hospital.Properties.Description
hospital.Properties.VarNames{4} = 'Wgt'

% Create a new dataset variable from an existing one
hospital.AtRisk = hospital.Smoker | (hospital.Age > 40)

% Use individual variables to explore the data
boxplot(hospital.Age,hospital.Sex)
h3 = hospital(hospital.Age<30,...
    {'LastName' 'Age' 'Sex' 'Smoker'})

% Sort the observations based on two variables
h4 = sortrows(hospital,{'Sex','Age'})
```

“Dataset Arrays” on page 2-112
dataset

Class: dataset

(Not Recommended) Construct dataset array

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

```matlab
A = dataset(varspec,'ParamName',Value)
A = dataset('File',filename,'ParamName',Value)
A = dataset('XLSFile',filename,'ParamName',Value)
A = dataset('XPTFile',xptfilename,'ParamName',Value)
```

**Description**

`A = dataset(varspec,'ParamName',Value)` creates dataset array `A` using the workspace variable input method `varspec` and one or more optional name/value pairs (see Parameter Name/Value Pairs).

The input method `varspec` can be one or more of the following:

- **VAR** — a workspace variable. `dataset` uses the workspace name for the variable name in `A`. To include multiple variables, specify `VAR_1,VAR_2,...,VAR_N`. Variables can be arrays of any size, but all variables must have the same number of rows. `VAR` can also be an expression. In this case, `dataset` creates a default name automatically.
- `{VAR,name}` — a workspace variable, `VAR` and a variable name, `name`. `dataset` uses `name` as the variable name. To include multiple variables and names, specify `{VAR_1,name_1}`, `{VAR_2,name_2}`,..., `{VAR_N,name_N}`.
- `{VAR,name_1,...,name_m}` — an `m`-columned workspace variable, `VAR`. `dataset` uses the names `name_1,...,name_m` as variable names. You must include a name for every column in `VAR`. Each column becomes a separate variable in `A`.

You can combine these input methods to include as many variables and names as needed. Names must be valid, unique MATLAB identifiers. For example input combinations, see Examples. For optional name/value pairs see Inputs.

To convert numeric arrays, cell arrays, structure arrays, or tables to dataset arrays, you can also use (respectively):

- `mat2dataset`
- `cell2dataset`
- `struct2dataset`
- `table2dataset`
Note  Dataset arrays may contain built-in types or array objects as variables. Array objects must implement each of the following:

- Standard MATLAB parenthesis indexing of the form $\text{var}(i, \ldots)$, where $i$ is a numeric or logical vector corresponding to rows of the variable
- A size method with a $\text{dim}$ argument
- A $\text{vertcat}$ method

A = dataset('File', filename, 'ParamName', Value) creates dataset array $A$ from column-oriented data in the text file specified by filename. Variables in $A$ are of type double if data in the corresponding column of the file, following the column header, are entirely numeric; otherwise the variables in $A$ are cell arrays of character vectors. dataset converts empty fields to either NaN (for a numeric variable) or the empty character vector (for a character-valued variable). dataset ignores insignificant white space in the file. You cannot specify both a file and workspace variables as input. See Name/Value Pairs for more information.

A = dataset('XLSFile', filename, 'ParamName', Value) creates dataset array $A$ from column-oriented data in the Excel spreadsheet specified by filename. Variables in $A$ are of type double if data in the corresponding column of the spreadsheet, following the column header, are entirely numeric; otherwise the variables in $A$ are cell arrays of character vectors. See Name/Value Pairs for more information.

A = dataset('XPTFile', xptfilename, 'ParamName', Value) creates a dataset array from a SAS® XPORT format file. Variable names from the XPORT format file are preserved. Numeric data types in the XPORT format file are preserved but all other data types are converted to cell arrays of character vectors. The XPORT format allows for 28 missing data types. dataset represents these in the file by an upper case letter, '.' or '_'. dataset converts all missing data to NaN values in $A$. See Name/Value Pairs for more information.

Parameter Name/Value Pairs

Specify one or more of the following name/value pairs when constructing a dataset:

VarNames
A string array or cell array \{name_1, ..., name_m\} naming the m variables in $A$ with the specified variable names. Names must be valid, unique MATLAB identifiers. The number of names must equal the number of variables in $A$. You cannot use the VarNames parameter if you provide names for individual variables using \{VAR, name\} pairs. To specify VarNames when using a file as input, set ReadVarNames to false.

ObsNames
A string array or cell array \{name_1, ..., name_n\} naming the n observations in $A$ with the specified observation names. The names need not be valid MATLAB identifiers, but must be unique. The number of names must equal the number of observations (rows) in $A$. To specify ObsNames when using a file as input, set ReadObsNames to false.

Name/value pairs available when using text files as inputs:
Delimiter

A character vector or string scalar indicating the character separating columns in the file. Values are:

- '\t' (tab, the default when no format is specified)
- ' ' (space, the default when a format is specified)
- ',' (comma)
- ';'; (semicolon)
- '|' (bar)

Format

A format character vector or string scalar, as accepted by textscan. dataset reads the file using textscan, and creates variables in A according to the conversion specifiers in the format character vector or string scalar. You may also provide any name/value pairs accepted by textscan. Using the Format parameter is much faster for large files. If ReadObsNames is true, then format should include a format specifier for the first column of the file.

HeaderLines

Numeric value indicating the number of lines to skip at the beginning of a file.

Default: 0

TreatAsEmpty

Specifies characters to treat as the empty character vector in a numeric column. Values may be a character array, a string array, or a cell array of character vectors. The parameter applies only to numeric columns in the file; dataset does not accept numeric literals such as '-99'.

Name/value pairs available when using text files or Excel spreadsheets as inputs:

ReadVarNames

A logical value indicating whether (true) or not (false) to read variable names from the first row of the file. The default is true. If ReadVarNames is true, variable names in the column headers of the file or range (if using an Excel spreadsheet) cannot be empty.

ReadObsNames

A logical value indicating whether (true) or not (false) to read observation names from the first column of the file or range (if using an Excel spreadsheet). The default is false. If ReadObsNames and ReadVarNames are both true, dataset saves the header of the first column in the file or range as the name of the first dimension in A.Properties.DimNames.

When reading from an XPT format file, the ReadObsNames parameter name/value pair determines whether or not to try to use the first variable in the file as observation names. Specify as a logical value (default false). If the contents of the first variable are not valid observation names then dataset reads the variable into a variable of the dataset array and does not set the observation names.

Name/value pairs available when using Excel spreadsheets as input:
Sheet
A positive scalar value of type double indicating the sheet number, or a quoted sheet name.

Range
A character vector or string scalar of the form 'C1:C2' where C1 and C2 are the names of cells at opposing corners of a rectangular region to be read, as for xlsread. By default, the rectangular region extends to the right-most column containing data. If the spreadsheet contains empty columns between columns of data, or if the spreadsheet contains figures or other non-tabular information, specify a range that contains only data.

Examples
Create a dataset array from workspace variables, including observation names:

load cereal
cereal = dataset(Calories,Protein,Fat,Sodium,Fiber,Carbo,...
    Sugars,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:10,2);

Create a dataset array from a single, multi-columned workspace variable, designating variable names for each column:

load cities
categories = cellstr(categories);
cities = dataset({ratings,categories{:}},...
    'ObsNames',cellstr(names))

Load data from a text or spreadsheet file

patients = dataset('File','hospital.dat',...
    'Delimiter','','ReadObsNames',true)
patients2 = dataset('XLSFile','hospital.xls',...
    'ReadObsNames',true)

1 Load patient data from the CSV file hospital.dat and store the information in a dataset array with observation names given by the first column in the data (patient identification):

patients = dataset('file','hospital.dat',...
    'format','%s%s%f%f%f%f%f%f%f%f%f%f','%s','%s','%s','%s','%s','ReadObsNames',true);

You can also load the data without specifying a format. dataset will automatically create dataset variables that are either double arrays or cell arrays of character vectors, depending on the contents of the file:

patients = dataset('file','hospital.dat',...
    'delimiter','','','ReadObsNames',true);

2 Make the {0,1}-valued variable smoke nominal, and change the labels to 'No' and 'Yes':

patients.smoke = nominal(patients.smoke,{'No','Yes'});

3 Add new levels to smoke as placeholders for more detailed histories of smokers:

patients.smoke = addlevels(patients.smoke,...
    {'0-5 Years','5-10 Years','LongTerm'});
Assuming the nonsmokers have never smoked, relabel the 'No' level:

\[
\text{patients.smoke} = \text{setlabels}(\text{patients.smoke}, 'Never', 'No');
\]

Drop the undifferentiated 'Yes' level from smoke:

\[
\text{patients.smoke} = \text{droplevels}(\text{patients.smoke}, 'Yes');
\]

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

Set each smoker to one of the new levels, by observation name:

\[
\text{patients.smoke('YPL-320')} = '5-10\ Years';
\]

Introduced in R2007a
dataset2cell

Class: dataset

(Not Recommended) Convert dataset array to cell array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

C = dataset2cell(D)

Description

C = dataset2cell(D) converts the dataset array D to a cell array C. Each variable of D becomes a column in C. If D is an M-by-N array, then C is (M+1)-by-N, with the variable names of D in the first row. If D contains observation names, then C is (M+1)-by-(N+1), with the observation names in the first column.

cell2dataset | dataset | export

Topics

“Dataset Arrays” on page 2-112
dataset2struct

Class: dataset

(Not Recommended) Convert dataset array to structure

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

\[
S = \text{dataset2struct}(D)
\]

\[
S = \text{dataset2struct}(D, 'AsScalar', true)
\]

**Description**

\[S = \text{dataset2struct}(D)\] converts a dataset array to a structure array. Each variable of \(D\) becomes a field in \(S\). If \(D\) is an \(M\)-by-\(N\) dataset array, then \(S\) is \(M\)-by-1 and has \(N\) fields. If \(D\) contains observation names, then \(S\) contains those names in the additional field ObsNames.

\[S = \text{dataset2struct}(D, 'AsScalar', true)\] converts a dataset array to a scalar structure. Each variable of \(D\) becomes a field in \(S\). If \(D\) is an \(M\)-by-\(N\) dataset array, then \(S\) has \(N\) fields, each of which has \(M\) rows. If \(D\) contains observation names, then \(S\) contains those names in the additional field ObsNames.

**Input Arguments**

\(D\)

\(M\)-by-\(N\) dataset array.

**Output Arguments**

\(S\)

\(M\)-by-1 structure array, with \(N\) fields. If the input dataset array contains observation names, then \(S\) has an additional field ObsNames.

If you specify 'AsScalar',true, then \(S\) is a scalar structure, with \(N\) fields, each with \(M\) rows.

**Examples**

**Convert Dataset Array to Structure Array**

Load sample dataset array.

load('hospital')
Create a dataset array, \(D\), that has only a subset of the observations and variables.

\[
D = \text{hospital}(1:8,\{'\text{LastName}', '\text{Sex}', '\text{Age}'\});
\]

\[
\text{size}(D)
\]

\[
\begin{array}{l}
\text{ans} = 1\times2 \\
8 & 3
\end{array}
\]

The dataset array \(D\) has 8 observations and 3 variables.

Convert \(D\) to a structure array.

\[
S = \text{dataset2struct}(D)
\]

\[
S = 8\times1 \text{ struct array with fields:}
\begin{align*}
\text{ObsNames} \\
\text{LastName} \\
\text{Sex} \\
\text{Age}
\end{align*}
\]

The structure is \(8\times1\), corresponding to the 8 observations in the dataset array. \(S\) also has the field \text{ObsNames}, since \(D\) had observation names.

Display the field data for the first element of \(S\).

\[
S(1)
\]

\[
\text{ans} = \text{struct with fields:}
\begin{align*}
\text{ObsNames: 'YPL-320'} \\
\text{LastName: 'SMITH'} \\
\text{Sex: Male} \\
\text{Age: 38}
\end{align*}
\]

This information corresponds to the first observation (row) of the dataset array.

**Convert Dataset Array to Scalar Structure**

Load sample dataset array.

\[
\text{load('hospital')}
\]

Create a dataset array, \(D\), that has only a subset of the observations and variables.

\[
D = \text{hospital}(1:8,\{'\text{LastName}', '\text{Sex}', '\text{Age}'\});
\]

\[
\text{size}(D)
\]

\[
\begin{array}{l}
\text{ans} = 1\times2 \\
8 & 3
\end{array}
\]

The dataset array \(D\) has 8 observations and 3 variables.
Convert D to a scalar structure array.

\[ S = \text{dataset2struct}(D,'AsScalar',\text{true}) \]

\[ S = \text{struct with fields:} \]
\[ \begin{align*}
\text{ObsNames}: & \{8 \times 1 \text{ cell}\} \\
\text{LastName}: & \{8 \times 1 \text{ cell}\} \\
\text{Sex}: & \{8 \times 1 \text{ nominal}\} \\
\text{Age}: & \{8 \times 1 \text{ double}\}
\end{align*} \]

The data in the fields of the scalar structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field ObsNames, since D had observation names.

Display the data for the field LastName.

\[ S.\text{LastName} \]

\[ \text{ans} = 8 \times 1 \text{ cell} \]
\[ \begin{align*}
\{\text{SMITH} \} \\
\{\text{JOHNSON} \} \\
\{\text{WILLIAMS} \} \\
\{\text{JONES} \} \\
\{\text{BROWN} \} \\
\{\text{DAVIS} \} \\
\{\text{MILLER} \} \\
\{\text{WILSON} \}
\end{align*} \]

The structure field LastName contains all of the data that was in the original dataset array variable, LastName.

**Topics**

“Dataset Arrays” on page 2-112
**dataset2table**

Convert dataset array to table

**Syntax**

```matlab
t = dataset2table(ds)
```

**Description**

`t = dataset2table(ds)` converts a dataset array to a table.

**Examples**

**Convert Dataset Array to Table**

Load the sample data, which contains nutritional information for 77 cereals.

```matlab
load cereal;
```

Create a dataset array containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```matlab
Calories = Calories(1:5);
Protein = Protein(1:5);
Fat = Fat(1:5);
Name = Name(1:5);
```

```matlab
cereal = dataset(Calories,Protein,Fat,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:6,2);
```

Convert the dataset array to a table.

```matlab
t = dataset2table(cereal)
```

<table>
<thead>
<tr>
<th>Calories</th>
<th>Protein</th>
<th>Fat</th>
</tr>
</thead>
<tbody>
<tr>
<td>100% Bran</td>
<td>70</td>
<td>4</td>
</tr>
<tr>
<td>100% Natural Bran</td>
<td>120</td>
<td>3</td>
</tr>
<tr>
<td>All-Bran</td>
<td>70</td>
<td>4</td>
</tr>
<tr>
<td>All-Bran with Extra Fiber</td>
<td>50</td>
<td>4</td>
</tr>
<tr>
<td>Almond Delight</td>
<td>110</td>
<td>2</td>
</tr>
</tbody>
</table>
Input Arguments

**ds** — Input dataset array
dataset array

Input dataset array to convert to a table, specified as a dataset array. Each variable in `ds` becomes a variable in the output table `t`.

Output Arguments

**t** — Output table
table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see “Tables” (MATLAB).

Topics
“Dataset Arrays” on page 2-112
“Tables” (MATLAB)

Introduced in R2013b
datasetfun

Class: dataset

(Not Recommended) Apply function to dataset array variables

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

```plaintext
b = datasetfun(fun,A)
[b,c,...] = datasetfun(fun,A)
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
[b,...] = datasetfun(fun,A,...,'DataVars',vars)
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)
```

**Description**

`b = datasetfun(fun,A)` applies the function specified by `fun` to each variable of the dataset array `A`, and returns the results in the vector `b`. The `i`th element of `b` is equal to `fun` applied to the `i`th dataset variable of `A`. `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called, and `datasetfun` concatenates them into the vector `b`. The outputs from `fun` must be one of the following types: numeric, logical, character, structure, or cell.

To apply functions that return results that are nonscalar or of different sizes and types, use the 'UniformOutput' or 'DatasetOutput' parameters described below.

Do not rely on the order in which `datasetfun` computes the elements of `b`, which is unspecified.

If `fun` is bound to more than one built-in function or file, (that is, if it represents a set of overloaded functions), `datasetfun` follows MATLAB dispatching rules in calling the function. (See “Function Precedence Order” (MATLAB).)

```plaintext
[b,c,...] = datasetfun(fun,A),
```

where `fun` is a function handle to a function that returns multiple outputs, returns vectors `b`, `c`, ..., each corresponding to one of the output arguments of `fun`. `datasetfun` calls `fun` each time with as many outputs as there are in the call to `datasetfun`. `fun` may return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

```plaintext
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
```

allows you to specify a function `fun` that returns values of different sizes or types. `datasetfun` returns a cell array (or multiple cell arrays), where the `i`th cell contains the value of `fun` applied to the `i`th dataset variable of `A`. Setting 'UniformOutput' to true is equivalent to the default behavior.

```plaintext
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
```

specifies that the output(s) of `fun` are returned as variables in a dataset array (or multiple dataset arrays). `fun` must return values
with the same number of rows each time it is called, but it may return values of any type. The variables in the output dataset array(s) have the same names as the variables in the input. Setting 'DatasetOutput' to false (the default) specifies that the type of the output(s) from datasetfun is determined by 'UniformOutput'.

[b,...] = datasetfun(fun,A,...,'DataVars',vars) allows you to apply fun only to the dataset variables in A specified by vars. vars is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames) specifies observation names for the dataset output when 'DatasetOutput' is true.

[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun), where efun is a function handle, specifies the MATLAB function to call if the call to fun fails. The error-handling function is called with the following input arguments:

- A structure with the fields identifier, message, and index, respectively containing the identifier of the error that occurred, the text of the error message, and the linear index into the input array(s) at which the error occurred
- The set of input arguments at which the call to the function failed

The error-handling function should either re-throw an error, or return the same number of outputs as fun. These outputs are then returned as the outputs of datasetfun. If 'UniformOutput' is true, the outputs of the error handler must also be scalars of the same type as the outputs of fun. For example, the following code could be saved in a file as the error-handling function:

```matlab
function [A,B] = errorFunc(S,varargin)
warning(S.identifier,S.message);
A = NaN;
B = NaN;
```

If an error-handling function is not specified, the error from the call to fun is rethrown.

**Examples**

**Work With Datasets Using Function Handles**

Use function handles to compute the mean and plot a histogram of selected variables in a dataset array.

Load the sample data.

```matlab
load hospital
```

Use datasetfun to compute the means of the Weight and BloodPressure variables, and store the results in a dataset array.

```matlab
stats = datasetfun(@mean,hospital,...
    'DataVars',{'Weight','BloodPressure'},...
    'UniformOutput',false)
```

```matlab
stats=1x2 cell array
    {1x2 double}
```
The variable `BloodPressure` contains two columns: One for the systolic measurement, and one for the diastolic measurement.

Display the mean of the blood pressure variable.

```matlab
stats{2}
an = 1x2
    122.7800   82.9600
```

Plot a histogram of the blood pressure variable.

```matlab
datasetfun(@hist,hospital,...
    'DataVars','BloodPressure',...
    'UniformOutput',false);
title('{\bf Blood Pressure}')
legend('Systolic','Diastolic','Location','N')
```

`grpstats`
daugment

D-optimal augmentation

Syntax

dCE2 = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns,model)
[dCE2,X] = daugment(...,param1,val1,param2,val2,...)

Description

dCE2 = daugment(dCE,mruns) uses a coordinate-exchange algorithm to D-optimally add mruns runs to an existing experimental design dCE for a linear additive model.

[dCE2,X] = daugment(dCE,mruns) also returns the design matrix X associated with the augmented design.

[dCE2,X] = daugment(dCE,mruns,model) uses the linear regression model specified in model. model is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of X for a full quadratic model with n terms is:

1 The constant term
2 The linear terms in order 1, 2, ..., n
3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., (n - 1, n)
4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, model can be a matrix specifying polynomial terms of arbitrary order. In this case, model should have one column for each factor and one row for each term in the model. The entries in any row of model are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in model specifies the term (X1.^0).*(X2.^1).*(X3.^2). A row of all zeros in model specifies a constant term, which can be omitted.

[dCE2,X] = daugment(...,param1,val1,param2,val2,...) specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bounds'</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix, where nfactors is the number of factors. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>'categorical'</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>'display'</td>
<td>Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.</td>
</tr>
<tr>
<td>'excludefun'</td>
<td>Handle to a function that excludes undesirable runs. If the function is f, it must support the syntax b = f(S), where S is a matrix of treatments with nfactors columns, where nfactors is the number of factors, and b is a vector of Boolean values with the same number of rows as S. b(i) is true if the ith row S should be excluded.</td>
</tr>
<tr>
<td>'init'</td>
<td>Initial design as an mruns-by-nfactors matrix, where nfactors is the number of factors. The default is a randomly selected set of points.</td>
</tr>
<tr>
<td>'levels'</td>
<td>Vector of number of levels for each factor.</td>
</tr>
<tr>
<td>'maxiter'</td>
<td>Maximum number of iterations. The default is 10.</td>
</tr>
<tr>
<td>'options'</td>
<td>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with statset. Applicable statset parameters are:</td>
</tr>
<tr>
<td></td>
<td>• 'UseParallel' — If true and if Parallel Computing Toolbox is installed, compute in parallel. If the Parallel Computing Toolbox is not installed, or 'UseParallel',false, then computation occurs in serial mode. Default is false, meaning serial computation.</td>
</tr>
<tr>
<td></td>
<td>• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
<tr>
<td></td>
<td>• Streams — A RandStream object or cell array of such objects. If you do not specify Streams, daugment uses the default stream or streams. If you choose to specify Streams, use a single object except in the case</td>
</tr>
<tr>
<td></td>
<td>• UseParallel is true</td>
</tr>
<tr>
<td></td>
<td>• UseSubstreams is false</td>
</tr>
<tr>
<td></td>
<td>In that case, use a cell array the same size as the Parallel pool.</td>
</tr>
<tr>
<td>'tries'</td>
<td>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</td>
</tr>
</tbody>
</table>

**Note** The daugment function augments an existing design using a coordinate-exchange algorithm; the 'start' parameter of the candexch function provides the same functionality using a row-exchange algorithm.
Examples

The following eight-run design is adequate for estimating main effects in a four-factor model:

```matlab
dCEmain = cordexch(4,8)
dCEmain =  
   1   -1   -1    1
   -1   -1     1    1
   -1    1    -1    1
    1    1     1   -1
    1    1     1    1
   -1    1    -1   -1
    1   -1    -1   -1
   -1   -1     1   -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```matlab
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =  
   1   -1   -1    1
   -1   -1     1    1
   -1    1    -1    1
    1    1     1   -1
    1    1     1    1
   -1    1    -1   -1
    1   -1    -1   -1
   -1   -1     1   -1
   -1    1     1     1
   -1    1    -1    -1
    1   -1    -1    1
    1    1     1    1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

Extended Capabilities

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced before R2006a
dbscan

Density-based spatial clustering of applications with noise (DBSCAN)

Syntax

idx = dbscan(X,epsilon,minpts)
idx = dbscan(X,epsilon,minpts,Name,Value)
idx = dbscan(D,epsilon,minpts,'Distance','precomputed')
[idx,corepts] = dbscan(____)

Description

idx = dbscan(X,epsilon,minpts) partitions observations in the n-by-p data matrix X into clusters using the DBSCAN algorithm (see Algorithms on page 32-1040). dbscan clusters the observations (or points) based on a threshold for a neighborhood search radius epsilon and a minimum number of neighbors minpts required to identify a core point. The function returns an n-by-1 vector (idx) containing cluster indices of each observation.

idx = dbscan(X,epsilon,minpts,Name,Value) specifies additional options using one or more name-value pair arguments. For example, you can specify 'Distance','minkowski','P',3 to use the Minkowski distance metric with an exponent of three in the DBSCAN algorithm.

idx = dbscan(D,epsilon,minpts,'Distance','precomputed') returns a vector of cluster indices for the precomputed pairwise distances D between observations. D can be the output of pdist or pdist2, or a more general dissimilarity vector or matrix conforming to the output format of pdist or pdist2, respectively.

[idx,corepts] = dbscan(____) also returns a logical vector corepts that contains the core points identified by dbscan, using any of the input argument combinations in the previous syntaxes.

Examples

Perform DBSCAN on Input Data

Cluster a 2-D circular data set using DBSCAN with the default Euclidean distance metric. Also, compare the results of clustering the data set using DBSCAN and k-Means clustering with the squared Euclidean distance metric.

Generate synthetic data that contains two noisy circles.

rng('default') % For reproducibility

% Parameters for data generation
N = 300; % Size of each cluster
r1 = 0.5; % Radius of first circle
r2 = 5; % Radius of second circle
theta = linspace(0,2*pi,N);
X1 = r1*[cos(theta),sin(theta)]+ rand(N,1);
X2 = r2*[cos(theta),sin(theta)]+ rand(N,1);
X = [X1;X2]; % Noisy 2-D circular data set

Visualize the data set.
scatter(X(:,1),X(:,2))

The plot shows that the data set contains two distinct clusters.

Perform DBSCAN clustering on the data. Specify an epsilon value of 1 and a minpts value of 5.
idx = dbscan(X,1,5); % The default distance metric is Euclidean distance

Visualize the clustering.
gscatter(X(:,1),X(:,2),idx);
title('DBSCAN Using Euclidean Distance Metric')
Using the Euclidean distance metric, DBSCAN correctly identifies the two clusters in the data set.

Perform DBSCAN clustering using the squared Euclidean distance metric. Specify an epsilon value of 1 and a minpts value of 5.

```matlab
idx2 = dbscan(X,1,5,'Distance','squaredeuclidean');
```

Visualize the clustering.

```matlab
gscatter(X(:,1),X(:,2),idx2);
title('DBSCAN Using Squared Euclidean Distance Metric')
```
Using the squared Euclidean distance metric, DBSCAN correctly identifies the two clusters in the data set.

Perform \( k \)-Means clustering using the squared Euclidean distance metric. Specify \( k = 2 \) clusters.

\[
\text{kidx} = \text{kmeans}(X,2); \quad \text{% The default distance metric is squared Euclidean distance}
\]

Visualize the clustering.

\[
\text{gscatter}(X(:,1),X(:,2),\text{kidx});
\text{title('K-Means Using Squared Euclidean Distance Metric')}
\]
Using the squared Euclidean distance metric, k-Means clustering fails to correctly identify the two clusters in the data set.

Perform DBSCAN on Pairwise Distances

Perform DBSCAN clustering using a matrix of pairwise distances between observations as input to the \texttt{dbscan} function, and find the number of outliers and core points. The data set is a Lidar scan, stored as a collection of 3-D points, that contains the coordinates of objects surrounding a vehicle.

Load the \(x, y, z\) coordinates of the objects.

\begin{verbatim}
load('lidar_subset.mat')
loc = lidar_subset;
\end{verbatim}

To highlight the environment around the vehicle, set the region of interest to span 20 meters to the left and right of the vehicle, 20 meters in front and back of the vehicle, and the area above the surface of the road.

\begin{verbatim}
xBound = 20; \text{ % in meters}
yBound = 20; \text{ % in meters}
zLowerBound = 0; \text{ % in meters}
\end{verbatim}

Crop the data to contain only points within the specified region.
indices = loc(:,1) <= xBound & loc(:,1) >= -xBound ... & loc(:,2) <= yBound & loc(:,2) >= -yBound ... & loc(:,3) > zLowerBound;
loc = loc(indices,:);

Visualize the data as a 2-D scatter plot. Annotate the plot to highlight the vehicle.
scatter(loc(:,1),loc(:,2),'.');
anotation('ellipse',[0.48 0.48 .1 .1],'Color','red')

The center of the set of points (circled in red) contains the roof and hood of the vehicle. All other points are obstacles.

Precompute a matrix of pairwise distances $D$ between observations by using the \texttt{pdist2} function.
$D = \text{pdist2(loc,loc)};$

Cluster the data by using \texttt{dbscan} with the pairwise distances. Specify an $\texttt{epsilon}$ value of 2 and a $\texttt{minpts}$ value of 50.
[idx, corepts] = dbscan(D,2,50,'Distance','precomputed');

Visualize the results and annotate the figure to highlight a specific cluster.
gscatter(loc(:,1),loc(:,2),idx);
anotation('ellipse',[0.54 0.41 .07 .07],'Color','red')

grid
As shown in the scatter plot, `dbscan` identifies 11 clusters and places the vehicle in a separate cluster.

`dbscan` assigns the group of points circled in red (and centered around $(3, -4)$) to the same cluster (group 7) as the group of points in the southeast quadrant of the plot. The expectation is that these groups should be in separate clusters. You can try using a smaller value of `epsilon` to split up large clusters and further partition the points.

The function also identifies some outliers (an `idx` value of $-1$) in the data. Find the number of points that `dbscan` identifies as outliers.

```matlab
sum(idx == -1)
ans = 412
```

`dbscan` identifies 412 outliers out of 19,070 observations.

Find the number of points that `dbscan` identifies as core points. A `corepts` value of 1 indicates a core point.

```matlab
sum(corepts == 1)
ans = 18446
```

`dbscan` identifies 18,446 observations as core points.

See “Determine Values for DBSCAN Parameters” on page 16-20 for a more extensive example.
Input Arguments

X — Input data
numeric matrix

Input data, specified as an n-by-p numeric matrix. The rows of X correspond to observations (or points), and the columns correspond to variables.

Data Types: single | double

D — Pairwise distances
numeric row vector | numeric square matrix | logical row vector | logical square matrix

Pairwise distances between observations, specified as a numeric row vector that is the output of pdist, numeric square matrix that is the output of pdist2, logical row vector, or logical square matrix. D can also be a more general dissimilarity vector or matrix that conforms to the output format of pdist or pdist2, respectively.

For the aforementioned specifications, the following table describes the formats that D can take, given an input matrix X that has n observations (rows) and p dimensions (columns).

<table>
<thead>
<tr>
<th>Specification</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric row vector (output of pdist(X))</td>
<td>A row vector of length n(n - 1)/2, corresponding to pairs of observations in X &lt;br&gt;Distances arranged in the order (2,1), (3,1), ..., (n,1), (3,2), ..., (n,2), ..., (n,n - 1))</td>
</tr>
<tr>
<td>Numeric square matrix (output of pdist2(X,X))</td>
<td>An n-by-n matrix, where D(i,j) is the distance between observations i and j in X &lt;br&gt;A symmetric matrix having diagonal elements equal to zero</td>
</tr>
<tr>
<td>Logical row vector</td>
<td>A row vector of length n(n - 1)/2, corresponding to pairs of observations in X &lt;br&gt;A logical row vector with elements indicating distances that are less than or equal to epsilon &lt;br&gt;Elements of D arranged in the order (2,1), (3,1), ..., (n,1), (3,2), ..., (n,2), ..., (n,n - 1))</td>
</tr>
<tr>
<td>Logical square matrix</td>
<td>An n-by-n matrix, where D(i,j) indicates the distance between observations i and j in X that are less than or equal to epsilon</td>
</tr>
</tbody>
</table>

Note If D is a logical vector or matrix, then the value of epsilon must be empty; for example, dbscan(D,[],5,'Distance','precomputed').

Data Types: single | double | logical

epsilon — Epsilon neighborhood
numeric scalar | []
Epsilon neighborhood of a point, specified as a numeric scalar that defines a neighborhood search radius around the point. If the epsilon neighborhood of a point contains at least \( \text{minpts} \) neighbors, then \text{dbscan} identifies the point as a core point.

The value of epsilon must be empty ([]) when \( D \) is a logical vector or matrix.

Example: \text{dbscan}(X,2.5,10)

Example: \text{dbscan}(D,[],5,'Distance','precomputed'), for a logical matrix or vector \( D \)

Data Types: \text{single} | \text{double}

\( \text{minpts} \) — Minimum number of neighbors required for core point
positive integer

Minimum number of neighbors required for a core point, specified as a positive integer. The epsilon neighborhood of a core point in a cluster must contain at least \( \text{minpts} \) neighbors, whereas the epsilon neighborhood of a border point can contain fewer neighbors than \( \text{minpts} \).

Example: \text{dbscan}(X,2.5,5)

Data Types: \text{single} | \text{double}

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \text{Name}, \text{Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \text{Name1,Value1,...,NameN,ValueN}.

Example: \text{dbscan}(D,2.5,5,'Distance','precomputed') specifies DBSCAN clustering using a precomputed matrix of pairwise distances \( D \) between observations, an epsilon neighborhood of 2.5, and a minimum of 5 neighbors.

**Distance** — Distance metric
character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of \text{'Distance'} and a character vector, string scalar, or function handle, as described in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'precomputed'</td>
<td>Precomputed distances. You must specify this option if the first input to \text{dbscan} is a vector or matrix of pairwise distances ( D ).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance (default)</td>
</tr>
<tr>
<td>'squaredeuclidean'</td>
<td>Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, ( S = \text{nanstd}(X) ). Use \text{Scale} to specify another value for ( S ).</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance using the sample covariance of ( X, C = \text{nancov}(X) ). Use \text{Cov} to specify another value for ( C ), where the matrix ( C ) is symmetric and positive definite.</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance</td>
</tr>
</tbody>
</table>

32-1037
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. Use P to specify a different exponent, where P is a positive scalar value.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference)</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between points (treated as vectors)</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample correlation between points (treated as sequences of values)</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values)</td>
</tr>
<tr>
<td>@distfun</td>
<td>Custom distance function handle. A distance function has the form function D2 = distfun(ZI,ZJ) % calculation of distance ... where • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. distfun must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:). If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</td>
</tr>
</tbody>
</table>

For definitions, see Distance Metrics on page 32-3925.

When you use the 'seuclidean', 'minkowski', or 'mahalanobis' distance metric, you can specify the additional name-value pair argument 'Scale', 'P', or 'Cov', respectively, to control the distance metrics.

Example: dbscan(X,2.5,5,'Distance','minkowski','P',3) specifies an epsilon neighborhood of 2.5, a minimum of 5 neighbors to grow a cluster, and use of the Minkowski distance metric with an exponent of 3 when performing the clustering algorithm.

**P — Exponent for Minkowski distance metric**
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3
Data Types: single | double
**Cov** — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | numeric matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a symmetric, positive definite, numeric matrix.

This argument is valid only if 'Distance' is 'mahalanobis'.

Data Types: `single` | `double`

**Scale** — Scaling factors for standardized Euclidean distance metric

`nanstd(X)` (default) | numeric vector of positive values

Scaling factors for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a numeric vector of positive values.

Each dimension (column) of X has a corresponding value in 'Scale'; therefore, 'Scale' is of length `p` (the number of columns in X). For each dimension of X, `dbscan` uses the corresponding value in 'Scale' to standardize the difference between X and a query point.

This argument is valid only if 'Distance' is 'seuclidean'.

Data Types: `single` | `double`

**Output Arguments**

**idx** — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has `n` rows, and each row of `idx` indicates the cluster assignment of the corresponding observation in X. An index equal to −1 indicates an outlier (or noise point).

**Note** Cluster assignment using the DBSCAN algorithm is dependent on the order of observations. Therefore, shuffling the rows of X can lead to different cluster assignments for the observations. For more details, see Algorithms on page 32-1040.

Data Types: `double`

**corepts** — Indicator for core points

logical vector

Indicator for core points, returned as an `n`-by-1 logical vector indicating the indices of the core points identified by `dbscan`. A value of 1 in any row of `corepts` indicates that the corresponding observation in X is a core point. Otherwise, `corepts` has a value of 0 for rows corresponding to observations that are not core points.

Data Types: `logical`
More About

Core Points

Core points in a cluster are points that have at least a minimum number of neighbors (\(\text{minpts}\)) in their epsilon neighborhood (\(\text{epsilon}\)). Each cluster must contain at least one core point.

Border Points

Border points in a cluster are points that have fewer than the required minimum number of neighbors for a core point (\(\text{minpts}\)) in their epsilon neighborhood (\(\text{epsilon}\)). Generally, the epsilon neighborhood of a border point contains significantly fewer points than the epsilon neighborhood of a core point.

Noise Points

Noise points are outliers that do not belong to any cluster.

Tips

- For improved speed when iterating over many values of \(\text{epsilon}\), consider passing in \(D\) as the input to \texttt{dbscan}. This approach prevents the function from having to compute the distances at every point of the iteration.
- If you use \texttt{pdist2} to precompute \(D\), do not specify the 'Smallest' or 'Largest' name-value pair arguments of \texttt{pdist2} to select or sort columns of \(D\). Selecting fewer than \(n\) distances results in an error, because \texttt{dbscan} expects \(D\) to be a square matrix. Sorting the distances in each column of \(D\) leads to a loss in the interpretation of \(D\) and can give meaningless results when used in the \texttt{dbscan} function.
- For efficient memory usage, consider passing in \(D\) as a logical matrix rather than a numeric matrix to \texttt{dbscan} when \(D\) is large. By default, MATLAB stores each value in a numeric matrix using 8 bytes (64 bits), and each value in a logical matrix using 1 byte (8 bits).
- To select a value for \(\text{minpts}\), consider a value greater than or equal to the number of dimensions of the input data plus one [1]. For example, for an \(n\)-by-\(p\) matrix \(X\), set 'minpts' equal to \(p+1\) or greater.
- One possible strategy for selecting a value for \(\text{epsilon}\) is to generate a \(k\)-distance graph for \(X\). For each point in \(X\), find the distance to the \(k\)th nearest point, and plot sorted points against this distance. Generally, the graph contains a knee. The distance that corresponds to the knee is typically a good choice for \(\text{epsilon}\), because it is the region where points start tailing off into outlier (noise) territory [1].

Algorithms

- DBSCAN is a density-based clustering algorithm that is designed to discover clusters and noise in data. The algorithm identifies three kinds of points: core points, border points, and noise points [1]. For specified values of \(\text{epsilon}\) and \(\text{minpts}\), the \texttt{dbscan} function implements the algorithm as follows:

1. From the input data set \(X\), select the first unlabeled observation \(x_1\) as the current point, and initialize the first cluster label \(C\) to 1.
2. Find the set of points within the epsilon neighborhood \(\text{epsilon}\) of the current point. These points are the neighbors.
If the number of neighbors is less than \texttt{minpts}, then label the current point as a noise point (or an outlier). Go to step 4.

\textbf{Note} \texttt{dbscan} can reassign noise points to clusters if the noise points later satisfy the constraints set by \texttt{epsilon} and \texttt{minpts} from some other point in \texttt{X}. This process of reassigning points happens for border points of a cluster.

Otherwise, label the current point as a core point belonging to cluster \texttt{C}.

3 Iterate over each neighbor (new current point) and repeat step 2 until no new neighbors are found that can be labeled as belonging to the current cluster \texttt{C}.

4 Select the next unlabeled point in \texttt{X} as the current point, and increase the cluster count by 1.

5 Repeat steps 2–4 until all points in \texttt{X} are labeled.

- If two clusters have varying densities and are close to each other, that is, the distance between two border points (one from each cluster) is less than \texttt{epsilon}, then \texttt{dbscan} can merge the two clusters into one.

- Every valid cluster might not contain at least \texttt{minpts} observations. For example, \texttt{dbscan} can identify a border point belonging to two clusters that are close to each other. In such a situation, the algorithm assigns the border point to the first discovered cluster. As a result, the second cluster is still a valid cluster, but it can have fewer than \texttt{minpts} observations.

\textbf{Topics}

“Introduction to DBSCAN” on page 16-19

\textbf{Introduced in R2019a}

**dcovary**

*D*-optimal design with fixed covariates

**Syntax**

\[
dCV = dcovary(nfactors, fixed)
\]

\[
[dCV,X] = dcovary(nfactors, fixed)
\]

\[
[dCV,X] = dcovary(nfactors, fixed, model)
\]

\[
[dCV,X] = daugment(...,param1,val1,param2,val2,...)
\]

**Description**

**dCV = dcovary(nfactors, fixed)** uses a coordinate-exchange algorithm to generate a *D*-optimal design for a linear additive model with *nfactors* factors, subject to the constraint that the model include the fixed covariate factors in *fixed*. The number of runs in the design is the number of rows in *fixed*. The design *dCV* augments *fixed* with initial columns for treatments of the model terms.

**[dCV,X] = dcovary(nfactors, fixed)** also returns the design matrix *X* associated with the design.

**[dCV,X] = dcovary(nfactors, fixed, model)** uses the linear regression model specified in *model*. *model* is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of *X* for a full quadratic model with *n* terms is:

1. The constant term
2. The linear terms in order 1, 2, ..., *n*
3. The interaction terms in order (1, 2), (1, 3), ..., (1, *n*), (2, 3), ..., (*n* - 1, *n*)
4. The squared terms in order 1, 2, ..., *n*

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors *X1*, *X2*, and *X3*, then a row [0 1 2] in *model* specifies the term \( (X1.\text{^0})*(X2.\text{^1})*(X3.\text{^2}) \). A row of all zeros in *model* specifies a constant term, which can be omitted.

**[dCV,X] = daugment(...,param1,val1,param2,val2,...)** specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bounds'</td>
<td>Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.</td>
</tr>
<tr>
<td>'categorical'</td>
<td>Indices of categorical predictors.</td>
</tr>
<tr>
<td>'display'</td>
<td>Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.</td>
</tr>
<tr>
<td>'excludefun'</td>
<td>Handle to a function that excludes undesirable runs. If the function is f, it must support the syntax b = f(S), where S is a matrix of treatments with nfactors columns and b is a vector of Boolean values with the same number of rows as S. b(i) is true if the ith row S should be excluded.</td>
</tr>
<tr>
<td>'init'</td>
<td>Initial design as an mruns-by-nfactors matrix. The default is a randomly selected set of points.</td>
</tr>
<tr>
<td>'levels'</td>
<td>Vector of number of levels for each factor.</td>
</tr>
<tr>
<td>'maxiter'</td>
<td>Maximum number of iterations. The default is 10.</td>
</tr>
<tr>
<td>'options'</td>
<td>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with statset. Applicable statset parameters are:</td>
</tr>
<tr>
<td></td>
<td>• 'UseParallel' — If true and if Parallel Computing Toolbox is installed, compute in parallel. If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is false, meaning serial computation.</td>
</tr>
<tr>
<td></td>
<td>• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
<tr>
<td></td>
<td>• Streams — A RandStream object or cell array of such objects. If you do not specify Streams, dcover uses the default stream or streams. If you choose to specify Streams, use a single object except in the case</td>
</tr>
<tr>
<td></td>
<td>• UseParallel is true</td>
</tr>
<tr>
<td></td>
<td>• UseSubstreams is false</td>
</tr>
<tr>
<td></td>
<td>In that case, use a cell array the same size as the Parallel pool.</td>
</tr>
<tr>
<td>'tries'</td>
<td>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</td>
</tr>
</tbody>
</table>

**Examples**

**Example 1**

Suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:
time = linspace(-1,1,8)';
[dCV1,X] = dcovary(3,time,'linear')
dCV1 =
   -1.0000    1.0000    1.0000   -1.0000
   1.0000   -1.0000   -1.0000   -0.7143
  -1.0000   -1.0000   -1.0000   -0.4286
   1.0000   -1.0000    1.0000   -0.1429
   1.0000    1.0000   -1.0000    0.1429
  -1.0000    1.0000   -1.0000    0.4286
   1.0000    1.0000    1.0000    0.7143
  -1.0000   -1.0000    1.0000    1.0000
X =
   1.0000   -1.0000    1.0000    1.0000   -1.0000
   1.0000    1.0000   -1.0000   -1.0000   -0.7143
   1.0000   -1.0000   -1.0000   -1.0000   -0.4286
   1.0000    1.0000   -1.0000    1.0000   -0.1429
   1.0000    1.0000    1.0000   -1.0000    0.1429
   1.0000   -1.0000    1.0000   -1.0000    0.4286
   1.0000    1.0000    1.0000    1.0000    0.7143
   1.0000   -1.0000   -1.0000    1.0000    1.0000
The column vector \texttt{time} is a fixed factor, normalized to values between ±1. The number of rows in the fixed factor specifies the number of runs in the design. The resulting design dCV gives factor settings for the three controlled model factors at each time.

\textbf{Example 2}

The following example uses the \texttt{dummyvar} function to block an eight-run experiment into 4 blocks of size 2 for estimating a linear additive model with two factors:

\texttt{fixed = dummyvar([1 1 2 2 3 3 4 4]);
dCV2 = dcovary(2,fixed(:,1:3),'linear')} 
dCV2 =
   1   1   1   0   0
  -1  -1   1   0   0
  -1   1   0   1   0
  -1   1   0   1   0
   1   1   0   0   1
  -1  -1   0   0   1
  -1   1   0   0   0
   1  -1   0   0   0

The first two columns of dCV2 contain the settings for the two factors; the last three columns are dummy variable codings for the four blocks.

\textbf{Extended Capabilities}

\textbf{Automatic Parallel Support}
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using \texttt{statset} and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options',statset('UseParallel',true)
For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

*Introduced before R2006a*
delete

Class: qrandstream
Delete handle object

Syntax
delete(h)

Description
delete(h) deletes the handle object h, where h is a scalar handle. The delete method deletes a handle object but does not clear the handle from the workspace. A deleted handle is no longer valid.

See Also
clear | isvalid | qrandstream
dendrogram

Dendrogram plot

Syntax

dendrogram(tree)
dendrogram(tree,Name,Value)

dendrogram(tree,P)
dendrogram(tree,P,Name,Value)

H = dendrogram( ___ )
[H,T,outperm] = dendrogram( ___ )

Description

dendrogram(tree) generates a dendrogram plot of the hierarchical binary cluster tree. A dendrogram consists of many U-shaped lines that connect data points in a hierarchical tree. The height of each U represents the distance between the two data points being connected.

• If there are 30 or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
• If there are more than 30 data points, then dendrogram collapses lower branches so that there are 30 leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

dendrogram(tree,Name,Value) uses additional options specified by one or more name-value pair arguments.

dendrogram(tree,P) generates a dendrogram plot with no more than P leaf nodes. If there are more than P data points in the original data set, then dendrogram collapses the lower branches of the tree. As a result, some leaves in the plot correspond to more than one data point.

dendrogram(tree,P,Name,Value) uses additional options specified by one or more name-value pair arguments.

H = dendrogram( ___ ) generates a dendrogram plot and returns a vector of line handles. You can use any of the input arguments from the previous syntaxes.

[H,T,outperm] = dendrogram( ___ ) also returns a vector containing the leaf node number for each object in the original data set, T, and a vector giving the order of the node labels of the leaves as shown in the dendrogram, outperm.

• It is useful to return T when the number of leaf nodes, P, is less than the total number of data points, so that some leaf nodes in the display correspond to multiple data points.
• The order of the node labels given in outperm is from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram.

Examples
**Plot Dendrogram**

Generate sample data.

```matlab
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram using the default options.

```matlab
tree = linkage(X,'average');
figure()
dendrogram(tree)
```

---

**Specify Dendrogram Leaf Node Order**

Generate sample data.

```matlab
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`.

```matlab
tree = linkage(X,'average');
```
D = pdist(X);  
leafOrder = optimaleaforder(tree,D)  
leafOrder = 1x10  
3 7 6 1 4 9 5 8 10 2  

Plot the dendrogram using an optimal leaf order.  
figure()  
dendrogram(tree,'Reorder',leafOrder)  

The order of the leaf nodes in the dendrogram plot corresponds - from left to right - to the permutation in leafOrder.  

**Specify Number of Nodes in Dendrogram Plot**  

Generate sample data.  

rng('default') % For reproducibility  
X = rand(100,2);  

There are 100 data points in the original data set, X.
Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram for the complete tree (100 leaf nodes) by setting the input argument `P` equal to 0.

```matlab
tree = linkage(X,'average');
dendrogram(tree,0)
```

Now, plot the dendrogram with only 25 leaf nodes. Return the mapping of the original data points to the leaf nodes shown in the plot.

```matlab
figure
[~,T] = dendrogram(tree,25);
```
List the original data points that are in leaf node 7 of the dendrogram plot.

```
find(T==7)
ans = 7×1
  7
  33
  60
  70
  74
  76
  86
```

**Change Dendrogram Orientation and Line Width**

Generate sample data.

```matlab
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram with a vertical orientation, using the default color threshold. Return handles to the lines so you can change the dendrogram line widths.
tree = linkage(X,'average');
H = dendrogram(tree,'Orientation','left','ColorThreshold','default');
set(H,'LineWidth',2)
If you do not specify \( P \), then `dendrogram` uses 30 as the maximum number of leaf nodes. To display the complete tree, set \( P \) equal to 0.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.  

Example: `'Orientation','left','Reorder',myOrder` specifies a vertical dendrogram with leaves in the order specified by `myOrder`.

**Reorder — Order of leaf nodes**

`vector`  

Order of leaf nodes in the dendrogram plot, specified as the comma-separated pair consisting of `'Reorder'` and a vector giving the order of nodes in the complete tree. The order vector must be a permutation of the vector `1:M`, where \( M \) is the number of data points in the original data set. Specify the order from left to right for horizontal dendrograms, and from bottom to top for vertical dendrograms.

If \( M \) is greater than the number of leaf nodes in the dendrogram plot, \( P \) (by default, \( P \) is 30), then you can only specify a permutation vector that does not separate the groups of leaves that correspond to collapsed nodes.

Data Types: `single` | `double`

**CheckCrossing — Indicator for whether to check for crossing branches**

`true` (default) | `false`  

Indicator for whether to check for crossing branches in the dendrogram plot, specified as the comma-separated pair consisting of `'CheckCrossing'` and either `true` or `false`. This option is only useful when you specify a value for `Reorder`.

When `CheckCrossing` has the value `true`, `dendrogram` issues a warning if the order of the leaf nodes causes crossing branches in the plot. If the dendrogram plot does not show a complete tree (because the number of data points in the original data set is greater than \( P \)), `dendrogram` only issues a warning when the order of the leaf nodes causes branch to cross in the dendrogram as shown in the plot. That is, there is no warning if the order causes crossing branches in the complete tree but not in the dendrogram as shown in the plot.

Data Types: `logical`

**ColorThreshold — Threshold for unique colors**

`'default'` | scalar value in the range \((0,\text{max}(\text{tree(:,3))))\)

Threshold for unique colors in the dendrogram plot, specified as the comma-separated pair consisting of `'ColorThreshold'` and either `'default'` or a scalar value in the range \((0,\text{max}(\text{tree(:,3))))\). If `ColorThreshold` has the value \( T \), then `dendrogram` assigns a unique color to each group of nodes in the dendrogram whose linkage is less than \( T \).

- If `ColorThreshold` has the value `'default'`, then the threshold, \( T \), is 70% of the maximum linkage, \( 0.7*\text{max}(\text{tree(:,3)}) \).
• If you do not specify a value for **ColorThreshold**, or if you specify a threshold outside the range $(0, \text{max}(\text{tree}(:,3)))$, then **dendrogram** uses only one color for the dendrogram plot.

**Orientation — Orientation of dendrogram**

'**top**' (default) | 'bottom' | 'left' | 'right'

Orientation of the dendrogram in the figure window, specified as the comma-separated pair consisting of '**Orientation**' and one of these values:

'**top**'    Top to bottom
'**bottom**'  Bottom to top
'**left**'  Left to right
'**right**'  Right to left

**Labels — Label for each data point**

character array | string array | cell array of character vectors

Label for each data point in the original data set, specified as the comma-separated pair consisting of '**Labels**' and a character array, string array or cell array of character vectors. **dendrogram** labels any leaves in the dendrogram plot containing a single data point with that data point’s label.

**Output Arguments**

**H** — Handles to lines

vector

Handles to lines in the dendrogram plot, returned as a vector.

**T** — Leaf node numbers

column vector

Leaf node numbers for each data point in the original data set, returned as a column vector of length $M$, where $M$ is the number of data points in the original data set.

When there are fewer than $P$ data points in the original data ($P$ is 30, by default), all data points are displayed in the dendrogram, with each node containing a single data point. In this case, $T$ is the identity map, $T = (1:M)^\prime$.

$T$ is useful when $P$ is less than the total number of data points. That is, when some leaf nodes in the dendrogram display correspond to multiple data points. For example, to find out which data points are contained in leaf node $k$ of the dendrogram plot, use $\text{find}(T==k)$.

**outperm** — Permutation of node labels

vector

Permutation of the node labels of the leaves of the dendrogram as shown in the plot, returned as a row vector. **outperm** gives the order from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram. If there are $P$ leaves in the dendrogram plot, **outperm** is a permutation of the vector $1:P$.

Introduced before R2006a
Description property

Class: dataset

(Not Recommended) Character vector describing data set

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Description**

Description is a character vector describing the data set. The default is an empty character vector.
designecoc

Coding matrix for reducing error-correcting output code to binary

Syntax

M = designecoc(K,name)
M = designecoc(K,name,Name,Value)

Description

M = designecoc(K,name) returns the coding matrix M that reduces the error-correcting output code (ECOC) design specified by name and K classes to a binary problem. M has K rows and L columns, with each row corresponding to a class and each column corresponding to a binary learner. name and K determine the value of L.

You can view or customize M, and then specify it as the coding matrix for training an ECOC multiclass classifier using fitcecoc.

M = designecoc(K,name,Name,Value) returns the coding matrix with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the number of trials when generating a dense or sparse, random coding matrix.

Examples

Train ECOC Classifiers Using a Custom Coding Design

Consider the arrhythmia data set. There are 16 classes in the study, 13 of which are represented in the data. The first class indicates that the subject did not have arrhythmia, and the last class indicates that the subject's arrhythmia state was not recorded. Suppose that the other classes are ordinal levels indicating the severity of arrhythmia. Train an ECOC classifier using a custom coding design specified by the description of the classes.

Load the arrhythmia data set.

load arrhythmia
K = 13; % Number of distinct classes

Construct a coding matrix that describes the nature of the classes.

OrdMat = designecoc(11,'ordinal');
nOM = size(OrdMat);
class1VSOrg = [1; -ones(11,1); 0];
class1VSClass16 = [1; zeros(11,1); -1];
OrdVSClass16 = [0; ones(11,1); -1];
Coding = [class1VSOrg class1VSClass16 OrdVSClass16,...
    [zeros(1,nOM(2)); OrdMat; zeros(1,nOM(2))]]

Coding = 13×13
Train an ECOC classifier using the custom coding design Coding and specify that the binary learners are decision trees.

```matlab
Mdl = fitcecoc(X,Y,'Coding',Coding,'Learner','Tree');
```

Estimate the in-sample classification error.

```matlab
genErr = resubLoss(Mdl)
genErr = 0.1460
```

**Choose Among Several Random Coding Designs**

If you request a random coding matrix by specifying sparserrandom or denserrandom, then, by default, designecoc generates 10,000 random matrices. Then, it chooses the matrix with the largest, minimal, pair-wise row distances based on the Hamming measure. You can specify to generate more matrices to increase the chance of obtaining a better one, or you can generate several coding matrices, and then see which performs best.

Load the arrhythmia data set. Reserve the observations classified into class 16 (i.e., those that do not have an arrhythmia classification) as new data.

```matlab
load arrhythmia
oosIdx = Y == 16;
isIdx = ~oosIdx;
Y = categorical(Y(isIdx));
tabulate(Y)
```

<table>

</tr>
</tbody>
</table>

\[ K = numel(unique(Y)); \]
Generate four random coding design matrices such that the first two are dense and the second two are sparse. Specify to find the best out of 20,000 variates.

rng(1); % For reproducibility

Coding = cell(4,1); % Preallocate for coding matrices
CodingTypes = {'denserandom','denserandom','sparserandom','sparserandom'};
for j = 1:4;
    Coding{j} = designecoc(K,CodingTypes{j},'NumTrials',2e4);
end

Coding is a 4-by-1 cell array, where each cell is a coding design matrix. The matrices have K rows, but the number of columns (i.e., binary learners) might vary.

Train and cross validate ECOC classifiers using the 15-fold cross validation. Specify that each ECOC classifier be trained using a classification tree, and the random coding matrix stored in Coding.

Mdl = cell(4,1); % Preallocate for the ECOC classifiers
for j = 1:4;
    Mdl{j} = fitcecoc(X(isIdx,:),Y,'Learners','tree','Coding',Coding{j},'KFold',15);
end

Warning: One or more of the unique class values in GROUP is not present in one or more folds. For classification problems with categorical response, use N instead of GROUP to obtain nonstratified partitions. For regression problems with continuous response, use N.

Mdl is a 4-by-1 cell array of ClassificationPartitionedECOC models. Several classes have low relative frequency in the data, and so there is a chance that, during cross validation, some in-sample folds will not train using observations from those classes.

Estimate the 15-fold classification error for each classifier.

genErr = nan(4,1);
for j = 1:4;
    genErr(j) = kfoldLoss(Mdl{j});
end

genErr

genErr = 4×1

0.2349
0.2093
0.2256
0.2209

Though the generalization error is still high, the best performing model, based solely on the out-of-sample classification error, is the model that used the coding design Coding{3}.

You can try to improve the generalization error by tuning some parameters of the binary learners. For example, you can specify to use the twoing rule or deviance for the split criterion, rather than the default Gini's diversity index. You might also specify to use surrogate splits since there are missing values in the data.
Input Arguments

**K** — Number of classes
positive integer

Number of classes, specified as a positive integer:

K specifies the number of rows of the coding matrix M.

Data Types: single | double

**name** — Coding design name
'binarycomplete' | 'denserandom' | 'onevsall' | 'onevsone' | 'sparserandom' | ...

Coding design name, specified as a value in the following table. The table summarizes the coding schemes.

<table>
<thead>
<tr>
<th>Value</th>
<th>Number of Binary Learners</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allpairs' and 'onevsone'</td>
<td>K(K − 1)/2</td>
<td>For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.</td>
</tr>
<tr>
<td>'binarycomplete'</td>
<td>2^(K − 1) − 1</td>
<td>This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.</td>
</tr>
<tr>
<td>'denserandom'</td>
<td>Random, but approximately 10 ( \log_2 K )</td>
<td>For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see &quot;Random Coding Design Matrices&quot; on page 32-1532.</td>
</tr>
<tr>
<td>'onevsall'</td>

<td>Number of Binary Learners</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'ordinal'</td>
<td>( K - 1 )</td>
<td>For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.</td>
</tr>
<tr>
<td>'sparserandom'</td>
<td>Random, but approximately ( 15 \log_2 K )</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1532.</td>
</tr>
<tr>
<td>'ternarycomplete'</td>
<td>( \frac{3^K - 2(K+1) + 1}{2} )</td>
<td>This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.</td>
</tr>
</tbody>
</table>

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'NumTrials',1000 specifies to generate 1000 random matrices.

**NumTrials — Number of random coding matrices to generate**

10000 (default) | positive integer

Number of random coding matrices to generate, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer.

The software:

- Generates NumTrials matrices, and selects the one with the maximal, pair-wise row distance.
- Ignores NumTrials for all values of name except 'denserandom' and 'sparserandom'.

Example: 'NumTrials',1000

Data Types: single | double

**Output Arguments**

M — Coding matrix

numeric matrix
Coding matrix that reduces an ECOC scheme to binary, returned as a numeric matrix. \(M\) has \(K\) rows and \(L\) columns, where \(L\) is the number of binary learners. Each row corresponds to a class and each column corresponds to a binary learner.

The elements of \(M\) are \(-1, 0,\) or \(1\), and the value corresponds to a dichotomous class assignment. This table describes the meaning of \(M(i,j)\), that is, the class that learner \(j\) assigns to observations in class \(i\).

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1)</td>
<td>Learner (j) assigns observations in class (i) to a negative class.</td>
</tr>
<tr>
<td>(0)</td>
<td>Before training, learner (j) removes observations in class (i) from the data set.</td>
</tr>
<tr>
<td>(1)</td>
<td>Learner (j) assigns observations in class (i) to a positive class.</td>
</tr>
</tbody>
</table>

The binary learners for designs denserandom, binarycomplete, and onevsall do not assign \(0\) to observations in any class.

**Tips**

- The number of binary learners grows with the number of classes. For a problem with many classes, the binarycomplete and ternarycomplete coding designs are not efficient. However:
  - If \(K \leq 4\), then use ternarycomplete coding design rather than sparserrandom.
  - If \(K \leq 5\), then use binarycomplete coding design rather than denserandom.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionchart`).

- Leave-one-out cross-validation (Leaveout) is inefficient for data sets with many observations. Instead, use \(k\)-fold cross-validation (KFold).

**Algorithms**

**Custom Coding Design Matrices**

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is \(-1, 0,\) or \(1\).
- Every column contains at least one \(-1\) and one \(1\).
- For all distinct column vectors \(u\) and \(v\), \(u \neq v\) and \(u \neq -v\).
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
• You can move vertically from 1 to -1 or -1 to 1.
• You can move horizontally from a nonzero element to another nonzero element.
• You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row \( i \) to row \( j \) using these rules, then classes \( i \) and \( j \) cannot be separated by the design. For example, in the coding design

\[
\begin{bmatrix}
1 & 0 \\
-1 & 0 \\
0 & 1 \\
0 & -1
\end{bmatrix}
\]

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

**Random Coding Design Matrices**

For a given number of classes \( K \), the software generates random coding design matrices as follows.

1. The software generates one of these matrices:
   a. Dense random — The software assigns 1 or -1 with equal probability to each element of the \( K \)-by-\( L_d \) coding design matrix, where \( L_d \approx 10\log_2 K \).
   b. Sparse random — The software assigns 1 to each element of the \( K \)-by-\( L_s \) coding design matrix with probability 0.25, -1 with probability 0.25, and 0 with probability 0.5, where \( L_s \approx 15\log_2 K \).

2. If a column does not contain at least one 1 and at least one -1, then the software removes that column.

3. For distinct columns \( u \) and \( v \), if \( u = v \) or \( u = -v \), then the software removes \( v \) from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

\[
\Delta(k_1, k_2) = 0.5 \sum_{l=1}^{L} |m_{k_1l}|m_{k_2l}|m_{k_1l} - m_{k_2l}|,
\]

where \( m_{kj} \) is an element of coding design matrix \( j \).

Introduced in R2014b
devianceTest

Package:
Analysis of deviance for generalized linear regression model

Syntax

tbl = devianceTest(mdl)

Description

tbl = devianceTest(mdl) returns an analysis of deviance table for the generalized linear regression model mdl. The table tbl gives the result of a test that determines whether the model mdl fits significantly better than a constant model.

Examples

Perform Deviance Test

Perform a deviance test on a generalized linear regression model.

Generate sample data using Poisson random numbers with two underlying predictors X(:,1) and X(:,2).

rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

Create a generalized linear regression model of Poisson data.

mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')

mdl =
Generalized linear regression model:
  log(y) ~ 1 + x1 + x2
  Distribution = Poisson

Estimated Coefficients:                 SE          tStat    pValue
  ___________________________    ______    ______    ______
  (Intercept)                 1.0405     0.022122    47.034      0
  x1                          0.9968     0.003362    296.49      0
  x2                          1.987      0.0063433    313.24      0

100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
Test whether the model differs from a constant in a statistically significant way.

```matlab
tbl = devianceTest(mdl)
```

```
tbl=2×4 table
            Deviance   DFE   chi2Stat   pValue
log(y) ~ 1            2.9544e+05     99   2.9533e+05       0
log(y) ~ 1 + x1 + x2         107.4     97   2.9533e+05       0
```

The small p-value indicates that the model significantly differs from a constant. Note that the model display of mdl includes the statistics shown in the second row of the table.

### Input Arguments

- **mdl** — Generalized linear regression model
  GeneralizedLinearModel object | CompactGeneralizedLinearModel object

  Generalized linear regression model, specified as a GeneralizedLinearModel object created using `fitglm` or `stepwiseglm`, or a CompactGeneralizedLinearModel object created using `compact`.

### Output Arguments

- **tbl** — Analysis of deviance summary statistics
  table

  Analysis of deviance summary statistics, returned as a table.

  tbl contains analysis of deviance statistics for both a constant model and the model mdl. The table includes these columns for each model.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>

</tr>
</tbody>
</table>
  - \( F \)-statistic is the difference between the deviance of the constant model and the deviance of the full model, divided by the estimated dispersion.
  - Chi-squared statistic is the difference between the deviance of the constant model and the deviance of the full model.
More About

Deviance

Deviance of a model $M_1$ is twice the difference between the loglikelihood of the model $M_1$ and the saturated model $M_S$. A saturated model is the model with the maximum number of parameters that you can estimate.

For example, if you have $n$ observations $(y_i, i = 1, 2, ..., n)$ with potentially different values for $X_i^T \beta$, then you can define a saturated model with $n$ parameters. Let $L(b, y)$ denote the maximum value of the likelihood function for a model with the parameters $b$. Then the deviance of the model $M_1$ is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where $b_1$ and $b_S$ contain the estimated parameters for the model $M_1$ and the saturated model, respectively. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where $n$ is the number of parameters in the saturated model and $p$ is the number of parameters in the model $M_1$.

Assume you have two different generalized linear regression models $M_1$ and $M_2$, and $M_1$ has a subset of the terms in $M_2$. You can assess the fit of the models by comparing the deviances $D_1$ and $D_2$ of the two models. The difference of the deviances is

$$D = D_2 - D_1 = -2(\log L(b_1, y) - \log L(b_S, y)) + 2(\log L(b_2, y) - \log L(b_1, y)) = -2(\log L(b_2, y) - \log L(b_1, y)).$$

Asymptotically, the difference $D$ has a chi-square distribution with degrees of freedom $v$ equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can obtain the $p$-value for this test by using $1 - \text{chi2cdf}(D, v)$.

Typically, you examine $D$ using a model $M_2$ with a constant term and no predictors. Therefore, $D$ has a chi-square distribution with $p - 1$ degrees of freedom. If the dispersion is estimated, the difference divided by the estimated dispersion has an $F$ distribution with $p - 1$ numerator degrees of freedom and $n - p$ denominator degrees of freedom.

**designMatrix**

**Class:** GeneralizedLinearMixedModel

Fixed- and random-effects design matrices

**Syntax**

\[
D = \text{designMatrix}(\text{glme})
\]

\[
D = \text{designMatrix}(\text{glme}, 'Fixed')
\]

\[
D = \text{designMatrix}(\text{glme}, 'Random')
\]

\[
D_{\text{sub}} = \text{designMatrix}(\text{glme}, 'Random', \text{gnumbers})
\]

\[
[D_{\text{sub}}, \text{gnames}] = \text{designMatrix}(\text{glme}, 'Random', \text{gnumbers})
\]

**Description**

\[
D = \text{designMatrix}(\text{glme}) \text{ or } D = \text{designMatrix}(\text{glme}, 'Fixed') \text{ returns the fixed-effects design matrix for the generalized linear mixed-effects model } \text{glme}.
\]

\[
D = \text{designMatrix}(\text{glme}, 'Random') \text{ returns the random-effects design matrix for the generalized linear mixed-effects model } \text{glme}.
\]

\[
D_{\text{sub}} = \text{designMatrix}(\text{glme}, 'Random', \text{gnumbers}) \text{ returns a subset of the random-effects design matrix for the generalized linear mixed-effects model } \text{glme} \text{ that corresponds to the grouping variables indicated by } \text{gnumbers}.
\]

\[
[D_{\text{sub}}, \text{gnames}] = \text{designMatrix}(\text{glme}, 'Random', \text{gnumbers}) \text{ also returns the grouping variable names that correspond to } \text{gnumbers}.
\]

**Input Arguments**

**\text{glme} — Generalized linear mixed-effects model**

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

**\text{gnumbers} — Grouping variable numbers**

array of integer values

Grouping variable numbers, specified as an array of integer values containing elements in the range \([1, R]\), where \(R\) is the length of the cell array that contains the grouping variables for the generalized linear mixed-effects model \(\text{glme}\).

For example, you can specify the grouping variables \(g_1, g_3, \text{ and } g_r\) as \([1, 3, r]\).

Data Types: single | double
Output Arguments

D — Design matrix

Design matrix of a generalized linear mixed-effects model glme returned as one of the following:

- Fixed-effects design matrix — \( n \times p \) matrix consisting of the fixed-effects design matrix of glme, where \( n \) is the number of observations and \( p \) is the number of fixed-effects terms.
- Random-effects design matrix — \( n \times k \) matrix, consisting of the random-effects design matrix of glme. Here, \( k \) is equal to \( \text{length}(B) \), where \( B \) is the random-effects coefficients vector of generalized linear mixed-effects model glme. The random-effects design matrix is returned as a sparse matrix. For more information, see “Sparse Matrices” (MATLAB).

If \( glme \) has \( R \) grouping variables \( g_1, g_2, \ldots, g_R \), with levels \( m_1, m_2, \ldots, m_R \), respectively, and if \( q_1, q_2, \ldots, q_R \) are the lengths of the random-effects vectors that are associated with \( g_1, g_2, \ldots, g_R \), respectively, then \( B \) is a column vector of length \( q_1 \times m_1 + q_2 \times m_2 + \ldots + q_R \times m_R \).

\( B \) is made by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as \([g_1\text{level}_{1}; \ g_1\text{level}_{2}; \ldots; \ g_1\text{level}_{m_1}; \ g_2\text{level}_{1}; \ g_2\text{level}_{2}; \ldots; \ g_2\text{level}_{m_2}; \ldots; \ g_R\text{level}_{1}; \ g_R\text{level}_{2}; \ldots; \ g_R\text{level}_{m_R}]'\).

Data Types: single | double

Ds sub — Submatrix of random-effects design matrix

Submatrix of random-effects design matrix that corresponds to the grouping variables specified by gnumbers, returned as an \( n \times k \) matrix, where \( k \) is length of the column vector Bsub.

Bsub contains the concatenated empirical Bayes predictors of random-effects vectors, corresponding to each level of the grouping variables, specified by gnumbers.

If, for example, gnumbers is \([1, 3, r]\), this corresponds to the grouping variables \( g_1, g_3, \) and \( g_r \). Then, Bsub contains the empirical Bayes predictors of random-effects vectors corresponding to each level of the grouping variables \( g_1, g_3, \) and \( g_r \), such as

\([g_1\text{level}_{1}; \ g_1\text{level}_{2}; \ldots; \ g_1\text{level}_{m_1}; \ g_3\text{level}_{1}; \ g_3\text{level}_{2}; \ldots; \ g_3\text{level}_{m_2}; \ g_r\text{level}_{1}; \ g_r\text{level}_{2}; \ldots; \ g_r\text{level}_{m_r}]'\).

Thus, Dsub*Bsub represents the contribution of all random effects corresponding to grouping variables \( g_1, g_3, \) and \( g_r \) to the response of glme.

If gnumbers is empty, then Dsub is the full random-effects design matrix.

Data Types: single | double

gnames — Names of grouping variables

k-by-1 cell array

Names of grouping variables corresponding to the integers in gnumbers if the design type is 'Random', returned as a k-by-1 cell array. If the design type is 'Fixed', then gnames is an empty matrix \([\ ]\).
Data Types: cell

Examples

Obtain Fixed- and Random-Effects Design Matrices

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[
defects_{ij} \sim \text{Poisson}(\mu_{ij}).\]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1\text{newprocess}_{ij} + \beta_2\text{time}_\text{dev}_{ij} + \beta_3\text{temp}_\text{dev}_{ij} + \beta_4\text{supplier}_C_{ij} + \beta_5\text{supplier}_B_{ij} + b_i,
\]

where

- \(\text{defects}_{ij}\) is the number of defects observed in the batch produced by factory \(i\) during batch \(j\).
- \(\mu_{ij}\) is the mean number of defects corresponding to factory \(i\) (where \(i = 1, 2, \ldots, 20\)) during batch \(j\) (where \(j = 1, 2, \ldots, 5\)).
• newprocess\(_{ij}\), time_dev\(_{ij}\), and temp_dev\(_{ij}\) are the measurements for each variable that correspond to factory \(i\) during batch \(j\). For example, newprocess\(_{ij}\) indicates whether the batch produced by factory \(i\) during batch \(j\) used the new process.

• supplier\(_{Ci}\) and supplier\(_{Bi}\) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \(i\) during batch \(j\).

• \(b_i \sim N(0, \sigma^2_b)\) is a random-effects intercept for each factory \(i\) that accounts for factory-specific variation in quality.

\[
\text{glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');}
\]

Extract the fixed-effects design matrix and display rows 1 through 10.

\[
\text{Dfe = designMatrix(glme,'Fixed'); disp(Dfe(1:10,:))}
\]

\[
\begin{array}{cccccccccccccccccccc}
1.0000 & 0 & 0.1834 & 0.2259 & 1.0000 & 0 \\
1.0000 & 0 & 0.3035 & 0.0725 & 0 & 1.0000 \\
1.0000 & 0 & 0.0717 & 0.1630 & 1.0000 & 0 \\
1.0000 & 0 & 0.1069 & 0.0809 & -1.0000 & -1.0000 \\
1.0000 & 0 & 0.0241 & 0.0319 & 1.0000 & 0 \\
1.0000 & 0 & 0.1214 & 0.1114 & 0 & 1.0000 \\
1.0000 & 0 & 0.0033 & 0.0553 & 1.0000 & 0 \\
1.0000 & 0 & 0.2350 & 0.0616 & 1.0000 & 0 \\
1.0000 & 0 & 0.0488 & 0.0177 & 0 & 1.0000 \\
1.0000 & 0 & 0.1148 & 0.0105 & 1.0000 & 0 \\
\end{array}
\]

Column 1 of the fixed-effects design matrix \(Dfe\) contains the constant term. Column 2, 3, and 4 contain the newprocess, time_dev, and temp_dev terms, respectively. Columns 5 and 6 contain dummy variables for supplier\(_C\) and supplier\(_B\), respectively.

Extract the random-effects design matrix and display rows 1 through 10.

\[
\text{Dre = designMatrix(glme,'Random'); disp(Dre(1:10,:))}
\]

\[
\begin{array}{cccccccccccccccccccc}
(1,1) & 1 \\
(2,1) & 1 \\
(3,1) & 1 \\
(4,1) & 1 \\
(5,1) & 1 \\
(6,2) & 1 \\
(7,2) & 1 \\
(8,2) & 1 \\
(9,2) & 1 \\
(10,2) & 1 \\
\end{array}
\]

Convert the sparse matrix \(Dre\) to a full matrix and display rows 1 through 10.

\[
\text{full(Dre(1:10,:))}
\]

\[
\begin{array}{cccccccccccccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]
Each column corresponds to a level of the grouping variable `factory`.

`GeneralizedLinearMixedModel` | `fitglme` | `fitted` | `residuals` | `response`
designMatrix

Class: LinearMixedModel

Fixed- and random-effects design matrices

Syntax

D = designMatrix(lme)
D = designMatrix(lme,'Fixed')

D = designMatrix(lme,'Random')
Dsub = designMatrix(lme,'Random',gnumbers)
[Dsub,gnames] = designMatrix(lme,'Random',gnumbers)

Description

D = designMatrix(lme) or D = designMatrix(lme,'Fixed') returns the fixed-effects design matrix for the linear mixed-effects model lme.

D = designMatrix(lme,'Random') returns the random-effects design matrix for the linear mixed-effects model lme.

Dsub = designMatrix(lme,'Random',gnumbers) returns a subset of the random-effects design matrix for the linear mixed-effects model lme corresponding to the grouping variables indicated by the integers in gnumbers.

[Dsub,gnames] = designMatrix(lme,'Random',gnumbers) also returns the grouping variable names corresponding to the integers in gnumbers.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

gnumbers — Grouping variable numbers
integer array

Grouping variable numbers, specified as an integer array, where R is the length of the cell array that contains the grouping variables for the linear mixed-effects model lme.

For example, you can specify the grouping variables g1, g3, and gr as follows.

Example: [1,3,r]

Data Types: double | single
Output Arguments

D — Design matrix
matrix

Design matrix of a linear mixed-effects model lme returned as one of the following:

- Fixed-effects design matrix — n-by-p matrix consisting of the fixed-effects design of lme, where n is the number of observations and p is the number of fixed-effects terms.
- Random-effects design matrix — n-by-k matrix, consisting of the random-effects design matrix of lme. Here, k is equal to length(B), where B is the random-effects coefficients vector of linear mixed-effects model lme.

If lme has R grouping variables g_1, g_2, ..., g_R, with levels m_1, m_2, ..., m_R, respectively, and if q_1, q_2, ..., q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, ..., g_R, respectively, then B is a column vector of length q_1*m_1 + q_2*m_2 + ... + q_R*m_R.

B is made by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as [g_1level_1; g_1level_2; ...; g_1level_m_1; g_2level_1; g_2level_2; ...; g_2level_m_2; ...; g_Rlevel_1; g_Rlevel_2; ...; g_Rlevel_m_R].

Data Types: single | double

Dsub — Submatrix of random-effects design matrix
matrix

Submatrix of random-effects design matrix corresponding to the grouping variables indicated by the integers in gnumbers, returned as an n-by-k matrix, where k is length of the column vector Bsub.

Bsub contains the concatenated best linear unbiased predictors (BLUPs) of random-effects vectors, corresponding to each level of the grouping variables, specified by gnumbers.

If, for example, gnumbers is [1, 3, r], this corresponds to the grouping variables g_1, g_3, and g_r. Then, Bsub contains the concatenated BLUPs of random-effects vectors corresponding to each level of the grouping variables g_1, g_3, and g_r, such as

[g_1level_1; g_1level_2; ...; g_1level_m_1; g_3level_1; g_3level_2; ...; g_3level_m_3; g_rlevel_1; g_rlevel_2; ...; g_rlevel_m_r].

Thus, Dsub*Bsub represents the contribution of all random effects corresponding to grouping variables g_1, g_3, and g_r to the response of lme.

If gnumbers is empty, then Dsub is the full random-effects design matrix.

Data Types: single | double

gnames — Names of grouping variables
k-by-1 cell array

Names of grouping variables corresponding to the integers in gnumbers if the design type is 'Random', returned as a k-by-1 cell array. If the design type is 'Fixed', then gnames is an empty matrix [].

Data Types: cell
Examples

Display Fixed- and Random-Effects Design Matrices

Load the sample data.

```matlab
load('shift.mat');
```

The data shows the deviations from the target quality characteristic measured from the products that 5 operators manufacture during three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```matlab
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```matlab
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Display the fixed-effects design matrix.

```matlab
designMatrix(lme)
```

```
ans = 15×3
1 1 0
1 0 0
1 0 1
1 1 0
1 0 0
1 0 1
1 1 0
1 0 0
1 0 1
1 1 0
1 0 0
1 0 1
1 1 0
```

The column of 1s represents the constant term in the model. `fitlme` takes the evening shift as the reference group and creates two dummy variables to represent the morning and night shifts, respectively.

Display the random-effects design matrix.

```matlab
designMatrix(lme,'random')
```

```
ans =
(1,1) 1
(2,1) 1
(3,1) 1
(4,2) 1
(5,2) 1
```
The first number, $i$, in the $(i,j)$ indices corresponds to the observation number, and $|j|$ corresponds to the level of the grouping variable, Operator, i.e., the operator number.

Show the full display of the random-effects design matrix.

```matlab
full(designMatrix(lme,'random'))
```

```
ans = 15×5
1     0     0     0     0
1     0     0     0     0
1     0     0     0     0
0     1     0     0     0
0     1     0     0     0
0     1     0     0     0
0     0     1     0     0
0     0     1     0     0
0     0     1     0     0
0     0     0     1     0
```

Each column corresponds to a level of the grouping variable, Operator.

### Random-Effects Design Matrix of Multiple Grouping Variables

Load the sample data.

```matlab
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define Tomato, Soil, and Fertilizer as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```
Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```matlab
D = full(designMatrix(lme,'random'));
```

The first three columns of matrix D contain the indicator variables fitlme creates for the three levels (Loamy, Silty, Sandy, respectively) of the first grouping variable, Soil. The next 15 columns contain the indicator variables created for the second grouping variable, Tomato nested under Soil. These are basically the elementwise products of the dummy variables representing the levels of Soil (Loamy, Silty, and Sandy, respectively) and the levels of Tomato (Cherry, Grape, Heirloom, Plum, Vine, respectively).

---

**Subset of the Random-Effects Design Matrix**

Load the sample data.

```matlab
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called ds, for practical purposes, and define Tomato, Soil, and Fertilizer as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the random-effects design matrix for the second grouping variable, and display the first 12 rows.

```matlab
[Dsub,gname] = designMatrix(lme,'random',2);
full(Dsub(1:12,:))
```

ans = 12×15

```
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
0     0     0     0     0     0     0     0     1     0     0     0     0     0     0
```
Dsub contains the dummy variables created for the second grouping variable, that is, tomato nested under soil. These are the elementwise products of the dummy variables representing the levels of Soil (Loamy, Silty, Sandy, respectively) and the levels of Tomato (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Display the name of the grouping variable.

```matlab
gname = 1x1 cell array
    {'Soil:Tomato'}
```

**dfittool**

Open Distribution Fitter app

**Note** The `distributionFitter` function was introduced in R2017a as a replacement for the `dfittool` function. Both functions continue to work to start the Distribution Fitter app.

**Syntax**

- `dfittool`
- `dfittool(y)`
- `dfittool(y,cens)`
- `dfittool(y,cens,freq)`
- `dfittool(y,cens,freq,dsname)`

**Description**

This page contains programmatic syntax information for the Distribution Fitter app. For general usage information, see [Distribution Fitter](#).

- `dfittool` opens the Distribution Fitter app, or brings focus to the app if it is already open.
- `dfittool(y)` opens the Distribution Fitter app populated with the data specified by the vector `y`.
- `dfittool(y,cens)` uses the vector `cens` to specify whether each observation in `y` is censored.
- `dfittool(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`.
- `dfittool(y,cens,freq,dsname)` creates a data set with the name `dsname`, using the data vector, `y`, censoring indicator, `cens`, and frequency vector, `freq`.

**Examples**

**Open Distribution Fitter App with Existing Data**

Load the `carsmall` sample data.

```matlab
load carsmall
```

Open the Distribution Fitter app using the `MPG` miles per gallon data.

```matlab
dfittool(MPG)
```
The Distribution Fitter app opens, populated with the MPG data, and displays the density (PDF) plot. You can use the app to display different plots and fit distributions to this data.

**Open Distribution Fitter App with Censoring Data**

Load the sample data.

```matlab
load 'lightbulb.mat'
```

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of `lightbulb` as the input data, and the third column as the censoring data. Name the data `lifetime`.

```matlab
dfittool(lightbulb(:,1),lightbulb(:,3),[],'lifetime')
```
To open the Data dialog box, click **Data**. In the **Manage data sets** pane, click to highlight the **lifetime** data set row. Finally, to open the View Data Set dialog, click **View**. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.

**Input Arguments**

**y** — Input data
array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: `single` | `double`

**cens** — Censoring indicator
`zeros(n)` (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of `cens` must be equal to the length of `y`. If `y(j)` is censored, then `(cens(j)==1)`. If `y(j)` is not censored, then `(cens(j)==0)`. If `cens` is omitted or empty, then no `y` values are censored.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

**freq** — Frequency data
`ones(n)` (default) | vector of scalar values

Frequency data, specified as a vector of scalar values. The length of `freq` must be equal to the length of `y`. If `freq` is omitted or empty, then all `y` values have a frequency of 1.
If you have frequency data (freq) but not censoring data (cens), then you must specify empty brackets ([ ]) for cens.

Data Types: single | double

dcname — Data set name
character vector | string scalar

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data (cens) or frequency data (freq), then you must specify empty brackets ([ ]) for both freq and cens.

Example: ‘MyData’

Data Types: char | string

Introduced before R2006a
DimNames property

Class: dataset

(Not Recommended) Two-element cell array of character vectors giving names of dimensions of data set

**Note** The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB table documentation for more information.

**Description**

A two-element cell array of character vectors giving the names of the two dimensions of the data set. The default is `{'Observations' 'Variables'}`.
discardSupportVectors

Package:
Discard support vectors of linear SVM binary learners in ECOC model

Syntax
Mdl = discardSupportVectors(MdlSV)

Description
Mdl = discardSupportVectors(MdlSV) returns a trained multiclass error-correcting output
codes (ECOC) model (Mdl) from the trained multiclass ECOC model (MdlSV), which contains at least
one linear CompactClassificationSVM binary learner. Both Mdl and MdlSV are objects of the
same type, either ClassificationECOC objects or CompactClassificationECOC objects.

Mdl has these characteristics:
• The Alpha, SupportVectors, and SupportVectorLabels properties of all the linear SVM
  binary learners on page 32-1086 are empty ([]).
• If you display any linear SVM binary learners stored in the cell array of trained models
  Mdl.BinaryLearners, the software lists the Beta property instead of Alpha.

Examples

Retain and Discard Support Vectors of SVM Binary Learners

When you train an ECOC model with linear SVM binary learners, fitcecoc empties the Alpha,
SupportVectorLabels, and SupportVectors properties of the binary learners by default. You can
choose instead to retain the support vectors and related values, and then discard them from the
model later.

Load Fisher's iris data set.

load fisheriris
rng(1); % For reproducibility

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in
the appropriate SVM template.

t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);

MdlSV is a trained ClassificationECOC model with linear SVM binary learners. By default,
fitcecoc implements a one-versus-one coding design, which requires three binary learners for
three-class learning.

Access the estimated α (alpha) values using dot notation.

alpha = cell(3,1);
alpha{1} = MdlSV.BinaryLearners{1}.Alpha;
alpha{2} = MdlSV.BinaryLearners{2}.Alpha;  
alpha{3} = MdlSV.BinaryLearners{3}.Alpha;  
alpha

alpha=3x1 cell array  
{ 3x1 double}  
{ 3x1 double}  
{23x1 double}

alpha is a 3-by-1 cell array that stores the estimated values of α.

Discard the support vectors and related values from the ECOC model.
Mdl = discardSupportVectors(MdlSV);
Mdl is similar to MdlSV, except that the Alpha, SupportVectorLabels, and SupportVectors properties of all the linear SVM binary learners are empty ([]).
areAllEmpty = @(x)isempty([x.Alpha x.SupportVectors x.SupportVectorLabels]);
cellfun(areAllEmpty,Mdl.BinaryLearners)
ans = 3x1 logical array
   1
   1
   1

Compare the sizes of the two ECOC models.
vars = whos('Mdl','MdlSV');
100*(1 - vars(1).bytes-vars(2).bytes)
ans = 4.8394
Mdl is about 5% smaller than MdlSV.

Reduce your memory usage by compacting Mdl and then clearing Mdl and MdlSV from the workspace.
CompactMdl = compact(Mdl);
clear Mdl MdlSV;

Predict the label for a random row of the training data using the more efficient SVM model.
idx = randsample(size(meas,1),1)
idx = 63
predictedLabel = predict(CompactMdl,meas(idx,:))
predictedLabel = 1x1 cell array  
{'versicolor'}
trueLabel = species(idx)
Input Arguments

MdlSV — Full or compact, trained multiclass ECOC model
ClassificationECOC model | CompactClassificationECOC model

Full or compact, trained multiclass ECOC model containing at least one linear SVM binary learner, specified as a ClassificationECOC or CompactClassificationECOC model.

More About

Linear SVM Binary Learner

In the context of this page, a linear support vector machine (SVM) binary learner is a binary SVM classifier created using a linear kernel function. If the jth binary learner in an ECOC model Mdl is a linear SVM binary learner, then Mdl.BinaryLearners{j} is a CompactClassificationSVM object, where Mdl.BinaryLearners{j}.KernelParameters.Function is 'linear'.

Tips

- By default and for efficiency, fitcecoc empties the Alpha, SupportVectorLabels, and SupportVectors properties for all linear SVM binary learners. fitcecoc lists Beta, rather than Alpha, in the model display.

  To store Alpha, SupportVectorLabels, and SupportVectors, pass a linear SVM template that specifies storing support vectors to fitcecoc. For example, enter:

  t = templateSVM('SaveSupportVectors',true)
  Mdl = fitcecoc(X,Y,'Learners',t);

  You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

Algorithms

predict and resubPredict estimate SVM scores \( f(x) \) for each linear SVM binary learner in an ECOC model using

\[
f(x) = x'\beta + b.
\]

\( \beta \) is the Beta property and \( b \) is the Bias property of the binary learners. You can access these properties for each linear SVM binary learner in the cell array Mdl.BinaryLearners. For more details on the SVM score calculation, see “Support Vector Machines for Binary Classification” on page 32-1690.

Introduced in R2015a
discardSupportVectors

**Package:** classreg.learning.classif

Discard support vectors for linear support vector machine (SVM) classifier

**Syntax**

```plaintext
Mdl = discardSupportVectors(MdlSV)
```

**Description**

`Mdl = discardSupportVectors(MdlSV)` returns the trained, linear support vector machine (SVM) model `Mdl`. Both `Mdl` and the trained, linear SVM model `MdlSV` are the same type of object. That is, they both are either `ClassificationSVM` objects or `CompactClassificationSVM` objects. However, `Mdl` and `MdlSV` differ in the following ways:

- The `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties are empty `[]` in `Mdl`.
- If you display `Mdl`, the software lists the `Beta` property instead of `Alpha`.

**Examples**

**Discard Support Vectors**

Create a linear SVM model that is more memory-efficient by discarding support vectors and other related parameters.

Load the `ionosphere` data set.

```plaintext
load ionosphere
```

Train a linear SVM model using the entire data set.

```plaintext
MdlSV = fitcsvm(X,Y)
```

```plaintext
MdlSV = ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    Alpha: [103x1 double]
    Bias: -3.8828
    KernelParameters: [1x1 struct]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'
```
Display the number of support vectors in MdlSV.

```matlab
numSV = size(MdlSV.SupportVectors,1)
numSV = 103
```

Display the number of predictor variables in `X`.

```matlab
p = size(X,2)
p = 34
```

By default, `fitcsvm` trains a linear SVM model for two-class learning. The software lists `Alpha` in the display. The model includes 103 support vectors and 34 predictors. If you discard the support vectors, the resulting model consumes less memory.

Discard the support vectors and other related parameters.

```matlab
Mdl = discardSupportVectors(MdlSV)
```

```matlab
Mdl =
    ClassificationSVM
      ResponseName: 'Y'
      CategoricalPredictors: []
      ClassNames: {'b'  'g'}
      ScoreTransform: 'none'
      NumObservations: 351
      Beta: [34x1 double]
      Bias: -3.8828
      KernelParameters: [1x1 struct]
      BoxConstraints: [351x1 double]
      ConvergenceInfo: [1x1 struct]
      IsSupportVector: [351x1 logical]
      Solver: 'SMO'
```

Display the coefficients in `Mdl`.

```matlab
Mdl.Alpha
ans =
[]
```

Display the support vectors in `Mdl`.

```matlab
Mdl.SupportVectors
ans =
[]
```

Display the support vector class labels in `Mdl`.

```matlab
Mdl.ClassNames
ans =
    'b'    'g'
```
The software lists Beta in the display instead of Alpha. The Alpha, SupportVectors, and SupportVectorLabels properties are empty.

Compare the sizes of the models.

vars = whos('MdlSV','Mdl');
100*(1 - vars(1).bytes-vars(2).bytes)
ans = 20.5743

Mdl is about 20% smaller than MdlSV.

Remove MdlSV from the workspace.

clear MdlSV

**Reduce Memory Consumption of SVM Models**

Compact an SVM model by discarding the stored support vectors and other related estimates. Predict the label for a row of the training data by using the compacted model.

Load the ionosphere data set.

load ionosphere
rng(1); % For reproducibility

Train an SVM model using the default options.

MdlSV = fitcsvm(X,Y);

MdlSV is a ClassificationSVM model containing nonempty values for its Alpha, SupportVectors, and SupportVectorLabels properties.

Reduce the size of the SVM model by discarding the training data, support vectors, and related estimates.

CMdlSV = compact(MdlSV); % Discard training data
CMdl = discardSupportVectors(CMdlSV); % Discard support vectors

CMdl is a CompactClassificationSVM model.

Compare the sizes of the SVM models MdlSV and CMdl.

vars = whos('MdlSV','CMdl');
100*(1 - vars(1).bytes-vars(2).bytes)
ans = 96.9302

The compacted model CMdl consumes much less memory than the full model.
Predict the label for a random row of the training data by using CMdl. The `predict` function accepts compacted SVM models, and, for linear SVM models, does not require the `Alpha`, `SupportVectors`, and `SupportVectorLabels` properties to predict labels for new observations.

```matlab
idx = randsample(size(X,1),1)
idx = 147
predictedLabel = predict(CMdl,X(idx,:))
predictedLabel = 1x1 cell array
    {'b'}
trueLabel = Y(idx)
trueLabel = 1x1 cell array
    {'b'}
```

### Input Arguments

- **MdlSV** — Trained, linear SVM model  
  `ClassificationSVM` model | `CompactClassificationSVM` model

  Trained, linear SVM model, specified as a `ClassificationSVM` or `CompactClassificationSVM` model.

  If the field `MdlSV.KernelParameters.Function` is not `'linear'` (that is, `MdlSV` is not a linear SVM model), the software returns an error.

### Tips

- For a trained, linear SVM model, the `SupportVectors` property is an \(n_{sv}\)-by-\(p\) matrix. \(n_{sv}\) is the number of support vectors (at most the training sample size) and \(p\) is the number of predictors, or features. The `Alpha` and `SupportVectorLabels` properties are vectors with \(n_{sv}\) elements. These properties can be large for complex data sets containing many observations or examples. The `Beta` property is a vector with \(p\) elements.
- If the trained SVM model has many support vectors, use `discardSupportVectors` to reduce the amount of space consumed by the trained, linear SVM model. You can display the size of the support vector matrix by entering `size(MdlSV.SupportVectors)`.

### Algorithms

`predict` and `resubPredict` estimate SVM scores \(f(x)\), and subsequently label and estimate posterior probabilities using

\[
f(x) = x'\beta + b.
\]

\(\beta\) is `Mdl.Beta` and \(b\) is `Mdl.Bias`, that is, the `Beta` and `Bias` properties of `Mdl`, respectively. For more details, see “Support Vector Machines for Binary Classification” on page 32-1690.
See Also
ClassificationECOC | ClassificationSVM | CompactClassificationSVM |
discardSupportVectors | fitcsvm | templateSVM

Introduced in R2015a
discardSupportVectors

Discard support vectors

Syntax

mdlOut = discardSupportVectors(mdl)

Description

mdlOut = discardSupportVectors(mdl) returns the trained, linear support vector machine (SVM) regression model mdlOut, which is similar to the trained, linear SVM regression model mdl, except:

- The Alpha and SupportVectors properties are empty ([]).
- If you display mdlOut, the software lists the Beta property instead of the Alpha property.

Input Arguments

mdl — Trained, linear SVM regression model
RegressionSVM model | CompactRegressionSVM model

Trained, linear SVM regression model, specified as a RegressionSVM or CompactRegressionSVM model.

If you train the model using a kernel function that is not linear (i.e., if the field mdl.KernelFunction is something other than 'linear'), the software returns an error. You can only discard support vectors for linear models.

Output Arguments

mdlOut — Trained, linear SVM regression model
RegressionSVM model | CompactRegressionSVM model

Trained, linear SVM regression model, returned as a RegressionSVM or CompactRegressionSVM model. mdlOut is the same type as mdl.

After discarding the support vectors, the properties Alpha and SupportVectors are empty ([]). The software lists the property Beta in its display, and does not list the property Alpha. The predict and resubPredict methods compute predicted responses using the coefficients stored in the Beta property.

Examples

Discard Support Vectors for SVM Regression Model

This model shows how to reduce the disk space used by a trained, linear SVM regression model by discarding the support vectors and other related parameters.
Load the carsmall data set. Specify Horsepower and Weight as the predictor variables (X), and MPG as the response variable (Y).

```matlab
load carsmall
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model, standardizing the data. Display the number of support vectors.

```matlab
mdl = fitrsvm(X,Y,'Standardize',true)
numSV = size(mdl.SupportVectors,1)
```

```matlab
mdl = RegressionSVM
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    Alpha: [77x1 double]
    Bias: 22.9131
    KernelParameters: [1x1 struct]
    Mu: [109.3441 2.9625e+03]
    Sigma: [45.3545 805.9668]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [93x1 logical]
    Solver: 'SMO'

Properties, Methods

numSV =
    77
```

By default, fitrsvm trains a linear SVM regression model. The software lists Alpha in the display. The model has 77 support vectors.

Note that the predictor and response variables contain several NaN values. When training a model, fitrsvm will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 93 of the 100 total observations contained in the sample data.

Discard the support vectors and other related parameters.

```matlab
mdlOut = discardSupportVectors(mdl)
mdlOut.Alpha
mdlOut.SupportVectors
```

```matlab
mdlOut = RegressionSVM
    PredictorNames: {'x1'  'x2'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
```
Beta: [2x1 double]
Bias: 22.9131
KernelParameters: [1x1 struct]
    Mu: [109.3441 2.9625e+03]
    Sigma: [45.3545 805.9668]
NumObservations: 93
BoxConstraints: [93x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [93x1 logical]
Solver: 'SMO'

Properties, Methods
ans =
    []
ans =
    []
The software lists Beta in the display instead of Alpha. The Alpha and SupportVectors properties are empty.

Compare the sizes of the models.
vars = whos('mdl','mdlOut');
[vars(1).bytes,vars(2).bytes]
ans =
    15004  13156
mdlOut consumes less memory than mdl because it does not store the support vectors.

Reduce Memory Consumption of SVM Regression Model
This example shows how to reduce the memory consumption of a full, trained SVM regression model by compacting the model and discarding the support vectors.

Load the carsmall sample data.
load carsmall
rng default  % for reproducibility
Train a linear SVM regression model using Weight as the predictor variable and MPG as the response variable. Standardize the data.
mdl = fitrsvm(Weight,MPG,'Standardize',true);

Note that MPG contains several NaN values. When training a model, fitrsvm will remove rows that contain NaN values from both the predictor and response data. As a result, the trained model uses only 94 of the 100 total observations contained in the sample data.
Compact the regression model to discard the training data and some information related to the training process.

```
compactMdl = compact(mdl);
```

`compactMdl` is a `CompactRegressionSVM` model that has the same parameters, support vectors, and related estimates as `mdl`, but no longer stores the training data.

Discard the support vectors and related estimates for the compacted model.

```
mdlOut = discardSupportVectors(compactMdl);
```

`mdlOut` is a `CompactRegressionSVM` model that has the same parameters as `mdl` and `compactMdl`, but no longer stores the support vectors and related estimates.

Compare the sizes of the three SVM regression models, `compactMdl`, `mdl`, and `mdlOut`.

```
vars = whos('compactMdl','mdl','mdlOut');
[vars(1).bytes,vars(2).bytes,vars(3).bytes]
ans =
    3601  13727   2305
```

The compacted model `compactMdl` consumes 3601 bytes of memory, while the full model `mdl` consumes 13727 bytes of memory. The model `mdlOut`, which also discards the support vectors, consumes 2305 bytes of memory.

**Tips**

For a trained, linear SVM regression model, the `SupportVectors` property is an \( n_{sv} \times p \) matrix. \( n_{sv} \) is the number of support vectors (at most the training sample size) and \( p \) is the number of predictor variables. If any of the predictors are categorical, then \( p \) includes the number of dummy variables necessary to account for all of the categorical predictor levels. The `Alpha` property is a vector with \( n_{sv} \) elements.

The `SupportVectors` and `Alpha` properties can be large for complex data sets that contain many observations or examples. However, the `Beta` property is a vector with \( p \) elements, which may be considerably smaller. You can use a trained SVM regression model to predict response values even if you discard the support vectors because the `predict` and `resubPredict` methods use `Beta` to compute the predicted responses.

If the trained, linear SVM regression model has many support vectors, use `discardSupportVectors` to reduce the amount of disk space that the trained, linear SVM regression model consumes. You can display the size of the support vector matrix by entering `size(mdlIn.SupportVectors)`.

**Algorithms**

The `predict` and `resubPredict` estimate response values using the formula

\[
  f(x) = \left( \frac{X}{S} \right) \beta + \beta_0,
\]

where:
• $\beta$ is the Beta value, stored as mdl.Beta.
• $\beta_0$ is the bias value, stored as mdl.Bias.
• $X$ is the training data.
• $S$ is the kernel scale value, stored as mdl.KernelParameters.Scale.

In this way, the software can use the value of mdl.Beta to make predictions even after discarding the support vectors.

*Introduced in R2015b*
disp

Class: cvpartition

Display cvpartition object

Syntax

disp(c)

Description

disp(c) prints the cvpartition object c.

See Also

cvpartition
disp

Class: dataset

(Not Recommended) Display dataset array

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

**Syntax**

disp(ds)

**Description**

disp(ds) prints the dataset array ds, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, disp prints the actual data using either short g, long g, or bank format, depending on the current command line setting. Otherwise, disp prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, disp prints quoted text. Otherwise, disp prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, disp prints the contents of each cell (or its size and type if too large). Otherwise, disp prints the size of each dataset element.

For time series variables, disp prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, disp prints the actual data. Otherwise, disp prints the size and type of each dataset element.

For other types of variables, disp prints the size and type of each dataset element.

Class: GeneralizedLinearMixedModel
Display generalized linear mixed-effects model

Syntax

disp(glme)

Description

disp(glme) displays fitted generalized linear mixed-effects model glme.

Input Arguments

- **glme** — Generalized linear mixed-effects model
  GeneralizedLinearMixedModel object
  Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Examples

Display a Generalized Linear Mixed-Effects Model

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (newprocess)
- Processing time for each batch, in hours (time)
- Temperature of the batch, in degrees Celsius (temp)
- Categorical variable indicating the supplier of the chemical used in the batch (supplier)
- Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by
factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[ \text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}) \]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i,
\]

where
- \( \text{defects}_{ij} \) is the number of defects observed in the batch produced by factory \( i \) during batch \( j \).
- \( \mu_{ij} \) is the mean number of defects corresponding to factory \( i \) (where \( i = 1, 2, \ldots, 20 \)) during batch \( j \) (where \( j = 1, 2, \ldots, 5 \)).
- \( \text{newprocess}_{ij}, \text{time}_\text{dev}_{ij}, \) and \( \text{temp}_\text{dev}_{ij} \) are the measurements for each variable that correspond to factory \( i \) during batch \( j \). For example, \( \text{newprocess}_{ij} \) indicates whether the batch produced by factory \( i \) during batch \( j \) used the new process.
- \( \text{supplier}_C_{ij} \) and \( \text{supplier}_B_{ij} \) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \( i \) during batch \( j \).
- \( b_i \sim N(0, \sigma^2_b) \) is a random-effects intercept for each factory \( i \) that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');}\]

Display the model.

    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std'}        0.31381

Group: Error
    Name                        Estimate
    {'sqrt(Dispersion)'}        1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

**Formula** indicates the model specification using Wilkinson's notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The **Fixed effects coefficients** table indicates that `fitglme` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the t-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and p-value that correspond to the t-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only **factory**), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, std indicates that `fitglme` returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`. 
More About

Akaike and Bayesian Information Criteria

The Akaike information criterion (AIC) is \( AIC = -2\log L_M + 2(\text{param}) \).

\( \log L_M \) depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then \( \log L_M \) is the maximized log likelihood.
- If you use 'MPL', then \( \log L_M \) is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then \( \log L_M \) is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

\text{param} is the total number of parameters estimated in the model. For most GLME models, \text{param} is equal to \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance, excluding the residual variance, and \( p \) is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then \text{param} is equal to \( (nc + p) \).

The Bayesian information criterion (BIC) is \( BIC = -2\log L_M + \ln(n_{eff})(\text{param}) \).

\( \log L_M \) depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then \( \log L_M \) is the maximized log likelihood.
- If you use 'MPL', then \( \log L_M \) is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then \( \log L_M \) is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

\( n_{eff} \) is the effective number of observations.

- If you use 'MPL', 'Laplace', or 'ApproximateLaplace', then \( n_{eff} = n \), where \( n \) is the number of observations.
- If you use 'REML', then \( n_{eff} = n - p \).

\text{param} is the total number of parameters estimated in the model. For most GLME models, \text{param} is equal to \( nc + p + 1 \), where \( nc \) is the total number of parameters in the random-effects covariance, excluding the residual variance, and \( p \) is the number of fixed-effects coefficients. However, if the dispersion parameter is fixed at 1.0 for binomial or Poisson distributions, then \text{param} is equal to \( (nc + p) \).

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, \( p \). So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

For models fitted using 'MPL' and 'REML', AIC and BIC are based on the log likelihood (or restricted log likelihood) of pseudo data from the final pseudo likelihood iteration. Therefore, a direct comparison of AIC and BIC values between models fitted using 'MPL' and 'REML' is not appropriate.

Class: LinearMixedModel
Display linear mixed-effects model

Syntax

display(lme)

Description

display(lme) displays the fitted linear mixed-effects model lme.

Input Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using fitlme or fitlmematrix.

Examples

Randomized Block Design

Load the sample data.

load('shift.mat');

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');

Display the model.

disp(lme)

   Name                Estimate    Lower      Upper
{ 'Res Std' }          0.76439     0.49315    1.1848

This display includes the model performance statistics, “Akaike and Bayesian Information Criteria” on page 32-1107, “Akaike and Bayesian Information Criteria” on page 32-1107, loglikelihood, and “Deviance” on page 32-1107.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column SE shows the standard errors of the coefficients. The column tStat includes the t-statistic values that correspond to each coefficient. DF is the residual degrees of freedom, and the pValue is the p-value that corresponds to the corresponding t-statistic value. The columns Lower and Upper display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.
More About

Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is

$$AIC = -2 \log L_M + 2(nc + p + 1),$$

where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, and $nc + p + 1$ is the number of parameters estimated in the model. $p$ is the number of fixed-effects coefficients, and $nc$ is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is

$$BIC = -2 \log L_M + \ln(n_{eff})(nc + p + 1),$$

where $\log L_M$ is the maximized log likelihood (or maximized restricted log likelihood) of the model, $n_{eff}$ is the effective number of observations, and $(nc + p + 1)$ is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then $n_{eff} = n$, where $n$ is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then $n_{eff} = n - p$.

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated, $p$. So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

Deviance

LinearMixedModel computes the deviance of model $M$ as minus two times the loglikelihood of that model. Let $L_M$ denote the maximum value of the likelihood function for model $M$. Then, the deviance of model $M$ is

$$-2 \log L_M.$$

A lower value of deviance indicates a better fit. Suppose $M_1$ and $M_2$ are two different models, where $M_1$ is nested in $M_2$. Then, the fit of the models can be assessed by comparing the deviances $Dev_1$ and $Dev_2$ of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom $v$ equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in $M_1$ and $M_2$. You can get the $p$-value for this test using $1 - \text{chi2cdf}(Dev, V)$, where $Dev = Dev_2 - Dev_1$.

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

$$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix},$$

$D$ is a $q$-by-$q$ symmetric positive semidefinite matrix.

$$H_1: D$ is a $(q+1)$-by-$(q+1)$ symmetric positive semidefinite matrix.

That is, $H_1$ states that the last row and column of $D$ are different from zero. Here, the bigger model $M_2$ has $q + 1$ parameters and the smaller model $M_1$ has $q$ parameters. And $Dev$ has a 50:50 mixture of $\chi^2_q$ and $\chi^2_{(q+1)}$ distributions (Stram and Lee, 1994).

distributionFitter

Open Distribution Fitter app

**Syntax**

distributionFitter
distributionFitter(y)
distributionFitter(y,cens)
distributionFitter(y,cens,freq)
distributionFitter(y,cens,freq,dsname)

**Description**

This page contains programmatic syntax information for the Distribution Fitter app. For general usage information, see [Distribution Fitter](#).

distributionFitter opens the Distribution Fitter app, or brings focus to the app if it is already open.
distributionFitter(y) opens the Distribution Fitter app populated with the data specified by the vector y.
distributionFitter(y,cens) uses the vector cens to specify whether each observation in y is censored.
distributionFitter(y,cens,freq) uses the vector freq to specify the frequency of each element of y.
distributionFitter(y,cens,freq,dsname) creates a data set with the name dsname, using the data vector, y, censoring indicator, cens, and frequency vector, freq.

**Examples**

**Open Distribution Fitter App with Existing Data**

Load the carsmall sample data.
load carsmall

Open the Distribution Fitter app using the MPG miles per gallon data.
distributionFitter(MPG)
The Distribution Fitter app opens, populated with the MPG data, and displays the density (PDF) plot. You can use the app to display different plots and fit distributions to this data.

Open Distribution Fitter App with Censoring Data

Load the sample data.

load 'lightbulb.mat'

The first column of the data contains the lifetime (in hours) of two types of light bulbs. The second column contains information about the type of light bulb. 1 indicates fluorescent bulbs, and 0 indicates the incandescent bulb. The third column contains censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Open the Distribution Fitter app using the first column of lightbulb as the input data, and the third column as the censoring data. Name the data lifetime.

distributionFitter(lightbulb(:,1),lightbulb(:,3),[],'lifetime')
To open the Data dialog box, click **Data**. In the **Manage data sets** pane, click to highlight the lifetime data set row. Finally, to open the View Data Set dialog, click **View**. The lifetime data appears in the second column and the corresponding censoring indicator appears in the third column.

**Input Arguments**

**y — Input data**
array of scalar values | variable representing an array of scalar values

Input data, specified as an array of scalar values or a variable representing an array of such values.

Data Types: `single` | `double`

**cens — Censoring indicator**
`zeros(n)` (default) | vector of 0 and 1 values

Censoring indicator, specified as a vector of 0 and 1 values. The length of `cens` must be equal to the length of `y`. If `y(j)` is censored, then `(cens(j)==1)`; if `y(j)` is not censored, then `(cens(j)==0)`. If `cens` is omitted or empty, then no `y` values are censored.

If you have frequency data (`freq`) but not censoring data (`cens`), then you must specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

**freq — Frequency data**
`ones(n)` (default) | vector of scalar values

Frequency data, specified as a vector of scalar values. The length of `freq` must be equal to the length of `y`. If `freq` is omitted or empty, then all `y` values have a frequency of 1.
If you have frequency data (\texttt{freq}) but not censoring data (\texttt{cens}), then you must specify empty brackets (\texttt{[]}) for \texttt{cens}.

Data Types: \texttt{single} | \texttt{double}

\texttt{dsname} — Data set name

character vector | string scalar

Data set name, specified as a character vector enclosed in single quotes or a string scalar enclosed in double quotes.

If you want to specify a data set name, but do not have censoring data (\texttt{cens}) or frequency data (\texttt{freq}), then you must specify empty brackets (\texttt{[]}) for both \texttt{freq} and \texttt{cens}.

Example: \texttt{‘MyData’}

Data Types: \texttt{char} | \texttt{string}

\textbf{Introduced in R2017a}
Probability Distribution Function

Interactive density and distribution plots

Description
The Probability Distribution Function user interface creates an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution. Explore the effects of changing parameter values on the shape of the plot, either by specifying parameter values or using interactive sliders.

Required Products
• MATLAB
• Statistics and Machine Learning Toolbox

Note: disttool does not provide printing, code generating, or data importing functionality in MATLAB Online™.

Open the Probability Distribution Function App
• At the command prompt, enter disttool.

Examples

Explore the Probability Distribution Function User Interface
This example shows how to use the Probability Distribution Function user interface to explore the shape of cdf and pdf plots for different probability distributions and parameter values.

Open the Probability Distribution Function user interface.
disttool
The interface opens with a plot of the cdf of the Normal distribution. The initial parameter settings are \( \text{Mu} = 0 \) and \( \text{Sigma} = 1 \).

Select **PDF** from the **Function type** drop-down menu to plot the pdf of the Normal distribution using the same parameter values.
Change the value of the location parameter $\mu$ to 1.
As the parameter values change, the shape of the plot also changes. Also, the value of X remains the same, but the density value changes because of the new parameter value.

Use the **Distribution** drop-down menu to change the distribution type from **Normal** to **Weibull**.
The shape of the plot changes, along with the names and values of the parameters.

**Parameters**

**Distribution — Probability distribution**
Normal (default) | Exponential | Poisson | Weibull | ...

Specify the probability distribution to explore by selecting a distribution name from the drop-down list. The drop-down list includes approximately 25 probability distribution options, including Normal, Exponential, Poisson, Weibull, and more.

**Function type — Probability distribution function type**
CDF (default) | PDF

Specify the probability distribution function type as CDF (cumulative distribution function) or PDF (probability density function) by selecting the function name from the drop-down list.

**Probability — Cumulative distribution function value**
numeric value in the range [0,1]
Specify the cumulative distribution function (cdf) value of interest as a numeric value in the range [0,1]. The corresponding random variable value appears in the X field below the plot. Alternatively, you can specify a value for X, and the Probability value will update automatically.

This option only appears if Function type is CDF. If Function type is PDF, then the probability density at the specified X value displays to the left of the plot.

**X — Random variable**
numeric value

Specify the random variable of interest as a numeric value. If the Function type is CDF, then the corresponding cumulative distribution function (cdf) value appears in the Probability field to the left of the plot. Alternatively, you can specify a value for Probability, and the X value will update automatically. If the Function type is PDF, then the corresponding probability density value appears to the left of the plot.

**Parameters — Parameter boundaries and values**
numeric value

Specify the parameter boundaries and values as numeric values. Each column contains a field for the upper bound, value, and lower bound of one parameter. The name and number of available parameters changes based on the distribution specified in the Distribution drop-down list. For example, if you select the Normal distribution, then disttool enables two columns: One column for the Mu parameter and one column for the Sigma parameter. If you select the Exponential distribution, then disttool enables one column for the Mu parameter.

**Tips**

To change the value of X (on the y-axis), or Probability or Density (on the x-axis):

- Type the values of interest into the Probability or X fields;
- Click on the point of interest on the plot; or
- Click and drag the reference lines across the plot.

**See Also**

Functions

distributionFitter | fitdist | makedist

Introduced before R2006a
**double**

**Class:** dataset

(Not Recommended) Convert dataset variables to double array

**Note** The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB table data type instead. See MATLAB table documentation for more information.

**Syntax**

\[ b = \text{double}(A) \]
\[ b = \text{double}(a,\text{vars}) \]

**Description**

\[ b = \text{double}(A) \] returns the contents of the dataset \( A \), converted to one double array. The classes of the variables in the dataset must support the conversion.

\[ b = \text{double}(a,\text{vars}) \] returns the contents of the dataset variables specified by \( \text{vars} \). \( \text{vars} \) is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

**See Also**

dataset | replacedata | single
droplevels

(Not Recommended) Drop levels from a nominal or ordinal array

**Note** The nominal and ordinal array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

**Syntax**

B = droplevels(A)
B = droplevels(A,oldlevels)

**Description**

B = droplevels(A) drops unused levels from the nominal or ordinal array A. The array B has the same size, type, and values as A, but has a list of potential levels that includes only those present in some element of A.

B = droplevels(A,oldlevels) removes the specified levels oldlevels from A.

droplevels removes levels, but does not remove elements. Elements of B that correspond to elements of A having levels in oldlevels all have an undefined level.

**Examples**

**Drop Levels From an Ordinal Array**

Bin patient ages into ordinal levels corresponding to 10-year intervals.

```matlab
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90),'%d'),{'s'});
A = ordinal(hospital.Age,labels,[],edges);
gllabels(A)
ans = 1x10 cell
Columns 1 through 7
{'0s'} {'10s'} {'20s'} {'30s'} {'40s'} {'50s'} {'60s'}
Columns 8 through 10
{'70s'} {'80s'} {'90s'}
```

Drop any levels that have no patients in them.

```matlab
A = droplevels(A);
gllabels(A)
```
ans = 1x4 cell
    {'20s'}    {'30s'}    {'40s'}    {'50s'}

Input Arguments

A — Nominal or ordinal array
    nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

oldlevels — Levels to remove
    string array | cell array of character vectors | 2-D character matrix

Levels to remove from the nominal or ordinal array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: char | string | cell

Output Arguments

B — Nominal or ordinal array
    nominal array | ordinal array

Nominal or ordinal array, returned as a nominal or ordinal array object.

See Also

addlevels | mergelevels | nominal | ordinal | reorderlevels

Topics

“Add and Drop Category Levels” on page 2-18

Introduced in R2007a
**dummyvar**

Create dummy variables

**Syntax**

\[
D = \text{dummyvar}(\text{group})
\]

**Description**

\(D = \text{dummyvar}(\text{group})\) returns a matrix \(D\) containing zeros and ones, whose columns are dummy variables for the grouping variables on page 2-45 in group. Each column of group is a single grouping variable, with values indicating category levels. The rows of group represent observations across all variables.

**Examples**

*Create Dummy Variables from Categorical Grouping Variable*

Create a column vector of categorical data specifying color types.

\[
\text{Colors} = \{'\text{Red}'';'\text{Blue}'';'\text{Green}'';'\text{Red}'';'\text{Green}'';'\text{Blue}'\};
\]

\[
\text{Colors} = \text{categorical} (\text{Colors});
\]

Create dummy variables for each color type.

\[
D = \text{dummyvar}(\text{Colors})
\]

\[
D = 6 \times 3
\]

\[
\begin{array}{ccc}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0 \\
1 & 0 & 0 \\
\end{array}
\]

The columns in \(D\) correspond to the levels in \(\text{Colors}\). For example, the first column of \(\text{dummyvar}\) corresponds to the first level, 'Blue', in \(\text{Colors}\).

Display the category levels of \(\text{Colors}\).

\[
\text{categories}(\text{Colors})
\]

\[
\text{ans} = 3 \times 1 \ \text{cell}
\]

\[
\begin{array}{c}
\{'\text{Blue}'\} \\
\{'\text{Green}'\} \\
\{'\text{Red}'\} \\
\end{array}
\]
Create Dummy Variables from Numeric Grouping Variables

Create a matrix group of data containing the effects of two machines and three operators on a process.

```matlab
machine = [1 1 1 1 2 2 2 2]';
operator = [1 2 3 1 2 3 1 2]';
group = [machine operator]
group = 8×2
1     1
1     2
1     3
1     1
2     2
2     3
2     1
2     2
```

Create dummy variables of the data in group.

```matlab
D = dummyvar(group)
D = 8×5
1     0     1     0     0
1     0     0     1     0
1     0     0     0     1
1     0     1     0     0
0     1     0     1     0
0     1     0     0     1
0     1     1     0     0
0     1     0     1     0
```

The first two columns of D represent observations of machine 1 and machine 2, respectively. The remaining columns represent observations of the three operators.

Create Dummy Variables from Multiple Grouping Variables

Create a cell array of phone types and a numeric vector of area codes.

```matlab
phone = {'mobile';'landline';'mobile';'mobile';'mobile';'landline';'landline'};
codes = [802 802 603 603 802 603 802]';
newcodes = categorical(codes);
```

Because the area code data has two levels (rather than 802 levels corresponding to the integers 1:802), convert codes to a categorical vector.

```matlab
newcodes = categorical(codes);
```

Combine the phone and newcodes grouping variables into the cell array group.

```matlab
group = {phone,newcodes};
```
Create dummy variables for the groups in `group`.

```
D = dummyvar(group)
```

```
D = 7x4
    1  0  0  1
    0  1  0  1
    1  0  1  0
    1  0  1  0
    1  0  0  1
    0  1  1  0
    0  1  0  1
```

The first two columns of `D` correspond to the phone types, and the last two columns correspond to the area codes.

### Input Arguments

`group` — Grouping variables
positive integer vector | categorical column vector | cell array | positive integer matrix

Grouping variables, specified as a positive integer vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables on page 2-45, or a positive integer matrix representing levels within multiple variables.

If `group` is a categorical vector, then the groups and their order match the output of the `categories` function applied to `group`. If `group` is a numeric vector, then `dummyvar` assumes that the groups and their order are `1:max(group)`. In this respect, `dummyvar` treats a numeric grouping variable differently from `grp2idx`. For information on the order of groups within grouping variables, see “Grouping Variables” on page 2-45.

**Example:**

```
[2 1 1 1 2 3 3 2]'
```

**Example:**

```
{Origin,Cylinders}
```

**Data Types:** `single` | `double` | `categorical` | `cell`

### Output Arguments

`D` — Dummy variables
numeric matrix

Dummy variables, returned as an `n`-by-`s` numeric matrix, where `n` is the number of rows of `group` and `s` is the sum of the number of levels in each column of `group`. From left to right, the columns of `D` are dummy variables created from the first column of `group`, followed by dummy variables created from the second column of `group`, and so on.

**Data Types:** `single` | `double`

### Tips

- Use dummy variables in regression analysis and ANOVA to indicate values of categorical predictors.
• **dummyvar** treats NaN values and undefined categorical levels in group as missing data and returns NaN values in D.

• If a column of ones is introduced in the matrix D, then the resulting matrix \( X = [\text{ones(size}(D,1),1) \ D] \) is rank deficient. If group has multiple columns, then the matrix D itself is rank deficient because dummy variables produced from any column of group always sum to a column of ones. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of group.

• If group is a numeric vector with levels that do not correspond exactly to the integers 1:max(group), first convert the data to a categorical vector by using categorical. You can then pass the result to dummyvar. For an example, see “Create Dummy Variables from Multiple Grouping Variables” on page 32-1128.

### Extended Capabilities

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

### See Also

anova1 | categories | grp2idx | regress

### Topics

“Grouping Variables” on page 2-45

“Dummy Variables” on page 2-48

“Linear Regression with Categorical Covariates” on page 2-52

**Introduced before R2006a**
dwtest

Durbin-Watson test with residual inputs

Syntax

```matlab
p = dwtest(r,x)
p = dwtest(r,x,Name,Value)
[p,d] = dwtest(____)
```

Description

`p = dwtest(r,x)` returns the `p`-value for the Durbin-Watson test on page 32-1133 of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

`p = dwtest(r,x,Name,Value)` returns the `p`-value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the `p`-value using a normal approximation.

`[p,d] = dwtest(____)` also returns the Durbin-Watson test statistic, `d`, using any of the input arguments from the previous syntaxes.

Examples

Test Residuals For Correlation

Load the sample census data.

```matlab
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```matlab
n = length(cdate);
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```matlab
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among the residuals, `r`.

```matlab
[p,d] = dwtest(r,x)
p = 3.6190e-15
d = 0.1308
```

The returned value `p = 3.6190e-15` indicates rejection of the null hypothesis at the 5% significance level.
One-Sided Hypothesis Test

Load the sample census data.

```matlab
load census
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```matlab
n = length(cdate);
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```matlab
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

```matlab
[p,d] = dwtest(r,x,'Tail','right')
p = 1.8095e-15
d = 0.1308
```

The returned value \( p = 1.8095 \times 10^{-15} \) indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.

Input Arguments

- **x** — Design matrix
  
  Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.
  
  Data Types: `single` | `double`

- **r** — Regression residuals
  
  Regression residuals, specified as a vector. Obtain \( r \) by performing a linear regression using a function such as `regress`, or by using the backslash operator.
  
  Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `‘Tail’,‘right’,‘Method’,‘approximate’` specifies a right-tailed hypothesis test and calculates the p-value using a normal approximation.
Method — Algorithm for computing $p$-value

Algorithm for computing the $p$-value, specified as the comma-separated pair consisting of 'Method' and one of these values:

'exact' Calculate an exact $p$-value using the Pan algorithm [2]. This is the default if the sample size is less than 400.

'approximate' Calculate the $p$-value using a normal approximation [1]. This is the default if the sample size is 400 or larger.

Example: 'Method','exact'

Tail — Type of alternative hypothesis

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both' Test the alternate hypothesis that autocorrelation among the residuals is not zero.

'right' Test the alternative hypothesis that autocorrelation among the residuals is greater than zero.

'left' Test the alternative hypothesis that autocorrelation among the residuals is less than zero.

Example: 'Tail','right'

Output Arguments

$p$ — $p$-value

scalar value in the range [0,1]

$p$-value of the test, returned as a scalar value in the range [0,1]. $p$ is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of $p$ cast doubt on the validity of the null hypothesis.

d — Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

More About

Durbin-Watson Test

The Durbin-Watson test tests the null hypothesis that linear regression residuals of time series data are uncorrelated, against the alternative hypothesis that autocorrelation exists.

The test statistic for the Durbin-Watson test is

32-1133
\[
DW = \frac{\sum_{i=1}^{n-1} \left( r_{i+1} - r_i \right)^2}{\sum_{i=1}^{n} r_i^2},
\]

where \( r_i \) is the \( i \)th raw residual, and \( n \) is the number of observations.

The \( p \)-value of the Durbin-Watson test is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. A significantly small \( p \)-value casts doubt on the validity of the null hypothesis and indicates autocorrelation among residuals.

**Alternative Functionality**

- You can create a linear regression model object by using `fitlm` or `stepwiselm` and use the object function `dwtest` to perform the Durbin-Watson test.

A `LinearModel` object provides the object properties and the object functions to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

**References**

**See Also**

dwtest | fitlm | regress

**Introduced in R2006a**
**dwtest**

Durbin-Watson test with linear regression model object

**Syntax**

```
p = dwtest(mdl)
p = dwtest(mdl,method)
p = dwtest(mdl,method,tail)
[p,DW] = dwtest(____)
```

**Description**

`p = dwtest(mdl)` returns the p-value of the “Durbin-Watson Test” on page 32-1136 on the residuals of the linear regression model `mdl`. The null hypothesis is that the residuals are uncorrelated, and the alternative hypothesis is that the residuals are autocorrelated.

`p = dwtest(mdl,method)` specifies the algorithm for computing the p-value.

`p = dwtest(mdl,method,tail)` specifies the alternative hypothesis.

`[p,DW] = dwtest(____)` also returns the Durbin-Watson statistic using any of the input argument combinations in the previous syntaxes.

**Examples**

**Test Residuals for Autocorrelation**

Determine whether a fitted linear regression model has autocorrelated residuals.

Load the `census` data set and create a linear regression model.

```
load census
mdl = fitlm(cdate,pop);
```

Find the p-value of the Durbin-Watson autocorrelation test.

```
p = dwtest(mdl)
p = 3.6190e-15
```

The small p-value indicates that the residuals are autocorrelated.

**Input Arguments**

`mdl` — Linear regression model

LinearModel object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`. 
**method — Algorithm for computing p-value**
'exact' | 'approximate'

Algorithm for computing the p-value, specified as one of these values:

- 'exact' — Calculate an exact p-value using Pan’s algorithm [2].
- 'approximate' — Calculate the p-value using a normal approximation [1].

The default is 'exact' when the sample size is less than 400, and 'approximate' otherwise.

**tail — Type of alternative hypothesis**
'both' (default) | 'right' | 'left'

Type of alternative hypothesis to test, specified as one of these values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Alternative Hypothesis</th>
</tr>
</thead>
<tbody>
<tr>
<td>'both'</td>
<td>Serial correlation is not 0.</td>
</tr>
<tr>
<td>'right'</td>
<td>Serial correlation is greater than 0 (right-tailed test).</td>
</tr>
<tr>
<td>'left'</td>
<td>Serial correlation is less than 0 (left-tailed test).</td>
</tr>
</tbody>
</table>

`dwtest` tests whether `mdl` has no serial correlation, against the specified alternative hypothesis.

**Output Arguments**

**p — p-value of test**
numeric value

p-value of the test, returned as a numeric value. `dwtest` tests whether the residuals are uncorrelated, against the alternative that autocorrelation exists among the residuals. A small p-value indicates that the residuals are autocorrelated.

**DW — Durbin-Watson statistic**
nonnegative numeric value

Durbin-Watson statistic value, returned as a nonnegative numeric value.

**More About**

**Durbin-Watson Test**

The Durbin-Watson test tests the null hypothesis that linear regression residuals of time series data are uncorrelated, against the alternative hypothesis that autocorrelation exists.

The test statistic for the Durbin-Watson test is

\[
DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^{n} r_i^2},
\]

where \( r_i \) is the \( i \)th raw residual, and \( n \) is the number of observations.
The p-value of the Durbin-Watson test is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. A significantly small p-value casts doubt on the validity of the null hypothesis and indicates autocorrelation among residuals.

**Introduced in R2012a**
ecdf

Empirical cumulative distribution function

Syntax

[f,x] = ecdf(y)
[f,x] = ecdf(y,Name,Value)
[f,x,flo,fup] = ecdf(____)

ecdf(ax,____)

description

[f,x] = ecdf(y) returns the empirical cumulative distribution function (cdf), f, evaluated at the points in x, using the data in the vector y.

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

[f,x] = ecdf(y,Name,Value) returns the empirical function values, f, evaluated at the points in x, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

[f,x,flo,fup] = ecdf(____) also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

cdf computes the confidence bounds using Greenwood's formula on page 32-1147. They are not simultaneous confidence bounds.

cdf(ax,____) draws a stairstep graph of the evaluated function by using the stairs function. Specify 'Bounds', 'on' to include the confidence bounds in the graph.

cdf(ax,____) plots on the axes specified by ax instead of the current axes (gca).

Examples

Compute Empirical Cumulative Distribution Function

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

rng('default') % for reproducibility
failuretime = random('wbl',3,1,15,1);

Compute the Kaplan-Meier estimate of the cdf for survival data.
\[
[f, x] = \text{ecdf}(\text{failuretime});
\]
\[
[f, x]
\]
\[
\text{ans} = 16 \times 2
\]
\[
\begin{array}{cc}
0 & 0.0895 \\
0.0667 & 0.0895 \\
0.1333 & 0.1072 \\
0.2000 & 0.1303 \\
0.2667 & 0.1313 \\
0.3333 & 0.2718 \\
0.4000 & 0.2968 \\
0.4667 & 0.6147 \\
0.5333 & 0.6684 \\
0.6000 & 1.3749 \\
\vdots & \\
\end{array}
\]

Plot the estimated cdf.
\[
\text{ecdf}(\text{failuretime})
\]

**Empirical Hazard Function of Right-Censored Data**

Compute and plot the hazard function of simulated right-censored survival data.
Generate failure times from a Birnbaum-Saunders distribution.

```matlab
genr('default') % For reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector:

```matlab
T = 0.9;
cens = (failuretime>T);
```

Plot the empirical hazard function for the data.

```matlab
ecdf(failuretime,'Function','cumulative hazard', ...
    'Censoring',cens,'Bounds','on');
```

**Compare Empirical Cumulative Distribution Function (CDF) with Known CDF**

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.

Generate failure times from an exponential distribution with mean failure time of 15.

```matlab
genr('default') % For reproducibility
y = exprnd(15,75,1);
```
Generate drop-out times from an exponential distribution with mean failure time of 30.

d = exprnd(30,75,1);

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

t = min(y,d);

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

censored = (y>d);

Compute the empirical cdf and confidence bounds.

[f,x,flo,fup] = ecdf(t,'Censoring',censored);

Plot the cdf and confidence bounds.

figure()
ecdf(t,'Censoring',censored,'Bounds','on');
hold on

Superimpose a plot of the known population cdf.

xx = 0:.1:max(t);
yy = 1-exp(-xx/15);
Empirical Survivor Function with Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

rng('default')  % For reproducibility
R = wblrnd(100,2,100,1);

Plot the survivor function for the data with 99% confidence bounds.

ecdf(R,'Function','survivor','Alpha',0.01,'Bounds','on')
hold on
Fit the Weibull survivor function.

```matlab
x = 1:1:250;
wblsurv = 1-cdf('weibull',x,100,2);
plot(x,wblsurv,'g-','LineWidth',2)
legend('Empirical','LCB','UCB','Population', ...  
    'Location','northeast')
```
The survivor function based on the actual distribution is within the confidence bounds.

**Input Arguments**

- **y** — Input data
  
  Vector
  
  Input data, specified as a vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

  - `ecdf` ignores `NaN` values in `y`. Additionally, any `NaN` values in the censoring vector (`'Censoring'`) or frequency vector (`'Frequency'`) cause `ecdf` to ignore the corresponding values in `y`.

  Data Types: `single` | `double`

- **ax** — Axes handle
  
  Handle
  
  Axes handle for the figure `ecdf` plots to, specified as a handle.

  For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

  Example: `ecdf(h,x)```
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example: 'Censoring', c, 'Function', 'cumulative hazard', 'Alpha', 0.025, 'Bounds', 'on' specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector c.

**Censoring — Indicator of censored data**

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including 'Censoring' and a Boolean array of the same size as x. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

`ecdf` ignores any NaN values in this censoring vector. Additionally, any NaN values in y or the frequency vector ('Frequency') cause `ecdf` to ignore the corresponding values in the censoring vector.

Example: If vector cdata stores the censored data information, enter 'Censoring', cdata.

Data Types: logical

**Frequency — Frequency of observations**

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of 'Frequency' and a vector containing nonnegative integer counts. This vector is the same size as the vector x. The jth element of this vector gives the number of times the jth element of x was observed. Default is one observation per element of x.

`ecdf` ignores any NaN values in this frequency vector. Additionally, any NaN values in y or the censoring vector ('Censoring') cause `ecdf` to ignore the corresponding values in the frequency vector.

Example: If failurefreq is a vector of frequencies, enter 'Frequency', failurefreq

Data Types: single | double

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval of the evaluated function, specified as the comma-separated pair consisting of 'Alpha' and a scalar value between in the range (0,1). Default is 0.05 for 95% confidence. For a given value alpha, the confidence level is \(100(1 - \alpha)\)%.

For instance, for a 99% confidence interval, you can specify the alpha value as follows.

Example: 'Alpha', 0.01

Data Types: single | double

**Function — Type of function returned**

'cdf' (default) | 'survivor' | 'cumulative hazard'
Type of function that `ecdf` evaluates and returns, specified as the comma-separated pair consisting of 'Function' and one of the following.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cdf'</td>
<td>Default. Cumulative distribution function.</td>
</tr>
<tr>
<td>'survivor'</td>
<td>Survivor function.</td>
</tr>
<tr>
<td>'cumulative hazard'</td>
<td>Cumulative hazard function.</td>
</tr>
</tbody>
</table>

Example: 'Function','cumulative hazard'

**Bounds** — Indicator for including bounds

'off' (default) | 'on'

Indicator for including bounds, specified as the comma-separated pair consisting of 'Bounds' and one of the following.

<table>
<thead>
<tr>
<th>Bound</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'off'</td>
<td>Default. Specify to omit bounds.</td>
</tr>
<tr>
<td>'on'</td>
<td>Specify to include bounds.</td>
</tr>
</tbody>
</table>

**Note** This name-value argument is used only for plotting.

Example: 'Bounds','on'

**Output Arguments**

**f** — Function values

column vector

Function values evaluated at the points in x, returned as a column vector.

**x** — Sorted observed points

column vector

Sorted observed points in the data vector y, returned as a column vector.

`ecdf` sorts y, removes duplicate values in the sorted y, and saves the results to the output x. The output x includes the minimum value of y as its first two values. These two values are useful for plotting the outputs of `ecdf` using the stairs function.

**flo** — Lower confidence bound

column vector

Lower confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood’s formula on page 32-1147. They are not simultaneous confidence bounds.

**fup** — Upper confidence bound

column vector

Upper confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood’s formula on page 32-1147. They are not simultaneous confidence bounds.
More About

Greenwood's Formula

Approximation for the variance of Kaplan-Meier estimator.

The variance estimate is given by

\[ V(S(t)) = S^2(t) \sum_{t_i < T} \frac{d_i}{r_i(r_i - d_i)}, \]

where \( r_i \) is the number at risk at time \( t_i \), and \( d_i \) is the number of failures at time \( t_i \).

References

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Plotting is not supported.
- Names in name-value pair arguments must be compile-time constants.
- Values in the 'Function' and 'Bounds' name-value pair arguments must also be compile-time constants. For example, to use the 'Function', 'survivor' name-value pair argument in the generated code, include \{coder.Constant('Function'),coder.Constant('survivor')\} in the -args value of codegen.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

ecdfhist

Histogram based on empirical cumulative distribution function

Syntax

[n,c] = ecdfhist(f,x)
[n,c] = ecdfhist(f,x,m)
n = ecdfhist(f,x,centers)
ecdfhist(____)

Description

[n,c] = ecdfhist(f,x) returns the heights, n, of histogram bars for 10 equally spaced bins and the position of the bin centers, c.

ecdfhist computes the bar heights from the increases in the empirical cumulative distribution function, f, at evaluation points, x. It normalizes the bar heights so that the area of the histogram is equal to 1. In contrast, histogram produces bars with heights representing bin counts.

[n,c] = ecdfhist(f,x,m) returns the histogram bars using m bins.

n = ecdfhist(f,x,centers) returns the heights of the histogram bars with bin centers specified by centers.

ecdfhist(____) plots the histogram bars.

Examples

Return Histogram Bar Heights and Bin Centers

Compute the histogram bar heights based on the empirical cumulative distribution function.

Generate failure times from a Birnbaum-Saunders distribution.

rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

T = 0.9;
cens = (failuretime>T);

Compute the empirical cumulative distribution function for the data.

[f,x] = ecdf(failuretime,'censoring',cens);

Now, find the bar heights of the histogram using the cumulative distribution function estimate.
Return Bar Heights and Bin Centers for a Given Number of Bins

Compute the bar heights for six bins using the empirical cumulative distribution function and also return the bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

T = 0.9;
cens = (failuretime>T);

First, compute the empirical cumulative distribution function for the data.

[f,x] = ecdf(failuretime,'censoring',cens);

Now, estimate the histogram with six bins using the cumulative distribution function estimate.

[n,c] = ecdffhist(f,x,6);
[n' c']

ans = 6×2
    1.9764  0.0998
    1.7647  0.2415
    1.1294  0.3831
    0.4235  0.5248
    0.7764  0.6665
    0.2118  0.8081
Draw Histogram for Given Bin Centers

Draw the histogram of the empirical cumulative distribution histogram for specified bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```matlab
rng default; % For reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```matlab
T = 0.9;
cens = (failuretime>T);
```

Define bin centers.

```matlab
centers = 0.1:0.1:1;
```

Compute the empirical cumulative distribution function for the data and draw the histogram for specified bin centers.

```matlab
[f,x] = ecdf(failuretime,'censoring',cens);
ecdfhist(f,x,centers);
axis([0 1 0 2.5])
```
Compare Histogram with Known Probability Distribution Function

Generate right-censored survival data and compare the histogram from cumulative distribution function with the known probability distribution function.

Generate failure times from an exponential distribution with mean failure time of 15.

```matlab
rng default; % For reproducibility
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```matlab
d = exprnd(30,75,1);
```

Record the minimum of these times as the observed failure times.

```matlab
t = min(y,d);
```

Generate censoring by finding the generated failure times that are greater than the drop-out times.

```matlab
censored = (y>d);
```

Calculate the empirical cdf and plot a histogram using the empirical cumulative distribution function.

```matlab
[f,x] = ecdf(t,'censoring',censored);
ecdfhist(f,x)
h = findobj(gca,'Type','patch');
h.FaceColor = [.8 .8 1];
hold on
```
Superimpose a plot of the known population pdf.

```matlab
xx = 0:.1:max(t);
yy = exp(-xx/15)/15;
plot(xx,yy,'r-','LineWidth',2)
hold off
```

**Input Arguments**

- **f** — Empirical cdf values
  
  Empirical cdf values at given evaluation points, `x`, specified as a vector.

  For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

  Example: `[f,x] = ecdf(failure); ecdfhist(f,x);`

  Data Types: `single` | `double`

- **x** — Evaluation points
  
  Evaluation points at which empirical cdf values, `f`, are calculated, specified as a vector.
For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

```matlab
Example: [f,x] = ecdf(failure); ecdfhist(f,x);
```

Data Types: `single` | `double`

### m — Number of bins
scalar

Number of bins, specified as a scalar.

For instance, you can draw a histogram with 8 bins as follows.

```matlab
Example: ecdfhist(f,x,8)
```

Data Types: `single` | `double`

### centers — Center points of bins
vector

Center points of bins, specified as a vector.

```matlab
Example: centers = 2:2:10; ecdfhist(f,x,centers);
```

Data Types: `single` | `double`

### Output Arguments

#### n — Heights of histogram bars
row vector

Heights of histogram bars `ecdfhist` calculates based on the empirical cdf values, returned as a row vector.

#### c — Position of bin centers
row vector

Position of bin centers, returned as a row vector.

### Introduced before R2006a
**edge**

Edge of k-nearest neighbor classifier

**Syntax**

\[
E = \text{edge}(\text{mdl}, \text{tbl}, \text{ResponseVarName}) \\
E = \text{edge}(\text{mdl}, \text{tbl}, Y) \\
E = \text{edge}(\text{mdl}, X, Y) \\
E = \text{edge}(..., 'Weights', \text{weights})
\]

**Description**

\[E = \text{edge}(\text{mdl}, \text{tbl}, \text{ResponseVarName})\] returns the classification edge for \( \text{mdl} \) with data \( \text{tbl} \) and classification \( \text{tbl}.\text{ResponseVarName} \). If \( \text{tbl} \) contains the response variable used to train \( \text{mdl} \), then you do not need to specify \( \text{ResponseVarName} \).

The classification edge (\( E \)) is a scalar value that represents the mean of the classification margins on page 32-1157.

\[E = \text{edge}(\text{mdl}, \text{tbl}, Y)\] returns the classification edge for \( \text{mdl} \) with data \( \text{tbl} \) and classification \( Y \).

\[E = \text{edge}(\text{mdl}, X, Y)\] returns the classification edge for \( \text{mdl} \) with data \( X \) and classification \( Y \).

\[E = \text{edge}(..., 'Weights', \text{weights})\] computes the edge with additional observation weights \( \text{weights} \), using any of the input arguments in the previous syntaxes.

**Examples**

**Edge Calculation**

Create a \( k \)-nearest neighbor classifier for the Fisher iris data, where \( k = 5 \).

Load the Fisher iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```matlab
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the edge of the classifier for minimum, mean, and maximum observations classified as 'setosa', 'versicolor', and 'virginica', respectively.

```matlab
NewX = [min(X);mean(X);max(X)];
Y = {'setosa';'versicolor';'virginica'};
E = edge(mdl,NewX,Y)
```

\( E = 1 \)
All five nearest neighbors of each NewX point classify as the corresponding Y entry.

**Input Arguments**

mdl — k-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName or Y.

If you train mdl using sample data contained in a table, then the input data for edge must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in tbl

Response variable name, specified as the name of a variable in tbl. If tbl contains the response variable used to train mdl, then you do not need to specify ResponseVarName.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable is stored as tbl.response, then specify it as 'response'. Otherwise, the software treats all columns of tbl, including tbl.response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of X represents one observation, and each column represents one variable.

Data Types: single | double

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.
weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of variable in tbl

Observation weights, specified as a numeric vector or the name of a variable in tbl.

If you specify weights as a numeric vector, then the size of weights must be equal to the number of rows in X or tbl.

If you specify weights as the name of a variable in tbl, then the name must be a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

If you specify weights, then the edge function weights the observation in each row of X or tbl with the corresponding weight in weights.

Example: 'Weights','w'

Data Types: single | double | char | string

More About

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

The classification margins form a column vector with the same number of rows as X or tbl.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-4144.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Topics

“Classification Using Nearest Neighbors” on page 18-11

Introduced in R2012a
edge

Class: ClassificationLinear
Classification edge for linear classification models

Syntax

e = edge(Mdl,X,Y)
e = edge( ___ ,Name,Value)

Description

e = edge(Mdl,X,Y) returns the classification edges on page 32-1164 for the binary, linear classification model Mdl using predictor data in X and corresponding class labels in Y. e contains a classification edge for each regularization strength in Mdl.

e = edge( ___ ,Name,Value) uses any of the previous syntaxes and additional options specified by one or more Name,Value pair arguments. For example, you can specify that columns in the predictor data correspond to observations or supply observation weights.

Input Arguments

Mdl — Binary, linear classification model
ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using fitclinear.

X — Predictor data
full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix. This orientation of X indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn','columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.
The data type of \( Y \) must be the same as the data type of \( \text{Mdl.ClassNames} \). (The software treats string arrays as cell arrays of character vectors.)

The distinct classes in \( Y \) must be a subset of \( \text{Mdl.ClassNames} \).

If \( Y \) is a character array, then each element must correspond to one row of the array.

The length of \( Y \) and the number of observations in \( X \) must be equal.

Data Types: \text{categorical} | \text{char} | \text{string} | \text{logical} | \text{single} | \text{double} | \text{cell}

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \text{Name,Value} arguments. \text{Name} is the argument name and \text{Value} is the corresponding value. \text{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \text{Name1,Value1,...,NameN,ValueN}.

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** IF you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

**Weights — Observation weights**

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, \text{edge} computes the weighted classification edge on page 32-1164.

Let \( n \) be the number of observations in \( X \).

- \text{numel(Weights)} must be \( n \).
- By default, \text{Weights} is \text{ones}(n,1).

\text{edge} normalizes \text{Weights} to sum up to the value of the prior probability in the respective class.

Data Types: \text{double} | \text{single}

**Output Arguments**

\text{e} — Classification edges

numeric scalar | numeric row vector

Classification edges on page 32-1164, returned as a numeric scalar or row vector.

\( e \) is the same size as \( \text{Mdl.Lambda} \). \( e(j) \) is the classification edge of the linear classification model trained using the regularization strength \( \text{Mdl.Lambda}(j) \).
Examples

Estimate Test-Sample Edge

Load the NLP data set.

```matlab
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```matlab
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to holdout 30% of the observations. Optimize the objective function using SpaRSA.

```matlab
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};
```

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a ClassificationLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

```matlab
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample edges.

```matlab
eTrain = edge(CMdl,X(trainIdx,:),Ystats(trainIdx))
eTrain = 15.6660
```

```matlab
eTest = edge(CMdl,X(testIdx,:),Ystats(testIdx))
eTest = 15.4767
```

Feature Selection Using Test-Sample Edges

One way to perform feature selection is to compare test-sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set.

```matlab
load nlpdata
```
$X$ is a sparse matrix of predictor data, and $Y$ is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages. For quicker execution time, orient the predictor data so that individual observations correspond to columns.

```matlab
Ystats = Y == 'stats';
X = X';
rng(1); % For reproducibility
```

Create a data partition which holds out 30% of the observations for testing.

```matlab
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition); % Test-set indices
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Partition is a `cvpartition` object that defines the data set partition.

Randomly choose half of the predictor variables.

```matlab
p = size(X,1); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Train two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```matlab
CVMdl = fitclinear(X,Ystats,'CVPartition',Partition,'Solver','sparsa',...  'ObservationsIn','columns');
PCVMdl = fitclinear(X(idxPart,:),Ystats,'CVPartition',Partition,'Solver','sparsa',...  'ObservationsIn','columns');
```

CVMdl and PCVMdl are `ClassificationPartitionedLinear` models.

Extract the trained `ClassificationLinear` models from the cross-validated models.

```matlab
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(CMdl,XTest,YTest,'ObservationsIn','columns')
fullEdge = 15.4767
partEdge = edge(PCMdl,XTest(idxPart,:),YTest,'ObservationsIn','columns')
partEdge = 13.4458
```

Based on the test-sample edges, the classifier that uses all of the predictors is the better model.
Find Good Lasso Penalty Using Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using Test-Sample Edges” on page 32-1160.

```matlab
load nlpdata
Ystats = Y == 'stats';
X = X';

Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-8}$ through $10^{1}$.

```matlab
Lambda = logspace(-8,1,11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $10^{-8}$.

```matlab
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

Extract the trained linear classification model.

```matlab
Mdl = CVMdl.Trained{1}
```

```matlab
Mdl = 
    ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
    Beta: [34023x11 double]
    Bias: [1x11 double]
    Lambda: [1x11 double]
    Learner: 'logistic'
```
Properties, Methods

Mdl is a ClassificationLinear model object. Because Lambda is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in Lambda.

Estimate the test-sample edges.

\[
e = \text{edge}(Mdl, X(:,testIdx), Ystats(testIdx), 'ObservationsIn', 'columns')
\]

\[
e = [0.9986, 0.9986, 0.9986, 0.9986, 0.9986, 0.9932, 0.9766, 0.9202, 0.8337, 0.8128, 0.8128]
\]

Because there are 11 regularization strengths, e is a 1-by-11 vector of edges.

Plot the test-sample edges for each regularization strength. Identify the regularization strength that maximizes the edges over the grid.

\[
\text{figure; plot(log10(Lambda), log10(e), '-o')}
\]

\[
[~, \text{maxEIdx}] = \text{max}(e);
\]

\[
\text{maxLambda} = \text{Lambda}(\text{maxEIdx});
\]

\[
\text{hold on; plot(log10(maxLambda), log10(e(maxEIdx)), 'ro');}
\]

\[
\text{ylabel('log}_{10} \text{ test-sample edge')}
\]

\[
\text{xlabel('log}_{10} \text{ Lambda')}
\]

\[
\text{legend('Edge', 'Max edge')}
\]

\[
\text{hold off}
\]
Several values of \( \text{Lambda} \) yield similarly high edges. Higher values of \( \text{lambda} \) lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

\[
\text{LambdaFinal} = \text{Lambda}(5);
\]

Train a linear classification model using the entire data set and specify the regularization strength yielding the maximal edge.

\[
\text{MdlFinal} = \text{fitclinear}(X,Y\text{stats},'\text{ObservationsIn}','\text{columns}',...
   '\text{Learner}','\text{logistic}','\text{Solver}','\text{sparsa}','\text{Regularization}','\text{lasso}',...
   '\text{Lambda}',\text{LambdaFinal});
\]

To estimate labels for new observations, pass \( \text{MdlFinal} \) and the new data to \text{predict}.

**More About**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.
**Classification Margin**

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. \( f(x) \) is the positive-class classification score for the observation x. The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

For linear classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

\[ f_j(x) = x\beta_j + b_j. \]

For the model with regularization strength \( j \), \( \beta_j \) is the estimated column vector of coefficients (the model property Beta(,:,j)) and \( b_j \) is the estimated, scalar bias (the model property Bias(j)).

The raw classification score for classifying x into the negative class is \(-f(x)\). The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see ScoreTransform).

**Algorithms**

By default, observation weights are prior class probabilities. If you supply weights using Weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the normalized weights to estimate the weighted edge.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**See Also**

ClassificationLinear fitlinear margin predict

Introduce in R2016a
edge

Classification edge

Syntax

E = edge(obj,X,Y)
E = edge(obj,X,Y,Name,Value)

Description

E = edge(obj,X,Y) returns the classification edge for obj with data X and classification Y.

E = edge(obj,X,Y,Name,Value) computes the edge with additional options specified by one or more Name,Value pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with fitcdiscr.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in obj.

Y

Class labels, with the same data type as exists in obj. The number of elements of Y must equal the number of rows of X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

weights

Observation weights, a numeric vector of length size(X,1). If you supply weights, edge computes the weighted classification edge.

Default: ones(size(X,1),1)

Output Arguments

E

Edge, a scalar representing the weighted average value of the margin.
Examples

Compute the classification edge and margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
E = edge(obj,X,species)

E =
 0.4980

M = margin(obj,X,species);
M(end-10:end)

ans =
 0.6551
 0.4838
 0.6551
 -0.5127
 0.5659
 0.4611
 0.4949
 0.1024
 0.2787
 -0.1439
 -0.4444

The classifier trained on all the data is better:

obj = fitcdiscr(meas,species);
E = edge(obj,meas,species)

E =
 0.9454

M = margin(obj,meas,species);
M(end-10:end)

ans =
 0.9983
 1.0000
 0.9991
 0.9978
 1.0000
 1.0000
 0.9999
 0.9882
 0.9937
 1.0000
 0.9649
More About

Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X. A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

edge

Package:

Classification edge for multiclass error-correcting output codes (ECOC) model

Syntax

e = edge(Mdl,tbl,ResponseVarName)
e = edge(Mdl,tbl,Y)
e = edge(Mdl,X,Y)
e = edge(___,Name,Value)

Description

e = edge(Mdl,tbl,ResponseVarName) returns the classification edge on page 32-1176 (e) for the trained multiclass error-correcting output codes (ECOC) classifier Mdl using the predictor data in table tbl and the class labels in tbl.ResponseVarName.

e = edge(Mdl,tbl,Y) returns the classification edge for the classifier Mdl using the predictor data in table tbl and the class labels in vector Y.

e = edge(Mdl,X,Y) returns the classification edge (e) for the classifier Mdl using the predictor data in matrix X and the class labels in vector Y.

e = edge(___,Name,Value) specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Test-Sample Edge of ECOC Model

Compute the test-sample classification edge of an ECOC model with SVM binary classifiers.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

Train an ECOC model using SVM binary classifiers. Specify a 30% holdout sample for testing, standardize the predictors using an SVM template, and specify the class order.
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training data.

Compute the test-sample edge.

testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);   
YTest = Y(testInds,:);   
e = edge(Mdl,XTest,YTest)

In [158]:
e = 0.4573

The average of the test-sample margins is approximately 0.46.

Mean of Test-Sample Weighted Margins of ECOC Model

Compute the mean of the test-sample weighted margins of an ECOC model.

Suppose that the observations in a data set are measured sequentially, and that the last 75 observations have better quality due to a technology upgrade. Incorporate this advancement by giving the better quality observations more weight than the other observations.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

load fisheriris
X = meas;   
Y = categorical(species); 
classOrder = unique(Y); % Class order 
rng(1); % For reproducibility

Define a weight vector that assigns twice as much weight to the better quality observations.

n = size(X,1); 
weights = [ones(n-75,1);2*ones(75,1)];

Train an ECOC model using SVM binary classifiers. Specify a 30% holdout sample and the weighting scheme. Standardize the predictors using an SVM template, and specify the class order.

t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Weights',weights,... 
'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier

PMdl is a trained ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC classifier that the software trained using the training data.

Compute the test-sample weighted edge using the weighting scheme.
testInds = test(PMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
e = edge(Mdl,XTest,YTest,'Weights',wTest)

e = 0.4798

The average weighted margin of the test sample is approximately 0.48.

**Select ECOC Model Features by Comparing Test-Sample Edges**

Perform feature selection by comparing test-sample edges from multiple models. Based solely on this comparison, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```matlab
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- fullX contains all predictors.
- partX contains the petal dimensions only.

```matlab
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set. Specify the partition definition, standardize the predictors using an SVM template, and specify the class order.

```matlab
t = templateSVM('Standardize',true);
fullPMdl = fitcecoc(fullX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
partPMdl = fitcecoc(partX,Y,'CVPartition',Partition,'Learners',t,...
    'ClassNames',classOrder);
fullMdl = fullPMdl.Trained{1};
partMdl = partPMdl.Trained{1};
```

fullPMdl and partPMdl are ClassificationPartitionedECOC models. Each model has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the corresponding training set.
Calculate the test-sample edge for each classifier.

```matlab
fullEdge = edge(fullMdl,XTest,YTest)
fullEdge = 0.4573
partEdge = edge(partMdl,XTest(:,3:4),YTest)
partEdge = 0.4839
```

`partMdl` yields an edge value comparable to the value for the more complex model `fullMdl`.

**Input Arguments**

- **Mdl** — Full or compact multiclass ECOC model
  - `ClassificationECOC` model object | `CompactClassificationECOC` model object
  Full or compact multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.
  To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

- **tbl** — Sample data
  - `table`
  Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.
  If you train `Mdl` using sample data contained in a table, then the input data for `edge` must also be in a table.

**Note**
If `Mdl.BinaryLearners` contains linear or kernel classification models (`ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a table. Instead, pass a matrix (`X`) and class labels (`Y`).

When training `Mdl`, assume that you set 'Standardize', `true` for a template object specified in the 'Learners' name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

**Data Types: table**

- **ResponseVarName** — Response variable name
  - `name of variable in tbl`
  Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.  

32-1172
If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `tbl.y`, then specify `ResponseVarName` as 'y'. Otherwise, the software treats all columns of `tbl`, including `tbl.y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

**X — Predictor data**
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. The variables in the columns of `X` must be the same as the variables that trained the classifier `Mdl`.

The number of rows in `X` must equal the number of rows in `Y`.

When training `Mdl`, assume that you set 'Standardize',true for a template object specified in the 'Learners' name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `double` | `single`

**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must have the same data type as `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The number of rows in `Y` must equal the number of rows in `tbl` or `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `edge(Mdl,X,Y,'BinaryLoss','exponential','Decoding','lossbased')` specifies an exponential binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

**BinaryLoss — Binary learner loss function**

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.
This table describes the built-in functions, where $y_j$ is a class label for a particular binary learner (in the set \{-1,1,0\}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$ is the binary loss formula.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-2y_js_j)]/\log(2)$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty,\infty)$</td>
<td>$\exp(-y_js_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty,\infty)$</td>
<td>$[1 - \text{sign}(y_js_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty,\infty)$</td>
<td>$\max(0,1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty,\infty)$</td>
<td>$(1 - y_js_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty,\infty)$</td>
<td>$\log[1 + \exp(-y_js_j)]/\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss','@customFunction'.

`customFunction` has this form:

```matlab
bLoss = customFunction(M,s)
```

where:

- $M$ is the $K$-by-$L$ coding matrix stored in `Mdl.CodingMatrix`.
- $s$ is the 1-by-$L$ row vector of classification scores.
- $bLoss$ is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- $K$ is the number of classes.
- $L$ is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-4169.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>All binary learners are SVMs or either linear or kernel</td>
<td>'hinge'</td>
</tr>
<tr>
<td>classification models of SVM learners.</td>
<td></td>
</tr>
<tr>
<td>All binary learners are ensembles trained by AdaboostM1 or GentleBoost.</td>
<td>'exponential'</td>
</tr>
<tr>
<td>All binary learners are ensembles trained by LogitBoost.</td>
<td>'binodeviance'</td>
</tr>
<tr>
<td>Assumption</td>
<td>Default Value</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior', true in fitcecoc.</td>
<td>'quadratic'</td>
</tr>
</tbody>
</table>

To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

**Decoding — Decoding scheme**

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-1176.

Example: 'Decoding', 'lossbased'

**ObservationsIn — Predictor data observation dimension**

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. Mdl.BinaryLearners must contain ClassificationLinear models.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', you can experience a significant reduction in execution time.

**Options — Estimation options**

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', statset('UseParallel', true).

**Verbose — Verbosity level**

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1
Data Types: single | double

Weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. If you supply weights, edge computes the weighted classification edge on page 32-1176.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of observations in X or tbl. The software normalizes Weights to sum up to the value of the prior probability in the respective class.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify Weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.

Data Types: single | double | char | string

Output Arguments

e — Classification edge
numeric scalar | numeric vector

Classification edge on page 32-1176, returned as a numeric scalar or vector. e represents the weighted mean of the classification margins on page 32-1176.

If Mdl.BinaryLearners contains ClassificationLinear models, then e is a 1-by-L vector, where L is the number of regularization strengths in the linear classification models (numel(Mdl.BinaryLearners{1}.Lambda)). The value e(j) is the edge for the model trained using regularization strength Mdl.BinaryLearners{1}.Lambda(j).

Otherwise, e is a scalar value.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.
Suppose the following:

- $m_{kj}$ is element $(k,j)$ of the coding design matrix $M$ (that is, the code corresponding to class $k$ of binary learner $j$).
- $s_j$ is the score of binary learner $j$ for an observation.
- $g$ is the binary loss function.
- $\hat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \arg\min_k \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where $y_j$ is a class label for a particular binary learner (in the set \{-1,1,0\}), $s_j$ is the score for observation $j$, and $g(y_j,s_j)$.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Score Domain</th>
<th>$g(y_j,s_j)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binodeviance'</td>
<td>Binomial deviance</td>
<td>$(-\infty, \infty)$</td>
<td>$\log[1 + \exp(-2y_j s_j)]/2\log(2)$</td>
</tr>
<tr>
<td>'exponential'</td>
<td>Exponential</td>
<td>$(-\infty, \infty)$</td>
<td>$\exp(-y_j s_j)/2$</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming</td>
<td>$[0,1]$ or $(-\infty, \infty)$</td>
<td>$[1 - \text{sign}(y_j s_j)]/2$</td>
</tr>
<tr>
<td>'hinge'</td>
<td>Hinge</td>
<td>$(-\infty, \infty)$</td>
<td>$\max(0,1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear</td>
<td>$(-\infty, \infty)$</td>
<td>$(1 - y_j s_j)/2$</td>
</tr>
<tr>
<td>'logit'</td>
<td>Logistic</td>
<td>$(-\infty, \infty)$</td>
<td>$\log[1 + \exp(-y_j s_j)]/2\log(2)$</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Quadratic</td>
<td>$[0,1]$</td>
<td>$[1 - y_j(2s_j - 1)]^2/2$</td>
</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.
Tips

• To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to this function.

For example: 'Options', statset('UseParallel',true)

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b
**edge**

Classification edge

**Syntax**

\[ E = \text{edge}(\text{ens}, \text{tbl}, \text{ResponseVarName}) \]
\[ E = \text{edge}(\text{ens}, \text{tbl}, Y) \]
\[ E = \text{edge}(\text{ens}, X, Y) \]
\[ E = \text{edge}(\_, \text{Name}, \text{Value}) \]

**Description**

\[ E = \text{edge}(\text{ens}, \text{tbl}, \text{ResponseVarName}) \] returns the classification edge for \( \text{ens} \) with data \( \text{tbl} \) and classification \( \text{tbl.ResponseVarName} \).

\[ E = \text{edge}(\text{ens}, \text{tbl}, Y) \] returns the classification edge for \( \text{ens} \) with data \( \text{tbl} \) and classification \( Y \).

\[ E = \text{edge}(\text{ens}, X, Y) \] returns the classification edge for \( \text{ens} \) with data \( X \) and classification \( Y \).

\[ E = \text{edge}(\_, \text{Name}, \text{Value}) \] computes the edge with additional options specified by one or more \( \text{Name}, \text{Value} \) pair arguments, using any of the previous syntaxes.

**Input Arguments**

**\( \text{ens} \)**

A classification ensemble constructed with \texttt{fitensemble}, or a compact classification ensemble constructed with \texttt{compact}.

**\( \text{tbl} \)**

Sample data, specified as a table. Each row of \( \text{tbl} \) corresponds to one observation, and each column corresponds to one predictor variable. \( \text{tbl} \) must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained \( \text{ens} \) using sample data contained in a \texttt{table}, then the input data for this method must also be in a table.

**\( \text{ResponseVarName} \)**

Response variable name, specified as the name of a variable in \( \text{tbl} \).

You must specify \( \text{ResponseVarName} \) as a character vector or string scalar. For example, if the response variable \( Y \) is stored as \( \text{tbl.Y} \), then specify it as 'Y'. Otherwise, the software treats all columns of \( \text{tbl} \), including \( Y \), as predictors when training the model.

**\( X \)**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in \( X \) must equal the number of predictors in \( \text{ens} \).
If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Y`

Class labels of observations in `tbl` or `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or `X`.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `edge` uses only these learners for calculating loss.

**Default:** 1:NumTrained

`mode`

Meaning of the output `E`:

- `'ensemble'` — `E` is a scalar value, the edge for the entire ensemble.
- `'individual'` — `E` is a vector with one element per trained learner.
- `'cumulative'` — `E` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** `'ensemble'`

`UseObsForLearner`

A logical matrix of size `N`-by-`T`, where:

- `N` is the number of rows of `X`.
- `T` is the number of weak learners in `ens`.

When `UseObsForLearner(i,j)` is `true`, learner `j` is used in predicting the class of row `i` of `X`.

**Default:** `true(N,T)`

`weights`

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes weighted classification edge.

**Default:** `ones(size(X,1),1)`
**Output Arguments**

\( E \)

The classification edge, a vector or scalar depending on the setting of the `mode` name-value pair. Classification edge is weighted average classification margin.

**Examples**

**Find Classification Edge of Training Data**

Find the classification edge for some of the data used to train a boosted ensemble classifier.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Train an ensemble of 100 boosted classification trees using AdaBoostM1.

```matlab
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ess = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Find the classification edge for the last few rows.

```matlab
E = edge(ens,X(end-10:end,:),Y(end-10:end))
```

\( E = 8.3310 \)

**More About**

**Margin**

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix \( X \).

**Score (ensemble)**

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from \(-\infty\) to \(\infty\).
- Bag scores range from \(0\) to \(1\).

**Edge**

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`. If you supply weights in the `weights` name-value pair, those weights are used instead of class probabilities.

edge

Classification edge for naive Bayes classifiers

Syntax

e = edge(Mdl,tbl,ResponseVarName)
e = edge(Mdl,tbl,Y)
e = edge(Mdl,X,Y)
e = edge(___,Name,Value)

Description

e = edge(Mdl,tbl,ResponseVarName) returns the classification edge on page 32-1187 (e) for
the naive Bayes classifier Mdl using the predictor data in table tbl and the class labels in
tbl.ResponseVarName.

e = edge(Mdl,tbl,Y) returns the classification edge (e) for the naive Bayes classifier Mdl using
predictor data in table tbl and the class labels in vector Y.

e = edge(Mdl,X,Y) returns the classification edge on page 32-1187 (e) for the naive Bayes
classifier Mdl using predictor data X and class labels Y.

e = edge(___,Name,Value) computes the classification edge with additional options specified by
one or more Name,Value pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier
ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or
CompactClassificationNaiveBayes model returned by fitcnb or compact, respectively.

tbl — Sample data
table

Sample data, specified as a table. Each row of tbl corresponds to one observation, and each column
corresponds to one predictor variable. Optionally, tbl can contain additional columns for the
response variable and observation weights. tbl must contain all the predictors used to train Mdl.
Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained Mdl using sample data contained in a table, then the input data for this method must
also be in a table.

Data Types: table

ResponseVarName — Response variable name
name of a variable in tbl
Response variable name, specified as the name of a variable in tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored as tbl.y, then specify it as 'y'. Otherwise, the software treats all columns of tbl, including y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained Mdl.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y and the number of rows of tbl or X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in tbl. The software weighs the observations in each row of X or tbl with the corresponding weight in Weights.

If you specify Weights as a vector, then the size of Weights must be equal to the number of rows of X or tbl.

If you specify Weights as the name of a variable in tbl, you must do so as a character vector or string scalar. For example, if the weights are stored as tbl.w, then specify Weights as 'w'. Otherwise, the software treats all columns of tbl, including tbl.w, as predictors.
If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: `double` | `char` | `string`

**Output Arguments**

- **e** — **Classification edge**
  - **scalar**

  Classification edge on page 32-1187, returned as a scalar. If you supply `Weights`, then `e` is the weighted classification edge.

**Examples**

### Estimate the Test Sample Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);      % For reproducibility
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```matlab
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1};          % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge.

```matlab
e = edge(CMdl,XTest,YTest)
e = 0.8244
```

The estimated test sample margin average is approximately 0.82. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.82. This indicates that the classifier labels with high confidence.

### Estimate the Test Sample Weighted Margin Mean of Naive Bayes Classifiers

Load Fisher's iris data set.
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);

Suppose that the setosa iris measurements are lower quality because they were measured with an older technology. One way to incorporate this is to weigh the setosa iris measurements less than the other observations.

Define a weight vector that weighs the better quality observations twice the other observations.

n = size(X,1);
idx = strcmp(Y,'setosa');
weights = ones(size(X,1),1);
weights(idx) = 0.5;

Train a naive Bayes classifier. Specify the weighting scheme and a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

CVMdl = fitcnb(X,Y,'Weights',weights,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1};          % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
wTest = weights(testInds);

CVMdl is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationNaiveBayes classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

e = edge(CMdl,XTest,YTest,'Weights',wTest)
e = 0.7893

The test sample weighted average margin is approximately 0.79. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.79. This indicates that the classifier labels with high confidence.

Select Naive Bayes Classifier Features by Comparing Test Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:
- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```matlab
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```matlab
FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

`FCVMdl` and `PCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(FCMdl,XTest,YTest)
fullEdge = 0.8244
partEdge = edge(PCMdl,XTest(:,3:4),YTest)
partEdge = 0.8420
```

The test-sample edges of the classifiers are nearly the same. However, the model trained using two predictors (`PCMdl`) is less complex.

**More About**

**Classification Edge**

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

**Classification Margins**

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve
as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

**Posterior Probability**

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is \( k \) for a given observation \((x_1, ..., x_p)\) is

\[
\hat{P}(Y = k | x_1, ..., x_p) = \frac{P(X_1, ..., X_p | y = k) \pi(Y = k)}{P(X_1, ..., X_p)}
\]

where:
- \( P(X_1, ..., X_p | y = k) \) is the conditional joint density of the predictors given they are in class \( k \). `Mdl.DistributionNames` stores the distribution names of the predictors.
- \( \pi(Y = k) \) is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- \( P(X_1, ..., X_p) \) is the joint density of the predictors. The classes are discrete, so

\[
P(X_1, ..., X_p) = \sum_{k = 1}^{K} P(X_1, ..., X_p | y = k) \pi(Y = k).
\]

**Prior Probability**

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

**Score**

The naive Bayes score is the class posterior probability given the observation.

**Extended Capabilities**

edge

Package: classreg.learning.classif

Find classification edge for support vector machine (SVM) classifier

Syntax

e = edge(SVMModel,TBL,ResponseVarName)
e = edge(SVMModel,TBL,Y)
e = edge(SVMModel,X,Y)
e = edge( ___ ,’Weights’,weights)

Description

e = edge(SVMModel,TBL,ResponseVarName) returns the classification edge on page 32-1193 (e) for the support vector machine (SVM) classifier SVMModel using the predictor data in table TBL and the class labels in TBL.ResponseVarName.

The classification edge (e) is a scalar value that represents the weighted mean of the classification margins on page 32-1193.

e = edge(SVMModel,TBL,Y) returns the classification edge on page 32-1193 (e) for the SVM classifier SVMModel using the predictor data in table TBL and the class labels in Y.

e = edge(SVMModel,X,Y) returns the classification edge for SVMModel using the predictor data in matrix X and the class labels in Y.

e = edge( ___ ,’Weights’,weights) computes the classification edge for the observation weights supplied in weights using any of the input arguments in the previous syntaxes.

Examples

Estimate Test Sample Edge of SVM Classifiers

Load the ionosphere data set.

load ionosphere
rng(1); % For reproducibility

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that ’g’ is the positive class.

CVSVMModel = fitcsvm(X,Y,’Holdout’,0.15,’ClassNames’ ,{‘b’,’g’},…
  ’Standardize’,true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample edge.

\[
e = \text{edge}(\text{CompactSVMModel}, X\text{Test}, Y\text{Test})
\]

\[
e = 5.0765
\]

The margin average of the test sample is approximately 5.

**Estimate Test Sample Weighted Margin Mean of SVM Classifiers**

Suppose that the observations in a data set are measured sequentially, and that the last 150 observations have better quality due to a technology upgrade. Incorporate this advancement by weighing the better quality observations more than the other observations.

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Define a weight vector that weighs the better quality observations two times the other observations.

```matlab
n = size(X,1);
weights = [ones(n-150,1);2*ones(150,1)];
```

Train an SVM classifier. Specify the weighting scheme and a 15% holdout sample for testing. Also, standardize the data and specify that 'g' is the positive class.

```matlab
CVSVMModel = fitcsvm(X,Y,'Weights',weights,'Holdout',0.15,...
    'ClassNames',{'b','g'},'Standardize',true);
```

```matlab
CompactSVMModel = CVSVMModel.Trained{1};
```

```matlab
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```

CVSVMModel is a trained ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```matlab
e = edge(CompactSVMModel,XTest,YTest,'Weights',wTest)
```

\[
e = 4.8341
\]

The weighted average margin of the test sample is approximately 5.
Select SVM Classifier Features by Comparing Test Sample Edges

Perform feature selection by comparing test sample edges from multiple models. Based solely on this comparison, the classifier with the highest edge is the best classifier.

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```matlab
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```matlab
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```matlab
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```matlab
fullEdge = edge(FCSVMModel,XTest,YTest)
fullEdge = 2.8319
```

```matlab
partEdge = edge(PCSVMModel,XTest(:,end-20:end),YTest)
partEdge = 1.5540
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors is better.

**Input Arguments**

- `SVMModel` — SVM classification model
  - `ClassificationSVM` model object
  - `CompactClassificationSVM` model object
SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

**TBL — Sample data**

Table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMModel using sample data contained in a table, then the input data for edge must also be in a table.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: table

**X — Predictor data**

Numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMModel classifier.

The length of Y and the number of rows in X must be equal.

If you set 'Standardize',true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: double | single

**ResponseVarName — Response variable name**

Name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify ResponseVarName as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.Response, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.
Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of SVMModel.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

The length of Y must equal the number of rows in TBL or the number of rows in X.

weights — Observation weights
ones(size(X,1),1) (default) | numeric vector | name of variable in TBL

Observation weights, specified as a numeric vector or the name of a variable in TBL.

If you specify weights as a numeric vector, then the size of weights must be equal to the number of rows in X or TBL.

If you specify weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.W, then specify weights as 'W'. Otherwise, the software treats all columns of TBL, including TBL.W, as predictors.

If you supply weights, edge computes the weighted classification edge on page 32-1193. The software weights the observations in each row of X or TBL with the corresponding weight in weights.

Example: 'Weights','W'

Data Types: single | double | char | string

More About

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

\[ m = 2yf(x). \]
x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. f(x) is the positive-class classification score for the observation x. The classification margin is commonly defined as \( m = yf(x) \).

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

**Classification Score**

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from \(-\infty\) to \(+\infty\). A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score \( f(x) \) is the trained SVM classification function. \( f(x) \) is also the numerical, predicted response for x, or the score for predicting x into the positive class.

\[
f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,
\]

where \((\alpha_1, ..., \alpha_n, b)\) are the estimated SVM parameters, \( G(x_j, x) \) is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x, or the score for predicting x into the negative class, is \(-f(x)\).

If \( G(x_j, x) = x_j'x \) (the linear kernel), then the score function reduces to

\[
f(x) = (x/s)'\beta + b.
\]

s is the kernel scale and \( \beta \) is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-145.

**Algorithms**

For binary classification, the software defines the margin for observation j, \( m_j \), as

\[
m_j = 2y_jf(x_j),
\]

where \( y_j \in \{-1,1\} \), and \( f(x_j) \) is the predicted score of observation j for the positive class. However, \( m_j = y_jf(x_j) \) is commonly used to define the margin.

**References**

Introduced in R2014a
**edge**

Classification edge

**Syntax**

```
E = edge(tree,TBL,ResponseVarName)
E = edge(tree,X,Y)
E = edge(____,Name,Value)
```

**Description**

`E = edge(tree,TBL,ResponseVarName)` returns the classification edge for `tree` with data `TBL` and classification `TBL.ResponseVarName`.

`E = edge(tree,X,Y)` returns the classification edge for `tree` with data `X` and classification `Y`.

`E = edge(____,Name,Value)` computes the edge with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights.

**Input Arguments**

- **tree** — Trained classification tree
  
  ClassificationTree model object | CompactClassificationTree model object

  Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

- **TBL** — Sample data
  
  table

  Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

  If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

  If you train `tree` using sample data contained in a table, then the input data for this method must also be in a table.

  Data Types: table

- **X** — Data to classify
  
  numeric matrix

  Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`. 

32-1196
Data Types: single | double

**ResponseVarName — Response variable name**

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: categorical | char | string | logical | single | double | cell

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Weights — Observation weights**

`ones(size(X,1),1)` (default) | name of a variable in TBL | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in TBL.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `TBL`.

If you specify `Weights` as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

If you supply weights, `edge` computes the weighted classification edge on page 32-1193. The software weights the observations in each row of `X` or `TBL` with the corresponding weight in `Weights`.

Data Types: single | double | char | string
Output Arguments

E — Classification edge
scalar value

Classification edge, returned as a scalar representing the weighted average value of the margin.

Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```matlab
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
E = edge(tree,X,species)

E =
    0.6299

M = margin(tree,X,species);
M(end-10:end)

ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000

The classification tree trained on all the data is better.

tree = fitctree(meas,species);
E = edge(tree,meas,species)

E =
    0.9384

M = margin(tree,meas,species);
M(end-10:end)

ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```
More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix $X$.

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor $X$ as true when $X < 0.15$ or $X > 0.95$, and $X$ is false otherwise.

Generate 100 random points and classify them:

```matlab
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```
Prune the tree:

```matlab
treel1 = prune(tree,'Level',1);
view(treel1,'Mode','Graph')
```
The pruned tree correctly classifies observations that are less than 0.15 as \textit{true}. It also correctly classifies observations from .15 to .94 as \textit{false}. However, it incorrectly classifies observations that are greater than .94 as \textit{false}. Therefore, the score for observations that are greater than .15 should be about \(0.05/0.85=0.06\) for \textit{true}, and about \(0.8/0.85=0.94\) for \textit{false}.

Compute the prediction scores for the first 10 rows of \(X\):

\[
[-,score] = \text{predict}(tree1, X(1:10));
\]

\[
\text{[score } X(1:10,:)]
\]

\[
\text{ans} = 10 \times 3
\]

\[
\begin{array}{ccc}
0.9059 & 0.0941 & 0.8147 \\
0.9059 & 0.0941 & 0.9058 \\
0 & 1.0000 & 0.1270 \\
0.9059 & 0.0941 & 0.9134 \\
0.9059 & 0.0941 & 0.6324 \\
0 & 1.0000 & 0.0975 \\
0.9059 & 0.0941 & 0.2785 \\
0.9059 & 0.0941 & 0.5469 \\
0.9059 & 0.0941 & 0.9575
\end{array}
\]
Indeed, every value of $X$ (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of $X$ have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in $X$ in the range $(.95, 1)$ instead of the expected 5 observations.

**Edge**

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in tree.Prior. If you supply weights in the weights name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

**See Also**

fitctree | loss | margin | predict
end

Class: dataset

(Not Recommended) Last index in indexing expression for dataset array

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

end(A,k,n)

Description

end(A,k,n) is called for indexing expressions involving the dataset A when end is part of the k-th index out of n indices. For example, the expression A(end-1,:) calls A's end method with end(A,1,2).

size
epsilon

Class: RepeatedMeasuresModel

Epsilon adjustment for repeated measures anova

Syntax

tbl = epsilon(rm)
tbl = epsilon(rm,C)

Description

tbl = epsilon(rm) returns the epsilon adjustment factors for repeated measures model rm.

tbl = epsilon(rm,C) returns the epsilon adjustment factors for the test based on the contrast matrix C.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts
matrix

Contrasts, specified as a matrix. The default value of C is the Q factor in a QR decomposition of the matrix M, where M is defined so that Y*M is the difference between all successive pairs of columns of the repeated measures matrix Y.

Data Types: single | double

Output Arguments

tbl — Epsilon adjustment factors
table

Epsilon adjustment factors for the repeated measures model rm, returned as a table. tbl contains four different adjustments for epsilon.

For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 9-55.

Data Types: table

**Examples**

**Epsilon Corrections for Repeated Measures ANOVA**

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  'VariableNames',{'species','meas1','meas2','meas3','meas4'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl = 3x8 table

```

32-1205
You can check the compound symmetry (sphericity) assumption using the `mauchly` method.

**Tips**
- The `mauchly` method tests for sphericity.
- The `ranova` method contains p-values based on each epsilon value.

**Algorithms**

`ranova` computes the regular p-value (in the `pValue` column of the `rmanova` table) using the F-statistic cumulative distribution function:

\[
p-value = 1 - \text{fcdf}(F, v_1, v_2).
\]

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor epsilon, \(\varepsilon\), to compute the corrected p-values as follows:

\[
p-value_{corrected} = 1 - \text{fcdf}(F, \varepsilon v_1, \varepsilon v_2).
\]

The `epsilon` method returns the epsilon adjustment values.

**evcdf**

Extreme value cumulative distribution function

**Syntax**

```matlab
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf(___,'upper')
```

**Description**

`p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

```matlab
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
```

returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100*(1 - alpha)% confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

```matlab
[p,plo,pup] = evcdf(___, 'upper')
```

returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the ‘upper’ argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

\[
\frac{X - \hat{\mu}}{\hat{\sigma}}
\]

and then transforming those bounds to the scale of the output `P`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X` and subtracting the resulting distribution values from 1. See “Extreme Value Distribution” on page B-40 for more details. If `x` has a Weibull distribution, then \(X = \log(x)\) has the type 1 extreme value distribution.

**Extended Capabilities**

evfit

Extreme value parameter estimates

Syntax

parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)

Description

parmhat = evfit(data) returns maximum likelihood estimates of the parameters of the type 1 extreme value distribution given the sample data in data. The sample data data must be a double-precision vector. parmhat(1) is the location parameter \( \mu \), and parmhat(2) is the scale parameter \( \sigma \).

[parmhat,parmci] = evfit(data,alpha) returns 95\% confidence intervals for the parameter estimates on the \( \mu \) and \( \sigma \) parameters in the 2-by-2 matrix parmci. The first column of the matrix of the extreme value fit contains the lower and upper confidence bounds for the parameter \( \mu \), and the second column contains the confidence bounds for the parameter \( \sigma \).

[parmhat,parmci] = evfit(data,alpha) returns 100(1 - alpha)\% confidence intervals for the parameter estimates, where alpha is a value in the range \([0 1]\) specifying the width of the confidence intervals. By default, alpha is 0.05, which corresponds to 95\% confidence intervals.

[...] = evfit(data,alpha,censoring) accepts a Boolean vector, censoring, of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

[...] = evfit(data,alpha,censoring,freq) accepts a frequency vector, freq of the same size as data. Typically, freq contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for alpha, censoring, or freq to use their default values.

[...] = evfit(data,alpha,censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. You can create options using the function statset. Enter statset('evfit') to see the names and default values of the parameters that evfit accepts in the options structure. See the reference page for statset for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating \( X \). See "Extreme Value Distribution" on page B-40 for more details. If \( x \) has a Weibull distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.
Extended Capabilities

Topics
“Extreme Value Distribution” on page B-40

Introduced before R2006a
**evinv**

Extreme value inverse cumulative distribution function

**Syntax**

```
X = evinv(P,mu,sigma)
[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)
```

**Description**

`X = evinv(P,mu,sigma)` returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

```
[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)
```
produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` is a scalar that specifies $100(1 - \alpha)\%$ confidence bounds for the estimated parameters, and has a default value of 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `evinv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$
\hat{\mu} + \hat{\sigma} q
$$

where `q` is the `P`th quantile from an extreme value distribution with parameters $\mu = 0$ and $\sigma = 1$. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See "Extreme Value Distribution" on page B-40 for more details. If `x` has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

Introduced before R2006a
eq

Class: qrandstream
Test handle equality

Syntax

h1 == h2
tf = eq(h1, h2)

Description

h1 == h2 performs element-wise comparisons between handle arrays h1 and h2. h1 and h2 must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of h1 or h2 is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

tf = eq(h1, h2) stores the result in a logical array of the same dimensions.

See Also
ge|gt|le|lt|ne|qrandstream
error

Class: CompactTreeBagger

Error (misclassification probability or MSE)

Syntax

err = error(B,TBLnew,Ynew)
err = error(B,Xnew,Ynew)
err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)

Description

err = error(B,TBLnew,Ynew) computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for the predictors contained in the table TBLnew given true response Ynew. You can omit Ynew if TBLnew contains the response variable. If you trained B using sample data contained in a table, then the input data for this method must also be in a table.

err = error(B,Xnew,Ynew) computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, the for predictors contained in the matrix Xnew given true response Ynew. If you trained B using sample data contained in a matrix, then the input data for this method must also be in a matrix.

For classification, Ynew can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector, or logical vector. For regression, Y must be a numeric vector.

err is a vector with one error measure for each of the NTrees trees in the ensemble B.

err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...) or err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...) specifies optional parameter name-value pairs:

<table>
<thead>
<tr>
<th>'Mode'</th>
<th>Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Weights'</td>
<td>Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.</td>
</tr>
</tbody>
</table>
'Trees' | Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.

'TreeWeights' | Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.

'UseInstanceForTree' | Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

### Algorithms

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
  - The error for individual trees in the ensemble
  - The cumulative error over all trees
  - The error for the entire ensemble
- Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
- Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
- Using the 'Weights' name-value pair argument, you can attribute each observation with a weight. For the formulae that follow, \( w_j \) is the weight of observation \( j \).
- Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

For regression problems, \( \text{error} \) estimates the weighted MSE of the ensemble of bagged regression trees for predicting \( Y \) given \( X \) using selected trees and observations.

1. \( \text{error} \) predicts responses for selected observations in \( X \) using the selected regression trees in the ensemble.
2. The MSE estimate depends on the value of 'Mode'.

- If you specify 'Mode', 'Individual', then the weighted MSE for tree \( t \) is

\[
\text{MSE}_t = \frac{1}{n} \sum_{j=1}^{n} w_j (y_j - \hat{y}_{tj})^2.
\]
\( \hat{y}_{tj} \) is the predicted response of observation \( j \) from selected regression tree \( t \). \texttt{error} sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Cumulative', then the weighted MSE is a vector of size \( T^* \) containing cumulative, weighted MSEs over the \( T^* \leq T \) selected trees. \texttt{error} follows these steps to estimate \( \text{MSE}^*_t \), the cumulative, weighted MSE using the first \( t \) selected trees.

  a For selected observation \( j, j = 1, \ldots, n \), \texttt{error} estimates \( \hat{y}_{\text{bag}, tj} \), the weighted average of the predictions among the first \( t \) selected trees (for details, see \texttt{predict}). For this computation, \texttt{error} uses the tree weights.

  b \texttt{error} estimates the cumulative, weighted MSE through tree \( t \).

\[
\text{MSE}^*_t = \frac{1}{n} \sum_{j=1}^{n} w_j (y_j - \hat{y}_{\text{bag}, tj})^2.
\]

\texttt{error} sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, \texttt{error} estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting \( Y \) given \( X \) using selected trees and observations.

- If you specify 'Mode', 'Individual', then the weighted misclassification rate for tree \( t \) is

\[
e_t = \frac{1}{n} \sum_{j=1}^{n} w_j I(y_j \neq \hat{y}_{tj}).
\]

\( \hat{y}_{tj} \) is the predicted class for selected observation \( j \) using from selected classification tree \( t \). \texttt{error} sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, \texttt{error} considers the one listed first in the \texttt{ClassNames} property of the \texttt{TreeBagger} model the most popular.

- If you specify 'Mode', 'Cumulative' then the weighted misclassification rate is a vector of size \( T^* \) containing cumulative, weighted misclassification rates over the \( T^* \leq T \) selected trees. \texttt{error} follows these steps to estimate \( e^*_t \), the cumulative, weighted misclassification rate using the first \( t \) selected trees.

  1 For selected observation \( j, j = 1, \ldots, n \), \texttt{error} estimates \( \hat{y}_{\text{bag}, tj} \), the weighted, most popular class among the first \( t \) selected trees (for details, see \texttt{predict}). For this computation, \texttt{error} uses the tree weights.

  2 \texttt{error} estimates the cumulative, weighted misclassification rate through tree \( t \).

\[
e^*_t = \frac{1}{n} \sum_{j=1}^{n} w_j I(y_j \neq \hat{y}_{\text{bag}, tj}).
\]

\texttt{error} sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular
classes, error considers the one listed first in the ClassNames property of the TreeBagger model the most popular.

- If you specify 'Mode','Ensemble', then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

“Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger” on page 18-119
**error**

*Class:* TreeBagger

Error (misclassification probability or MSE)

**Syntax**

\[
\text{err} = \text{error}(B, \text{TBLnew}, \text{Ynew})
\]

\[
\text{err} = \text{error}(B, \text{Xnew}, \text{Ynew})
\]

\[
\text{err} = \text{error}(B, \text{TBLnew}, \text{Ynew}, '\text{param1}', \text{val1}, '\text{param2}', \text{val2}, ...)
\]

\[
\text{err} = \text{error}(B, \text{Xnew}, \text{Ynew}, '\text{param1}', \text{val1}, '\text{param2}', \text{val2}, ...)
\]

**Description**

\[
\text{err} = \text{error}(B, \text{TBLnew}, \text{Ynew})
\]

computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

\[
\text{err} = \text{error}(B, \text{Xnew}, \text{Ynew})
\]

computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, the for predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

For classification, `Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. For regression, `Y` must be a numeric vector. \( \text{err} \) is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

\[
\text{err} = \text{error}(B, \text{TBLnew}, \text{Ynew}, '\text{param1}', \text{val1}, '\text{param2}', \text{val2}, ...)
\] or \[
\text{err} = \text{error}(B, \text{Xnew}, \text{Ynew}, '\text{param1}', \text{val1}, '\text{param2}', \text{val2}, ...)
\]

specifies optional parameter name-value pairs:

<table>
<thead>
<tr>
<th><strong>'Mode'</strong></th>
<th>Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and ( \text{err} ) is a vector of length <code>NTrees</code>, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:<code>NTrees</code>). If set to 'individual', ( \text{err} ) is a vector of length <code>NTrees</code>, where each element is an error from each tree in the ensemble. If set to 'ensemble', ( \text{err} ) is a scalar showing the cumulative error for the entire ensemble.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>'Weights'</strong></td>
<td>Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in <code>X</code>.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'Trees'</td>
<td>Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.</td>
</tr>
<tr>
<td>'TreeWeights'</td>
<td>Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.</td>
</tr>
<tr>
<td>'UseInstanceForTree'</td>
<td>Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.</td>
</tr>
</tbody>
</table>

**Algorithms**

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
  - The error for individual trees in the ensemble
  - The cumulative error over all trees
  - The error for the entire ensemble
- Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
- Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
- Using the 'Weights' name-value pair argument, you can attribute each observation with a weight. For the formulae that follow, $w_i$ is the weight of observation $i$.
- Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

For regression problems, error estimates the weighted MSE of the ensemble of bagged regression trees for predicting Y given X using selected trees and observations.

1. error predicts responses for selected observations in X using the selected regression trees in the ensemble.
2. The MSE estimate depends on the value of 'Mode'.
   - If you specify 'Mode', 'Individual', then the weighted MSE for tree $t$ is
     \[
     MSE_t = \frac{1}{n} \sum_{j=1}^{n} w_i (y_j - \hat{y}_{ij})^2.
     \]
**y** is the predicted response of observation **j** from selected regression tree **t**. **error** sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Cumulative', then the weighted MSE is a vector of size **T** containing cumulative, weighted MSEs over the **T** ≤ **T** selected trees. **error** follows these steps to estimate MSE**, the cumulative, weighted MSE using the first **t** selected trees.

  a For selected observation **j**, **j** = 1,...,**n**, **error** estimates **y** **bag**, **t j** the weighted average of the predictions among the first **t** selected trees (for details, see predict). For this computation, **error** uses the tree weights.

  b **error** estimates the cumulative, weighted MSE through tree **t**.

\[
\text{MSE}_{t}^{*} = \frac{1}{n} \sum_{j=1}^{n} w_{j} (y_{j} - \text{y}_{\text{bag}, tj})^{2}.
\]

**error** sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, **error** estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting **Y** given **X** using selected trees and observations.

- If you specify 'Mode', 'Individual', then the weighted misclassification rate for tree **t** is

\[
e_{t} = \frac{1}{n} \sum_{j=1}^{n} w_{j} I(y_{j} \neq \text{y}_{tj}).
\]

**y** **t j** is the predicted class for selected observation **j** using from selected classification tree **t**. **error** sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, **error** considers the one listed first in the **ClassNames** property of the **TreeBagger** model the most popular.

- If you specify 'Mode', 'Cumulative' then the weighted misclassification rate is a vector of size **T** containing cumulative, weighted misclassification rates over the **T** ≤ **T** selected trees. **error** follows these steps to estimate **e** **t***, the cumulative, weighted misclassification rate using the first **t** selected trees.

  1 For selected observation **j**, **j** = 1,...,**n**, **error** estimates **y** **bag**, **t j** the weighted, most popular class among the first **t** selected trees (for details, see **predict**). For this computation, **error** uses the tree weights.

  2 **error** estimates the cumulative, weighted misclassification rate through tree **t**.

\[
e_{t}^{*} = \frac{1}{n} \sum_{j=1}^{n} w_{j} I(y_{j} \neq \text{y}_{\text{bag}, tj}).
\]

**error** sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular
classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

- If you specify `'Mode','Ensemble'`, then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

evalclusters

Evaluate clustering solutions

Syntax

eva = evalclusters(x,clust,criterion)
eva = evalclusters(x,clust,criterion,Name,Value)

Description

eva = evalclusters(x,clust,criterion) creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

eva = evalclusters(x,clust,criterion,Name,Value) creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

Examples

Evaluate the Clustering Solution Using Calinski-Harabasz Criterion

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

load fisheriris;

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using kmeans.

rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])

eva =
    CalinskiHarabaszEvaluation with properties:
        NumObservations: 150
          InspectedK: [1 2 3 4 5 6]
      CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
         OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.
**Evaluate a Matrix of Clustering Solutions**

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

Load the sample data.

```matlab
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use `kmeans` to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

```matlab
clust = zeros(size(meas,1),6);
for i=1:6
    clust(:,i) = kmeans(meas,i,'emptyaction','singleton','replicate',5);
end
```

Each row of `clust` corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```matlab
eva = evalclusters(meas,clust,'CalinskiHarabasz')
eva =
    CalinskiHarabaszEvaluation with properties:
        NumObservations: 150
        InspectedK: [1 2 3 4 5 6]
        CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
        OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

**Specify Clustering Algorithm with a Function Handle**

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

```matlab
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

```matlab
myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton','replicate',5));
```
Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

eva = evalclusters(meas,myfunc,'CalinskiHarabasz','klist',[1:6])

eva =
    CalinskiHarabaszEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
    OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

**Input Arguments**

**x** — Input data matrix

Input data, specified as an N-by-P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

**clust** — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

- 'kmeans' Cluster the data in x using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
- 'linkage' Cluster the data in x using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
- 'gmdistribution' Cluster the data in x using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If **criterion** is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form

```
C = clustfun(DATA,K),
```

where **DATA** is the data to be clustered, and **K** is the number of clusters. The output of **clustfun** must be one of the following:

- A vector of integers representing the cluster index for each observation in **DATA**. There must be **K** unique values in this vector.
- A numeric n-by-K matrix of score for **n** observations and **K** classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If **criterion** is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify **clust** as a n-by-K matrix containing the proposed clustering solutions. **n** is the number of
observations in the sample data, and $K$ is the number of proposed clustering solutions. Column $j$ contains the cluster indices for each of the $N$ points in the $j$th clustering solution.

Data Types: single | double | char | string | function_handle

**criterion** — Clustering evaluation criterion
'ScalinskiHarabasz' | 'DaviesBouldin' | 'gap' | 'silhouette'

Clustering evaluation criterion, specified as one of the following.

- 'ScalinskiHarabasz': Create a `CalinskiHarabaszEvaluation` clustering evaluation object containing Scalinski-Harabasz index values.
- 'DaviesBouldin': Create a `DaviesBouldinEvaluation` cluster evaluation object containing Davies-Bouldin index values.
- 'gap': Create a `GapEvaluation` cluster evaluation object containing gap criterion values.
- 'silhouette': Create a `SilhouetteEvaluation` cluster evaluation object containing silhouette values.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

**For All Criteria**

- **KList** — List of number of clusters to evaluate
  vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList',[1:6]`

Data Types: single | double

**For Silhouette and Gap**

- **Distance** — Distance metric
  'sqEuclidean'(default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

- 'sqEuclidean': Squared Euclidean distance
### Distance Metric Options

- **'Euclidean'**
  - Euclidean distance. This option is not valid for the **kmeans** clustering algorithm.

- **'cityblock'**
  - Sum of absolute differences

- **'cosine'**
  - One minus the cosine of the included angle between points (treated as vectors)

- **'correlation'**
  - One minus the sample correlation between points (treated as sequences of values)

- **'Hamming'**
  - Percentage of coordinates that differ. This option is only valid for the **Silhouette** criterion.

- **'Jaccard'**
  - Percentage of nonzero coordinates that differ. This option is only valid for the **Silhouette** criterion.

For detailed information about each distance metric, see **pdist**.

You can also specify a function for the distance metric using a function handle (MATLAB). The distance function must be of the form \( d2 = \text{distfun}(XI,XJ) \), where \( XI \) is a 1-by-\( n \) vector corresponding to a single row of the input matrix \( X \), and \( XJ \) is an \( mJ \)-by-\( n \) matrix corresponding to multiple rows of \( X \). \( \text{distfun} \) must return an \( mJ \)-by-1 vector of distances \( d2 \), whose \( k \)th element is the distance between \( XI \) and \( XJ(k,:) \).

**Distance** only accepts a function handle if the clustering algorithm \( \text{clust} \) accepts a function handle as the distance metric. For example, the **kmeans** clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the **kmeans** algorithm and then specify a function handle for **Distance**, the software errors.

- If criterion is **'silhouette'**, you can also specify **Distance** as the output vector created by the function **pdist**.
- When \( \text{clust} \) is **'kmeans'** or **'gmdistribution'**, evalclusters uses the distance metric specified for **Distance** to cluster the data.
- If \( \text{clust} \) is **'linkage'**, and **Distance** is either **'sqEuclidean'** or **'Euclidean'**, then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If \( \text{clust} \) is **'linkage'** and **Distance** is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for **Distance** must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** `'Distance','Euclidean'`

Data Types: **single** | **double** | **char** | **string** | **function_handle**

### For Silhouette Only

**ClusterPriors — Prior probabilities for each cluster**

- **'empirical'** *(default)* | **'equal'*

Prior probabilities for each cluster, specified as the comma-separated pair consisting of **'ClusterPriors'** and one of the following.
'empirical' Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.

'equal' Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: 'ClusterPriors','empirical'

For Gap Only

B — Number of reference data sets
100 (default) | positive integer value

Number of reference data sets generated from the reference distribution ReferenceDistribution, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B',150

Data Types: single | double

ReferenceDistribution — Reference data generation method
'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA' Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x.

'uniform' Generate reference data uniformly over the range of each feature in the data matrix x.

Example: 'ReferenceDistribution','uniform'

SearchMethod — Method for selecting optimal number of clusters
'globalMaxSE' (default)| 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'globalMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{GAPMAX} - \text{SE(GAPMAX)}, \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, \( \text{GAPMAX} \) is the largest gap value, and \( \text{SE(GAPMAX)} \) is the standard error corresponding to the largest gap value.
'firstMaxSE' Evaluate each proposed number of clusters in KList and select the smallest number of clusters satisfying

\[ \text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1), \]

where \( K \) is the number of clusters, \( \text{Gap}(K) \) is the gap value for the clustering solution with \( K \) clusters, and \( \text{SE}(K + 1) \) is the standard error of the clustering solution with \( K + 1 \) clusters.

Example: 'SearchMethod','globalMaxSE'

**Output Arguments**

**eva** — Clustering evaluation data
clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

**Introduced in R2013b**
evlike

Extreme value negative log-likelihood

Syntax

nlogL = evlike(params,data)
[nlogL,AVAR] = evlike(params,data)
[...] = evlike(params,data,censoring)
[...] = evlike(params,data,censoring,freq)

Description

nlogL = evlike(params,data) returns the negative of the log-likelihood for the type 1 extreme value distribution. params(1) is the tail location parameter, mu, and params(2) is the scale parameter, sigma. nlogL is a scalar.

[nlogL,AVAR] = evlike(params,data) returns the inverse of Fisher's information matrix, AVAR. If the input parameter values in params are the maximum likelihood estimates, the diagonal elements of AVAR are their asymptotic variances. AVAR is based on the observed Fisher's information, not the expected information.

[...] = evlike(params,data,censoring) accepts a Boolean vector of the same size as data, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

[...] = evlike(params,data,censoring,freq) accepts a frequency vector of the same size as data. freq typically contains integer frequencies for the corresponding elements in data, but can contain any nonnegative values. Pass in [] for censoring to use its default value.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating data. See “Extreme Value Distribution” on page B-40 for more details. If x has a Weibull distribution, then X = log(x) has the type 1 extreme value distribution.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

**evpdf**

Extreme value probability density function

**Syntax**

\[ Y = \text{evpdf}(X,\mu,\sigma) \]

**Description**

\[ Y = \text{evpdf}(X,\mu,\sigma) \]

returns the pdf of the type 1 extreme value distribution with location parameter \( \mu \) and scale parameter \( \sigma \), evaluated at the values in \( X \). \( X, \mu, \) and \( \sigma \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for \( \mu \) and \( \sigma \) are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating \( X \). See “Extreme Value Distribution” on page B-40 for more details. If \( x \) has a Weibull distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.

**Extended Capabilities**

**C/C++ Code Generation**
 Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**
 Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**

“Extreme Value Distribution” on page B-40

**Introduced before R2006a**
evrnd

Extreme value random numbers

Syntax

R = evrnd(mu,sigma)
R = evrnd(mu,sigma,m,n,...)
R = evrnd(mu,sigma,[m,n,...])

Description

R = evrnd(mu,sigma) generates random numbers from the extreme value distribution with parameters specified by location parameter mu and scale parameter sigma. mu and sigma can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for mu or sigma is expanded to a constant array with the same dimensions as the other input.

R = evrnd(mu,sigma,m,n,...) or R = evrnd(mu,sigma,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the extreme value distribution with parameters mu and sigma. mu and sigma can each be scalars or arrays of the same size as R.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating R. See "Extreme Value Distribution" on page B-40 for more details. If x has a Weibull distribution, then X = log(x) has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

• The output is nonscalar.
• An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

evstat

Extreme value mean and variance

Syntax

\[ [M,V] = evstat(mu,sigma) \]

Description

\[ [M,V] = evstat(mu,sigma) \] returns the mean of and variance for the type 1 extreme value
distribution with location parameter \( \mu \) and scale parameter \( \sigma \). \( \mu \) and \( \sigma \) can be vectors,
matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a
constant array of the same size as the other input. The default values for \( \mu \) and \( \sigma \) are 0 and 1,
respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used
here is suitable for modeling minima; the mirror image of this distribution can be used to model
maxima. See “Extreme Value Distribution” on page B-40 for more details. If \( x \) has a Weibull
distribution, then \( X = \log(x) \) has the type 1 extreme value distribution.

Topics

“Extreme Value Distribution” on page B-40

Introduced before R2006a
expcdf

Exponential cumulative distribution function

Syntax

\[
p = \text{expcdf}(x)
\]

\[
p = \text{expcdf}(x,\mu)
\]

\[
[p, p\text{Lo}, p\text{Up}] = \text{expcdf}(x,\mu,\text{pCov})
\]

\[
[p, p\text{Lo}, p\text{Up}] = \text{expcdf}(x,\mu,\text{pCov},\text{alpha})
\]

\[
\text{___} = \text{expcdf}(\text{___},'\text{upper}')
\]

Description

\[
p = \text{expcdf}(x)
\]
returns the cumulative distribution function (cdf) of the standard exponential distribution, evaluated at the values in \(x\).

\[
p = \text{expcdf}(x,\mu)
\]
returns the cdf of the exponential distribution with mean \(\mu\), evaluated at the values in \(x\).

\[
[p, p\text{Lo}, p\text{Up}] = \text{expcdf}(x,\mu,\text{pCov})
\]
also returns the 95\% confidence interval \([p\text{Lo}, p\text{Up}]\) of \(p\) when \(\mu\) is an estimate with variance \(\text{pCov}\).

\[
[p, p\text{Lo}, p\text{Up}] = \text{expcdf}(x,\mu,\text{pCov},\text{alpha})
\]
specifies the confidence level for the confidence interval \([p\text{Lo}, p\text{Up}]\) to be \(100(1-\text{alpha})\%\).

\[
\text{___} = \text{expcdf}(\text{___},'\text{upper}')
\]
returns the complement of the cdf, evaluated at the values in \(x\), using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1. 'upper' can follow any of the input argument combinations in the previous syntaxes.

Examples

Standard Exponential Distribution cdf

Compute the probability that an observation in the standard exponential distribution falls in the interval \([1 2]\).

\[
p = \text{expcdf([1 2])};
p(2) - p(1)
\]

\[
an = 0.2325
\]

Compute Exponential cdf

The median of the exponential distribution is \(\mu\text{log}(2)\).
Confirm the median by computing the cdf of $\mu \log(2)$ for several different choices of $\mu$.

```matlab
mu = 1:10:60;
p = expcdf(log(2)*mu,mu)
p = 1×6
   0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
```

The cdf of the mean is always equal to $1 - 1/e$ (~0.6321).

Confirm the result by computing the exponential cdf of the mean for means one through six.

```matlab
mu = 1:6;
x = mu;
p = expcdf(x,mu)
p = 1×6
   0.6321    0.6321    0.6321    0.6321    0.6321    0.6321
```

**Confidence Interval of Exponential cdf Value**

Find a confidence interval estimating the probability that an observation is in the interval $[0, 1]$ using exponentially distributed data.

Generate a sample of 1000 random numbers drawn from the exponential distribution with mean 5.

```matlab
rng('default') % For reproducibility
x = exprnd(5,1000,1);
```

Estimate the mean with a confidence interval.

```matlab
[muhat,muci] = expfit(x)
uhat = 5.0129
muci = 2×1
   4.7161
   5.3387
```

Estimate the variance of the mean estimate.

```matlab
[~,nCov] = explike(muhat,x)
nCov = 0.0251
```

Create the confidence interval estimating the probability an observation is in the interval $[0, 1]$.

```matlab
[p,pLo,pUp] = expcdf(1,muhat,nCov);
pCi = [pLo; pUp]
pCi = 2×1
```

32-1235
expcdf calculates the confidence interval using a normal approximation for the distribution of the log estimate of the mean. Compute a more accurate confidence interval for \( p \) by evaluating expcdf on the confidence interval \( \text{muci} \).

\[
p_{\text{Ci2}} = \expcdf(1, \text{muci})
\]

\[
p_{\text{Ci2}} = [0.1911, 0.1708]
\]

The bounds \( p_{\text{Ci2}} \) are reversed because a lower mean makes the event more likely and a higher mean makes the event less likely.

**Complementary cdf (Tail Distribution)**

Determine the probability that an observation from the exponential distribution with mean 1 is in the interval \([50 \ Inf]\).

\[
p_{1} = 1 - \expcdf(50, 1)
\]

\[
p_{1} = 0
\]

\( \expcdf(50, 1) \) is nearly 1, so \( p_{1} \) becomes 0. Specify 'upper' so that expcdf computes the extreme upper-tail probabilities more accurately.

\[
p_{2} = \expcdf(50, 1, 'upper')
\]

\[
p_{2} = 1.9287 \times 10^{-22}
\]

**Input Arguments**

\( x \) — Values at which to evaluate cdf  
nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the cdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the cdf at multiple values, specify \( x \) using an array.
- To evaluate the cdfs of multiple distributions, specify \( \mu \) using an array.

If either or both of the input arguments \( x \) and \( \mu \) are arrays, then the array sizes must be the same. In this case, expcdf expands each scalar input into a constant array of the same size as the array inputs. Each element in \( p \) is the cdf value of the distribution specified by the corresponding element in \( \mu \), evaluated at the corresponding element in \( x \).

Example: \([3 \ 4 \ 7 \ 9]\)

Data Types: single | double
**mu — Mean**

1 (default) | positive scalar value | array of positive scalar values

Mean of the exponential distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify x using an array.
- To evaluate the cdfs of multiple distributions, specify mu using an array.

If either or both of the input arguments x and mu are arrays, then the array sizes must be the same. In this case, expcdf expands each scalar input into a constant array of the same size as the array inputs. Each element in p is the cdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in x.

Example: [1 2 3 5]

Data Types: single | double

**pCov — Variance of Mean Estimate**

positive scalar value

Variance of the estimate of mu, specified as a positive scalar value.

You can estimate mu from data by using expfit or mle. You can then estimate the variance of mu by using explike. The resulting confidence interval bounds are based on a normal approximation for the distribution of the log of the mu estimate. You can get a more accurate set of bounds by applying expcdf to the confidence interval returned by expfit. For an example, see “Confidence Interval of Exponential cdf Value” on page 32-1235.

Example: 0.10

Data Types: single | double

**alpha — Significance level**

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is 100(1–alpha)%, where alpha is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

**Output Arguments**

**p — cdf values**

scalar value | array of scalar values

cdf values evaluated at x, returned as a scalar value or an array of scalar values. p is the same size as x and mu after any necessary scalar expansion. Each element in p is the cdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in x.

**pLo — Lower confidence bound for p**

scalar value | array of scalar values
Lower confidence bound for p, returned as a scalar value or an array of scalar values. \( p_{\text{Lo}} \) has the same size as p.

\( p_{\text{Up}} \) — Upper confidence bound for p
scalar value | array of scalar values

Upper confidence bound for p, returned as a scalar value or an array of scalar values. \( p_{\text{Up}} \) has the same size as p.

**More About**

**Exponential cdf**

The exponential distribution is a one-parameter family of curves. The parameter \( \mu \) is the mean.

The cdf of the exponential distribution is

\[
p = F(x | \mu) = \int_0^x \frac{1}{\mu} e^{-t/\mu} dt = 1 - e^{-x/\mu}.
\]

The result \( p \) is the probability that a single observation from the exponential distribution with mean \( \mu \) falls in the interval \([0, x]\). A common alternative parameterization of the exponential distribution is to use \( \lambda \) defined as the mean number of events in an interval as opposed to \( \mu \), which is the mean wait time for an event to occur. \( \lambda \) and \( \mu \) are reciprocals.

For more information, see “Exponential Distribution” on page B-33.

**Alternative Functionality**

- `expcdf` is a function specific to the exponential distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create an `ExponentialDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `expcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

**Extended Capabilities**

Topics
“Exponential Distribution” on page B-33

Introduced before R2006a
**expfit**

Exponential parameter estimates

**Syntax**

```
muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)
```

**Description**

`muhat = expfit(data)` estimates the mean of exponentially distributed sample data in the vector `data`.

`[muhat,muci] = expfit(data)` also returns the 95% confidence interval for the mean parameter estimates in `muci`. The first row of `muci` is the lower bound of the confidence interval, and the second row is the upper bound.

`[muhat,muci] = expfit(data,alpha)` returns the 100(1-alpha)% confidence interval for the parameter estimate `muhat`, where `alpha` is a value in the range [0 1] specifying the width of the confidence interval. By default, `alpha` is 0.05, which corresponds to the 95% confidence interval.

`[...] = expfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = expfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

**Examples**

The following estimates the mean `mu` of exponentially distributed data, and returns a 95% confidence interval for the estimate:

```
mu = 3;
data = exprnd(mu,100,1); % Simulated data
[muhat,muci] = expfit(data)
muhat =
    2.7511
muci =
    2.2826   3.3813
```

Introduced before R2006a
ExhaustiveSearcher

Create exhaustive nearest neighbor searcher

Description

ExhaustiveSearcher model objects store the training data, distance metric, and parameter values of the distance metric for an exhaustive nearest neighbor search. The exhaustive search algorithm finds the distance from each query observation to all n observations in the training data, which is an n-by-K numeric matrix.

Once you create an ExhaustiveSearcher model object, find neighboring points in the training data to the query data by performing a nearest neighbor search using knnsearch or a radius search using rangesearch. The exhaustive search algorithm is more efficient than the Kd-tree algorithm when K is large (that is, $K > 10$), and it is more flexible than the Kd-tree algorithm with respect to distance metric choices. The ExhaustiveSearcher model object also supports sparse data.

Creation

Use either the createns function or the ExhaustiveSearcher function (described here) to create an ExhaustiveSearcher object. Both functions use the same syntax except that the createns function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The createns function also creates a KDTreeSearcher object. Specify 'NSMethod','exhaustive' to create an ExhaustiveSearcher object. The default is 'exhaustive' if $K > 10$, the training data is sparse, or the distance metric is not the Euclidean, city block, Chebychev, or Minkowski.

Syntax

Mdl = ExhaustiveSearcher(X)
Mdl = ExhaustiveSearcher(X,Name,Value)

Description

Mdl = ExhaustiveSearcher(X) creates an exhaustive nearest neighbor searcher object (Mdl) using the n-by-K numeric matrix of training data (X).

Mdl = ExhaustiveSearcher(X,Name,Value) specifies additional options using one or more name-value pair arguments. You can specify the distance metric and set the distance metric parameter (DistParameter) property. For example, ExhaustiveSearcher(X,'Distance','chebychev') creates an exhaustive nearest neighbor searcher object that uses the Chebychev distance. To specify DistParameter, use the Cov, P, or Scale name-value pair argument.

Input Arguments

X — Training data
numeric matrix
Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: ‘Distance’,’mahalanobis’,’Cov’,eye(3) specifies to use the Mahalanobis distance when searching for nearest neighbors and a 3-by-3 identity matrix for the covariance matrix in the Mahalanobis distance metric.

Distance — Distance metric

‘euclidean’ (default) | character vector | string scalar | custom distance function

Distance metric used when you call knnsearch or rangesearch to find nearest neighbors for future query points, specified as the comma-separated pair consisting of ‘Distance’ and a character vector, string scalar, or function handle.

This table describes the supported distance metrics specified as character vectors or string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as row vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, which is the percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the ‘P’ name-value pair argument.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the ‘Cov’ name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the ‘Scale’ name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>

For more details, see “Distance Metrics” on page 18-11.
You can specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form function D2 = distfun(ZI, ZJ).
- Take as arguments:
  - A 1-by-K vector ZI containing a single row from X or from the query points Y, where K is the number of columns in X.
  - An m-by-K matrix ZJ containing multiple rows of X or Y, where m is a positive integer.
- Return an m-by-1 vector of distance D2, where D2(j) is the distance between the observations ZI and ZJ(j,:).

The software does not use the distance metric for creating an ExhaustiveSearcher model object, so you can alter the distance metric by using dot notation after creating the object.

Example: 'Distance','mahalanobis'

**Cov** — Covariance matrix for Mahalanobis distance metric

nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a K-by-K positive definite matrix, where K is the number of columns in X. This argument is valid only if 'Distance' is 'mahalanobis'.

Example: 'Cov',eye(3)

Data Types: single | double

**P** — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

**Scale** — Scale parameter value for standardized Euclidean distance metric

nanstd(X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length K, where K is the number of columns in X. The software scales each difference between the training and query data using the corresponding element of Scale. This argument is valid only if 'Distance' is 'seuclidean'.

Example: 'Scale',quantile(X,0.75) - quantile(X,0.25)

Data Types: single | double

**Properties**

**X** — Training data

numeric matrix

This property is read-only.
Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. \( X \) has \( n \) rows, each corresponding to an observation (that is, an instance or example), and \( K \) columns, each corresponding to a predictor (that is, a feature).

The input argument \( X \) of createNNS or ExhaustiveSearcher sets this property.

Data Types: single | double

**Distance — Distance metric**

character vector | string scalar | custom distance function

Distance metric used when you call \texttt{knnsearch} or \texttt{rangesearch} to find nearest neighbors for future query points, specified as a character vector or string scalar ('chebychev', 'cityblock', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'minkowski', 'mahalanobis', 'seuclidean', or 'spearman'), or a function handle.

The 'Distance' name-value pair argument of createNNS or ExhaustiveSearcher sets this property.

The software does not use the distance metric for creating an ExhaustiveSearcher model object, so you can alter it by using dot notation.

**DistParameter — Distance metric parameter values**

[] | positive scalar

Distance metric parameter values, specified as empty ([ ]) or a positive scalar.

This table describes the distance parameters of the supported distance metrics.

<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mahalanobis'</td>
<td>A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. By default, the software sets the covariance using ( \text{nancov}(\text{Mdl}.X) ).</td>
</tr>
<tr>
<td></td>
<td>The 'Cov' name-value pair argument of createNNS or ExhaustiveSearcher sets this property.</td>
</tr>
<tr>
<td></td>
<td>You can alter DistParameter by using dot notation, for example, ( \text{Mdl}.\text{DistParameter} = \text{CovNew} ), where ( \text{CovNew} ) is a ( K )-by-( K ) positive definite numeric matrix.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>A positive scalar indicating the exponent of the Minkowski distance. By default, the exponent is 2.</td>
</tr>
<tr>
<td></td>
<td>The 'P' name-value pair argument of createNNS or ExhaustiveSearcher sets this property.</td>
</tr>
<tr>
<td></td>
<td>You can alter DistParameter by using dot notation, for example, ( \text{Mdl}.\text{DistParameter} = \text{PNew} ), where ( \text{PNew} ) is a positive scalar.</td>
</tr>
</tbody>
</table>
### Distance Metric

<table>
<thead>
<tr>
<th>Distance Metric</th>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'seuclidean'</td>
<td>A positive numeric vector indicating the values used by the software to scale the predictors when computing the standardized Euclidean distance. By default, the software:</td>
</tr>
<tr>
<td></td>
<td>1. Estimates the standard deviation of each predictor (column) of X using <code>scale = nanstd(Mdl.X)</code></td>
</tr>
<tr>
<td></td>
<td>2. Scales each coordinate difference between the rows in X and the query matrix by dividing by the corresponding element of <code>scale</code></td>
</tr>
</tbody>
</table>

The 'Scale' name-value pair argument of `createns` or `ExhaustiveSearcher` sets this property.

You can alter `DistParameter` by using dot notation, for example, `Mdl.DistParameter = sNew`, where `sNew` is a K-dimensional positive numeric vector.

If `Mdl.Distance` is not one of the parameters listed in this table, then `Mdl.DistParameter` is [], which means that the specified distance metric formula has no parameters.

Data Types: single | double

### Object Functions

- `knnsearch` Find k-nearest neighbors using searcher object
- `rangesearch` Find all neighbors within specified distance using searcher object

### Examples

#### Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
[n,k] = size(X)
n = 150
k = 4

X has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.

```matlab
Mdl1 = ExhaustiveSearcher(X)
```

```matlab
Mdl1 =
    ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]```
ExhaustiveSearcher

Mdl1 is an ExhaustiveSearcher model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can prepare an exhaustive nearest neighbor searcher by using createns and specifying 'exhaustive' as the search method.

Mdl2 = createns(X,'NSMethod','exhaustive')

Mdl2 = ExhaustiveSearcher with properties:
     Distance: 'euclidean'
               DistParameter: []
               X: [150x4 double]

Mdl2 is also an ExhaustiveSearcher model object, and it is equivalent to Mdl1.

To search X for the nearest neighbors to a batch of query data, pass the ExhaustiveSearcher model object and the query data to knnsearch or rangesearch.

Specify the Mahalanobis Distance for Nearest Neighbor Search

Load Fisher's iris data set. Focus on the petal dimensions.

load fisheriris
X = meas(:,[3 4]); % Predictors

Prepare an exhaustive nearest neighbor searcher. Specify the Mahalanobis distance metric.

Mdl = createns(X,'Distance','mahalanobis')

Mdl = ExhaustiveSearcher with properties:
     Distance: 'mahalanobis'
               DistParameter: [2x2 double]
               X: [150x2 double]

Because the distance metric is Mahalanobis, createns creates an ExhaustiveSearcher model object by default.

Access properties of Mdl by using dot notation. For example, use Mdl.DistParameter to access the Mahalanobis covariance parameter.

Mdl.DistParameter
ans = 2x2
     3.1163    1.2956
     1.2956    0.5810

You can pass query data and Mdl to:
- `knnsearch` to find indices and distances of nearest neighbors
- `rangesearch` to find indices of all nearest neighbors within a distance that you specify

**Alter Properties of ExhaustiveSearcher Model**

Create an `ExhaustiveSearcher` model object and alter the `Distance` property by using dot notation.

Load Fisher's iris data set.
```matlab
load fisheriris
X = meas;
```

Train a default exhaustive searcher algorithm using the entire data set as training data.
```matlab
Mdl = ExhaustiveSearcher(X)
```

```matlab
Mdl = 
ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]
```

Specify that the neighbor searcher use the Mahalanobis metric to compute the distances between the training and query data.
```matlab
Mdl.Distance = 'mahalanobis'
```

```matlab
Mdl = 
ExhaustiveSearcher with properties:
    Distance: 'mahalanobis'
    DistParameter: [4x4 double]
    X: [150x4 double]
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Mahalanobis distance.

**Search for Nearest Neighbors of Query Data Using Mahalanobis Distance**

Create an exhaustive searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find $k$-nearest neighbors.

Load Fisher's iris data set.
```matlab
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.
rng('default');             % For reproducibility
n = size(meas,1);           % Sample size
qIdx = randsample(n,5);     % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis
distance for finding nearest neighbors.

Mdl = createns(X,'Distance','mahalanobis')

Mdl =
ExhaustiveSearcher with properties:

    Distance: 'mahalanobis'
    DistParameter: [4x4 double]
        X: [145x4 double]

Because the distance metric is Mahalanobis, createns creates an ExhaustiveSearcher model
object by default.

The software uses the covariance matrix of the predictors (columns) in the training data for
computing the Mahalanobis distance. To display this value, use Mdl.DistParameter.

Mdl.DistParameter

ans = 4x4

    0.6547   -0.0368    1.2320    0.5026
-0.0368    0.1914   -0.3227   -0.1193
 1.2320   -0.3227    3.0671    1.2842
 0.5026   -0.1193    1.2842    0.5800

Find the indices of the training data (Mdl.X) that are the two nearest neighbors of each point in the
query data (Y).

IdxNN = knnsearch(Mdl,Y,'K',2)

IdxNN = 5x2

    5   6
 98  95
104 128
135  65
102 115

Each row of IdxNN corresponds to a query data observation. The column order corresponds to the
order of the nearest neighbors with respect to ascending distance. For example, based on the
Mahalanobis metric, the second nearest neighbor of Y(3,:) is X(128,:).

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.
Usage notes and limitations:

- The `knnsearch` and `rangesearch` functions support code generation.
- When you train an `ExhaustiveSearcher` model object, the value of the 'Distance' name-value pair argument cannot be a custom distance function.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-13.

**Introduced in R2010a**
expinv

Exponential inverse cumulative distribution function

Syntax

\[ x = \text{expinv}(p) \]
\[ x = \text{expinv}(p,\mu) \]
\[ [x, x_{\text{Lo}}, x_{\text{Up}}] = \text{expinv}(p,\mu,\text{pCov}) \]
\[ [x, x_{\text{Lo}}, x_{\text{Up}}] = \text{expinv}(p,\mu,\text{pCov},\alpha) \]

Description

\[ x = \text{expinv}(p) \] returns the inverse cumulative distribution function (icdf) of the standard exponential distribution, evaluated at the values in \( p \).

\[ x = \text{expinv}(p,\mu) \] returns the icdf of the exponential distribution with mean \( \mu \), evaluated at the values in \( p \).

\[ [x, x_{\text{Lo}}, x_{\text{Up}}] = \text{expinv}(p,\mu,\text{pCov}) \] also returns the 95% confidence interval \([x_{\text{Lo}}, x_{\text{Up}}]\) of \( x \) when \( \mu \) is an estimate with variance \( \text{pCov} \).

\[ [x, x_{\text{Lo}}, x_{\text{Up}}] = \text{expinv}(p,\mu,\text{pCov},\alpha) \] specifies the confidence level for the confidence interval \([x_{\text{Lo}}, x_{\text{Up}}]\) to be \( 100(1-\alpha) \)%.

Examples

Compute Exponential icdf

Assume that the lifetime of light bulbs are exponentially distributed with a mean of 700 hours. Find the median lifetime using \text{expinv}.

\[
\text{expinv}(0.50,700)
\]
\[
\text{ans} = 485.2030
\]

Half of the light bulbs will burn out within the first 485 hours of use.

Confidence Interval of Exponential icdf Value

Find a confidence interval estimating the median using exponentially distributed data.

Generate a sample of 1000 exponentially distributed random numbers with mean 5.

\[
\text{rng('default')} % For reproducibility
\]
\[
x = \text{exprnd}(5,100,1);
\]

Estimate the mean with a confidence interval.
[\text{muhat}, \text{muci}] = \text{expfit}(x)
\text{muhat} = 4.5852
\text{muci} = 2\times1
\begin{align*}
&\begin{array}{c}
3.8043 \\
5.6355
\end{array}
\end{align*}

Estimate the variance of the mean estimate.

[~,\text{pCov}] = \text{explike}(\text{muhat},x)
\text{pCov} = 0.2102

Create a confidence interval for the median.

[x,xLo,xUp] = \text{expinv}(0.5,\text{muhat},\text{pCov});
\text{xCi} = [\text{xLo}; \text{xUp}]
\text{xCi} = 2\times1
\begin{align*}
&\begin{array}{c}
2.6126 \\
3.8664
\end{array}
\end{align*}

Alternatively, compute a more accurate confidence interval for x by evaluating \text{expinv} on the confidence interval muci.

\text{xCi2} = \text{expinv}(0.5,\text{muci})
\text{xCi2} = 2\times1
\begin{align*}
&\begin{array}{c}
2.6369 \\
3.9062
\end{array}
\end{align*}

\textbf{Input Arguments}

\textit{p} — \textbf{Probability values at which to evaluate icdf}

scalar value in [0,1] | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value or an array of scalar values, where each element is in the range [0,1].

- To evaluate the icdf at multiple values, specify \textit{p} using an array.
- To evaluate the icdfs of multiple distributions, specify \textit{mu} using an array.

If either or both of the input arguments \textit{p} and \textit{mu} are arrays, then the array sizes must be the same. In this case, \text{expinv} expands each scalar input into a constant array of the same size as the array inputs. Each element in \textit{x} is the icdf value of the distribution specified by the corresponding element in \textit{mu}, evaluated at the corresponding element in \textit{p}.

Example: [0.1,0.5,0.9]
Data Types: single | double
mu — Mean
1 (default) | positive scalar value | array of positive scalar values

Mean of the exponential distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify p using an array.
- To evaluate the icdfs of multiple distributions, specify mu using an array.

If either or both of the input arguments p and mu are arrays, then the array sizes must be the same. In this case, expinv expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in p.

Example: [1 2 3 5]
Data Types: single | double

pCov — Variance of mean estimate
positive scalar value

Variance of the estimate of mu, specified as a positive scalar.

You can estimate mu from data by using expfit. You can then estimate the variance of mu by using explike. The resulting confidence interval bounds are based on a normal approximation for the distribution of the log of the mu estimate. You can get a more accurate set of bounds by applying expinv to the confidence interval returned by expfit. For an example, see “Confidence Interval of Exponential icdf Value” on page 32-1251.

Example: 0.10
Data Types: single | double

alpha — Significance level
0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is 100(1–alpha)% , where alpha is the probability that the confidence interval does not contain the true value.

Example: 0.01
Data Types: single | double

Output Arguments

x — icdf values
scalar value | array of scalar values

icdf values evaluated at the probability values in p, returned as a scalar value or an array of scalar values. x is the same size as p and mu after any necessary scalar expansion. Each element in x is the icdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in p.

xLo — Lower confidence bound for x
scalar value | array of scalar values
Lower confidence bound for $x$, returned as a scalar value or an array of scalar values. $x_{\text{Lo}}$ has the same size as $x$.

$x_{\text{Up}}$ — Upper confidence bound for $x$
scalar value | array of scalar values

Upper confidence bound for $x$, returned as a scalar value or an array of scalar values. $x_{\text{Up}}$ has the same size as $x$.

**More About**

**Exponential icdf**

The exponential distribution is a one-parameter family of curves. The parameter $\mu$ is the mean.

The icdf of the exponential distribution is

$$x = F^{-1}(p \mid \mu) = -\mu \ln(1 - p).$$

The result $x$ is the value such that an observation from an exponential distribution with parameter $\mu$ will falls in the range $[0,x]$ with probability $p$. A common alternative parameterization of the exponential distribution is to use $\lambda$ defined as the mean number of events in an interval as opposed to $\mu$, which is the mean wait time for an event to occur. $\lambda$ and $\mu$ are reciprocals.

For more information, see “Exponential Distribution” on page B-33.

**Alternative Functionality**

- `expinv` is a function specific to the exponential distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create an `ExponentialDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `expinv` is faster than the generic function `icdf`.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**

“Exponential Distribution” on page B-33
Introduced before R2006a
explike

Exponential negative log-likelihood

**Syntax**

\[ n\text{logL} = \text{explike}(\text{param},\text{data}) \]
\[ [n\text{logL},avar] = \text{explike}(\text{param},\text{data}) \]
\[ [...] = \text{explike}(\text{param},\text{data},\text{censoring}) \]
\[ [...] = \text{explike}(\text{param},\text{data},\text{censoring},\text{freq}) \]

**Description**

\( n\text{logL} = \text{explike}(\text{param},\text{data}) \) returns the negative of the log-likelihood for the exponential distribution. \( \text{param} \) is the mean parameter, \( \mu \). \( n\text{logL} \) is a scalar.

\( [n\text{logL},avar] = \text{explike}(\text{param},\text{data}) \) returns the inverse of Fisher's information, \( avar \), a scalar. If the input parameter value in \( \text{param} \) is the maximum likelihood estimate, \( avar \) is its asymptotic variance. \( avar \) is based on the observed Fisher's information, not the expected information.

\( [...] = \text{explike}(\text{param},\text{data},\text{censoring}) \) accepts a Boolean vector, \( \text{censoring} \), of the same size as \( \text{data} \), which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

\( [...] = \text{explike}(\text{param},\text{data},\text{censoring},\text{freq}) \) accepts a frequency vector, \( \text{freq} \), of the same size as \( \text{data} \). The vector \( \text{freq} \) typically contains integer frequencies for the corresponding elements in \( \text{data} \), but can contain any nonnegative values. Pass in \([]\) for \( \text{censoring} \) to use its default value.

**Extended Capabilities**

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Exponential Distribution” on page B-33

**Introduced before R2006a**
export

Class: dataset

(Not Recommended) Write dataset array to file

Note The dataset data type is not recommended. To work with heterogeneous data, use the MATLAB table data type instead. See MATLAB table documentation for more information.

Syntax

export(DS,'file',filename)
export(DS)
export(DS,'file',filename,'Delimiter',delim)
export(DS,'XLSfile',filename)
export(DS,'XPTFile',filename)
export(DS,...,'WriteVarNames',false)
export(DS,...,'WriteObsNames',false)

Description

export(DS,'file',filename) writes the dataset array DS to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, 'Observations'). export overwrites any existing file named filename.

export(DS) writes to a text file whose default name is the name of the dataset array DS appended by '.txt'. If export cannot construct the file name from the dataset array input, it writes to the file 'dataset.txt'. export overwrites any existing file.

export(DS,'file',filename,'Delimiter',delim) writes the dataset array DS to a text file using the delimiter delim. delim must be one of the following:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

export(DS,'XLSfile',filename) writes the dataset array DS to a Microsoft Excel spreadsheet file, including variable names and observation names (if present). You can specify the 'Sheet' and 'Range' parameter name/value pairs, with parameter values as accepted by the xlsread function. Since export uses the xlsxwrite function internally, this syntax is only compatible with Microsoft Excel for Windows, and does not work on a Mac. For more information, see xlsxwrite.

export(DS,'XPTFile',filename) writes the dataset array DS to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. export saves observation names to a variable called obsnames, unless the WriteObsNames parameter described below is false. The
The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

`export(DS,...,'WriteVarNames',false)` does not write the variable names to the text file.
`export(DS,...,'WriteVarNames',true)` is the default, writing the names as column headings in the first line of the file.

`export(DS,...,'WriteObsNames',false)` does not write the observation names to the text file.
`export(DS,...,'WriteObsNames',true)` is the default, writing the names as the first column of the file.

In some cases, `export` creates a text file that does not represent A exactly, as described below. If you use `dataset` to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save A as a MAT-file if you need to import it again as a dataset array.

`export` writes out numeric variables using long g format, and categorical or character variables as unquoted text.

For non-character variables with more than one column, `export` writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

`export` writes out variables that have more than two dimensions as a single empty field in each line of the file.

For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a .mat file.

**Examples**

Move data between external text files and dataset arrays in the MATLAB workspace:

```matlab
A = dataset('file','sat2.dat','delimiter',',')
A =
    Test        Gender  Score
    'Verbal'    'Male'   470
    'Verbal'    'Female' 530
    'Quantitative' 'Male'  520
    'Quantitative' 'Female' 480

export(A(A.Score > 500,:), 'file','HighScores.txt')

B = dataset('file','HighScores.txt','delimiter','\t')
B =
    Test        Gender  Score
    'Verbal'    'Female' 530
    'Quantitative' 'Male'  520
```

32-1258

dataset
**exppdf**

Exponential probability density function

**Syntax**

\[
y = \text{exppdf}(x) \\
y = \text{exppdf}(x, \mu)
\]

**Description**

\( y = \text{exppdf}(x) \) returns the probability density function (pdf) of the standard exponential distribution, evaluated at the values in \( x \).

\( y = \text{exppdf}(x, \mu) \) returns the pdf of the exponential distribution with mean \( \mu \), evaluated at the values in \( x \).

**Examples**

**Compute Exponential pdf**

Compute the density of the observed value 5 in the standard exponential distribution.

\[
y_1 = \text{exppdf}(5) \\
y_1 = 0.0067
\]

Compute the density of the observed value 5 in the exponential distributions specified by means 1 through 5.

\[
y_2 = \text{exppdf}(5, 1:5) \\
y_2 = 1 \times 5 \\
 0.0067 \quad 0.0410 \quad 0.0630 \quad 0.0716 \quad 0.0736
\]

Compute the density of the observed values 1 through 5 in the exponential distributions specified by means 1 through 5, respectively.

\[
y_3 = \text{exppdf}(1:5, 1:5) \\
y_3 = 1 \times 5 \\
 0.3679 \quad 0.1839 \quad 0.1226 \quad 0.0920 \quad 0.0736
\]

**Input Arguments**

- \( x \) — Values at which to evaluate pdf
  - nonnegative scalar value | array of nonnegative scalar values
Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify x using an array.
- To evaluate the pdfs of multiple distributions, specify mu using an array.

If either or both of the input arguments x and mu are arrays, then the array sizes must be the same. In this case, exppdf expands each scalar input into a constant array of the same size as the array inputs. Each element in y is the pdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in x.

Example: [3 4 7 9]

Data Types: single | double

mu — mean
1 (default) | positive scalar value | array of positive scalar values

Mean of the exponential distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify x using an array.
- To evaluate the pdfs of multiple distributions, specify mu using an array.

If either or both of the input arguments x and mu are arrays, then the array sizes must be the same. In this case, exppdf expands each scalar input into a constant array of the same size as the array inputs. Each element in y is the pdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in x.

Example: [1 2 3 5]

Data Types: single | double

Output Arguments

y — pdf values
scalar value | array of scalar values

Pdf values evaluated at the values in x, returned as a scalar value or an array of scalar values. y is the same size as x and mu after any necessary scalar expansion. Each element in y is the pdf value of the distribution specified by the corresponding element in mu, evaluated at the corresponding element in x.

More About

Exponential pdf

The exponential distribution is a one-parameter family of curves. The parameter \( \mu \) is the mean.

The pdf of the exponential distribution is

\[
y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}.
\]
A common alternative parameterization of the exponential distribution is to use $\lambda$ defined as the mean number of events in an interval as opposed to $\mu$, which is the mean wait time for an event to occur. $\lambda$ and $\mu$ are reciprocals.

For more information, see “Exponential Distribution” on page B-33.

**Alternative Functionality**

- `exppdf` is a function specific to the exponential distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create an `ExponentialDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `exppdf` is faster than the generic function `pdf`.
- Use the Probability Distribution Function app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

**Extended Capabilities**

**C/C++ Code Generation**
Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Topics**
“Exponential Distribution” on page B-33

**Introduced before R2006a**
exprnd

Exponential random numbers

Syntax

\[
\begin{align*}
    r &= \text{exprnd}(\mu) \\
    r &= \text{exprnd}(\mu, s_1, \ldots, s_N) \\
    r &= \text{exprnd}(\mu, s)
\end{align*}
\]

Description

\[ r = \text{exprnd}(\mu) \] generates a random number from the exponential distribution with mean \( \mu \).

\[ r = \text{exprnd}(\mu, s_1, \ldots, s_N) \] generates an array of random numbers from the exponential distribution, where \( s_1, \ldots, s_N \) indicates the size of each dimension.

\[ r = \text{exprnd}(\mu, s) \] generates an array of random numbers from the exponential distribution, where vector \( s \) specifies \( \text{size}(r) \).

Examples

Generate Exponential Random Number

Generate a single random number from the exponential distribution with mean 5.

\[
\begin{align*}
    r &= \text{exprnd}(5) \\
    r &= 1.0245
\end{align*}
\]

Generate Array of Exponential Random Numbers

Generate a 1-by-6 array of exponential random numbers with unit mean.

\[
\begin{align*}
    \mu_1 &= \text{ones}(1, 6); \quad \% \, 1\text{-by-}6 \text{ array of ones} \\
    r_1 &= \text{exprnd}(\mu_1)
\end{align*}
\]

\[
\begin{array}{ccccccc}
    0.2049 & 0.0989 & 2.0637 & 0.0906 & 0.4583 & 2.3275 \\
\end{array}
\]

By default, \text{exprnd} generates an array that is the same size as \( \mu \).

If you specify \( \mu \) as a scalar, then \text{exprnd} expands it into a constant array with dimensions specified by \( s_1, \ldots, s_N \).

Generate a 2-by-6 array of exponential random numbers with mean 3.
mu2 = 3;
sz1 = 2;
sz2 = 6;
r2 = exprnd(mu2,sz1,sz2)

r2 = 2×6
    3.8350  0.1303  5.5428  0.1313  0.6684  2.5899
    1.8106  0.1072  0.0895  2.1685  5.8582  0.2641

If you specify both mu and sz1,...,szn as arrays, then the dimensions specified by sz1,...,szn must match the dimension of mu.

Generate a 1-by-6 array of exponential random numbers with means 5 through 10.

mu3 = 5:10;
sz = [1 6];
r3 = exprnd(mu3,sz)

r3 = 1×6
    1.1647  0.2481  2.9539  26.6582  1.4719  0.6829

**Input Arguments**

- **mu** — mean
  1 (default) | positive scalar value | array of positive scalar values

  Mean of the exponential distribution, specified as a positive scalar value or an array of positive scalar values.

  To generate random numbers from multiple distributions, specify mu using an array. Each element in r is the random number generated from the distribution specified by the corresponding element in mu.

  Example: [1 2 3 5]

  Data Types: single | double

- **sz1,...,szN** — Size of each dimension (as separate arguments)
  integers

  Size of each dimension, specified as separate arguments of integers.

  If mu is an array, then the specified dimensions sz1,...,szN must match the dimensions of mu. The default values of sz1,...,szN are the dimensions of mu.

  - If you specify a single value sz1, then r is a square matrix of size sz1-by-sz1.
  - If the size of any dimension is 0 or negative, then r is an empty array.
  - Beyond the second dimension, exprnd ignores trailing dimensions with a size of 1. For example, exprnd(4,3,1,1,1) produces a 3-by-1 vector of random numbers from the distribution with mean 4.

  Example: 2,4
Data Types: single | double

sz — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers.

If mu is an array, then the specified dimensions sz must match the dimensions of mu. The default values of sz are the dimensions of mu.

- If you specify a single value [sz1], then r is a square matrix of size sz1-by-sz1.
- If the size of any dimension is 0 or negative, then r is an empty array.
- Beyond the second dimension, exprnd ignores trailing dimensions with a size of 1. For example, exprnd(4,[3 1 1 1]) produces a 3-by-1 vector of random numbers from the distribution with mean 4.

Example: [2 4]

Data Types: single | double

Output Arguments

r — Exponential random numbers
nonnegative scalar value | array of nonnegative scalar values

Exponential random numbers, returned as a nonnegative scalar value or an array of nonnegative scalar values with the dimensions specified by sz1,...,szN or sz. Each element in r is the random number generated from the distribution specified by the corresponding element in mu.

Alternative Functionality

- exprnd is a function specific to the exponential distribution. Statistics and Machine Learning Toolbox also offers the generic function random, which supports various probability distributions. To use random, create an ExponentialDistribution probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function exprnd is faster than the generic function random.
- To generate random numbers interactively, use randtool, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.
For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

expstat

Exponential mean and variance

Syntax

[m,v] = expstat(mu)

Description

[m,v] = expstat(mu) returns the mean of and variance for the exponential distribution with parameters mu. mu can be a vectors, matrix, or multidimensional array. The mean of the exponential distribution is \( \mu \), and the variance is \( \mu^2 \).

Examples

[m,v] = expstat([1 10 100 1000])
m =
    1   10   100  1000
v =
    1   100  10000 1000000

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics
“Exponential Distribution” on page B-33

Introduced before R2006a
factoran

Factor analysis

Syntax

\begin{align*}
&\text{lambda} = \text{factoran}(X, m) \\
&[\text{lambda}, \psi] = \text{factoran}(X, m) \\
&[\text{lambda}, \psi, T] = \text{factoran}(X, m) \\
&[\text{lambda}, \psi, T, \text{stats}] = \text{factoran}(X, m) \\
&[\text{lambda}, \psi, T, \text{stats}, F] = \text{factoran}(X, m) \\
&[\ldots] = \text{factoran}(\ldots, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \ldots)
\end{align*}

Description

\(\text{lambda} = \text{factoran}(X, m)\) returns the maximum likelihood estimate, \(\text{lambda}\), of the factor loadings matrix, in a common factor analysis model with \(m\) common factors. \(X\) is an \(n\)-by-\(d\) matrix where each row is an observation of \(d\) variables. The \((i,j)\)th element of the \(d\)-by-\(m\) matrix \(\text{lambda}\) is the coefficient, or loading, of the \(j\)th factor for the \(i\)th variable. By default, \text{factoran} calls the function \text{rotatefactors} to rotate the estimated factor loadings using the 'varimax' option.

\([\text{lambda}, \psi] = \text{factoran}(X, m)\) also returns maximum likelihood estimates of the specific variances as a column vector \(\psi\) of length \(d\).

\([\text{lambda}, \psi, T] = \text{factoran}(X, m)\) also returns the \(m\)-by-\(m\) factor loadings rotation matrix \(T\).

\([\text{lambda}, \psi, T, \text{stats}] = \text{factoran}(X, m)\) also returns a structure \(\text{stats}\) containing information relating to the null hypothesis, \(H_0\), that the number of common factors is \(m\). \(\text{stats}\) includes the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loglike</td>
<td>Maximized log-likelihood value</td>
</tr>
<tr>
<td>dfe</td>
<td>Error degrees of freedom = (((d-m)^2 - (d+m))/2)</td>
</tr>
<tr>
<td>chisq</td>
<td>Approximate chi-squared statistic for the null hypothesis</td>
</tr>
<tr>
<td>p</td>
<td>Right-tail significance level for the null hypothesis</td>
</tr>
</tbody>
</table>

\text{factoran} does not compute the chisq and \(p\) fields unless \(\text{dfe}\) is positive and all the specific variance estimates in \(\psi\) are positive (see “Heywood Case” on page 32-1276 below). If \(X\) is a covariance matrix, then you must also specify the 'nobs' parameter if you want \text{factoran} to compute the chisq and \(p\) fields.

\([\text{lambda}, \psi, T, \text{stats}, F] = \text{factoran}(X, m)\) also returns, in \(F\), predictions of the common factors, known as factor scores. \(F\) is an \(n\)-by-\(m\) matrix where each row is a prediction of \(m\) common factors. If \(X\) is a covariance matrix, \text{factoran} cannot compute \(F\). \text{factoran} rotates \(F\) using the same criterion as for \(\text{lambda}\).

\([\ldots] = \text{factoran}(\ldots, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \ldots)\) enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'xtype'</td>
<td>Type of input in the matrix X. 'xtype' can be one of:</td>
</tr>
<tr>
<td>- 'data'</td>
<td>Raw data (default)</td>
</tr>
<tr>
<td>- 'covariance'</td>
<td>Positive definite covariance or correlation matrix</td>
</tr>
<tr>
<td>'scores'</td>
<td>Method for predicting factor scores. 'scores' is ignored if X is not raw data.</td>
</tr>
<tr>
<td>- 'wls'</td>
<td>Bartlett</td>
</tr>
<tr>
<td>- 'regression'</td>
<td>Thomson</td>
</tr>
<tr>
<td>'start'</td>
<td>Starting point for the specific variances psi in the maximum likelihood optimization. Can be specified as:</td>
</tr>
<tr>
<td>- 'random'</td>
<td>Chooses d uniformly distributed values on the interval [0,1].</td>
</tr>
<tr>
<td>- 'Rsquared'</td>
<td>Chooses the starting vector as a scale factor times diag(inv(corrcoef(X))) (default). For examples, see Jöreskog [2].</td>
</tr>
<tr>
<td>Positive integer</td>
<td>Performs the given number of maximum likelihood fits, each initialized as with 'random'. factoran returns the fit with the highest likelihood.</td>
</tr>
<tr>
<td>Matrix</td>
<td>Performs one maximum likelihood fit for each column of the specified matrix. The i\textsuperscript{th} optimization is initialized with the values from the i\textsuperscript{th} column. The matrix must have d rows.</td>
</tr>
<tr>
<td>'rotate'</td>
<td>Method used to rotate factor loadings and scores. 'rotate' can have the same values as the 'Method' parameter of rotatefactors. See the reference page for rotatefactors for a full description of the available methods.</td>
</tr>
<tr>
<td>- 'none'</td>
<td>Performs no rotation.</td>
</tr>
<tr>
<td>- 'equamax'</td>
<td>Special case of the orthomax rotation. Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</td>
</tr>
<tr>
<td>- 'orthomax'</td>
<td>Orthogonal rotation that maximizes a criterion based on the variance of the loadings. Use the 'coeff', 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</td>
</tr>
<tr>
<td>- 'parsimax'</td>
<td>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>-----------</td>
<td>-------</td>
</tr>
<tr>
<td>'pattern'</td>
<td>Performs either an oblique rotation (the default) or an orthogonal rotation to best match a specified pattern matrix. Use the 'type' parameter to choose the type of rotation. Use the 'target' parameter to specify the pattern matrix.</td>
</tr>
<tr>
<td>'procrustes'</td>
<td>Performs either an oblique (the default) or an orthogonal rotation to best match a specified target matrix in the least squares sense. Use the 'type' parameter to choose the type of rotation. Use 'target' to specify the target matrix.</td>
</tr>
<tr>
<td>'promax'</td>
<td>Performs an oblique procrustes rotation to a target matrix determined by factoran as a function of an orthomax solution. Use the 'power' parameter to specify the exponent for creating the target matrix. Because 'promax' uses 'orthomax' internally, you can also specify the parameters that apply to 'orthomax'.</td>
</tr>
<tr>
<td>'quartimax'</td>
<td>Special case of the orthomax rotation (default). Use the 'normalize','reltol', and 'maxit' parameters to control the details of the rotation.</td>
</tr>
<tr>
<td>'varimax'</td>
<td>Special case of the orthomax rotation (default). Use the 'normalize','reltol', and 'maxit' parameters to control the details of the rotation.</td>
</tr>
<tr>
<td>Function</td>
<td>Function handle to rotation function of the form $[B,T] = \text{myrotation}(A,...)$ where $A$ is a $d$-by-$m$ matrix of unrotated factor loadings, $B$ is a $d$-by-$m$ matrix of rotated loadings, and $T$ is the corresponding $m$-by-$m$ rotation matrix. Use the factoran parameter 'userargs' to pass additional arguments to this rotation function. See “User-Defined Rotation Function” on page 32-1275.</td>
</tr>
<tr>
<td>'coeff'</td>
<td>Coefficient, often denoted as $\gamma$, defining the specific 'orthomax' criterion. Must be from 0 to 1. The value 0 corresponds to quartimax, and 1 corresponds to varimax. Default is 1.</td>
</tr>
<tr>
<td>'normalize'</td>
<td>Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for 'orthomax' or 'varimax' rotation. Default is 1.</td>
</tr>
<tr>
<td>'reltol'</td>
<td>Relative convergence tolerance for 'orthomax' or 'varimax' rotation. Default is $\sqrt{\text{eps}}$.</td>
</tr>
<tr>
<td>'maxit'</td>
<td>Iteration limit for 'orthomax' or 'varimax' rotation. Default is 250.</td>
</tr>
</tbody>
</table>
Factor Analysis

Parameter | Value
--- | ---
'target' | Target factor loading matrix for 'procrustes' rotation. Required for 'procrustes' rotation. No default value.
'type' | Type of 'procrustes' rotation. Can be 'oblique' (default) or 'orthogonal'.
'power' | Exponent for creating the target matrix in the 'promax' rotation. Must be $\geq 1$. Default is 4.
'userargs' | Denotes the beginning of additional input values for a user-defined rotation function. factoran appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix $A$. See “User-Defined Rotation Function” on page 32-1275.
'nobs' | If $X$ is a covariance or correlation matrix, indicates the number of observations that were used in its estimation. This allows calculation of significance for the null hypothesis even when the original data are not available. There is no default. 'nobs' is ignored if $X$ is raw data.
'delta' | Lower bound for the specific variances $\psi$ during the maximum likelihood optimization. Default is 0.005.
'optimopts' | Structure that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. Create this structure with the function statset. Enter statset('factoran') to see the names and default values of the parameters that factoran accepts in the options structure. See the reference page for statset for more information about these options.

Examples

Estimate and Plot Factor Loadings

Load the sample data.

load carbig

Define the variable matrix.

$X = \begin{bmatrix} \text{Acceleration} & \text{Displacement} & \text{Horsepower} & \text{MPG} & \text{Weight} \end{bmatrix}$

$X = X(\text{all}(-\text{isnan}(X),2),:);$  

Estimate the factor loadings using a minimum mean squared error prediction for a factor analysis with two common factors.

$[\Lambda,P,\Psi,T,\text{stats},F] = \text{factoran}(X,2,'\text{scores}',\text{'}regression\text{'});$  

$\text{inv}(T'*T); \quad % \text{Estimated correlation matrix of } F, == \text{eye}(2)$

$\Lambda*\Lambda' + \text{diag}(\Psi); \quad % \text{Estimated correlation matrix}$

$\Lambda*\text{inv}(T); \quad % \text{Unrotate the loadings}$

$F*T'; \quad % \text{Unrotate the factor scores}$

Create biplot of two factors.

$\text{biplot}(\Lambda,'\text{LineWidth}',2,'\text{MarkerSize}',20)$
Estimate the factor loadings using the covariance (or correlation) matrix.

\[
\begin{align*}
\text{[Lambda, Psi, T]} &= \text{factoran(cov(X), 2, 'xtype', 'cov')} \\
\text{Lambda} &= 5 \times 2 \\
  &\quad \begin{bmatrix} -0.2432 & -0.8500 \\ 0.8773 & 0.3871 \\ 0.7618 & 0.5930 \\ -0.7978 & -0.2786 \\ 0.9692 & 0.2129 \end{bmatrix} \\
\text{Psi} &= 5 \times 1 \\
  &\quad \begin{bmatrix} 0.2184 \\ 0.0804 \\ 0.0680 \\ 0.2859 \\ 0.0152 \end{bmatrix} \\
\text{T} &= 2 \times 2 \\
  &\quad \begin{bmatrix} 0.9476 & 0.3195 \\ 0.3195 & -0.9476 \end{bmatrix}
\end{align*}
\]

% [Lambda, Psi, T] = factoran(corrcoef(X), 2, 'xtype', 'cov')
Although the estimates are the same, the use of a covariance matrix rather than raw data doesn't let you request scores or significance level.

Use promax rotation.

```matlab
[Lambda, Psi, T, stats, F] = factoran(X, 2, 'rotate', 'promax', ...
    'powerpm', 4);
inv(T'*T)                            % Estimated correlation of F,
ans = 2x2
    1.0000   -0.6391
   -0.6391    1.0000
% no longer eye(2)
Lambda*inv(T'*T)*Lambda'+diag(Psi)   % Estimated correlation of X
ans = 5x5
    1.0000   -0.5424   -0.6893    0.4309   -0.4167
   -0.5424    1.0000    0.8979   -0.8078    0.9328
   -0.6893    0.8979    1.0000   -0.7730    0.8647
    0.4309   -0.8078   -0.7730    1.0000   -0.8326
   -0.4167    0.9328    0.8647   -0.8326    1.0000
```

Plot the unrotated variables with oblique axes superimposed.

```matlab
invT = inv(T);
Lambda0 = Lambda*invT;
figure()
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...
    [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ...
    'Color', 'r', 'linewidth', 2)
grid on
hold on
biplot(Lambda0, 'LineWidth', 2, 'MarkerSize', 20)
xlabel('Loadings for unrotated Factor 1')
ylabel('Loadings for unrotated Factor 2')
```
Plot the rotated variables against the oblique axes.

figure()
biplot(Lambda,'LineWidth',2,'MarkerSize',20)
User-Defined Rotation Function

Syntax for passing additional arguments to a user-defined rotation function:

```matlab
[Lambda, Psi, T] = ...
factoran(X, 2, 'rotate', @myrotation, 'userargs', 1, 'two');
```

More About

Factor Analysis Model

`factoran` computes the maximum likelihood estimate (MLE) of the factor loadings matrix Λ in the factor analysis model

\[ x = \mu + \Lambda f + e \]

where \( x \) is a vector of observed variables, \( \mu \) is a constant vector of means, \( \Lambda \) is a constant \( d \)-by-\( m \) matrix of factor loadings, \( f \) is a vector of independent, standardized common factors, and \( e \) is a vector of independent specific factors. \( x, \mu, \) and \( e \) are of length \( d \). \( f \) is of length \( m \).

Alternatively, the factor analysis model can be specified as

\[ \text{cov}(x) = \Lambda \Lambda^T + \Psi \]
where $\Psi = \text{cov}(e)$ is a d-by-d diagonal matrix of specific variances.

**Tips**

**Observed Data Variables**

The variables in the observed data matrix $X$ must be linearly independent, i.e., $\text{cov}(X)$ must have full rank, for maximum likelihood estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

`factoran` standardizes the observed data $X$ to zero mean and unit variance before estimating the loadings $\lambda$. This does not affect the model fit, because MLEs in this model are invariant to scale. However, $\lambda$ and $\psi$ are returned in terms of the standardized variables, i.e., $\lambda\lambda' + \text{diag}(\psi)$ is an estimate of the correlation matrix of the original data $X$ (although not after an oblique rotation). See “Estimate and Plot Factor Loadings” on page 32-1271 and “User-Defined Rotation Function” on page 32-1275.

**Heywood Case**

If elements of $\psi$ are equal to the value of the 'delta' parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e., $m$ is too large), but can also be the result of underfitting.

**Rotation of Factor Loadings and Scores**

Unless you explicitly specify no rotation using the 'rotate' parameter, `factoran` rotates the estimated factor loadings, $\lambda$, and the factor scores, $F$. The output matrix $T$ is used to rotate the loadings, i.e., $\lambda = \lambda_0*T$, where $\lambda_0$ is the initial (unrotated) MLE of the loadings. $T$ is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of $T$ is known as the primary axis rotation matrix, while $T$ itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

`factoran` computes factor scores that have been rotated by $\text{inv}(T')$, i.e., $F = F_0 * \text{inv}(T')$, where $F_0$ contains the unrotated predictions. The estimated covariance of $F$ is $\text{inv}(T'*T)$, which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

**References**

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

`pcacov` and `factoran` do not work directly on tall arrays. Instead, use `C = gather(cov(X))` to compute the covariance matrix of a tall array. Then, you can use `pcacov` or `factoran` on the in-memory covariance matrix. Alternatively, you can use `pca` directly on a tall array.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Introduced before R2006a
fcdf

F cumulative distribution function

Syntax

\[
p = \text{fcdf}(x,v1,v2) \\
p = \text{fcdf}(x,v1,v2,'upper')
\]

Description

\[
p = \text{fcdf}(x,v1,v2)
\]
computes the \( F \) cdf at each of the values in \( x \) using the corresponding numerator degrees of freedom \( v1 \) and denominator degrees of freedom \( v2 \). \( x, v1, \) and \( v2 \) can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs. \( v1 \) and \( v2 \) parameters must contain real positive values, and the values in \( x \) must lie on the interval \([0 \ Inf]\).

\[
p = \text{fcdf}(x,v1,v2,'upper')
\]
returns the complement of the \( F \) cdf at each value in \( x \), using an algorithm that more accurately computes the extreme upper tail probabilities.

The \( F \) cdf is

\[
p = F(x|v1,v2) = \int_0^x \frac{\Gamma\left(\frac{v1+v2}{2}\right)}{\Gamma\left(\frac{v1}{2}\right)\Gamma\left(\frac{v2}{2}\right)} \frac{v1^{v1/2} t^{v1/2 - 1}}{\left[1 + \left(\frac{v1}{v2}\right)t\right]^{v1+v2/2}} dt
\]

The result, \( p \), is the probability that a single observation from an \( F \) distribution with parameters \( v1 \) and \( v2 \) will fall in the interval \([0 x]\).

Examples

Compute \( F \) Distribution CDF

The following illustrates a useful mathematical identity for the \( F \) distribution.

\[
\text{nu1} = 1:5; \\
\text{nu2} = 6:10; \\
x = 2:6;
\]

\[
\text{F1} = \text{fcdf}(x,\text{nu1},\text{nu2})
\]

\[
\text{F1} = 1\times5
\]

\[
0.7930 \quad 0.8854 \quad 0.9481 \quad 0.9788 \quad 0.9919
\]

\[
\text{F2} = 1 - \text{fcdf}(1./x,\text{nu2},\text{nu1})
\]

\[
\text{F2} = 1\times5
\]

Introduced before R2006a
feval

Package:

Predict responses of generalized linear regression model using one input for each predictor

Syntax

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)

Description

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn) returns the predicted response of mdl to the new input predictors Xnew1,Xnew2,...,Xnewn.

Examples

Predict Response Values

Create a generalized linear regression model, and plot its responses to a range of input data.

Generate sample data using Poisson random numbers with two underlying predictors X(:,1) and X(:,2).

rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);

Create a generalized linear regression model of Poisson data.

mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');

Generate a range of values for X(:,1) and X(:,2), and plot the predictions at the values.

[Xtest1,Xtest2] = meshgrid(min(X(:,1)):.5:max(X(:,1)),min(X(:,2)):.5:max(X(:,2)));
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
Input Arguments

mdl — Generalized linear regression model
GeneralizedLinearModel object | CompactGeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm, or a CompactGeneralizedLinearModel object created using compact.

Xnew1,Xnew2,...,Xnewn — New predictor input values
vector | matrix | table | dataset array

New predictor values, specified as a vector, matrix, table, or dataset array.

- If you pass multiple inputs Xnew1,Xnew2,...,Xnewn and each includes observations for one predictor variable, then each input must be a vector. Each vector must have the same size. If you specify a predictor variable as a scalar, then feval expands the scalar argument into a constant vector of the same size as the other arguments.
- If you pass a single input Xnew1, then Xnew1 must be a table, dataset array, or matrix.
  - If Xnew1 is a table or dataset array, it must contain predictors that have the same predictor names as in the PredictorNames property of mdl.
  - If Xnew1 is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create mdl. Note that Xnew1 must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating
mdl must be numeric. To treat numerical predictors as categorical, identify the predictors using the 'CategoricalVars' name-value pair argument when you create mdl.

Data Types: single | double | table

Output Arguments

ypred — Predicted response values
numeric vector

Predicted response values at Xnew1, Xnew2, ..., Xnewn, returned as a numeric vector.

For a binomial model, feval uses 1 as the BinomialSize parameter, so the values in ypred are predicted probabilities. To return the numbers of successes in the trials, use the predict function and specify the number of trials by using the 'BinomialSize' name-value pair argument.

For a model with an offset, feval uses 0 as the offset value. To specify the offset value used when you fit a model, use the predict function and the 'Offset' name-value pair argument.

Tips

- A regression object is, mathematically, a function that estimates the relationship between the response and predictors. The feval function enables an object to behave like a function in MATLAB. You can pass feval to another function that accepts a function input, such as fminsearch and integral.
- feval can be simpler to use with a model created from a table or dataset array. When you have new predictor data, you can pass it to feval without creating a table or matrix.

Alternative Functionality

- predict gives the same predictions as feval if you use the default values for the 'Offset' and 'BinomialSize' name-value pair arguments of predict. The prediction values can be different if you specify other values for these arguments. The predict function also returns confidence intervals on its predictions. Note that the predict function accepts a single input argument containing all predictor variables, rather than multiple input arguments with one input for each predictor variable.
- random predicts responses with added noise.

Introduced in R2012a
feval

Package:
Predict responses of linear regression model using one input for each predictor

Syntax

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)

Description

ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn) returns the predicted response of mdl to the new input predictors Xnew1,Xnew2,...,Xnewn.

Examples

Plot Different Categorical Levels

Fit a mileage model to the carsmall data set, including the Year categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data set and fit the model.

load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');

Create a scatter plot of MPG versus Weight, grouped by Year.
gscatter(tbl.Weight,tbl.MPG,tbl.Year);
Plot curves of the model predictions for the various years and weights by using `feval`.

```matlab
w = linspace(min(tbl.Weight), max(tbl.Weight))';
line(w, feval(mdl, w, '70'), 'Color', 'r')
line(w, feval(mdl, w, '76'), 'Color', 'g')
line(w, feval(mdl, w, '82'), 'Color', 'b')
```
Input Arguments

mdl — Linear regression model object
LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using fitlm or stepwiselm, or a CompactLinearModel object created by using compact.

Xnew1,Xnew2,...,Xnewn — New predictor input values
vector | matrix | table | dataset array

New predictor values, specified as a vector, matrix, table, or dataset array.

- If you pass multiple inputs Xnew1,Xnew2,...,Xnewn and each includes observations for one predictor variable, then each input must be a vector. Each vector must have the same size. If you specify a predictor variable as a scalar, then feval expands the scalar argument into a constant vector of the same size as the other arguments.
- If you pass a single input Xnew1, then Xnew1 must be a table, dataset array, or matrix.
  - If Xnew1 is a table or dataset array, it must contain predictors that have the same predictor names as in the PredictorNames property of mdl.
  - If Xnew1 is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create mdl. Note that Xnew1 must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating...
mdl must be numeric. To treat numerical predictors as categorical, identify the predictors using the 'CategoricalVars' name-value pair argument when you create mdl.

Data Types: single | double | table

Output Arguments

ypred — Predicted response values
numeric vector

Predicted response values at Xnew1,Xnew2,...,Xnewn, returned as a numeric vector.

Tips

• A regression object is, mathematically, a function that estimates the relationship between the response and predictors. The feval function enables an object to behave like a function in MATLAB. You can pass feval to another function that accepts a function input, such as fminsearch and integral.
• feval can be simpler to use with a model created from a table or dataset array. When you have new predictor data, you can pass it to feval without creating a table or matrix.

Alternative Functionality

• predict gives the same predictions as feval by using a single input argument containing all predictor variables, rather than multiple input arguments with one input for each predictor variable. predict also gives confidence intervals on its predictions.
• random predicts responses with added noise.

“Linear Regression” on page 11-8

Introduced in R2012a
feval

**Class:** NonLinearModel

Evaluate nonlinear regression model prediction

**Syntax**

```matlab
ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)
```

**Description**

```matlab
ypred = feval(mdl,Xnew1,Xnew2,...,Xnewn)
```

returns the predicted response of `mdl` to the input `[Xnew1,Xnew2,...,Xnewn]`.

**Input Arguments**

- `mdl`
  
  Nonlinear regression model, constructed by `fitnlm`.

- `Xnew1,Xnew2,...,Xnewn`
  
  Predictor components. `Xnewi` can be one of:
  
  - Scalar
  - Vector
  - Array
  
  Each nonscalar component must have the same size (number of elements in each dimension).

  If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

**Output Arguments**

- `ypred`
  
  Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

**Examples**

**Predict a Nonlinear Model from a Table**

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
       b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using nanmean.

Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)

MPGnew = 21.8073

Alternatives

predict gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. predict also gives confidence intervals on its predictions.

random predicts with added noise.

**ff2n**

Two-level full factorial design

**Syntax**

```
dFF2 = ff2n(n)
```

**Description**

dFF2 = ff2n(n) gives factor settings dFF2 for a two-level full factorial design with n factors. dFF2 is m-by-n, where m is the number of treatments in the full-factorial design. Each row of dFF2 corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

**Examples**

```
dFF2 = ff2n(3)
dFF2 =  
     0  0  0  
     0  0  1  
     0  1  0  
     0  1  1  
     1  0  0  
     1  0  1  
     1  1  0  
     1  1  1  
```

**See Also**

`fullfact`

Introduced before R2006a
**fillprox**

**Class:** TreeBagger

Proximity matrix for training data

**Syntax**

B = fillprox(B)
B = fillprox(B,'param1',val1,'param2',val2,...)

**Description**

B = fillprox(B) computes a proximity matrix for the training data and stores it in the Properties field of B.

B = fillprox(B,'param1',val1,'param2',val2,...) specifies optional parameter name/value pairs:

- **'Trees'** Either 'all' or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is 'all'.
- **'NumPrint'** Number of training cycles (grown trees) after which TreeBagger displays a diagnostic message showing training progress. Default is no diagnostic messages.

**See Also**

outlierMeasure | proximity
findobj

Class: qrandstream

Find objects matching specified conditions

Syntax

hm = findobj(h, 'conditions')

Description

The findobj method of the handle class follows the same syntax as the MATLAB findobj command, except that the first argument must be an array of handles to objects.

hm = findobj(h, 'conditions') searches the handle object array h and returns an array of handle objects matching the specified conditions. Only the public members of the objects of h are considered when evaluating the conditions.

See Also

findobj | qrandstream
findprop

Class: qrandstream

Find property of MATLAB handle object

Syntax

p = findprop(h,'propname')

Description

p = findprop(h,'propname') finds and returns the meta.property object associated with property name propname of scalar handle object h. propname must be a character vector. It can be the name of a property defined by the class of h or a dynamic property added to scalar object h.

If no property named propname exists for object h, an empty meta.property array is returned.

See Also
dynamicprops | findobj | meta.property | qrandstream
**finv**

F inverse cumulative distribution function

**Syntax**

\[ X = \text{finv}(P, V1, V2) \]

**Description**

\( X = \text{finv}(P, V1, V2) \) computes the inverse of the F cdf with numerator degrees of freedom \( V1 \) and denominator degrees of freedom \( V2 \) for the corresponding probabilities in \( P \). \( P, V1, \) and \( V2 \) can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. \( V1 \) and \( V2 \) parameters must contain real positive values, and the values in \( P \) must lie on the interval \([0 1]\). The F inverse function is defined in terms of the F cdf as

\[
x = F^{-1}(p \mid \nu_1, \nu_2) = \{x : F(x \mid \nu_1, \nu_2) = p\}
\]

where

\[
p = F(x \mid \nu_1, \nu_2) = \int_0^x \frac{1}{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\nu_1/2} \left(\frac{t}{2}\right)^{\nu_1/2} \left[1 + \frac{(\nu_1/\nu_2)t}{\nu_1 + \nu_2}\right]^{-\nu_1/2} dt
\]

**Examples**

Find a value that should exceed 95% of the samples from an F distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

\[ x = \text{finv}(0.95, 5, 10) \]

\[ x = 3.3258 \]

You would observe values greater than 3.3258 only 5% of the time by chance.

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

**GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“F Distribution” on page B-45

Introduced before R2006a
fishertest

Fisher's exact test

Syntax

h = fishertest(x)
[h,p,stats] = fishertest(x)
[___] = fishertest(x,Name,Value)

Description

h = fishertest(x) returns a test decision for Fisher's exact test of the null hypothesis that there are no nonrandom associations between the two categorical variables in x, against the alternative that there is a nonrandom association. The result h is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

[h,p,stats] = fishertest(x) also returns the significance level p of the test and a structure stats containing additional test results, including the odds ratio and its asymptotic confidence interval.

[___] = fishertest(x,Name,Value) returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test or conduct a one-sided test.

Examples

Conduct Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu this winter. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

Create a 2-by-2 contingency table containing the survey data. Row 1 contains data for the individuals who did not receive a flu shot, and row 2 contains data for the individuals who received a flu shot. Column 1 contains the number of individuals who got the flu, and column 2 contains the number of individuals who did not.

x = table([3;1],[6;7], {'VariableNames',{'Flu','NoFlu'},'RowNames',{'NoShot','Shot'}})

Use Fisher's exact test to determine if there is a nonrandom association between receiving a flu shot and getting the flu.
h = fishertest(x)

h = logical
  0

The returned test decision h = 0 indicates that fishertest does not reject the null hypothesis of no nonrandom association between the categorical variables at the default 5% significance level. Therefore, based on the test results, individuals who do not get a flu shot do not have different odds of getting the flu than those who got the flu shot.

**Conduct a One-Sided Fisher's Exact Test**

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

x = [3,6;1,7];

Use a right-tailed Fisher's exact test to determine if the odds of getting the flu is higher for individuals who did not receive a flu shot than for individuals who did. Conduct the test at the 1% significance level.

[h,p,stats] = fishertest(x,'Tail','right','Alpha',0.01)

h = logical
  0

p = 0.3353

stats = struct with fields:
  OddsRatio: 3.5000
  ConfidenceInterval: [0.1289 95.0408]

The returned test decision h = 0 indicates that fishertest does not reject the null hypothesis of no nonrandom association between the categorical variables at the 1% significance level. Since this is a right-tailed hypothesis test, the conclusion is that individuals who do not get a flu shot do not have greater odds of getting the flu than those who got the flu shot.

**Generate a Contingency Table Using crosstab**

Load the hospital data.

load hospital

The hospital dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.
To determine if smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex,hospital.Smoker)
```

```
tbl = 2x2
    40    13
    26    21

chi2 = 4.5083
p = 0.0337
labels = 2x2 cell
    {'Female'}    {'0'}
    {'Male'  }    {'1'}
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a chi-squared test of independence. The returned value `p = 0.0337` is an approximate p-value based on the chi-squared distribution.

Use the contingency table generated by `crosstab` to perform Fisher's exact test on the data.

```
[h,p,stats] = fishertest(tbl)
```

```
h = logical
    1

p = 0.0375
```

```
stats = struct with fields:
    OddsRatio: 2.4852
    ConfidenceInterval: [1.0624  5.8135]
```

The result `h = 1` indicates that `fishertest` rejects the null hypothesis of nonassociation between smoking status and gender at the 5% significance level. In other words, there is an association between gender and smoking status. The odds ratio indicates that the male patients have about 2.5 times greater odds of being smokers than the female patients.

The returned p-value of the test, `p = 0.0375`, is close to, but not exactly the same as, the result obtained by `crosstab`. This is because `fishertest` computes an exact p-value using the sample data, while `crosstab` uses a chi-squared approximation to compute the p-value.

### Input Arguments

- **x** — Contingency table  
  2-by-2 matrix of nonnegative integer values | 2-by-2 table of nonnegative integer values
Contingency table, specified as a 2-by-2 matrix or table containing nonnegative integer values. A contingency table contains the frequency distribution of the variables in the sample data. You can use crosstab to generate a contingency table from sample data.

Example: \([4,0;0,4]\)

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Alpha', 0.01, 'Tail', 'right' specifies a right-tailed hypothesis test at the 1% significance level.

**Alpha — Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha', 0.01

Data Types: single | double

**Tail — Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'both'
  - Two-tailed test. The alternative hypothesis is that there is a nonrandom association between the two variables in \(x\), and the odds ratio is not equal to 1.

- 'right'
  - Right-tailed test. The alternative hypothesis is that the odds ratio is greater than 1.

- 'left'
  - Left-tailed test. The alternative hypothesis is that the odds ratio is less than 1.

Example: 'Tail', 'right'

Output Arguments

**h — Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If \(h\) is 1, then fishertest rejects the null hypothesis at the \(Alpha\) significance level.
- If \(h\) is 0, then fishertest fails to reject the null hypothesis at the \(Alpha\) significance level.

**p — p-value**

scalar value in the range \([0,1]\)
\( p \)-value of the test, returned as a scalar value in the range \([0,1]\). \( p \) is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of \( p \) cast doubt on the validity of the null hypothesis.

**stats — Test data**

Structure

Test data, returned as a structure with the following fields:

- **OddsRatio** — A measure of association between the two variables.
- **ConfidenceInterval** — Asymptotic confidence interval for the odds ratio. If any of the cell frequencies in \( x \) are 0, then `fishertest` does not compute a confidence interval and instead displays \([-\infty \; \infty]\).

**More About**

**Fisher's Exact Test**

Fisher's exact test is a nonparametric statistical test used to test the null hypothesis that no nonrandom associations exist between two categorical variables, against the alternative that there is a nonrandom association between the variables.

Fisher's exact test provides an alternative to the chi-squared test for small samples, or samples with very uneven marginal distributions. Unlike the chi-squared test, Fisher's exact test does not depend on large-sample distribution assumptions, and instead calculates an exact \( p \)-value based on the sample data. Although Fisher's exact test is valid for samples of any size, it is not recommended for large samples because it is computationally intensive. If all of the frequency counts in the contingency table are greater than or equal to \( 1e7 \), then `fishertest` errors. For contingency tables that contain large count values or are well-balanced, use `crosstab` or `chi2gof` instead.

`fishertest` accepts a 2-by-2 contingency table as input, and computes the \( p \)-value of the test as follows:

1. Calculate the sums for each row, column, and total number of observations in the contingency table.
2. Using a multivariate generalization of the hypergeometric probability function, calculate the conditional probability of observing the exact result in the contingency table if the null hypothesis were true, given its row and column sums. The conditional probability is

\[
P_{\text{cutoff}} = \frac{(R_1! R_2!)(C_1! C_2)!}{N! \prod_{i,j} n_{ij}!},
\]

where \( R_1 \) and \( R_2 \) are the row sums, \( C_1 \) and \( C_2 \) are the column sums, \( N \) is the total number of observations in the contingency table, and \( n_{ij} \) is the value in the \( i \)th row and \( j \)th column of the table.
3. Find all possible matrices of nonnegative integers consistent with the row and column sums. For each matrix, calculate the associated conditional probability using the equation for \( P_{\text{cutoff}} \).
4. Use these values to calculate the \( p \)-value of the test, based on the alternative hypothesis of interest.

- For a two-sided test, sum all of the conditional probabilities less than or equal to \( P_{\text{cutoff}} \) for the observed contingency table. This represents the probability of observing a result as extreme as
as, or more extreme than, the actual outcome if the null hypothesis were true. Small \( p \)-values cast doubt on the validity of the null hypothesis, in favor of the alternative hypothesis of association between the variables.

- For a left-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency less than or equal to \( n_{11} \).
- For a right-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency greater than or equal to \( n_{11} \) in the observed contingency table.

The odds ratio is

\[
OR = \frac{n_{11}n_{22}}{n_{21}n_{12}}.
\]

The null hypothesis of conditional independence is equivalent to the hypothesis that the odds ratio equals 1. The left-sided alternative is equivalent to an odds ratio less than 1, and the right-sided alternative is equivalent to an odds ratio greater than 1.

The asymptotic 100(1 - \( \alpha \))% confidence interval for the odds ratio is

\[
CI = \left[ \exp \left( L - \Phi^{-1} \left( \frac{1 - \alpha}{2} \right) SE \right), \exp \left( L + \Phi^{-1} \left( \frac{1 - \alpha}{2} \right) SE \right) \right],
\]

where \( L \) is the log odds ratio, \( \Phi^{-1}(\bullet) \) is the inverse of the normal inverse cumulative distribution function, and \( SE \) is the standard error for the log odds ratio. If the 100(1 - \( \alpha \))% confidence interval does not contain the value 1, then the association is significant at the \( \alpha \) significance level. If any of the four cell frequencies are 0, then \text{fishertest} does not compute the confidence interval and instead displays [-Inf Inf].

\text{fishertest} only accepts 2-by-2 contingency tables as input. To test the independence of categorical variables with more than two levels, use the chi-squared test provided by \text{crosstab}.

**See Also**
\text{chi2gof} | \text{crosstab}

**Introduced in R2014b**
ClassificationDiscriminant.fit

Class: ClassificationDiscriminant

(Not Recommended) Fit discriminant analysis classifier

Note ClassificationDiscriminant.fit is not recommended. Use fitcdiscr instead.

Syntax

obj = ClassificationDiscriminant.fit(x,y)
obj = ClassificationDiscriminant.fit(x,y,Name,Value)

Description

obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.

obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name,Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.

Input Arguments

x — Predictor values
matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.

ClassificationDiscriminant.fit considers NaN values in x as missing values. ClassificationDiscriminant.fit does not use observations with missing values for x in the fit.

Data Types: single | double

y — Classification values
numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of character vectors. Each row of y represents the classification of the corresponding row of x.

ClassificationDiscriminant.fit considers NaN values in y to be missing values. ClassificationDiscriminant.fit does not use observations with missing values for y in the fit.

Data Types: single | double | logical | char | cell
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

ClassNames — Class names
array

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array. Use the data type that exists in y. The default is the class names that exist in y. Use ClassNames to order the classes or to select a subset of classes for training.

Data Types: single | double | logical | char

Cost — Cost of misclassification
square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i. Alternatively, Cost can be a structure S having two fields: S.ClassNames containing the group names as a variable of the same type as y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.

Data Types: single | double | struct

CrossVal — Cross-validation flag
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'CrossVal','on'

CVPartition — Cross-validated model partition
cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Delta — Linear coefficient threshold
0 (default) | nonnegative scalar value
Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of \( Mdl \) has magnitude smaller than \( \Delta \), \( Mdl \) sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set \( \Delta \) to a higher value to eliminate more predictors.

**Delta** must be 0 for quadratic discriminant models.

**DiscrimType** — Discriminant type

- `'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudolinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Predictor Covariance Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'linear'</code></td>
<td>Regularized linear discriminant analysis (LDA)</td>
<td>• All classes have the same covariance matrix.</td>

</tr>
</tbody>
</table>

**Note** To use regularization, you must specify `'linear'`. To specify the amount of regularization, use the \texttt{Gamma} name-value pair argument.

Example: `'DiscrimType','quadratic'`

**FillCoeffs** — Coeffs property flag

- `'on'` | `'off'`
Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs','off'

**Gamma** — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than DiscrimType.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
  - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering Mdl.Gamma at the command line.
  - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets DiscrimType to 'linear'.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set DiscrimType to 'diagLinear' or 'diagQuadratic' for diagonal covariance matrices.

Example: 'Gamma',1

Data Types: single | double

**Holdout** — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold** — Number of folds

10 (default) | positive integer value greater than 1
Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k, then the software:

1. Randomly partitions the data into k sets
2. For each set, reserves the set as validation data, and trains the model using the other k - 1 sets
3. Stores the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag
'ref' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is size(Mdl.X,1), the software:

1. Reserves the observation as validation data, and trains the model using the other n - 1 observations
2. Stores the n compact, trained models in the cells of a n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Example: 'Leaveout', 'on'

PredictorNames — Predictor variable names
{'X1', 'X2', ...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X.

Data Types: cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- 'empirical' determines class probabilities from class frequencies in y. If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure S with two fields:
- `S.ClassNames` containing the class names as a variable of the same type as `y`  
- `S.ClassProbs` containing a vector of corresponding probabilities

Example: 'Prior','uniform'  
Data Types: `single` | `double` | `char` | `struct`

**ResponseName — Response variable name**  
'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable `y`.  
Example: 'ResponseName','Response'  
Data Types: `char`

**SaveMemory — Flag to save covariance matrix**  
'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.  
Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.  
Example: 'SaveMemory','on'

**ScoreTransform — Score transformation**  
'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of `'ScoreTransform'` and a character vector or function handle.  
This table summarizes the available character vectors.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1-x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'          | $-1$ for $x < 0$  
                   | 0 for $x = 0$  
                   | $1$ for $x > 0$ |
| 'symmetric'     | $2x - 1$                                         |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to $-1$ |
For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | function_handle

Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in X. fitdiscr normalizes the weights to sum to 1.

Data Types: single | double

Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, obj is of class ClassificationDiscriminant, and you can use the predict method to predict the response of new data.

Examples

Construct a Discriminant Analysis Classifier

Load the sample data.

load fisheriris

Construct a discriminant analysis classifier using the sample data.

obj = ClassificationDiscriminant.fit(meas,species)

obj =
    ClassificationDiscriminant
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DiscrimType: 'linear'
Mu: [3x4 double]
Coefs: [3x3 struct]

Properties, Methods

More About

Discriminant Classification

The model for discriminant analysis is:

• Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model
  assumes X has a Gaussian mixture distribution (gmdistribution).
  • For linear discriminant analysis, the model has the same covariance matrix for each class, only
    the means vary.
  • For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

\[ \hat{y} = \arg\min_{y = 1, \ldots, K} \sum_{k = 1}^{K} \hat{P}(k|x)C(y|k), \]

where

• \( \hat{y} \) is the predicted classification.
• \( K \) is the number of classes.
• \( \hat{P}(k|x) \) is the posterior probability on page 20-6 of class \( k \) for observation \( x \).
• \( C(y|k) \) is the cost on page 20-7 of classifying an observation as \( y \) when its true class is \( k \).

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Alternatives

The classify function also performs discriminant analysis. classify is usually more awkward to use:

• classify requires you to fit the classifier every time you make a new prediction.
• classify does not perform cross validation.
• classify requires you to fit the classifier when changing prior probabilities.

ClassificationDiscriminant | fitcdiscr

Topics
“Discriminant Analysis Classification” on page 20-2
ClassificationKNN.fit

(Not Recommended) Fit k-nearest neighbor classifier

**Note** ClassificationKNN.fit is not recommended. Use fitcknn instead.

**Syntax**

mdl = ClassificationKNN.fit(X,y)
mdl = ClassificationKNN.fit(X,y,Name,Value)

**Description**

mdl = ClassificationKNN.fit(X,y) returns a classification model based on the input variables (also known as predictors, features, or attributes) X and output (response) y.

mdl = ClassificationKNN.fit(X,y,Name,Value) fits a model with additional options specified by one or more Name,Value pair arguments.

If you use one of these options, mdl is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, mdl is of class ClassificationKNN.

**Input Arguments**

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

The length of Y and the number of observations in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

Y — Classification values
numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors, with the same number of rows as X. Each row of Y represents the classification of the corresponding row of X.

Data Types: single | double | cell | logical | char
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

BreakTies — Tie-breaking algorithm
'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the predict method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of 'BreakTies' and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

Example: 'BreakTies','nearest'

BucketSize — Maximum data points in node
50 (default) | positive integer value

Maximum number of data points in the leaf node of the kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when NSMethod is 'kdtree'.

Example: 'BucketSize',40

Data Types: single | double

CategoricalPredictors — Categorical predictor flag
[] | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

The predictor data for ClassificationKNN.fit must be either all continuous or all categorical.

- If the predictor data is in a table (Tbl), ClassificationKNN.fit assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If Tbl includes both continuous and categorical values, then you must specify the value of 'CategoricalPredictors' so that ClassificationKNN.fit can determine how to treat all predictors, as either continuous or categorical variables.
- If the predictor data is a matrix (X), ClassificationKNN.fit assumes that all predictors are continuous. To identify all predictors in X as categorical, specify 'CategoricalPredictors' as 'all'.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

Example: 'CategoricalPredictors','all'
ClassNames — Class names
numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in y.

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names in y.

Data Types: single | double | char | logical | cell

Cost — Cost of misclassification
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.

Data Types: single | double | struct

Cov — Covariance matrix
nanncov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

CrossVal — Cross-validation flag
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If 'on', fitcknn creates a cross-validated model with 10 folds. Use the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross validate mdl later using the crossval method.

Example: 'CrossVal','on'

CVPartition — Cross-validated model partition
cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition. You can only use one of these four
options at a time to create a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Distance — Distance metric**

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' | 'hamming'

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

<table>
<thead>
<tr>
<th>NSMethod</th>
<th>Distance Metric Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>exhaustive</td>
<td>Any distance metric of ExhaustiveSearcher</td>
</tr>
<tr>
<td>kdtree</td>
<td>'cityblock', 'chebychev', 'euclidean', or 'minkowski'</td>
</tr>
</tbody>
</table>

This table includes valid distance metrics of ExhaustiveSearcher.

<table>
<thead>
<tr>
<th>Distance Metric Names</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>
<td>City block distance.</td>
</tr>
<tr>
<td>'chebychev'</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>'correlation'</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>'cosine'</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>'euclidean'</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>'hamming'</td>
<td>Hamming distance, percentage of coordinates that differ.</td>
</tr>
<tr>
<td>'jaccard'</td>
<td>One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>'mahalanobis'</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by nancov(X). To specify a different value for C, use the 'Cov' name-value pair argument.</td>
</tr>
<tr>
<td>'minkowski'</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, S = nanstd(X). To specify another value for S, use the Scale name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>
Distance Metric Names | Description
--- | ---
@distfun | Distance function handle. \textit{distfun} has the form
\[
\text{function } D2 = \text{distfun}(ZI,ZJ) \\
\% \text{calculation of distance} \\
\ldots \\
\text{where} \\
\begin{itemize}
  \item ZI is a 1-by-\(N\) vector containing one row of \(X\) or \(Y\). 
  \item ZJ is an \(M2\)-by-\(N\) matrix containing multiple rows of \(X\) or \(Y\). 
  \item D2 is an \(M2\)-by-1 vector of distances, and \(D2(k)\) is the distance between observations \(ZI\) and \(ZJ(k,:).\)
\end{itemize}

If you specify \texttt{CategoricalPredictors} as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see "Distance Metrics" on page 18-11.

Example: 'Distance','minkowski'

Data Types: char | function handle

**DistanceWeight — Distance weighting function**

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'equal'</td>
<td>No weighting</td>
</tr>
<tr>
<td>'inverse'</td>
<td>Weight is 1/distance</td>
</tr>
<tr>
<td>'squaredinverse'</td>
<td>Weight is 1/distance(^2)</td>
</tr>
<tr>
<td>@fcn</td>
<td>(fcn) is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @((d))(d.^(\text{-2})).</td>
</tr>
</tbody>
</table>

Example: 'DistanceWeight','inverse'

Data Types: char | function handle

**Exponent — Minkowski distance exponent**

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

**Holdout — Fraction of data for holdout validation**

0 (default) | scalar value in the range \([0,1]\)
Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range $[0, 1]$. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

IncludeTies — Tie inclusion flag
false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies', true

Data Types: logical

KFold — Number of folds
10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold', 8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag
'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

NSMethod — Nearest neighbor search method
'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a kd-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
• 'cityblock'
• 'minkowski'
• 'chebychev'
• 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point \(x_{\text{new}}\), the software computes the distance values from all points in \(X\) to \(x_{\text{new}}\) to find nearest neighbors.

The default is 'kdtree' when \(X\) has 10 or fewer columns, \(X\) is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod','exhaustive'

**NumNeighbors** — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in \(X\) to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3
Data Types: single | double

**PredictorNames** — Predictor variable names

{'x1','x2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in \(X\).

If you specify the predictors as a table (\(tbl\)), then **PredictorNames** must be a subset of the variable names in \(tbl\). In this case, the software uses only the variables in **PredictorNames** to train the model. If you use formula to specify the model, then you cannot use the **PredictorNames** name-value pair.

Example: 'PredictorNames',{'PedalWidth','PedalLength'}
Data Types: cell

**Prior** — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in (Y).</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to (1/K), where (K) is the number of classes.</td>
</tr>
</tbody>
</table>

32-1315
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'
Data Types: char | single | double | struct

ResponseName — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable Y.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName', 'Response'
Data Types: char

Scale — Distance scale

nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when ‘Distance’ is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Weights — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weighs the observations in each row of X or tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or tbl.

If you specify the input data as a table tbl, then Weights can be the name of a variable in tbl that contains a numeric vector. In this case, you must specify Weights as a character vector containing
the variable name. For example, if the weights vector \( w \) is stored as \( tbl.w \), then specify it as \('w'\).

Otherwise, the software treats all columns of \( tbl \), including \( w \), as predictors when training the model.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: \( \text{single} \) | \( \text{double} \)

**Output Arguments**

\( \text{mdl} \) — \( k \)-nearest neighbor classifier model

ClassificationKNN object

\( k \)-nearest neighbor classifier model, specified as a ClassificationKNN object.

**Examples**

**Train \( k \)-Nearest Neighbor Classifier**

Train a \( k \)-nearest neighbor classifier for Fisher's iris data, where \( k \), the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```matlab
load fisheriris
X = meas;
Y = species;
```

\( X \) is a numeric matrix that contains four petal measurements for 150 irises. \( Y \) is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

\( Mdl \) is a trained ClassificationKNN classifier, and some of its properties appear in the Command Window.

To access the properties of \( Mdl \), use dot notation.

\( Mdl.ClassNames \)
Train a k-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```matlab
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
     'NSMethod','exhaustive','Distance','minkowski',...
     'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of `Mdl` by double-clicking `Mdl` in the Workspace window. This opens the Variable Editor.
More About

Prediction

ClassificationKNN predicts the classification of a point \( x_{\text{new}} \) using a procedure equivalent to this:

1. Find the \( \text{NumNeighbors} \) points in the training set \( X \) that are nearest to \( x_{\text{new}} \).
2. Find the \( \text{NumNeighbors} \) response values \( Y \) to those nearest points.
3. Assign the classification label \( y_{\text{new}} \) that has the largest posterior probability among the values in \( Y \).

For details, see “Posterior Probability” on page 32-4144 in the predict documentation.

ClassificationKNN | fitcknn | predict

Topics
“Construct KNN Classifier” on page 18-27
“Modify KNN Classifier” on page 18-28
“Classification Using Nearest Neighbors” on page 18-11
ClassificationTree.fit

Class: ClassificationTree

(Not Recommended) Fit classification tree

**Note** ClassificationTree.fit is not recommended. Use fitctree instead.

**Syntax**

```matlab
tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)
```

**Description**

`tree = ClassificationTree.fit(x,y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree, where each branching node is split based on the values of a column of `x`.

`tree = ClassificationTree.fit(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, `tree` is of class ClassificationTree, and you can use the predict method to make predictions.

**Input Arguments**

- `x` — Predictor values
  
  matrix of floating point values

  Predictor values, specified as a matrix of floating point values.

  `ClassificationTree.fit` considers NaN values in `x` as missing values.
  `ClassificationTree.fit` does not use observations with all missing values for `x` in the fit.
  `ClassificationTree.fit` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

  Data Types: `single` | `double`

- `y` — predictor values
  
  numeric vector | categorical vector | logical vector | character array | cell array of character vectors

  Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.
Each row of \( y \) represents the classification of the corresponding row of \( x \). For numeric \( y \), consider using \texttt{fitrtree} instead. \texttt{ClassificationTree.fit} considers NaN values in \( y \) to be missing values.

\texttt{ClassificationTree.fit} does not use observations with missing values for \( y \) in the fit.

Data Types: \texttt{single} \texttt{| double} \texttt{| char} \texttt{| logical} \texttt{| cell}

Name-Value Pair Arguments

Specify optional comma-separated pairs of \texttt{Name,Value} arguments. \texttt{Name} is the argument name and \texttt{Value} is the corresponding value. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

\texttt{AlgorithmForCategorical} — Algorithm for best split on categorical predictor

\texttt{'Exact'} | \texttt{'PullLeft'} | \texttt{'PCA'} | \texttt{'OVAByClass'}

Algorithm to find the best split on a categorical predictor with \( L \) levels for data with \( K \geq 3 \) classes, specified as the comma-separated pair consisting of \texttt{'AlgorithmForCategorical'} and one of the following.

- \texttt{'Exact'}: Consider all \( 2^{L-1} - 1 \) combinations
- \texttt{'PullLeft'}: Pull left by purity
- \texttt{'PCA'}: Principal component-based partition
- \texttt{'OVAByClass'}: One versus all by class

\texttt{ClassificationTree.fit} selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For \( K = 2 \) classes, \texttt{ClassificationTree.fit} always performs the exact search.

Example: \texttt{AlgorithmForCategorical}, \texttt{'PCA'}

\texttt{CategoricalPredictors} — Categorical predictors list

\texttt{numeric or logical vector} \texttt{| cell array of character vectors} \texttt{| character matrix} \texttt{| 'all'}

Categorical predictors list, specified as the comma-separated pair consisting of \texttt{'CategoricalPredictors'} and one of the following.

- A numeric vector with indices from 1 to \( p \), where \( p \) is the number of columns of \( x \).
- A logical vector of length \( p \), where \texttt{true} entry means that the corresponding column of \( x \) is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in \texttt{PredictorNames} values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in \texttt{PredictorNames} values. Pad the names with extra blanks so each row of the character matrix has the same length.
- \texttt{'all'}, meaning all predictors are categorical.

Example: \texttt{CategoricalPredictors}, \texttt{'all'}

Data Types: \texttt{single} \texttt{| double} \texttt{| char}

\texttt{ClassNames} — Class names

\texttt{numeric vector} \texttt{| categorical vector} \texttt{| logical vector} \texttt{| character array} \texttt{| cell array of character vectors}
Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in y.

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names that exist in y.

**Cost — Cost of misclassification**

square matrix | structure

Cost of misclassification a point, specified as the comma-separated pair consisting of 'Cost' and one of the following.

- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j

**CrossVal — Flag to grow cross-validated tree**

'on' (default) | 'off'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', ClassificationTree.fit grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Example: 'CrossVal','on'

**CVPartition — Partition for cross-validation tree**

cvpartition object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the cvpartition class created using cvpartition.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout — Fraction of data for holdout validation**

1 (default) | scalar value in the range (0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.
Example: 'Holdout', 0.1
Data Types: single | double

**KFold — Number of folds**
10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold', 8
Data Types: single | double

**Leaveout — Leave-one-out cross validation flag**
'off' (default) | 'on'

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

**MaxCat — Maximum category levels**
10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree.fit` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree.fit` finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

Example: 'MaxCat', 8

**MergeLeaves — Leaf merge flag**
'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree.fit` does not merge leaves.

Example: 'MergeLeaves', 'off'

**MinLeaf — Minimum number of leaf node observations**
1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both MinParent and MinLeaf, `ClassificationTree.fit` uses the setting that gives larger leaves: MinParent=max(MinParent, 2*MinLeaf).
Example: 'MinLeaf',3
Data Types: single | double

MinParent — Minimum number of branch node observations
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Example: 'MinParent',8
Data Types: single | double

NVarToSample — Number of predictors for split
'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NVarToSample',3
Data Types: single | double

PredictorNames — Predictor variable names
{'x1','x2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in x.

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- 'empirical' determines class probabilities from class frequencies in y. If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as y
  - S.ClassProbs containing a vector of corresponding probabilities

If you set values for both weights and prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Prune — Pruning flag
'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', ClassificationTree.fit grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' ClassificationTree.fit grows the classification tree without pruning.

Example: 'Prune','off'

**PruneCriterion — Pruning criterion**

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

Example: 'PruneCriterion','impurity'

**ResponseName — Response variable name**

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable y.

Example: 'ResponseName','Response'

**ScoreTransform — Score transform function**

'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following values representing a built-in transformation function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1 - x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'        | -1 for $x < 0$  
|               | 0 for $x = 0$          
|               | 1 for $x > 0$          |
| 'symmetric'   | $2x - 1$                    |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{x}) - 1$         |

Example: 'ScoreTransform','logit'

**SplitCriterion — Split criterion**

'gdi' (default) | 'twoing' | 'deviance'
Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion','deviance'

**Surrogate — Surrogate decision splits flag**

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', ClassificationTree.fit finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, ClassificationTree.fit finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', ClassificationTree.fit finds all surrogate splits at each branch node.
  The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate','on'

**Weights — Observation weights**

ones(size(x,1),1) (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is equal to the number of rows in x. ClassificationTree.fit normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

**Output Arguments**

**tree** — Classification tree  
classification tree object

Classification tree object, returned as a classification tree object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method. Instead, use kfoldPredict to predict responses for observations not used for training.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

**Examples**

**Construct a Classification Tree**

Construct a classification tree for the data in ionosphere.mat.
load ionosphere

tc = ClassificationTree.fit(X,Y)

tc = ClassificationTree
  ResponseName: 'Y'
  CategoricalPredictors: []
  ClassNames: {'b'  'g'}
  ScoreTransform: 'none'
  NumObservations: 351

More About

Impurity and Node Error

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- Gini's Diversity Index (gdi) — The Gini index of a node is
  \[ 1 - \sum_i p(i)^2, \]
  where the sum is over the classes \( i \) at the node, and \( p(i) \) is the observed fraction of classes with class \( i \) that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With \( p(i) \) defined the same as for the Gini index, the deviance of a node is
  \[ -\sum_i p(i)\log_2 p(i). \]
  A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let \( L(i) \) denote the fraction of members of class \( i \) in the left child node after a split, and \( R(i) \) denote the fraction of members of class \( i \) in the right child node after a split. Choose the split criterion to maximize
  \[ P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2, \]
  where \( P(L) \) and \( P(R) \) are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If \( j \) is the class with the largest number of training samples at a node, the node error is
1 – \[ p(j). \]

ClassificationTree | fitctree | kfoldPredict | predict
GeneralizedLinearModel.fit

(Not Recommended) Create generalized linear regression model

**Note** GeneralizedLinearModel.fit is not recommended. Use fitglm instead.

**Syntax**

```matlab
mdl = GeneralizedLinearModel.fit(tbl)
mdl = GeneralizedLinearModel.fit(X,y)
mdl = GeneralizedLinearModel.fit(...,modelspec)
mdl = GeneralizedLinearModel.fit(...,Name,Value)
mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)
```

**Description**

- `mdl = GeneralizedLinearModel.fit(tbl)` creates a generalized linear model of a table or dataset array `tbl`.
- `mdl = GeneralizedLinearModel.fit(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.
- `mdl = GeneralizedLinearModel.fit(...,modelspec)` creates a generalized linear model as specified by `modelspec`.
- `mdl = GeneralizedLinearModel.fit(...,Name,Value)` or `mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

`tbl` — Input data
table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if `'Distribution'` is `'binomial'`.

- By default, `GeneralizedLinearModel.fit` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.
The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical `1` (`true`) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

**X — Predictor variables**

*matrix*

Predictor variables, specified as an `n`-by-`p` matrix, where `n` is the number of observations and `p` is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

**y — Response variable**

*vector | matrix*

Response variable, specified as a vector or matrix.

- If 'Distribution' is not 'binomial', then `y` must be an `n`-by-1 vector, where `n` is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. The data type must be single or double.
- If 'Distribution' is 'binomial', then `y` can be an `n`-by-1 vector or `n`-by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

**modelspec — Model specification**

*character vector or string scalar naming the model | t-by-(p + 1) terms matrix | character vector or string scalar formula in the form 'Y ~ terms'*

Model specification, specified as one of the following:

- Character vector or string scalar specifying the type of model.
<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear term for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept term and linear and squared terms for each predictor.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree ( i ) in the first predictor, degree ( j ) in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and ( x_1, x_2, x_2^2, x_2^3, x_1^2, x_1x_2, ) and ( x_1^3x_2^2 ) terms, where ( x_1 ) and ( x_2 ) are the first and second predictors, respectively.</td>
</tr>
</tbody>
</table>

- \( t \)-by-\((p+1) \) matrix, namely terms matrix on page 32-1338, specifying terms to include in model, where \( t \) is the number of terms and \( p \) is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-1338 in the form
  \[ Y \sim \text{terms}, \]
  where the terms are in "Wilkinson Notation" on page 32-1338.

Example: 'quadratic'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**BinomialSize — Number of trials for binomial distribution**

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of 'BinomialSize' and the variable name in tbl, a numeric scalar, or a numeric vector of the same length as the response. This is the parameter \( n \) for the fitted binominal distribution. BinomialSize applies only when the Distribution parameter is 'binomial'.

If BinomialSize is a scalar value, that means all observations have the same number of trials.

As an alternative to BinomialSize, you can specify the response as a two-column matrix with counts in column 1 and BinomialSize in column 2.
Data Types: `single` | `double` | `char` | `string`

**CategoricalVars — Categorical variable list**

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `CategoricalVars` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `GeneralizedLinearModel.fit` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `CategoricalVars` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `CategoricalVars',[2,3]
Example: `CategoricalVars`,logical([0 1 1 0 0 0])

Data Types: `single` | `double` | `logical` | `string` | `cell`

**DispersionFlag — Indicator to compute dispersion parameter**

false for `binomial` and `poisson` distributions (default) | true

Indicator to compute dispersion parameter for `binomial` and `poisson` distributions, specified as the comma-separated pair consisting of `DispersionFlag` and one of the following.

<table>
<thead>
<tr>
<th>true</th>
<th>Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>Default. Use the theoretical value when computing standard errors.</td>
</tr>
</tbody>
</table>

The fitting function always estimates the dispersion for other distributions.

Example: `DispersionFlag`,true

**Distribution — Distribution of the response variable**

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of `Distribution` and one of the following.

<table>
<thead>
<tr>
<th>'normal'</th>
<th>Normal distribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>'binomial'</td>
<td>Binomial distribution</td>
</tr>
<tr>
<td>'poisson'</td>
<td>Poisson distribution</td>
</tr>
<tr>
<td>'gamma'</td>
<td>Gamma distribution</td>
</tr>
<tr>
<td>'inverse gaussian'</td>
<td>Inverse Gaussian distribution</td>
</tr>
</tbody>
</table>

Example: `Distribution','gamma`
Exclude — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.
Example: 'Exclude', [2,3]
Example: 'Exclude', logical([0 1 1 0 0 0])
Data Types: single | double | logical

Intercept — Indicator for constant term
true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.
Example: 'Intercept', false

Link — Link function
canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

<table>
<thead>
<tr>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>$f(\mu) = \mu$</td>
<td>$\mu = Xb$</td>
</tr>
<tr>
<td>'log'</td>
<td>$f(\mu) = \log(\mu)$</td>
<td>$\mu = \exp(Xb)$</td>
</tr>
<tr>
<td>'logit'</td>
<td>$f(\mu) = \log(\mu/(1-\mu))$</td>
<td>$\mu = \exp(Xb)/(1 + \exp(Xb))$</td>
</tr>
<tr>
<td>'probit'</td>
<td>$f(\mu) = \Phi^{-1}(\mu)$</td>
<td>$\mu = \Phi(Xb)$</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>$f(\mu) = \log(-\log(1 - \mu))$</td>
<td>$\mu = 1 - \exp(-\exp(Xb))$</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>$f(\mu) = 1/\mu$</td>
<td>$\mu = 1/(Xb)$</td>
</tr>
<tr>
<td>p (a number)</td>
<td>$f(\mu) = \mu^p$</td>
<td>$\mu = Xb^{1/p}$</td>
</tr>
</tbody>
</table>
The link function defines the relationship \( f(\mu) = X^*b \) between the mean response \( \mu \) and the linear combination of predictors \( X^*b \).

For more information on the canonical link functions, see “Canonical Link Function” on page 32-1339.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

**Offset — Offset variable**

[] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and the variable name in tbl or a numeric vector with the same length as the response.

GeneralizedLinearModel.fit uses Offset as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

\[ f(\mu) = \text{Offset} + X^*b, \]

where \( f \) is the link function, \( \mu \) is the mean response, and \( X^*b \) is the linear combination of predictors \( X \). The Offset predictor has coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor \( A \). By using the log link function and by specifying \( \log(A) \) as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char | string

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in \( X \), or all variables in tbl except for ResponseVar.
For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: ‘PredictorVars’,[2,3]
Example: ‘PredictorVars’,logical([0 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**

last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of ‘ResponseVar’ and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use ‘ResponseVar’ when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: ‘ResponseVar’, ‘yield’
Example: ‘ResponseVar’, logical([0 0 1 0 0])
Data Types: single | double | logical | char | string

**VarNames — Names of variables**

{"x1","x2",...,"xn","y"} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of ‘VarNames’ and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

‘VarNames’ is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the addTerms function or the removeTerms function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the step or stepwiseglm function with the name-value pair arguments ‘Lower’ and ‘Upper’, respectively.

Before specifying ‘VarNames’, varNames, you can verify the variable names in varNames by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

`cellfun(@isvarname, varNames)`

If the variable names in varNames are not valid, then convert them by using the matlab.lang.makeValidName function.
varNames = matlab.lang.makeValidName(varNames);

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}
Data Types: string | cell

Weights — Observation weights
ones(n,1) (default) | n-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.
Data Types: single | double

Output Arguments

mdl — Generalized linear regression model
GeneralizedLinearModel object

Generalized linear regression model, specified as a GeneralizedLinearModel object created using fitglm or stepwiseglm.

Examples

Create Generalized Linear Regression Model

Fit a logistic regression model of the probability of smoking as a function of age, weight, and sex, using a two-way interaction model.

Load the hospital data set.
load hospital

Convert the dataset array to a table.

tbl = dataset2table(hospital);

Specify the model using a formula that includes two-way interactions and lower-order terms.

modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';

Create the generalized linear model.

mdl = fitglm(tbl,modelspec,'Distribution','binomial')

mdl = Generalized linear regression model:
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial

Estimated Coefficients:

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large $p$-value indicates that the model might not differ statistically from a constant.

**More About**

**Terms Matrix**

A terms matrix $T$ is a $t$-by-$(p + 1)$ matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i,j)$ is the exponent of variable $j$ in term $i$.

For example, suppose that an input includes three predictor variables $A$, $B$, and $C$ and the response variable $Y$ in the order $A$, $B$, $C$, and $Y$. Each row of $T$ represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — $B$; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A*C$
- $[2 \ 0 \ 0 \ 0]$ — $A^2$
- $[0 \ 1 \ 2 \ 0]$ — $B*(C^2)$

The $0$ at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include $0$ for the response variable in the last column of each row.

**Formula**

A formula for model specification is a character vector or string scalar of the form `$Y \sim terms$'.

- $Y$ is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- `$Y \sim A + B + C$' specifies a three-variable linear model with intercept.
- `$Y \sim A + B + C - 1$' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include $-1$ in the formula.

**Wilkinson Notation**

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.
Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Term in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>A^k, where k is a positive integer</td>
<td>A, A^2, ..., A^k</td>
</tr>
<tr>
<td>A + B</td>
<td>A, B</td>
</tr>
<tr>
<td>A*B</td>
<td>A, B, A*B</td>
</tr>
<tr>
<td>A:B</td>
<td>A*B only</td>
</tr>
<tr>
<td>–B</td>
<td>Do not include B</td>
</tr>
<tr>
<td>A*B + C</td>
<td>A, B, C, A*B</td>
</tr>
<tr>
<td>A + B + C + A:B</td>
<td>A, B, C, A*B</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using –1.

For more details, see “Wilkinson Notation” on page 11-90.

**Canonical Link Function**

The default link function for a generalized linear model is the canonical link function.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Canonical Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'normal'</td>
<td>'identity'</td>
<td>f(μ) = μ</td>
<td>μ = Xb</td>
</tr>
<tr>
<td>'binomial'</td>
<td>'logit'</td>
<td>f(μ) = log(μ/(1 - μ))</td>
<td>μ = exp(Xb)/(1 + exp(Xb))</td>
</tr>
<tr>
<td>'poisson'</td>
<td>'log'</td>
<td>f(μ) = log(μ)</td>
<td>μ = exp(Xb)</td>
</tr>
<tr>
<td>'gamma'</td>
<td>-1</td>
<td>f(μ) = 1/μ</td>
<td>μ = 1/(Xb)</td>
</tr>
<tr>
<td>'inverse gaussian'</td>
<td>-2</td>
<td>f(μ) = 1/μ^2</td>
<td>μ = (Xb)^{-1/2}</td>
</tr>
</tbody>
</table>

**Tips**

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
• For other methods such as devianceTest, or properties of the GeneralizedLinearModel object, see GeneralizedLinearModel.

Alternatives

You can also construct a generalized linear model using fitglm.

Use stepwiseglm to select a model specification automatically. Use step, addTerms, or removeTerms to adjust a fitted model.

Topics

“Generalized Linear Model Workflow” on page 12-28
“Generalized Linear Models” on page 12-9
(Not Recommended) Gaussian mixture parameter estimates

Note  gmdistribution.fit is not recommended. Use fitgmdist instead.

Syntax

obj = gmdistribution.fit(X,k)
ojb = gmdistribution.fit(...,param1,val1,param2,val2,...)

Description

obj = gmdistribution.fit(X,k) uses an Expectation Maximization (EM) algorithm to construct an object obj of the gmdistribution class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with k components for data in the n-by-m matrix X, where n is the number of observations and m is the dimension of the data.

gmdistribution treats NaN values as missing data. Rows of X with NaN values are excluded from the fit.

obj = gmdistribution.fit(...,param1,val1,param2,val2,...) provides control over the iterative EM algorithm. Parameters and values are listed below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Start'</td>
<td>Method used to choose initial component parameters. One of the following:</td>
</tr>
<tr>
<td></td>
<td>• 'randSample' — To select k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j). This is the default.</td>
</tr>
<tr>
<td></td>
<td>• 'plus' — The software selects k observations from X using the k-means+ algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j).</td>
</tr>
<tr>
<td></td>
<td>• S — A structure array with fields mu, Sigma, and PComponents. See gmdistribution for descriptions of values.</td>
</tr>
<tr>
<td></td>
<td>• s — A vector of length n containing an initial guess of the component index for each point.</td>
</tr>
<tr>
<td>'Replicates'</td>
<td>A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.</td>
</tr>
<tr>
<td>'CovType'</td>
<td>'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>'SharedCov'</td>
<td>Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.</td>
</tr>
<tr>
<td>'Regularize'</td>
<td>A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.</td>
</tr>
<tr>
<td>'Options'</td>
<td>Options structure for the iterative EM algorithm, as created by statset. gmdistribution.fit uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of 1e-6.</td>
</tr>
</tbody>
</table>

In some cases, gmdistribution may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to true to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases gmdistribution may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

### Examples

Generate data from a mixture of two bivariate Gaussian distributions using the mvnrnd function:

```matlab
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1, SIGMA1, 1000); mvnrnd(MU2, SIGMA2, 1000)];
scatter(X(:,1),X(:,2),10,'.')
hold on
```
Next, fit a two-component Gaussian mixture model:

```matlab
options = statset('Display','final');
obj = gmdistribution.fit(X,2,'Options',options);
10 iterations, log-likelihood = -7046.78

h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```
Among the properties of the fit are the parameter estimates:

\[
\text{ComponentMeans} = \text{obj.mu}
\]
\[
\text{ComponentMeans} = \\
0.9391 & 2.0322 \\
-2.9823 & -4.9737
\]

\[
\text{ComponentCovariances} = \text{obj.Sigma}
\]
\[
\text{ComponentCovariances}(::,1) = \\
1.7786 & -0.0528 \\
-0.0528 & 0.5312
\]
\[
\text{ComponentCovariances}(::,2) = \\
1.0491 & -0.0150 \\
-0.0150 & 0.9816
\]

\[
\text{MixtureProportions} = \text{obj.PComponents}
\]
\[
\text{MixtureProportions} = \\
0.5000 & 0.5000
\]

The Akaike information is minimized by the two-component model:

\[
\text{AIC} = \text{zeros}(1,4);
\text{obj} = \text{cell}(1,4);
\text{for~} k = 1:4 \\
\text{obj}{k} = \text{gmdistribution.fit}(X,k); \\
\text{AIC}(k) = \text{obj}{k}.\text{AIC};
\text{end}
\]
\[
[\text{minAIC, numComponents}] = \text{min(AIC)};
\]
numComponents
numComponents =
    2

model = obj{2}
model =
Gaussian mixture distribution
with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:       0.9391    2.0322
Component 2:
Mixing proportion: 0.500000
Mean:      -2.9823   -4.9737

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

**LinearModel.fit**

(Not Recommended) Create linear regression model

**Note** LinearModel.fit is not recommended. Use fitlm instead.

**Syntax**

```matlab
mdl = LinearModel.fit(tbl)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit(____,modelspec)
mdl = LinearModel.fit(____,Name,Value)
mdl = LinearModel.fit(____,modelspec,Name,Value)
```

**Description**

`mdl = LinearModel.fit(tbl)` creates a linear model of a table or dataset array `tbl`.

`mdl = LinearModel.fit(X,y)` creates a linear model of the responses `y` to a data matrix `X`.

`mdl = LinearModel.fit(____,modelspec)` creates a linear model of the type specified by `modelspec`, using any of the previous syntaxes.

`mdl = LinearModel.fit(____,Name,Value)` or `mdl = LinearModel.fit(____,modelspec, Name,Value)` creates a linear model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify which predictor variables to include in the fit or include observation weights.

**Input Arguments**

`tbl` — Input data
table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

- By default, **LinearModel.fit** takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:
• You cannot specify modelspec using a formula.
• You cannot use a formula to specify the terms to add or remove when you use the addTerms function or the removeTerms function, respectively.
• You cannot use a formula to specify the lower and upper bounds of the model when you use the step or stepwiselm function with the name-value pair arguments 'Lower' and 'Upper', respectively.

You can verify the variable names in tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

\[
\text{cellfun(@isvarname,tbl.Properties.VariableNames)}
\]

If the variable names in tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

\[
tbl.Properties.VariableNames = \text{matlab.lang.makeValidName(tbl.Properties.VariableNames)};
\]

**X — Predictor variables**

Matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

Data Types: single | double

**y — Response variable**

Vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X.

Data Types: single | double | logical

**modelspec — Model specification**

'linear' (default) | character vector or string scalar naming the model | t-by-(p + 1) terms matrix | character vector or string scalar formula in the form 'Y ~ terms'

Model specification, specified as one of the following.

• A character vector or string scalar naming the model.

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear term for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>Value</td>
<td>Model Type</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept term and linear and squared terms for each predictor.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and ( x_1, x_2, x_2^2, x_2^3, x_1 x_2, ) and ( x_1 x_2^2 ) terms, where ( x_1 ) and ( x_2 ) are the first and second predictors, respectively.</td>
</tr>
</tbody>
</table>

- \( t \)-by-\((p + 1) \) matrix, namely terms matrix on page 32-1358, specifying terms to include in the model, where \( t \) is the number of terms and \( p \) is the number of predictor variables, and plus 1 is for the response variable.

- A character vector or string scalar representing a formula on page 32-1359 in the form

  \[
  Y \sim \text{terms},
  \]

  where the terms are specified using Wilkinson Notation on page 32-1359.

Example: 'quadratic'

Example: '\( Y \sim X_1 + X_2^2 + X_1: X_2 \)'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**CategoricalVars — Categorical variable list**

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array tbl, then, by default, LinearModel.fit treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix X, then the default value of 'CategoricalVars' is an empty matrix []. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]
Example: 'CategoricalVars',logical([0 1 1 0 0])
Data Types: single | double | logical | string | cell

**Exclude — Observations to exclude**

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]
Example: 'Exclude',logical([0 1 1 0 0 0])
Data Types: single | double | logical

**Intercept — Indicator for constant term**

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept',false

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**

last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the
response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar', 'yield'
Example: 'ResponseVar', [4]
Example: 'ResponseVar', logical([0 0 1 0 0])

Data Types: single | double | logical | char | string

RobustOpts — Indicator of robust fitting type
'
off' (default) | 'on' | character vector | string scalar | structure

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of these values.

- 'off' — No robust fitting. LinearModel.fit uses ordinary least squares.
- 'on' — Robust fitting using the 'bisquare' weight function with the default tuning constant.
- Character vector or string scalar — Name of a robust fitting weight function from the following table. LinearModel.fit uses the corresponding default tuning constant specified in the table.
- Structure with the two fields RobustWgtFun and Tune.

  - The RobustWgtFun field contains the name of a robust fitting weight function from the following table or a function handle of a custom weight function.
  - The Tune field contains a tuning constant. If you do not set the Tune field, LinearModel.fit uses the corresponding default tuning constant.

<table>
<thead>
<tr>
<th>Weight Function</th>
<th>Description</th>
<th>Default Tuning Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>'andrews'</td>
<td>( w = (\text{abs}(r)&lt;\pi) .* \sin(r) ./ r )</td>
<td>1.339</td>
</tr>
<tr>
<td>'bisquare'</td>
<td>( w = \text{(abs}(r)&lt;1) .* (1 - r.^2)^2 ) (also called biweight)</td>
<td>4.685</td>
</tr>
<tr>
<td>'cauchy'</td>
<td>( w = 1 ./ (1 + r.^2) )</td>
<td>2.385</td>
</tr>
<tr>
<td>'fair'</td>
<td>( w = 1 ./ (1 + \text{abs}(r)) )</td>
<td>1.400</td>
</tr>
<tr>
<td>'huber'</td>
<td>( w = 1 ./ \text{max}(1, \text{abs}(r)) )</td>
<td>1.345</td>
</tr>
<tr>
<td>'logistic'</td>
<td>( w = \tanh(r) ./ r )</td>
<td>1.205</td>
</tr>
<tr>
<td>'ols'</td>
<td>Ordinary least squares (no weighting function)</td>
<td>None</td>
</tr>
<tr>
<td>'talwar'</td>
<td>( w = 1 * (\text{abs}(r)&lt;1) )</td>
<td>2.795</td>
</tr>
<tr>
<td>'welsch'</td>
<td>( w = \exp(-r.^2)) )</td>
<td>2.985</td>
</tr>
<tr>
<td>function handle</td>
<td>Custom weight function that accepts a vector ( r ) of scaled residuals, and returns a vector of weights the same size as ( r )</td>
<td>1</td>
</tr>
</tbody>
</table>

- The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant
increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- The value \( r \) in the weight functions is

\[
r = \frac{\text{resid}}{\text{tune} \times \text{s} \times \sqrt{1 - h}}
\]

where \( \text{resid} \) is the vector of residuals from the previous iteration, \( \text{tune} \) is the tuning constant, \( h \) is the vector of leverage values from a least-squares fit, and \( s \) is an estimate of the standard deviation of the error term given by

\[
s = \frac{\text{MAD}}{0.6745}.
\]

\( \text{MAD} \) is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If \( X \) has \( p \) columns, the software excludes the smallest \( p \) absolute deviations when computing the median.

For robust fitting, `LinearModel.fit` uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).

Example: 'RobustOpts','andrews'

**VarNames — Names of variables**

\{'x1','x2','...','xn','y'\} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of **'VarNames'** and a string array or cell array of character vectors including the names for the columns of \( X \) first, and the name for the response variable \( y \) last.

- **'VarNames'** is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the **addTerms** function or the **removeTerms** function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the **step** or **stepwiselm** function with the name-value pair arguments **'Lower'** and **'Upper'**, respectively.

Before specifying **'VarNames'**, **varNames**, you can verify the variable names in **varNames** by using the **isvarname** function. The following code returns logical 1 (true) for each variable that has a valid variable name.

\[
\text{cellfun}(@\text{isvarname},\text{varNames})
\]

If the variable names in **varNames** are not valid, then convert them by using the **matlab.lang.makeValidName** function.

\[
\text{varNames} = \text{matlab.lang.makeValidName}(\text{varNames});
\]

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: string | cell
Weights — Observation weights
ones(n, 1) (default) | n-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model
LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, see the LinearModel class page.

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the carsmall data set, a matrix input data set.

load carsmall
X = [Weight, Horsepower, Acceleration];

Fit a linear regression model by using fitlm.

mdl = fitlm(X, MPG)

mdl =
Linear regression model:
  y ~ 1 + x1 + x2 + x3

Estimated Coefficients:
     Estimate    SE         tStat       pValue
    __________    _________    _________    __________
    (Intercept)        47.977       3.8785        12.37    4.8957e-21
    x1             -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
    x3              -0.011583      0.19333    -0.059913       0.95236

Number of observations: 93, Error degrees of freedom: 89
Root Mean Squared Error: 4.09
R-squared: 0.752,  Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27
The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, \( y \sim 1 + x_1 + x_2 + x_3 \), corresponds to
\[
y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \epsilon.
\]

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```matlab
mdl.Coefficients
ans=4x4 table
            Estimate       SE       tStat       pValue
(Intercept)     47.977       3.8785      12.37    4.8957e-21
x1              -0.0065416    0.0011274      -5.8023    9.8742e-08
x2              -0.042943     0.024313      -1.7663       0.08078
x3              -0.011583      0.19333    -0.059913       0.95236
```

The `Coefficient` property includes these columns:

- **Estimate** — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (intercept) is 47.977.
- **SE** — Standard error of the coefficients.
- **tStat** — t-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that \( tStat = \frac{Estimate}{SE} \). For example, the t-statistic for the intercept is \( \frac{47.977}{3.8785} = 12.37 \).
- **pValue** — p-value for the t-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the p-value of the t-statistic for x2 is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- **Number of observations** — Number of rows without any NaN values. For example, Number of observations is 93 because the MPG data vector has six NaN values and the Horsepower data vector has one NaN value for a different observation, where the number of rows in X and MPG is 100.
- **Error degrees of freedom** — \( n - p \), where \( n \) is the number of observations, and \( p \) is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the Error degrees of freedom is \( 93 - 4 = 89 \).
- **Root mean squared error** — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- **R-squared and Adjusted R-squared** — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the R-squared value suggests that the model explains approximately 75% of the variability in the response variable MPG.
- **F-statistic vs. constant model** — Test statistic for the F-test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- **p-value** — p-value for the F-test on the model. For example, the model is significant with a p-value of 7.3816e-27.
You can find these statistics in the model properties (NumObservations, DFE, RMSE, and Rsquared) and by using the anova function.

\[
\text{anova(mdl,'summary')}
\]

\[
\begin{array}{cccc}
\text{SumSq} & \text{DF} & \text{MeanSq} & \text{F} & \text{pValue} \\
\hline
\text{Total} & 6004.8 & 92 & 65.269 & \\
\text{Model} & 4516 & 3 & 1505.3 & 89.987 \quad 7.3816\times10^{-27} \\

\end{array}
\]

**Linear Regression with Categorical Predictor**

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use anova to test the significance of the categorical variable.

**Model with Categorical Predictor**

Load the carsmall data set and create a linear regression model of MPG as a function of Model_Year. To treat the numeric vector Model_Year as a categorical variable, identify the predictor using the 'CategoricalVars' name-value pair argument.

\[
\text{load carsmall}
\]

\[
\text{mdl} = \text{fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})}
\]

\[
\text{mdl} = \\
\text{Linear regression model:} \\
\quad MPG \sim 1 + \text{Model}_\text{Year}
\]

**Estimated Coefficients:**

\[
\begin{array}{ccccc}
\text{Estimate} & \text{SE} & \text{tStat} & \text{pValue} \\
\hline
\text{( Intercept) } & 17.69 & 1.0328 & 17.127 & 3.2371\times10^{-30} \\
\text{Model}_\text{Year}_76 & 3.8839 & 1.4059 & 2.7625 & 0.0069402 \\
\text{Model}_\text{Year}_82 & 14.02 & 1.4369 & 9.7571 & 8.2164\times10^{-16} \\
\end{array}
\]

**Number of observations:** 94, **Error degrees of freedom:** 91
**Root Mean Squared Error:** 5.56
**R-squared:** 0.531, **Adjusted R-Squared:** 0.521
**F-statistic vs. constant model:** 51.6, **p-value:** 1.07e-15

The model formula in the display, MPG ~ 1 + Model_Year, corresponds to

\[
\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,
\]

where \(I_{\text{Year} = 76}\) and \(I_{\text{Year} = 82}\) are indicator variables whose value is one if the value of Model_Year is 76 and 82, respectively. The Model_Year variable includes three distinct values, which you can check by using the unique function.
unique(Model_Year)
ans = 3×1
    70
    76
    82

`fitlm` chooses the smallest value in `Model_Year` as a reference level ('70') and creates two indicator variables $I_{\text{Year}} = 76$ and $I_{\text{Year}} = 82$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

**Model with Full Indicator Variables**

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```matlab
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

mdl =  
Linear regression model:  
$MPG \sim Model_Year_{70} + Model_Year_{76} + Model_Year_{82}$

**Estimated Coefficients:**

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model_Year_70</td>
<td>17.69</td>

<td>17.127</td>
<td>3.2371e-30</td>
</tr>
<tr>
<td>Model_Year_76</td>
<td>21.574</td>
<td>0.95387</td>
<td>22.617</td>
<td>4.0156e-39</td>
</tr>
<tr>
<td>Model_Year_82</td>
<td>31.71</td>
<td>0.99896</td>
<td>31.743</td>
<td>5.2234e-51</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 91  
Root Mean Squared Error: 5.56

**Choose Reference Level in Model**

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```matlab
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

categories(Year)
If you use Year as a predictor variable, then fitlm chooses the first category '70' as a reference level. Reorder Year by using the reordercats function.

```matlab
Year_reordered = reordercats(Years,{'76','70','82'});
categories(Year_reordered)
```

The first category of Year_reordered is '76'. Create a linear regression model of MPG as a function of Year_reordered.

```matlab
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

mdl2 =

```
Linear regression model:
  MPG ~ 1 + Model_Year

Estimated Coefficients:
                  Estimate       SE       tStat     pValue
    __________    _______    _______    __________
  (Intercept)    21.574     0.95387     22.617    4.0156e-39
  Model_Year_70  -3.8839     1.4059     -2.7625    0.0069402
  Model_Year_82   10.136     1.3812      7.3385    8.7634e-11
```

mdl2 uses '76' as a reference level and includes two indicator variables I_{Year = 70} and I_{Year = 82}.

**Evaluate Categorical Predictor**

The model display of mdl2 includes a p-value of each term to test whether or not the corresponding coefficient is equal to zero. Each p-value examines each indicator variable. To examine the categorical variable Model_Year as a group of indicator variables, use anova. Use the 'components'(default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```matlab
anova(mdl2,'components')
```

ans=2x5 table

```
    SumSq  DF  MeanSq    F    pValue
  __________  __  ______   __    __________
Model_Year    3190.1    2  1595.1  51.56    1.0694e-15
```

The model display of mdl2 includes a p-value of each term to test whether or not the corresponding coefficient is equal to zero. Each p-value examines each indicator variable. To examine the categorical variable Model_Year as a group of indicator variables, use anova. Use the 'components'(default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```matlab
anova(mdl2,'components')
```

ans=2x5 table

```
    SumSq  DF  MeanSq    F    pValue
  __________  __  ______   __    __________
Model_Year    3190.1    2  1595.1  51.56    1.0694e-15
```
The component ANOVA table includes the $p$-value of the Model_Year variable, which is smaller than the $p$-values of the indicator variables.

**Specify Response and Predictor Variables for Linear Model**

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```matlab
load hospital
```

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.

```matlab
mdl = fitlm(hospital,'interactions','ResponseVar','Weight',... 'PredictorVars',{'Sex','Age','Smoker'},... 'CategoricalVar',{'Sex','Smoker'})
```

```matlab
mdl =
Linear regression model:
    Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

<td>0.78211</td>
</tr>
</tbody>
</table>

Number of observations: 100, Error degrees of freedom: 93
Root Mean Squared Error: 8.75
R-squared: 0.898, Adjusted R-Squared: 0.892
F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

**Fit Robust Linear Regression Model**

Load the hald data set, which measures the effect of cement composition on its hardening heat.

```matlab
load hald
```
This data set includes the variables ingredients and heat. The matrix ingredients contains the percent composition of four chemicals present in the cement. The vector heat contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```matlab
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl = 
Linear regression model (robust fit):
  y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                          Estimate     SE        tStat     pValue
  __________    _______    ________    ________

x3              0.13346     0.8166     0.16343     0.87424
x4             -0.12052     0.7672    -0.15709     0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,  Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-103, which compares the results of a robust fit to a standard least-squares fit.

**More About**

**Terms Matrix**

A terms matrix $T$ is a $t$-by-$(p + 1)$ matrix specifying terms in a model, where $t$ is the number of terms, $p$ is the number of predictor variables, and +1 accounts for the response variable. The value of $T(i,j)$ is the exponent of variable $j$ in term $i$.

For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of $T$ represents one term:

- $[0 0 0 0]$ — Constant term or intercept
- $[0 1 0 0]$ — B; equivalently, $A^0 * B^1 * C^0$
- $[1 0 1 0]$ — $A*C$
- $[2 0 0 0]$ — $A^2$
- $[0 1 2 0]$ — $B*(C^2)$

The $0$ at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include $0$ for the response variable in the last column of each row.
**Formula**

A formula for model specification is a character vector or string scalar of the form '$Y \sim \text{terms}$'.

- $Y$ is the response name.
- terms represents the predictor terms in a model using Wilkinson notation.

For example:

- '"Y ~ A + B + C"' specifies a three-variable linear model with intercept.
- '"Y ~ A + B + C - 1"' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include $-1$ in the formula.

**Wilkinson Notation**

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Term in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>$A^k$, where $k$ is a positive integer</td>
<td>$A, A^2, ..., A^k$</td>
</tr>
<tr>
<td>$A + B$</td>
<td>$A, B$</td>
</tr>
<tr>
<td>$A*B$</td>
<td>$A, B, A*B$</td>
</tr>
<tr>
<td>$A:B$</td>
<td>$A*B$ only</td>
</tr>
<tr>
<td>$-B$</td>
<td>Do not include $B$</td>
</tr>
<tr>
<td>$A*B + C$</td>
<td>$A, B, C, A*B$</td>
</tr>
<tr>
<td>$A + B + C + A:B$</td>
<td>$A, B, C, A*B$</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using $-1$.

For more details, see “Wilkinson Notation” on page 11-90.
**Tips**

- Use robust fitting (RobustOpts name-value pair) to reduce the effect of outliers automatically.
- Do not use robust fitting when you want to subsequently adjust a model using step.
- For other methods or properties of the LinearModel object, see LinearModel.

**Algorithms**

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is robustfit.

**Alternatives**

You can also construct a linear model using fitlm.

You can construct a model in a range of possible models using stepwiselm. However, you cannot use robust regression and stepwise regression together.

**See Also**

LinearModel | fitlm | predict | stepwiselm

**LinearMixedModel.fit**

**Class:** LinearMixedModel

(Not Recommended) Fit linear mixed-effects model using tables

**Note**  
LinearMixedModel.fit is not recommended. Use fitlme instead.

**Syntax**

```  
lme = LinearMixedModel.fit(tbl,formula)  
lme = LinearMixedModel.fit(tbl,formula,Name,Value)  
```

**Description**

`lme = LinearMixedModel.fit(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = LinearMixedModel.fit(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

**Input Arguments**

- **tbl** — Input data

  table | dataset array

  Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`.

  Data Types: table

- **formula** — Formula for model specification

  character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

  Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For full description, see “Formula” on page 32-1376.

  Example: `'y ~ treatment +(1|block)'`

  Data Types: char | string
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

CovariancePattern — Pattern of covariance matrix

'CovariancePattern' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.

'CovariancePattern'

- 'FullCholesky' — Default. Full covariance matrix using the Cholesky parameterization. \( \text{fitlme} \) estimates all elements of the covariance matrix.

- 'Full' — Full covariance matrix, using the log-Cholesky parameterization. \( \text{fitlme} \) estimates all elements of the covariance matrix.

- 'Diagonal' — Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

- 'Isotropic' — Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_b^2 & 0 & 0 \\
0 & \sigma_b^2 & 0 \\
0 & 0 & \sigma_b^2
\end{pmatrix}
\]

where \( \sigma_b^2 \) is the common variance of the random-effects terms.
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2
\end{pmatrix}
\]

where \( \sigma_{b1}^2 \) is the common variance of the random-effects terms and \( \sigma_{b1,b2} \) is the common covariance between any two random-effects term.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \( \text{PAT}(a,b) = \text{false} \), then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern', {'Full','Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'
Default. Maximum likelihood estimation

'REML'
Restricted maximum likelihood estimation

Example: 'FitMethod','REML'

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.
Example: 'Exclude',[13,67]
Data Types: single | double | logical

**DummyVarCoding — Coding to use for dummy variables**
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

**Optimizer — Optimization algorithm**
'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

- 'quasinewton'
  Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using `statset('LinearMixedModel')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.

- 'fminunc'
  You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

**OptimizerOptions — Options for optimization algorithm**
structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
If 'Optimizer' is 'quasinewton', then use statset('LinearMixedModel') to change the optimization parameters. If you don’t change the optimization parameters, then LinearMixedModel uses the default options created by statset('LinearMixedModel').

The 'quasinewton' optimizer uses the following fields in the structure created by statset('LinearMixedModel').

**TolFun — Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true

**CheckHessian — Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.
Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Examples

Random-Intercept Model

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable FluRate, the nominal variable Region that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Fit a linear mixed-effects model with the nationwide a random intercept that varies by Date. The model corresponds to

\[ y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma_b^2), \]

and the error term has the distribution,

\[ \epsilon_{im} \sim N(0, \sigma^2). \]

lme = LinearMixedModel.fit(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')

</tbody>
</table>

The confidence limits for the standard deviation of the random-effects term, \( \sigma_b \), do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

\[
\hat{y}_{28} = \hat{\beta}_0 \hat{\beta}_1 \text{WtdILI}_{28} + \hat{\beta}_{10/30/2005} \\
= 0.1639 + 0.7236 \times (1.343) + 0.3318 \\
= 1.46749,
\]

where \( \hat{\beta} \) is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```matlab
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```
y_hat = 1.4674

You can display the fitted value using the fitted method.

F = fitted(lme);
F(28)
ans = 1.4674

Randomized-Block Design

Load the sample data.

load('shift.mat');

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and LinearMixedModel.fit creates a matrix called a fixed effects design matrix to describe the effect of Shift. This matrix has two columns, Shift_Evening and Shift_Morning, where

\[
\begin{array}{ll}
\text{Shift} & \text{Evening} = 0, \quad \text{if Morning} \\
\text{Shift} & \text{Morning} = 1, \quad \text{if Evening} \\
& -1, \quad \text{if Night}
\end{array}
\]

The model corresponds to

\begin{align*}
\text{Morning Shift: } \text{QCDev}_{im} &= \beta_0 + \beta_2 \text{Shift} \_\text{Morning}_i + b_{0m} + \epsilon_{im}, \\
\text{Evening Shift: } \text{QCDev}_{im} &= \beta_0 + \beta_1 \text{Shift} \_\text{Evening}_i + b_{0m} + \epsilon_{im}, \\
\text{Night Shift: } \text{QCDev}_{im} &= \beta_0 - \beta_1 \text{Shift} \_\text{Evening}_i - \beta_2 \text{Shift} \_\text{Morning}_i + b_{0m} + \epsilon_{im},
\end{align*}

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, ..., 15 \), and \( m = 1, 2, ..., 5 \). The random effects and the observation error have the following distributions:

\[ b_{0m} \sim N(0, \sigma_b^2) \]

and

\[ \epsilon_{im} \sim N(0, \sigma^2). \]
lme = LinearMixedModel.fit(shift,'QCDev ~ Shift + (1|Operator)',...

B = 5×1
       0.5775
       1.1757
      -2.1715
       2.3655
      -1.9472
The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

\[ \hat{y}_{\text{Evening, Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift}_\text{Evening} + \hat{b}_{03} \]

\[ = 3.6525 - 0.53293 - 2.1715 \]

\[ = 0.94807. \]

You can also display this value as follows.

\[ F = \text{fitted(lme)}; \]
\[ F(\text{shift.Shift=='Evening' & shift.Operator=='3'}) \]
\[ \text{ans} = 0.9481 \]

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

\[ \hat{y}_{\text{Morning, Operator3}} = \hat{\beta}_0 + \hat{\beta}_2 \text{Shift}_\text{Morning} + \hat{b}_{03} \]

\[ = 3.6525 - 0.91973 - 2.1715 \]

\[ = 0.56127. \]

You can also display this value in the following way.

\[ F(\text{shift.Shift=='Morning' & shift.Operator=='3'}) \]
\[ \text{ans} = 0.5613 \]

The operator tends to make a smaller magnitude of error in the morning shift.

**Split-Plot Experiment**

Load the sample data.

\[ \text{load('fertilizer.mat');} \]

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called \( ds \), for practical purposes, and define \( \text{Tomato} \), \( \text{Soil} \), and \( \text{Fertilizer} \) as categorical variables.

\[ ds = \text{fertilizer}; \]
\[ ds.\text{Tomato} = \text{nominal}(ds.\text{Tomato}); \]
\[ ds.\text{Soil} = \text{nominal}(ds.\text{Soil}); \]
\[ ds.\text{Fertilizer} = \text{nominal}(ds.\text{Fertilizer}); \]

Fit a linear mixed-effects model, where \( \text{Fertilizer} \) and \( \text{Tomato} \) are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.
This model corresponds to

\[ y_{imjk} = \beta_0 + \sum_{m=2}^{4} \beta_1 m I[F]_{im} + \sum_{j=2}^{5} \beta_2 j I[T]_{ij} + \sum_{j=2}^{5} \sum_{m=2}^{4} \beta_3 m j I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S*T)_{jk} + \epsilon_{imjk}, \]

where \( i = 1, 2, \ldots, 60 \), the index \( m \) corresponds to the fertilizer types, \( j \) corresponds to the tomato types, and \( k = 1, 2, 3 \) corresponds to the blocks (soil). \( S_k \) represents the \( k \)th soil type, and \((S*T)_{jk}\) represents the \( j \)th tomato type nested in the \( k \)th soil type. \( I[F]_{im} \) is the dummy variable representing level \( m \) of the fertilizer. Similarly, \( I[T]_{ij} \) is the dummy variable representing the level \( j \) of the tomato type.

The random effects and observation error have the following prior distributions:

\[ b_{0k} \sim N(0, \sigma^2_S) \]
\[ b_{0jk} \sim N(0, \sigma^2_{S*T}) \]
\[ \epsilon_{imjk} \sim N(0, \sigma^2) \]

\[ \text{lme = LinearMixedModel.fit(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')} \]

\[ \text{lme} = \text{Linear mixed-effects model fit by ML} \]

Model information:
- Number of observations: 60
- Fixed effects coefficients: 20
- Random effects coefficients: 18
- Covariance parameters: 3

Formula:
\[ \text{Yield} \sim 1 + \text{Tomato} * \text{Fertilizer} + (1 | \text{Soil}) + (1 | \text{Soil:Tomato}) \]

Model fit statistics:
- AIC: 522.57
- BIC: 570.74
- LogLikelihood: -238.29
- Deviance: 476.57

</tbody>
</table>
The p-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using 'effects' contrasts.
The confidence interval for the standard deviations of the random-effects terms ($\sigma^2$), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term Tomato:Fertilizer and the random-effects term $(1 | \text{Soil})$.

```matlab
lme = LinearMixedModel.fit(ds,'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

### Longitudinal Study with a Covariate

Load the sample data.

```matlab
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables `I[.]`. Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i + \\
+ \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) + \\
+ b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
\]

where \(i = 1, 2, ..., 120\), and \(m = 1, 2, ..., 20\). \(\beta_j\) are the fixed-effects coefficients, \(j = 0, 1, ..., 8\), and \(b_{0m}\) and \(b_{1m}\) are random effects. \(IW\) stands for initial weight and \(I[\cdot]\) is a dummy variable representing a type of program. For example, \(I[PB]\) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2)
\]

\[
b_{1m} \sim N(0, \sigma_1^2)
\]

\[
\varepsilon_{im} \sim N(0, \sigma^2).
\]

```matlab
lme = LinearMixedModel.fit(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)')
lme =
Linear mixed-effects model fit by ML
Model information:

0.72915      -0.15592      0.22214

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)
\[
\begin{array}{cccc}
\text{Name1} & \text{Name2} & \text{Type} & \text{Estimate} \\
{'(Intercept)'} & {'(Intercept)'} & {'std'} & 0.18407 \\
{'}Week' & {'(Intercept)'} & {'corr'} & 0.66841 \\
{'}Week' & {'}Week' & {'std'} & 0.15033 \\
\end{array}
\]

pValue       Lower         Upper
0.12281    0.27587
0.21077    0.88573
0.11004    0.20537

Group: Error
\[
\begin{array}{cccc}
\text{Name} & \text{Estimate} & \text{Lower} & \text{Upper} \\
{'}Res Std' & 0.10261 & 0.087882 & 0.11981 \\
\end{array}
\]

The p-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different.
relative to the weight loss of subjects who are in Program A. The lower and upper limits of the
covariance parameters for the random effects do not include 0, thus they are significant. You can also
test the significance of the random effects using the compare method.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~
terms'. For the linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|
grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-
effects and the random-effects terms.

Suppose a table tbl contains the following:

- A response variable, y
- Predictor variables, Xj, which can be continuous or grouping variables
- Grouping variables, g1, g2, ..., gR,

where the grouping variables in Xj and g_r can be categorical, logical, character arrays, string arrays,
or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random1|g1) + ... + (randomR|gR)', the term
fixed corresponds to a specification of the fixed-effects design matrix X, random1 is a specification
of the random-effects design matrix Z1 corresponding to grouping variable g1, and similarly randomR
is a specification of the random-effects design matrix ZR corresponding to grouping variable gR. You
can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in
models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>X^k, where k is a positive integer</td>
<td>X, X^2, ..., X^k</td>
</tr>
<tr>
<td>X1 + X2</td>
<td>X1, X2</td>
</tr>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1.*X2 only</td>
</tr>
<tr>
<td>- X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you
explicitly remove the term using -1. Here are some examples for linear mixed-effects model
specification.
Examples:

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>
<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (X1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>
</tbody>
</table>

**Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[
b \sim \mathcal{N}(0, \sigma^2 D(\theta)),\]

where \(D\) is a \(q\)-by-\(q\) symmetric and positive semidefinite matrix, parameterized by a variance component vector \(\theta\), \(q\) is the number of variables in the random-effects term, and \(\sigma^2\) is the observation error variance. Since the covariance matrix of the random effects, \(D\), is symmetric, it has \(q(q+1)/2\) free parameters. Suppose \(L\) is the lower triangular Cholesky factor of \(D(\theta)\) such that

\[
D(\theta) = L(\theta)L(\theta)^T,
\]

then the \(q(q+1)/2\)-by-1 unconstrained parameter vector \(\theta\) is formed from elements in the lower triangular part of \(L\).

For example, if

\[
L = \begin{bmatrix}
L_{11} & 0 & 0 \\
L_{21} & L_{22} & 0 \\
L_{31} & L_{32} & L_{33}
\end{bmatrix},
\]

then
Log-Cholesky Parameterization

When the diagonal elements of $L$ in Cholesky parameterization are constrained to be positive, then the solution for $L$ is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of $L$ are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$
\theta = \begin{bmatrix}
\log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33}) 
\end{bmatrix}.
$$

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using fitlmematrix.

Alternatives

You can also construct a linear mixed-effects model using fitlme. If your data is in matrix format, then use fitlmematrix.

Class: NonLinearModel

(Not Recommended) Fit nonlinear regression model

Note: NonLinearModel.fit is not recommended. Use fitnlm instead.

Syntax

mdl = NonLinearModel.fit(tbl,modelfun,beta0)
mld = NonLinearModel.fit(X,y,modelfun,beta0)
mld = NonLinearModel.fit(...,modelfun,beta0,Name,Value)

Description

mdl = NonLinearModel.fit(tbl,modelfun,beta0) fits the model specified by modelfun to variables in the table or dataset array tbl, and returns the nonlinear model mdl. NonLinearModel.fit estimates model coefficients using an iterative procedure starting from the initial values in beta0.

mdl = NonLinearModel.fit(X,y,modelfun,beta0) fits a nonlinear regression model using the column vector y as a response variable and the columns of the matrix X as predictor variables.

mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value) fits a nonlinear regression model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

tbl — Input data
table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable must be numeric.

- If you specify modelfun using a formula, the model specification in the formula specifies the predictor and response variables.
- If you specify modelfun using a function handle, the last variable is the response variable and the others are the predictor variables, by default. You can set a different column as the response variable by using the ResponseVar name-value pair argument. To select a subset of the columns as predictors, use the PredictorVars name-value pair argument.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot specify modelfun using a formula.

You can verify the variable names in tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,tbl.Properties.VariableNames)
If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

Data Types: `table`

**X — Predictor variables**

`matrix`

Predictor variables, specified as an `n`-by-`p` matrix, where `n` is the number of observations and `p` is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

**y — Response variable**

`vector`

Response variable, specified as an `n`-by-1 vector, where `n` is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

**modelfun — Functional form of the model**

`function handle` | `character vector or string scalar in the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - `b` is a coefficient vector with the same number of elements as `beta0`.
  - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

  `modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- Character vector or string scalar representing a formula in the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`. The variable names in the formula must be valid MATLAB identifiers.

Data Types: `function_handle` | `char` | `string`

**beta0 — Coefficients**

`numeric vector`

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`
**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**CoefficientNames — Names of the model coefficients**

{’b1’, ’b2’, ..., ’bk’} (default) | character vector | string array | cell array of character vectors

Names of the model coefficients, specified as a character vector, string array, or cell array of character vectors.

Data Types: char | string | cell

**ErrorModel — Form of the error variance model**

’constant’ (default) | ’proportional’ | ’combined’

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>’constant’</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>’proportional’</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>’combined’</td>
<td>a, b</td>
<td>[1, 1]</td>
</tr>
</tbody>
</table>

The only allowed error model when using Weights is ’constant’.

**Note** options.RobustWgtFun must have value [ ] when using an error model other than ’constant’.

Example: ‘ErrorModel’, ’proportional’

**ErrorParameters — Initial estimates of the error model parameters**

numeric array

Initial estimates of the error model parameters for the chosen ErrorModel, specified as a numeric array.

You can only use the ’constant’ error model when using Weights.

**Note** options.RobustWgtFun must have value [ ] when using an error model other than ’constant’.

For example, if ’ErrorModel’ has the value ’combined’, you can specify the starting value 1 for a and the starting value 2 for b as follows.
Example: 'ExcludeParameters', [1,2]

**Exclude — Observations to exclude**

Logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]
Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Options — Options for controlling the iterative fitting procedure**

[ ] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

<table>
<thead>

</tbody>
</table>

Data Types: struct

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**

last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]

Data Types: single | double | logical | char | string

**VarNames — Names of variables**

{‘x1’,‘x2’,...,’xn’,‘y’} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.
Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: string | cell

Weights — Observation weights
ones(n,1) (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in tbl or y.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W, NonLinearModel estimates the error variance at observation i by MSE*(1/W(i)), where MSE is the mean squared error.

Data Types: single | double | function_handle

Output Arguments

mdl — Nonlinear model
NonLinearModel object

Nonlinear model representing a least-squares fit of the response to the data, returned as a NonLinearModel object.

If the Options structure contains a nonempty RobustWgtFun field, the model is not a least-squares fit, but uses the RobustWgtFun robust fitting function.

For properties and methods of the nonlinear model object, mdl, see the NonLinearModel class page.

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

load carbig
tbl = table(Horsepower, Weight, MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(tbl, modelfun, beta0)

mdl =
Nonlinear regression model:
  MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:

    Estimate     SE         tStat      pValue
    _________    _______    ________    ________
    b1    -49.383     119.97    -0.41164     0.68083

32-1384
Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...  
             b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)

mdl = 
    Nonlinear regression model:         
    y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:
  Estimate       SE    tStat     pValue
  ________    _______    ________    ________
  b1     -49.383     119.97    -0.41164     0.68083
  b2      376.43     567.05     0.66384     0.50719
  b3    -0.78193    0.47168     -1.6578    0.098177
  b4      422.37     776.02     0.54428     0.58656
  b5    -0.24127    0.48325    -0.49926     0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the carbig data. Strive for more accuracy by lowering the TolFun option, and observe the iterations by setting the Display option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
```
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... 
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];

Create options to lower TolFun and to report iterative display, and create a model using the options.

opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);

Specify Nonlinear Regression Using Model Character Vector

Specify a nonlinear regression model for estimation using a function handle or character vector.

Load sample data.

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Use a function handle to specify the Hougen-Watson model for the rate data.

mdl = NonLinearModel.fit(X,y,@hougen,beta0)

mdl =
Nonlinear regression model:
 y ~ hougen(b,X)

Estimated Coefficients:

<table>
<thead>
<tr>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>b1</td>
<td>1.2526</td>
<td>0.86701</td>
<td>1.4447</td>
</tr>
<tr>
<td>b2</td>
<td>0.062776</td>
<td>0.043561</td>
<td>1.4411</td>
</tr>
<tr>

</tr>
<tr>
<td>b5</td>
<td>1.1914</td>
<td>0.83671</td>
<td>1.4239</td>
</tr>
</tbody>
</table>

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a character vector to specify the Hougen-Watson model for the rate data.

\[
\text{myfun} = 'y\sim b_1 x_2 - x_3/b_5/(1+b_2 x_1+b_3 x_2+b_4 x_3)';
\]

\[
\text{mdl2 = NonLinearModel.fit(X,y,myfun,beta0)}
\]

\[
\text{mdl2 = Nonlinear regression model:}
\]
\[
y \sim (b_1 x_2 - x_3/b_5)/(1 + b_2 x_1 + b_3 x_2 + b_4 x_3)
\]

\[
\text{Estimated Coefficients:}
\]

**Estimate Nonlinear Regression Using Robust Fitting Options**

Generate sample data from the nonlinear regression model

\[
y = b_1 + b_2 \exp(-b_3 x) + \epsilon,
\]

where \(b_1\), \(b_2\), and \(b_3\) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

\[
\text{modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));}
\]

\[
\text{rng('default') } \% \text{ for reproducibility}
\]

\[
b = [1;3;2];
\]

\[
x = exprnd(2,100,1);
\]

\[
y = modelfun(b,x) + normrnd(0,0.5,100,1);
\]

Set robust fitting options.

\[
\text{opts = statset('nlinfit');}
\]

\[
\text{opts.RobustWgtFun = 'bisquare';}
\]

Fit the nonlinear model using the robust fitting options. Here, use a character vector to specify the model.

\[
b0 = [2;2;2];
\]

\[
\text{modelstr = 'y ~ b1 + b2*exp(-b3*x)';}
\]
mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)

mdl =
Nonlinear regression model (robust fit):
  y ~ b1 + b2*exp(-b3*x)

Estimated Coefficients:
        Estimate     SE       tStat       pValue
    ______    _______    ______    __________
    b1    1.0218     0.07202    14.188    2.1344e-25
    b2    3.6619     0.25429    14.401     7.974e-26
    b3    2.9732     0.38496     7.723    1.0346e-11

Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.
   a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);

Fit the Hougen-Watson model to the rate data using the specified observation weights function.
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)

mdl =
Nonlinear regression model:
  y ~ hougen(b,X)

Estimated Coefficients:
        Estimate     SE       tStat       pValue
    ______    _______    ______    __________
    b1    0.83085     0.58224     1.427    0.19142
    b2    0.04095     0.02966    1.3805    0.20477
    b3    0.025063    0.019673    1.274    0.23842
    b4    0.080053    0.057812    1.3847    0.20353
    b5    1.8261       1.281    1.4256    0.19183

Number of observations: 13, Error degrees of freedom: 8
Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```matlab
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```matlab
mdl =
    Nonlinear regression model:
       y ~ hougen(b,X)

    Estimated Coefficients:  (intercept)      Estimate      SE       tStat    pValue
                        b1            1.2526        0.86702     1.4447    0.18654
                        b2           0.062776       0.043561     1.4411    0.18753
                        b3           0.040048       0.030885     1.2967    0.23089
                        b4           0.11242        0.075158     1.4957    0.17309
                        b5           1.1914         0.83671     1.4239    0.1923

    Number of observations: 13, Error degrees of freedom: 8
    Root Mean Squared Error: 1.27
    R-Squared: 0.999,  Adjusted R-Squared 0.998
    F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

RegressionTree.fit

Class: RegressionTree

(Not Recommended) Binary decision tree for regression

Note RegressionTree.fit is not recommended. Use fitrtree instead.

Syntax

tree = RegressionTree.fit(x,y)
tree = RegressionTree.fit(x,y,Name,Value)

Description

tree = RegressionTree.fit(x,y) returns a regression tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree where each branching node is split based on the values of a column of x.

tree = RegressionTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,…,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

Input Arguments

x — Predictor values
matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of x represents one variable, and each row represents one observation.

RegressionTree.fit considers NaN values in x as missing values. RegressionTree.fit does not use observations with all missing values for x the fit. RegressionTree.fit uses observations with some missing values for x to find splits on variables for which these observations have valid values.

Data Types: single | double

y — Response values
vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as x. Each entry in y is the response to the data in the corresponding row of x.
RegressionTree.fit considers NaN values in y to be missing values. RegressionTree.fit does not use observations with missing values for y in the fit.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

CategoricalPredictors — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.
- A numeric vector with indices from 1 to p, where p is the number of columns of x.
- A logical vector of length p, where a true entry means that the corresponding column of x is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in the PredictorNames property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | struct | cell

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', RegressionTree.fit grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Example: 'CrossVal','on'

CVPartition — Partition for cross-validation tree

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the cvpartition class created using cvpartition.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.
Data Types: single | double

**MinParent** — Minimum number of branch node observations
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: MinParent=max(MinParent,2*MinLeaf).

Example: 'MinParent',8
Data Types: single | double

**NVarToSample** — Number of predictors for split
'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NVarToSample',3
Data Types: single | double

**PredictorNames** — Predictor variable names
{'x1','x2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in x.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PedalWidth'}
Data Types: cell

**Prune** — Pruning flag
'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', RegressionTree.fit computes the full tree and the optimal sequence of pruned subtrees. When 'off', RegressionTree.fit computes the full tree without pruning.

Example: 'Prune','off'

**PruneCriterion** — Pruning criterion
'mse' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

Example: 'PruneCriterion','mse'

**QEToler** — Quadratic error tolerance
1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below
QEToler*QED, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: ‘QEToler’,1e4

**ResponseName — Response variable name**

'y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable in y.

Example: 'ResponseName','Response'

Data Types: char

**ResponseTransform — Response transform function**

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector 'none' means @(x)x, or no transformation.

Add or change a ResponseTransform function using dot notation:

tree.ResponseTransform = @function

Example: 'ResponseTransform','none'

Data Types: function_handle

**SplitCriterion — Split criterion**

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion','MSE'

**Surrogate — Surrogate decision splits flag**

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', **RegressionTree.fit** finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, **RegressionTree.fit** finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', **RegressionTree.fit** finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate','on'

Data Types: single | double
Weights — Observation weights
ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x.

Data Types: single | double

Output Arguments

Tree — Regression tree
regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

Examples

Predict Values Using a Regression Tree

Load the sample data.
load carsmall

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

tree = RegressionTree.fit([Weight, Cylinders], MPG,...
   'MinParent',20,...
   'PredictorNames',{'W','C'})

tree = RegressionTree
   PredictorNames: {'W' 'C'}
   ResponseName: 'Y'
   CategoricalPredictors: []
   ResponseTransform: 'none'
   NumObservations: 94

Properties, Methods

Predict the mileage of a car that weighs 2200 lbs and has four cylinders.
predict(tree,[2200,4])
ans = 29.6111

Topics

“Splitting Categorical Predictors in Classification Trees” on page 19-25
**fitcauto**

Automatically select classification model with optimized hyperparameters

**Syntax**

```matlab
Mdl = fitcauto(Tbl,ResponseVarName)
Mdl = fitcauto(Tbl,formula)
Mdl = fitcauto(Tbl,Y)
Mdl = fitcauto(X,Y)
Mdl = fitcauto(____,Name,Value)
```

```matlab
[Mdl,OptimizationResults] = fitcauto(____)
```

**Description**

Given predictor and response data, **fitcauto** automatically tries a selection of classification model types with different hyperparameter values. The function uses Bayesian optimization to select models and their hyperparameter values, and computes the cross-validation classification error for each model. After the optimization is complete, **fitcauto** returns the model, trained on the entire data set, that is expected to best classify new data. You can use the **predict** and **loss** object functions of the returned model to classify new data and compute the test set classification error, respectively.

Use **fitcauto** when you are uncertain which classifier types best suit your data. For information on alternative methods for tuning hyperparameters of classification models, see “Alternative Functionality” on page 32-1457.

```matlab
Mdl = fitcauto(Tbl,ResponseVarName) returns a classification model Mdl with tuned hyperparameters. The table Tbl contains the predictor variables and the response variable, where ResponseVarName is the name of the response variable.
```

```matlab
Mdl = fitcauto(Tbl,formula) uses formula to specify the response variable and the predictor variables to consider among the variables in Tbl.
```

```matlab
Mdl = fitcauto(Tbl,Y) uses the predictor variables in table Tbl and the class labels in vector Y.
```

```matlab
Mdl = fitcauto(X,Y) uses the predictor variables in matrix X and the class labels in vector Y.
```

```matlab
Mdl = fitcauto(____,Name,Value) specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, use the **HyperparameterOptimizationOptions** name-value pair argument to specify how the Bayesian optimization is performed.
```

```matlab
[Mdl,OptimizationResults] = fitcauto(____) additionally returns OptimizationResults, a BayesianOptimization object containing the results of the model selection and hyperparameter tuning process.
```

**Examples**
### Automatically Select Classifier Using Table Data

Use `fitcauto` to automatically select a classification model with optimized hyperparameters, given predictor and response data stored in a table.

### Load Data

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```matlab
load carbig
```

Categorize the cars based on whether they were made in the USA.

```matlab
Origin = categorical(cellstr(Origin));
Origin = mergecats(Origin,{'France','Japan','Germany',... 'Sweden','Italy','England','NotUSA'});
```

Create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `Origin`.

```matlab
cars = table(Acceleration,Displacement,Horsepower,... Model_Year,MPG,Weight,Origin);
```

### Partition Data

Partition the data into training and test sets. Use approximately 80% of the observations for the model selection and hyperparameter tuning process, and 20% of the observations to test the performance of the final model returned by `fitcauto`. Use `cvpartition` to partition the data.

```matlab
rng('default') % For reproducibility of the data partition
c = cvpartition(Origin,'Holdout',0.2);
trainingIdx = training(c); % Training set indices
carsTrain = cars(trainingIdx,:);
testIdx = test(c); % Test set indices
carsTest = cars(testIdx,:);
```

### Run `fitcauto`

Pass the training data to `fitcauto`. By default, `fitcauto` determines appropriate model types to try, uses Bayesian optimization to find good hyperparameter values, and returns a trained model `Mdl` with the best expected performance.

```matlab
Mdl = fitcauto(carsTrain,'Origin');
```

Warning: It is recommended that you first standardize all numeric predictors when optimizing the model. This warning can be ignored if you have already standardized the predictors.

Optimization completed. MaxObjectiveEvaluations of 150 reached. Total function evaluations: 150 Total elapsed time: 1758.9912 seconds. Total objective function evaluation time: 985.2563

Best observed feasible point is an ensemble model with:
Method: Bag
NumLearningCycles: 201
MinLeafSize: 1

Observed objective function value = 0.098462
Estimated objective function value = 0.11265
Function evaluation time = 9.241

Best estimated feasible point (according to models) is an ensemble model with:
Method: Bag
NumLearningCycles: 256
MinLeafSize: 1

Estimated objective function value = 0.10991
Estimated function evaluation time = 11.0259

The final model returned by fitcauto corresponds to the best estimated feasible point. Before returning the model, the function retrains it using the entire training data (carsTrain), the listed Learner (or model) type, and the displayed hyperparameter values.
**Evaluate Test Set Performance**

Evaluate the performance of the model on the test set.

\[
testAccuracy = 1 - \text{loss}(\text{Mdl}, \text{carsTest}, '\text{Origin}')
\]

\[
testAccuracy = 0.9520
\]

\[
\text{confusionchart(carsTest.Origin, predict(Mdl, carsTest))}
\]

![Confusion Matrix Diagram](image)

**Automatically Select Classifier Using Matrix Data**

Use `fitcauto` to automatically select a classification model with optimized hyperparameters, given predictor and response data stored in separate variables.

**Load Data**

Load the `humanactivity` data set. This data set contains 24,075 observations of five physical human activities: Sitting (1), Standing (2), Walking (3), Running (4), and Dancing (5). Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The variable `feat` contains the predictor data matrix of the 60 features for the 24,075 observations, and the response variable `actid` contains the activity IDs for the observations as integers.

\[
\text{load } \text{humanactivity}
\]
Partition Data

Partition the data into training and test sets. Use 90% of the observations to select a model, and 10% of the observations to validate the final model returned by fitcauto. Use cvpartition to reserve 10% of the observations for testing.

```matlab
rng('default') % For reproducibility of the partition
c = cvpartition(actid,'Holdout',0.10);
trainingIndices = training(c); % Indices for the training set
XTrain = feat(trainingIndices,:);
YTrain = actid(trainingIndices);
testIndices = test(c); % Indices for the test set
XTest = feat(testIndices,:);
YTest = actid(testIndices);
```

Run fitcauto

Pass the training data to fitcauto. By default, fitcauto determines appropriate model (or learner) types to try, uses Bayesian optimization to find good hyperparameter values for those models, and returns a trained model with the best expected performance. Specify to run the optimization in parallel (requires Parallel Computing Toolbox™). Return a second output OptimizationResults that contains the details of the Bayesian optimization.

Expect this model selection process to take some time.

```matlab
options = struct('UseParallel',true);
[Mdl,OptimizationResults] = fitcauto(XTrain,YTrain,'HyperparameterOptimizationOptions',options);
```

Warning: It is recommended that you first standardize all numeric predictors when optimizing the

Starting parallel pool (parpool) using the 'local' profile ...

</table>

**Summary:**
- Objective: Minimize the error rate
- Objective runtime: The time taken for the objective function to evaluate each point
- BestSoFar (observed): The best observed value of the objective function
- BestSoFar (estim.): The estimated best value of the objective function
- Learner: The type of learner used (e.g., decision tree, support vector machine, knn, ensemble)

The table above shows a summary of the optimization process for different learners and hyperparameters. Each row represents a trial with a specific learner and hyperparameters, along with the observed objective value, runtime, and the best so far observed and estimated values.

</table>
Optimization completed.
MaxObjectiveEvaluations of 150 reached.
Total function evaluations: 150
Total elapsed time: 5515.7636 seconds.
Total objective function evaluation time: 27568.0193

Best observed feasible point is an ensemble model with:
Method: AdaBoostM2
NumLearningCycles: 294
MinLeafSize: 106
MaxNumSplits: 94

Observed objective function value = 0.0038767
Estimated objective function value = 0.006912
Function evaluation time = 158.7495

Best estimated feasible point (according to models) is an ensemble model with:
Method: AdaBoostM2
NumLearningCycles: 210
MinLeafSize: 129
MaxNumSplits: 100

Estimated objective function value = 0.0065889
Estimated function evaluation time = 129.4444
The final model returned by fitcauto corresponds to the best estimated feasible point. Before returning the model, the function retracts it using the entire training data (XTrain and YTrain), the listed Learner (or model) type, and the displayed hyperparameter values.

**Evaluate Test Set Performance**

Evaluate the final model performance on the test data set.

\[
\text{testAccuracy} = 1 - \text{loss(Mdl,XTest,YTest)}
\]

\[
\text{testAccuracy} = 0.9963
\]

The final model correctly classifies over 99% of the observations.

**Combine Feature Selection and Automated Classifier Selection**

Use fitcauto to automatically select a classification model with optimized hyperparameters, given predictor and response data stored in a table. Before passing data to fitcauto, perform feature selection to remove unimportant predictors from the data set.

**Load and Partition Data**

Read the sample file CreditRating_Historical.dat into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Preview the first few rows of the data set.

\[
\text{creditrating} = \text{readtable('CreditRating_Historical.dat')};
\]

\[
\text{head(creditrating)}
\]

\[
\begin{array}{cccccccc}
\text{ID} & \text{WC_TA} & \text{RE_TA} & \text{EBIT_TA} & \text{MVE_BVTD} & \text{S_TA} & \text{Industry} & \text{Rating} \\
62394 & 0.013 & 0.104 & 0.036 & 0.447 & 0.142 & 3 & \{'BB'\} \\
48608 & 0.232 & 0.335 & 0.062 & 1.969 & 0.281 & 8 & \{'A'\} \\
42444 & 0.311 & 0.367 & 0.074 & 1.935 & 0.366 & 1 & \{'A'\} \\
48631 & 0.194 & 0.263 & 0.062 & 1.017 & 0.228 & 4 & \{'BBB'\} \\
43768 & 0.121 & 0.413 & 0.057 & 3.647 & 0.466 & 12 & \{'AAA'\} \\
39255 & -0.117 & -0.799 & 0.01 & 0.179 & 0.082 & 4 & \{'CCC'\} \\
62236 & 0.087 & 0.158 & 0.049 & 0.816 & 0.324 & 2 & \{'BBB'\} \\
39354 & 0.005 & 0.181 & 0.034 & 2.597 & 0.388 & 7 & \{'AA'\} \\
\end{array}
\]

Because each value in the ID variable is a unique customer ID, that is, \(\text{length(unique(creditrating.ID))}\) is equal to the number of observations in creditrating, the ID variable is a poor predictor. Remove the ID variable from the table, and convert the Industry variable to a categorical variable.

\[
\text{creditrating} = \text{removevars(creditrating,'ID')};
\]

\[
\text{creditrating.Industry} = \text{categorical(creditrating.Industry)};
\]

Partition the data into training and test sets. Use approximately 85% of the observations for the model selection and hyperparameter tuning process, and 15% of the observations to test the performance of the final model returned by fitcauto on new data. Use cvpartition to partition the data.
32

Functions

rng('default') % For reproducibility of the partition
c = cvpartition(creditrating.Rating,'Holdout',0.15);
trainingIndices = training(c); % Indices for the training set
testIndices = test(c); % Indices for the test set
creditTrain = creditrating(trainingIndices,:);
creditTest = creditrating(testIndices,:);

Perform Feature Selection
Before passing the training data to fitcauto, find the important predictors by using the fscchi2
function. Visualize the predictor scores by using the bar function. Because some scores can be Inf,
and bar discards Inf values, plot the finite scores first and then plot a finite representation of the
Inf scores in a different color.
[idx,scores] = fscchi2(creditTrain,'Rating');
bar(scores(idx)) % Represents finite scores
hold on
veryImportant = isinf(scores);
finiteMax = max(scores(~veryImportant));
bar(finiteMax*veryImportant(idx)) % Represents Inf scores
hold off
xticklabels(strrep(creditTrain.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)
legend({'Finite Scores','Inf Scores'})

32-1426


Notice that the *Industry* predictor has a low score corresponding to a *p*-value that is greater than 0.05, which indicates that *Industry* might not be an important feature. Remove the *Industry* feature from the training and test data sets.

```matlab
creditTrain = removevars(creditTrain,'Industry');
creditTest = removevars(creditTest,'Industry');
```

**Run fitcauto**

`fitcauto` does not support tables for linear or kernel classification models. To include these model (or learner) types, convert the predictor data to matrix form before passing the training data to `fitcauto`. Convert the test data as well. This conversion is possible because all the remaining predictors are numeric.

```matlab
predictorTrain = removevars(creditTrain,'Rating');
XTrain = table2array(predictorTrain);
YTrain = creditTrain.Rating;
predictorTest = removevars(creditTest,'Rating');
XTest = table2array(predictorTest);
YTest = creditTest.Rating;
```

Pass the training data to `fitcauto`. The function uses Bayesian optimization to select models and their hyperparameter values, and returns a trained model `Mdl` with the best expected performance. Specify to try all available learner types and run the optimization in parallel (requires Parallel Computing Toolbox™). Return a second output `Results` that contains the details of the Bayesian optimization.

Expect this process to take some time.

```matlab
options = struct('UseParallel',true);
[Mdl,Results] = fitcauto(XTrain,YTrain, ...
    'Learners','all','HyperparameterOptimizationOptions',options);
```

Warning: It is recommended that you first standardize all numeric predictors when optimizing the Naive Bayes ‘Width’ parameter. Ignore this warning if you have done that.

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
Copying objective function to workers...
Done copying objective function to workers.

Min objective vs. Number of function evaluations

Optimization completed.
MaxObjectiveEvaluations of 240 reached.
Total function evaluations: 240
Total elapsed time: 1954.7195 seconds.
Total objective function evaluation time: 2414.1608

Best observed feasible point is a multiclass svm model with:
Coding (ECOC):     onevsone
BoxConstraint:     0.035844
KernelScale:        0.08166

Observed objective function value = 0.2399
Estimated objective function value = 0.24266
Function evaluation time = 1.4853

Best estimated feasible point (according to models) is a multiclass svm model with:
Coding (ECOC):     onevsone
BoxConstraint:     0.018425
KernelScale:        0.05816

Estimated objective function value = 0.2408
Estimated function evaluation time = 1.6217

The final model returned by fitcauto corresponds to the best estimated feasible point. Before returning the model, the function retrains it using the entire training data (XTrain and YTrain), the listed Learner (or model) type, and the displayed hyperparameter values.

Evaluate Test Set Performance

The model Mdl corresponds to the best point in the Bayesian optimization according to the 'min-visited-mean' criterion. To gauge how the model will perform on new data, look at the observed cross-validation accuracy of the model (cvAccuracy) and its general estimated performance based on the Bayesian optimization (estimatedAccuracy).

[x,~,iteration] = bestPoint(Results,'Criterion','min-visited-mean');

cvError = Results.ObjectiveTrace(iteration);
cvAccuracy = 1 - cvError

cvAccuracy = 0.7601

estimatedError = predictObjective(Results,x);
estimatedAccuracy = 1 - estimatedError

estimatedAccuracy = 0.7592

Evaluate the performance of the model on the test set. Create a confusion matrix from the results, and specify the order of the classes in the confusion matrix.

testAccuracy = 1 - loss(Mdl,XTest,YTest)

testAccuracy = 0.7438

cm = confusionchart(YTest,predict(Mdl,XTest));
sortClasses(cm,{'AAA','AA','A','BBB','BB','B','CCC'})
**Input Arguments**

**Tbl — Sample data**

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

**Note** `fitcauto` does not support tables for linear or kernel classification models. That is, if you want `Learners` to include 'linear' or 'kernel' models, you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a matrix of predictor data (`X`) and an array of responses (`Y`) instead.
Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the ClassNames name-value pair argument.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

Data Types: char | string

Y — Class labels
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors.

- If Y is a character array, then each element of the class labels must correspond to one row of the array.
• The length of Y and the number of rows in Tbl or X must be equal.
• A good practice is to specify the class order by using the ClassNames name-value pair argument.

Data Types: single | double | categorical | logical | char | string | cell

**X — Predictor data**

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one predictor.

The length of Y and the number of rows in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

**Note** The software treats NaN, empty character vector (''), empty string (''), <missing>, and <undefined> elements as missing data. The software removes rows of data corresponding to missing values in the response variable. However, the treatment of missing values in the predictor data X or Tbl varies among models (or learners).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1,...,NameN, ValueN.

Example:

`'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 200, 'Verbose', 2)` specifies to run 200 iterations of the optimization process (that is, try 200 model hyperparameter combinations), and to display information in the Command Window about the next model hyperparameter combination to be evaluated.

**Optimization Options**

**Learners — Types of classification models**

`'auto'` (default) | `'all'` | `'all-linear'` | `'all-nonlinear'` | one or more learner names

Types of classification models to try during the optimization, specified as the comma-separated pair consisting of `Learners` and a value in the first table below or one or more learner names in the second table. Specify multiple learner names as a string or cell array.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'auto'</code></td>
<td>fitcauto automatically selects a subset of learners, suitable for the given predictor and response data. The learners can have model hyperparameter values that differ from the default. For more information, see &quot;Automatic Selection of Learners&quot; on page 32-1456.</td>
</tr>
<tr>
<td><code>'all'</code></td>
<td>fitcauto selects all possible learners.</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
'all-linear' | fitcauto selects all linear learners: 'discr' (with a linear discriminant type), 'linear', and 'svm' (with a linear kernel).
'all-nonlinear' | fitcauto selects all nonlinear learners: 'discr' (with a quadratic discriminant type), 'ensemble', 'kernel', 'knn', 'nb', 'svm' (with a Gaussian or polynomial kernel), and 'tree'.

<table>
<thead>
<tr>
<th>Learner Name</th>
<th>Description</th>

<td>Binary decision classification tree</td>
</tr>
</tbody>
</table>

Example: 'Learners','all'
Example: 'Learners','ensemble'
Example: 'Learners',{'svm','tree'}
Data Types: char | string | cell

**OptimizeHyperparameters — Hyperparameters to optimize**

`'auto'` (default) | 'all'

Hyperparameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and 'auto' or 'all'. The optimizable hyperparameters depend on the model (or learner), as described in this table.
<table>
<thead>
<tr>
<th>Learner Name</th>
<th>Hyperparameters for 'auto'</th>
<th>Additional Hyperparameters for 'all'</th>
<th>Notes</th>
</tr>
</thead>
</table>
| 'discr'      | Delta, Gamma              | DiscrimType                         | • When the Learners value is 'all-linear', the fitcauto function chooses among the DiscrimType values of 'linear', 'diaglinear', and 'pseudolinear', regardless of the OptimizeHyperparameters value.  
• When the Learners value is 'all-nonlinear', the fitcauto function chooses among the DiscrimType values of 'quadratic', 'diagquadratic', and 'pseudoquadratic', regardless of the OptimizeHyperparameters value.  
For more information, including hyperparameter search ranges, see OptimizeHyperparameters. |
| 'ensemble'   | Method, NumLearningCycles, LearnRate, MinLeafSize | MaxNumSplits, NumVariablesToSample, SplitCriterion | • When the ensemble Method value is a boosting method, the ensemble NumBins value is 50.  
For more information, including hyperparameter search ranges, see OptimizeHyperparameters. |
<table>
<thead>
<tr>
<th>Learner Name</th>
<th>Hyperparameters for 'auto'</th>
<th>Additional Hyperparameters for 'all'</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>'kernel'</td>
<td>KernelScale, Lambda, Coding (for three or more classes only)</td>
<td>Learner, NumExpansionDimensions</td>
<td>For more information, including hyperparameter search ranges, see OptimizeHyperparameters and OptimizeHyperparameters (for three or more classes only).</td>
</tr>
<tr>
<td>'knn'</td>
<td>Distance, NumNeighbors</td>
<td>DistanceWeight, Exponent, Standardize</td>
<td>For more information, including hyperparameter search ranges, see OptimizeHyperparameters.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Lambda, Learner, Coding (for three or more classes only)</td>
<td>Regularization</td>
<td>For more information, including hyperparameter search ranges, see OptimizeHyperparameters and OptimizeHyperparameters (for three or more classes only).</td>
</tr>
<tr>
<td>'nb'</td>
<td>DistributionNames, Width</td>
<td>Kernel</td>
<td>For more information, including hyperparameter search ranges, see OptimizeHyperparameters.</td>
</tr>
<tr>
<td>Learner Name</td>
<td>Hyperparameters for 'auto'</td>
<td>Additional Hyperparameters for 'all'</td>
<td>Notes</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------</td>
<td>-------------------------------------</td>
<td>-------</td>
</tr>
</tbody>
</table>
| 'svm'        | BoxConstraint, KernelScale, Coding (for three or more classes only) | KernelFunction, PolynomialOrder, Standardize | • When the Learners value is 'all-linear', the fitcauto function does not optimize the KernelFunction or PolynomialOrder hyperparameters when the OptimizeHyperparameters value is 'all'.
• When the Learners value is 'all-nonlinear', the fitcauto function chooses among the KernelFunction values of 'gaussian' and 'polynomial', regardless of the OptimizeHyperparameters value. For more information, including hyperparameter search ranges, see OptimizeHyperparameters and OptimizeHyperparameters (for three or more classes only). |
| 'tree'       | MinLeafSize                | MaxNumSplits, NumVariablesToSample, SplitCriterion | For more information, including hyperparameter search ranges, see OptimizeHyperparameters. |

**Note** When Learners is set to a value other than 'auto', the default values for the model hyperparameters not being optimized match the default fit function values, unless otherwise indicated in the table notes. When Learners is set to 'auto', both optimized hyperparameter search ranges and nonoptimized hyperparameter values can vary, depending on the characteristics of the training data.

Example: 'OptimizeHyperparameters','all'
### HyperparameterOptimizationOptions — Options for optimization

Options for the optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxObjectiveEvaluations</td>
<td>Maximum number of objective function evaluations</td>
<td>30*(L), where (L) is the number of learners</td>
</tr>
<tr>
<td>MaxTime</td>
<td>Time limit, specified as a positive real number. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.</td>
<td>Inf</td>
</tr>
<tr>
<td>ShowPlots</td>
<td>Logical value indicating whether to show plots. If true, this field plots the best observed and estimated objective function values (so far) against the iteration number.</td>
<td>true</td>
</tr>
<tr>
<td>SaveIntermediateResults</td>
<td>Logical value indicating whether to save results. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.</td>
<td>false</td>
</tr>
<tr>
<td>Verbose</td>
<td>Display at the command line:</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>• 0 — No iterative display</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 1 — Iterative display</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 2 — Iterative display with additional information about the next point to be evaluated</td>
<td></td>
</tr>
<tr>
<td>UseParallel</td>
<td>Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results.</td>
<td>false</td>
</tr>
</tbody>
</table>
| Repartition              | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. 

true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false                                                                 |
Specify only one of the following three options.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVPartition</td>
<td>cvpartition object, created by cvpartition</td>
<td>'Kfold',5 if you do not specify any cross-validation field</td>
</tr>
<tr>
<td>Holdout</td>
<td>Scalar in the range (0,1) representing the holdout fraction</td>
<td></td>
</tr>
<tr>
<td>Kfold</td>
<td>Integer greater than 1</td>
<td></td>
</tr>
</tbody>
</table>

Example: 'HyperparameterOptimizationOptions',struct('UseParallel',true)

Data Types: struct

Classification Options

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitcauto assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. However, learners that use decision trees assume that mathematically ordered categorical vectors are continuous variables. If the predictor data is a matrix (X), fitcauto assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

For more information on how fitting functions treat categorical predictors, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

ClassNames — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors
Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify a square matrix Cost and the true class of an observation is i, then Cost(i,j) is the cost of classifying a point into class j. That is, rows correspond to the true classes and columns correspond to the predicted classes. To specify the class order for the corresponding rows and columns of Cost, also specify the ClassNames name-value pair argument.
- If you specify a structure S, then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as Y
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default value for Cost is ones(K) – eye(K), where K is the number of distinct classes.

Example: 'Cost',[0 1; 2 0]

Data Types: single | double | struct

PredictorNames — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.

By default, `PredictorNames` is `{'x1','x2',...}`.

If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcauto` uses only the predictor variables in `PredictorNames` and the response variable in training.

`PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.

By default, `PredictorNames` contains the names of all predictor variables.

A good practice is to specify the predictors for training using either `PredictorNames` or `formula` only.

Example: `{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `Prior` and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in <code>Y</code>.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to <code>1/K</code>, where <code>K</code> is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements to sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure <code>S</code> with two fields:</td>
</tr>
<tr>
<td></td>
<td>• <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>.</td>
</tr>
<tr>
<td></td>
<td>• <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements to sum to 1.</td>
</tr>
</tbody>
</table>

Example: `{'Prior',struct('ClassNames',{{'b','g'}},'ClassProbs',1:2)}`

Data Types: `single` | `double` | `char` | `string` | `struct`

**ResponseName — Response variable name**

`Y` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `ResponseName` and a character vector or string scalar:

- If you supply `Y`, then you can use `ResponseName` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `ResponseName`.

Example: `{'ResponseName','myYVariableName'}`

Data Types: `char` | `string`
Example: 'ResponseName','response'
Data Types: char | string

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$\frac{1}{1 + e^{-2x}}$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1 - x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$\frac{1}{1 + e^{-x}}$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'             | -1 for $x < 0$
|                    | 0 for $x = 0$
|                    | 1 for $x > 0$                            |
| 'symmetric'        | $2x - 1$                                  |
| 'symmetricismax'   | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit'   | $\frac{2}{1 + e^{-x}} - 1$               |

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'
Data Types: char | string | function_handle

Weights — Observation weights

positive numeric vector | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a positive numeric vector or the name of a variable in Tbl. The software weights the observations in each row of $X$ or Tbl with the corresponding value in Weights. The length of Weights must equal the number of rows in $X$ or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response variable when training the model.

By default, Weights is ones(n,1), where n is the number of observations in $X$ or Tbl.

The software normalizes Weights to sum to the value of the prior probability in the respective class.
Data Types: single | double | char | string

Output Arguments

Md1 — Trained classification model
classification model object

Trained classification model, returned as one of the classification model objects in this table.

OptimizationResults — Optimization results
BayesianOptimization object

Optimization results, returned as a BayesianOptimization object. For more information on the
Bayesian optimization process, see "Bayesian Optimization" on page 32-1457.

Tips

• Depending on the size of your data and the number of learners you specify, fitcauto can take
some time to run. If you have a Parallel Computing Toolbox license, you can speed up
computations by running the optimization in parallel. To do so, specify
'HyperparameterOptimizationOptions',struct('UseParallel',true). You can include
other fields in the structure to control other aspects of the optimization. See
HyperparameterOptimizationOptions.

Algorithms

Automatic Selection of Learners

When you specify 'Learners','auto', the fitcauto function analyzes the predictor and response
data in order to choose appropriate learners. The function considers whether the data set has any of
these characteristics:
• Categorical predictors
• Missing values for more than 5% of the data
• Imbalanced data, where the ratio of the number of observations in the largest class to the number of observations in the smallest class is greater than 5
• More than 100 observations in the smallest class
• Wide data, where the number of predictors is greater than or equal to the number of observations
• High-dimensional data, where the number of predictors is greater than 100
• Large data, where the number of observations is greater than 50,000
• Binary response variable
• Ordinal response variable

The selected learners are always a subset of those listed in the Learners table. However, the associated models tried during the optimization process can have different default values for hyperparameters not being optimized, as well as different search ranges for hyperparameters being optimized.

Bayesian Optimization

The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of fitcauto, a point is a learner type together with a set of hyperparameter values for the learner (see Learners and OptimizeHyperparameters), and the objective function is the cross-validation classification error, by default. In the case of fitcauto, Bayesian optimization internally maintains a multi-TreeBagger model of the objective function. That is, the objective function model splits along the learner type and, for a given learner, the model is a TreeBagger ensemble for regression. (This underlying model differs from the Gaussian process model employed by other Statistics and Machine Learning Toolbox functions that use Bayesian optimization.) Bayesian optimization trains the underlying model by using objective function evaluations, and determines the next point to evaluate by using an acquisition function (‘expected-improvement’). For more information, see “Expected Improvement” on page 10-4. The acquisition function balances between sampling at points with low modeled objective function values and exploring areas that are not well modeled yet. At the end of the optimization, fitcauto chooses the point with the minimum objective function model value, among the points considered during the optimization. For more information, see the 'Criterion','min-visited-mean' name-value pair argument of bestPoint.

Alternative Functionality

• If you are unsure which models work best for you data set, you can alternatively use the Classification Learner app. Using the app, you can perform hyperparameter tuning for different models, and choose the optimized model that performs best. Although you must select a specific model before you can tune the model hyperparameters, Classification Learner provides greater flexibility for selecting optimizable hyperparameters and setting hyperparameter values. However, you cannot optimize in parallel, choose 'linear' or 'kernel' learners, specify observation weights, or specify prior probabilities in the app. For more information, see “Hyperparameter Optimization in Classification Learner App” on page 23-48.

• If you know which models might suit your data, you can alternatively use the corresponding model fit functions and specify the 'OptimizeHyperparameters' name-value pair argument to tune hyperparameters. You can compare the results across the models to select the best classifier. For an example of this process, see “Moving Towards Automating Model Selection Using Bayesian Optimization” on page 18-172.

Topics
“Automated Classifier Selection with Bayesian Optimization” on page 18-180
“Hyperparameter Optimization in Classification Learner App” on page 23-48

Introduced in R2020a
**fitcdiscr**

Fit discriminant analysis classifier

**Syntax**

```matlab
Mdl = fitcdiscr(Tbl,ResponseVarName)
Mdl = fitcdiscr(Tbl,formula)
Mdl = fitcdiscr(Tbl,Y)
Mdl = fitcdiscr(X,Y)
Mdl = fitcdiscr( ___ ,Name,Value)
```

**Description**

`Mdl = fitcdiscr(Tbl,ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl,formula)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl,Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X,Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr( ___ ,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can optimize hyperparameters to minimize the model's cross-validation loss, or specify the cost of misclassification, the prior probabilities for each class, or the observation weights.

**Examples**

**Train Discriminant Analysis Model**

Load Fisher's iris data set.

```matlab
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```matlab
Mdl = fitcdiscr(meas,species)
```

```matlab
Mdl = ClassificationDiscriminant
    ResponseName: 'Y'
    CategoricalPredictors: []
```
Mdl is a ClassificationDiscriminant model. To access its properties, use dot notation. For example, display the group means for each predictor.

Mdl.Mu
ans = 3×4

5.0060    3.4280    1.4620    0.2460
5.9360    2.7700    4.2600    1.3260
6.5880    2.9740    5.5520    2.0260

To predict labels for new observations, pass Mdl and predictor data to predict.

Optimize Discriminant Analysis Model

This example shows how to optimize hyperparameters automatically using fitcsvm. The example uses Fisher’s iris data.

Load the data.

load fisheriris

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

rng(1)
Mdl = fitcsvm(meas,species,'OptimizeHyperparameters','auto',...
'CategoricalPredictors',[],'CrossVal','on',...)

struct('AcquisitionFunctionName','expected-improvement-plus'))

Optimize Discriminant Analysis Model on Tall Array

This example shows how to optimize hyperparameters of a discriminant analysis model automatically using a tall array. The sample data set airlinesmall.csv is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the mapreducer function.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat 'NA' values as missing data so that datastore replaces them with NaN values. Create a tall table that contains the data in the datastore.

ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek', ...
                          'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds); % Tall table

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

 tt =
Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

\[
Y = \text{tt.DepDelay} > 10 \quad \% \text{ Class labels}
\]

\[
Y = \\
M \times 1 \text{ tall logical array} \\
1 \\
0 \\
1 \\
1 \\
0 \\
1 \\
0 \\
0 \\
: \\
:
\]

Create a tall array for the predictor data.

\[
X = \text{tt}(:,1:\text{end-1}) \quad \% \text{ Predictor data}
\]

\[
X = \\
M \times 6 \text{ tall double matrix} \\
10 \quad 21 \quad 3 \quad 642 \quad 8 \quad 308 \\
10 \quad 26 \quad 1 \quad 1021 \quad 8 \quad 296 \\
10 \quad 23 \quad 5 \quad 2055 \quad 21 \quad 480 \\
10 \quad 23 \quad 5 \quad 1332 \quad 13 \quad 296 \\
10 \quad 22 \quad 4 \quad 629 \quad 4 \quad 373 \\
10 \quad 28 \quad 3 \quad 1446 \quad 59 \quad 308 \\
10 \quad 8 \quad 4 \quad 928 \quad 3 \quad 447 \\
10 \quad 10 \quad 6 \quad 859 \quad 11 \quad 954 \\
: \quad : \quad : \quad : \quad : \quad :
\]

Remove rows in \(X\) and \(Y\) that contain missing data.
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);

Standardize the predictor variables.

Z = zscore(X);

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'DiscrimType' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'DiscrimType'.) For reproducibility, use the 'expected-improvement-plus' acquisition function and set the seeds of the random number generators using rng and tallrng. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

rng('default')
tallrng('default')

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the ClassNames name-value pair argument.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.
You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

The software considers NaN, ' ' (empty character vector), " " (empty string), <missing>, and <undefined> values in Y to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: categorical | char | string | logical | single | double | cell

X — Predictor data
numeric matrix

Predictor values, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

fitcdiscr considers NaN values in X as missing values. fitcdiscr does not use observations with missing values for X in the fit.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note. You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'DiscrimType','quadratic','SaveMemory','on' specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

Model Parameters

ClassNames — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors
Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:
- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',[{'a','c'}].

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Cost of misclassification
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:
- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.

Data Types: single | double | struct

Delta — Linear coefficient threshold
0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of Mdl has magnitude smaller than Delta, Mdl sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Data Types: single | double

DiscrimType — Discriminant type
'linear' (default) | 'quadratic' | 'diaglinear' | 'diagquadratic' | 'pseudolinear' | 'pseudoquadratic'
Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector or string scalar in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Predictor Covariance Treatment</th>
</tr>
</thead>
</table>
| 'linear'    | Regularized linear discriminant analysis (LDA)   | • All classes have the same covariance matrix.  
|             |                                                  | • \( \Sigma_{\gamma} = (1 - \gamma)\hat{\Sigma} + \gamma\text{diag}(\hat{\Sigma}) \).  
|             |                                                  | \( \hat{\Sigma} \) is the empirical, pooled covariance matrix and \( \gamma \) is the amount of regularization. |
| 'diaglinear'| LDA                                              | All classes have the same, diagonal covariance matrix. |
| 'pseudolinear'| LDA                                | All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse. |
| 'quadratic' | Quadratic discriminant analysis (QDA)            | The covariance matrices can vary among classes. |
| 'diagquadratic' | QDA                               | The covariance matrices are diagonal and can vary among classes. |
| 'pseudoquadratic' | QDA                              | The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse. |

**Note** To use regularization, you must specify 'linear'. To specify the amount of regularization, use the Gamma name-value pair argument.

Example: 'DiscrimType','quadratic'

**FillCoeffs — Coeffs property flag**

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs','off'

**Gamma — Amount of regularization**

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than DiscrimType.
• If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

• For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering Mdl.Gamma at the command line.

• For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.

• If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets DiscrimType to 'linear'.

• If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set DiscrimType to 'diagLinear' or 'diagQuadratic' for diagonal covariance matrices.

Example: 'Gamma',1
Data Types: single | double

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

• If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  
  • The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  
  • By default, PredictorNames is {'x1','x2',...}.

• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcdiscr uses only the predictor variables in PredictorNames and the response variable in training.

  • PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.

  • By default, PredictorNames contains the names of all predictor variables.

  • A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in $Y$.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to $1/K$, where $K$ is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to $\text{Mdl.ClassNames}$ or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure $S$ with two fields:</td>
</tr>
<tr>
<td></td>
<td>• $S.\text{ClassNames}$ contains the class names as a variable of the same type as $Y$.</td>
</tr>
<tr>
<td></td>
<td>• $S.\text{ClassProbs}$ contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar:

- If you supply $Y$, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**SaveMemory — Flag to save covariance matrix**

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then fitcdiscr does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then fitcdiscr computes and stores the full covariance matrix in $\text{Mdl}$.

Specify SaveMemory as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory','on'

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...
Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1 - x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'           | -1 for $x < 0$
0 for $x = 0$
1 for $x > 0$                                               |
| 'symmetric'      | $2x - 1$                                                         |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$                                             |

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

Weights — Observation weights
numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string
Cross-Validation Options

CrossVal — Cross-validation flag
'on' (default) | 'off'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'CrossVal','on'

CVPartition — Cross-validation partition
[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

Holdout — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

KFold — Number of folds
10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:
Randomly partition the data into k sets.

For each set, reserve the set as validation data, and train the model using the other k - 1 sets.

Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold', 5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other n - 1 observations.
2. Store the n compact, trained models in the cells of an n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

**Hyperparameter Optimization Options**

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Delta','Gamma'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitcdiscr by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.
The eligible parameters for `fitcdiscr` are:

- **Delta** — `fitcdiscr` searches among positive values, by default log-scaled in the range $[1e^{-6}, 1e3]$.
- **DiscrimType** — `fitcdiscr` searches among 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'.
- **Gamma** — `fitcdiscr` searches among real values in the range $[0, 1]$.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcdiscr', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Discriminant Analysis Model” on page 32-1460.

Example: 'auto'

### `HyperparameterOptimizationOptions` — Options for optimization

Structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>

</tr>
<tr>
<td>ShowPlots</td>
<td>Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.</td>
<td>true</td>
</tr>
<tr>
<td>SaveIntermediateResults</td>
<td>Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.</td>
<td>false</td>
</tr>
</tbody>
</table>
Field Name | Values | Default
--- | --- | ---
Verbose | Display to the command line.  
- 0 — No iterative display  
- 1 — Iterative display  
- 2 — Iterative display with extra information  
For details, see the `bayesopt` `Verbose` name-value pair argument. | 1

UseParallel | Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7. | false

Repartition | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization.  
true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false

Use no more than one of the following three field names.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>

Example:  
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

**Mdl — Trained discriminant analysis classification model**  
`ClassificationDiscriminant` model object | `ClassificationPartitionedModel` cross-validated model object

Trained discriminant analysis classification model, returned as a `ClassificationDiscriminant` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationDiscriminant` model object.
To reference properties of \( Mdl \), use dot notation. For example, to display the estimated component means at the Command Window, enter \( Mdl.Mu \).

**More About**

**Discriminant Classification**

The model for discriminant analysis is:

- Each class \( (Y) \) generates data \( (X) \) using a multivariate normal distribution. That is, the model assumes \( X \) has a Gaussian mixture distribution (\texttt{gmdistribution})
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

\texttt{predict} classifies so as to minimize the expected classification cost:

\[
\hat{y} = \arg\min_{y = 1, \ldots, K} \sum_{k=1}^{K} \hat{P}(k|x)C(y|k),
\]

where

- \( \hat{y} \) is the predicted classification.
- \( K \) is the number of classes.
- \( \hat{P}(k|x) \) is the posterior probability on page 20-6 of class \( k \) for observation \( x \).
- \( C(y|k) \) is the cost on page 20-7 of classifying an observation as \( y \) when its true class is \( k \).

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

**Tips**

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Alternative Functionality**

**Functions**

The \texttt{classify} function also performs discriminant analysis. \texttt{classify} is usually more awkward to use.

- \texttt{classify} requires you to fit the classifier every time you make a new prediction.
- \texttt{classify} does not perform cross-validation or hyperparameter optimization.
- \texttt{classify} requires you to fit the classifier when changing prior probabilities.
Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

• Supported syntaxes are:
  • Mdl = fitcdiscr(Tbl,Y)
  • Mdl = fitcdiscr(X,Y)
  • Mdl = fitcdiscr(___,'Name',Value)
  • [Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(___,'Name',Value) — fitcdiscr returns the additional output arguments FitInfo and HyperparameterOptimizationResults when you specify the 'OptimizeHyperparameters' name-value pair argument.
  
• The FitInfo output argument is an empty structure array currently reserved for possible future use.

• The HyperparameterOptimizationResults output argument is a BayesianOptimization object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

'HyperparameterOptimizationResults' is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty at the time you create the model. The values in 'HyperparameterOptimizationResults' depend on the value you specify for the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model.

• If you specify 'bayesopt' (default), then HyperparameterOptimizationResults is an object of class BayesianOptimization.

• If you specify 'gridsearch' or 'randomsearch', then HyperparameterOptimizationResults is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

• Supported name-value pair arguments, and any differences, are:
  • 'ClassNames'
  • 'Cost'
  • 'DiscrimType'
  • 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitcdiscr(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
  • 'OptimizeHyperparameters' — The only eligible parameter to optimize is 'DiscrimType'. Specifying 'auto' uses 'DiscrimType'.
  • 'PredictorNames'
  • 'Prior'
  • 'ResponseName'
• 'ScoreTransform'
• 'Weights'
• For tall arrays and tall tables, fitcdiscr returns a CompactClassificationDiscriminant object, which contains most of the same properties as a ClassificationDiscriminant object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these ClassificationDiscriminant properties:
  • ModelParameters
  • NumObservations
  • HyperparameterOptimizationResults
  • RowsUsed
  • XCentered
  • W
  • X
  • Y

Additionally, the compact object does not support these ClassificationDiscriminant methods:
  • compact
  • crossval
  • cvshrink
  • resubEdge
  • resubLoss
  • resubMargin
  • resubPredict

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

“Improving Discriminant Analysis Models” on page 20-15
“Regularize Discriminant Analysis Classifier” on page 20-21

Introduced in R2014a
fitcecoc

Fit multiclass models for support vector machines or other classifiers

Syntax

Mdl = fitcecoc(Tbl,ResponseVarName)
Mdl = fitcecoc(Tbl,formula)
Mdl = fitcecoc(Tbl,Y)
Mdl = fitcecoc(X,Y)
Mdl = fitcecoc(____,Name,Value)
[Mdl,HyperparameterOptimizationResults] = fitcecoc(____,Name,Value)

Description

Mdl = fitcecoc(Tbl,ResponseVarName) returns a full, trained, multiclass, error-correcting output codes (ECOC) model on page 32-1529 using the predictors in table Tbl and the class labels in Tbl.ResponseVarName. fitcecoc uses \( \frac{K(K-1)}{2} \) binary support vector machine (SVM) models using the one-versus-one coding design on page 32-1527, where \( K \) is the number of unique class labels (levels). Mdl is a ClassificationECOC model.

Mdl = fitcecoc(Tbl,formula) returns an ECOC model using the predictors in table Tbl and the class labels. formula is an explanatory model of the response and a subset of predictor variables in Tbl used for training.

Mdl = fitcecoc(Tbl,Y) returns an ECOC model using the predictors in table Tbl and the class labels in vector Y.

Mdl = fitcecoc(X,Y) returns a trained ECOC model using the predictors X and the class labels Y.

Mdl = fitcecoc(____,Name,Value) returns an ECOC model with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes.

For example, specify different binary learners, a different coding design, or to cross-validate. It is good practice to cross-validate using the Kfold Name,Value pair argument. The cross-validation results determine how well the model generalizes.

[Mdl,HyperparameterOptimizationResults] = fitcecoc(____,Name,Value) also returns hyperparameter optimization details when you specify the OptimizeHyperparameters name-value pair argument and use linear or kernel binary learners. For other Learners, the HyperparameterOptimizationResults property of Mdl contains the results.

Examples

Train Multiclass Model Using SVM Learners

Train a multiclass error-correcting output codes (ECOC) model using support vector machine (SVM) binary learners.
Load Fisher's iris data set. Specify the predictor data \( X \) and the response data \( Y \).

```matlab
load fisheriris
X = meas;
Y = species;
```

Train a multiclass ECOC model using the default options.

```matlab
Mdl = fitcecoc(X,Y)
```

```
Mdl = 
    ClassificationECOC
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
    CodingName: 'onevsone'

Properties, Methods
```

\( \text{Mdl} \) is a \text{ClassificationECOC} model. By default, \text{fitcecoc} uses SVM binary learners and a one-versus-one coding design. You can access \( \text{Mdl} \) properties using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
CodingMat = 3x3
    1  1  0
   -1  0  1
    0 -1 -1
```

A one-versus-one coding design for three classes yields three binary learners. The columns of \( \text{CodingMat} \) correspond to the learners, and the rows correspond to the classes. The class order is the same as the order in \( \text{Mdl.CClassNames} \). For example, \( \text{CodingMat}(:,1) \) is \([1; -1; 0]\) and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Because 'setosa' corresponds to 1, it is the positive class; 'versicolor' corresponds to -1, so it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1}    \% The first binary learner
ans =
    classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
```
CategoricalPredictors: []
ClassNames: [-1 1]
ScoreTransform: 'none'
Beta: [4x1 double]
Bias: 1.4505
KernelParameters: [1x1 struct]

Properties, Methods

Compute the resubstitution classification error:

```matlab
test = resubLoss(Mdl)
test = 0.0067
```

The classification error on the training data is small, but the classifier might be an overfitted model. You can cross-validate the classifier using `crossval` and compute the cross-validation classification error instead.

**Train Multiclass Linear Classification Model**

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```matlab
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```matlab
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 32-5388 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```matlab
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```matlab
Mdl =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
    CodingMatrix: [13x78 double]
```
Properties, Methods

Alternatively, you can train an ECOC model composed of default linear classification models using 'Learners','Linear'.

To conserve memory, fitcecoc returns trained ECOC models composed of linear classification learners in CompactClassificationECOC model objects.

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data \( X \) and the response data \( Y \).

```matlab
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```matlab
t = templateSVM('Standardize',true)
t = 
Fit template for classification SVM.
```

```matlab
Alpha: [0x1 double]
BoxConstraint: []
CacheSize: []
CachingMethod: ''
ClipAlphas: []
DeltaGradientTolerance: []
Epsilon: []
GapTolerance: []
IterationLimit: []
KernelFunction: ''
KernelScale: []
KernelOffset: []
KernelPolynomialOrder: []
NumPrint: []
Nu: []
OutlierFraction: []
RemoveDuplicates: []
ShrinkagePeriod: []
Solver: ''
StandardizeData: 1
SaveSupportVectors: []
VerbosityLevel: []
Version: 2
Method: 'SVM'
Type: 'classification'
```
t is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```matlab
Mdl = fitcecoc(X,Y,'Learners',t,...
            'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a ClassificationECOC classifier. You can access its properties using dot notation.

Cross-validate Mdl using 10-fold cross-validation.

```matlab
CVMdl = crossval(Mdl);
```

CVMdl is a ClassificationPartitionedECOC cross-validated ECOC classifier.

Estimate the generalized classification error.

```matlab
genError = kfoldLoss(CVMdl)
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

### Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```matlab
load fisheriris
X = meas(:,3:4); % Petal dimensions
Y = species;
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```matlab
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```matlab
load fisheriris
X = meas(:,3:4); % Petal dimensions
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```matlab
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
t is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.
```

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by predict or resubPredict) using the 'FitPosterior' name-value pair argument. Specify the class order using the 'ClassNames' name-value pair argument. Display diagnostic messages during training by using the 'Verbose' name-value pair argument.

```matlab
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
              'ClassNames',{'setosa','versicolor','virginica'},...'
              'Verbose',2);
```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1

Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 1

Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2

Fitting posterior probabilities for learner 3 (SVM).

Mdl is a ClassificationECOC model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the 'Verbose' name-value pair argument.

[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);

Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...

Mdl.BinaryLoss

ans = 'quadratic'

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

idx = randsample(size(X,1),10,1);
Mdl.ClassNames

ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }

table(Y(idx),label(idx),Posterior(idx,:),...'
    'VariableNames',
    {'TrueLabel', 'PredLabel', 'Posterior'})

ans=10×3 table
     TrueLabel          PredLabel        Posterior
    ______________    ______________    ______________________________________
    {'virginica' }    {'virginica' }     0.0039321     0.0039869       0.99208
    {'virginica' }    {'virginica' }      0.017067      0.018263       0.96467
    {'virginica' }    {'virginica' }      0.014948      0.015856        0.9692
    {'versicolor'}    {'versicolor'}    2.2197e-14       0.87317       0.12683

32-1495
The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```matlab
xMax = max(X);
xMin = min(X);
x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);
[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```matlab
contourf(x1Grid,x2Grid,...
        reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh,'Location','NorthWest')
hold off
```
Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when \texttt{fitcecoc} uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the arrhythmia data set.

\begin{verbatim}
load arrhythmia
[n,p] = size(X)

n = 452
p = 279

isLabels = unique(Y);
numLabels = numel(isLabels)

numLabels = 13

tabulate(categorical(Y))
\end{verbatim}

</table>

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

**Train One-Versus-All ECOC Classifier**

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```matlab
 tTree = templateTree('surrogate','on');
 tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning ('NumBins',50) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the 'NumBins' name-value pair argument. This argument is valid only when fitcecoc uses a tree learner. If you specify the 'NumBins' value, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

- Parallel computing ('Options',statset('UseParallel',true)) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are 1/K, where K = 13 is the number of distinct classes.

```matlab
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
              'Prior','uniform','NumBins',50,'Options',options);
```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

Mdl is a ClassificationECOC model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

CVMdl = crossval(Mdl,'Options',options);

Warning: One or more folds do not contain points from all the groups.

CVMdl is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering CVMdl.Trained{1}.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using confusionchart. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
Reproduce Binned Data

Reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

```matlab
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Optimize ECOC Classifier

Optimize hyperparameters automatically using fitcecoc.

Load the fisheriris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng default
Mdl = fitcecoc(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Train Multiclass ECOC Model with SVMs and Tall Arrays

Create two multiclass ECOC models trained on tall data. Use linear binary learners for one of the models and kernel binary learners for the other. Compare the resubstitution classification error of the two models.

In general, you can perform multiclass classification of tall data by using fitcecoc with linear or kernel binary learners. When you use fitcecoc to train a model on tall arrays, you cannot use SVM binary learners directly. However, you can use either linear or kernel binary classification models that use SVMs.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the mapreducer function.

Create a datastore that references the folder containing Fisher's iris data set. Specify 'NA' values as missing data so that datastore replaces them with NaN values. Create tall versions of the predictor and response data.

```matlab
ds = datastore('fisheriris.csv','TreatAsMissing','NA');
t = tall(ds);
Starting parallel pool (parpool) using the 'local' profile ... Connected to the parallel pool (number of workers: 6).
X = [t.SepalLength t.SepalWidth t.PetalLength t.PetalWidth];
Y = t.Species;
```

Standardize the predictor data.

```matlab
Z = zscore(X);
```

Train a multiclass ECOC model that uses tall data and linear binary learners. By default, when you pass tall arrays to fitcecoc, the software trains linear binary learners that use SVMs. Because the response data contains only three unique classes, change the coding scheme from one-versus-all.
(which is the default when you use tall data) to one-versus-one (which is the default when you use in-memory data).

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```matlab
rng('default')
tallrng('default')
mdlLinear = fitcecoc(Z,Y,'Coding','onevsone')
```

```
Training binary learner 1 (Linear) out of 3.
Training binary learner 2 (Linear) out of 3.
Training binary learner 3 (Linear) out of 3.
```

```matlab
mdlLinear =
    classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3×1 cell}
    CodingMatrix: [3×3 double]
```

Properties, Methods

`mdlLinear` is a `CompactClassificationECOC` model composed of three binary learners.

Train a multiclass ECOC model that uses tall data and kernel binary learners. First, create a `templateKernel` object to specify the properties of the kernel binary learners; in particular, increase the number of expansion dimensions to $2^{16}$.

```matlab
tKernel = templateKernel('NumExpansionDimensions',2^16)
```

```
tKernel =
    Fit template for classification Kernel.
    BetaTolerance: []
    BlockSize: []
    BoxConstraint: []
    Epsilon: []
    NumExpansionDimensions: 65536
    GradientTolerance: []
    HessianHistorySize: []
    IterationLimit: []
    KernelScale: []
    Lambda: []
    Learner: 'svm'
    LossFunction: []
    Stream: []
    VerbosityLevel: []
    Version: 1
    Method: 'Kernel'
    Type: 'classification'
```

By default, the kernel binary learners use SVMs.
Pass the templateKernel object to fitcecoc and change the coding scheme to one-versus-one.

```matlab
mdlKernel = fitcecoc(Z,Y,'Learners',tKernel,'Coding','onevsone')
```

Training binary learner 1 (Kernel) out of 3.
Training binary learner 2 (Kernel) out of 3.
Training binary learner 3 (Kernel) out of 3.

```matlab
mdlKernel =
    classreg.learning.classif.CompactClassificationECOC
        ResponseName: 'Y'
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        BinaryLearners: {3×1 cell}
        CodingMatrix: [3×3 double]
```

mdlKernel is also a `CompactClassificationECOC` model composed of three binary learners.

Compare the resubstitution classification error of the two models.

```matlab
errorLinear = gather(loss(mdlLinear,Z,Y))
```

Evaluating tall expression using the Parallel Pool 'local':
  - Pass 1 of 1: Completed in 1.5 sec
Evaluation completed in 1.5 sec

```matlab
errorLinear = 0.0333
```

```matlab
errorKernel = gather(loss(mdlKernel,Z,Y))
```

Evaluating tall expression using the Parallel Pool 'local':
  - Pass 1 of 1: Completed in 17 sec
Evaluation completed in 17 sec

```matlab
errorKernel = 0.0067
```

mdlKernel misclassifies a smaller percentage of the training data than mdlLinear.

### Input Arguments

- **Tbl** — Sample data
table

Sample data, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable using `ResponseVarName`.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, specify a formula using `formula`. 

32-1505
If Tbl does not contain the response variable, specify a response variable using $Y$. The length of response variable and the number of Tbl rows must be equal.

**Note** For training linear or kernel classification models, fitcecoc does not support tables. That is, if Learners is 'linear' or 'kernel', contains a linear classification model learner template (see templateLinear), or contains a kernel classification learner template (see templateKernel), you cannot supply Tbl, ResponseVarName, or formula. Supply a matrix of predictor data ($X$) and an array of responses ($Y$) instead.

**Data Types:** table

**ResponseVarName — Response variable name**

name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable $Y$ is stored as Tbl.$Y$, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including $Y$, as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If $Y$ is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the ClassNames name-value pair argument.

**Data Types:** char | string

**formula — Explanatory model of response variable and subset of predictor variables**

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, $Y$ represents the response variable, and $X1$, $X2$, and $X3$ represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

**Data Types:** char | string
**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, then each element must correspond to one row of the array.

The length of Y and the number of rows of Tbl or X must be equal.

It is good practice to specify the class order using the ClassNames name-value pair argument.

Data Types: categorical | char | string | logical | single | double | cell

**X — Predictor data**
full matrix | sparse matrix

Predictor data, specified as a full or sparse matrix.

The length of Y and the number of observations in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

**Note**

- For linear classification learners, if you orient X so that observations correspond to columns and specify 'ObservationsIn','columns', then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient X so that observations correspond to rows.
- fitcecoc supports sparse matrices for training linear classification models only.

Data Types: double | single

**Note**  
The software treats NaN, empty character vector (''), empty string ('"'), and <undefined> elements as missing data. The software removes rows of X corresponding to missing values in Y. However, the treatment of missing values in X varies among binary learners. For details, see the training functions for your binary learners: fitcdiscr, fitckernel, fitcknn, fitclinear, fitcnb, fitcsvm, fitctree, or fitcensemble. Removing observations decreases the effective training or cross-validation sample size.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note**  
You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for
‘OptimizeHyperparameters’ only by using the ‘HyperparameterOptimizationOptions’ name-value pair argument.

ECOC Classifier Options

Coding — Coding design
‘onevsone’ (default) | ‘allpairs’ | ‘binarycomplete’ | ‘denserandom’ | ‘onevsall’ | ‘ordinal’ | ‘sparserandom’ | ‘ternarycomplete’ | numeric matrix

Coding design name, specified as the comma-separated pair consisting of ‘Coding’ and a numeric matrix or a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Number of Binary Learners</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘allpairs’ and ‘onevsone’</td>
<td>(K(K-1)/2)</td>
<td>For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.</td>
</tr>
<tr>
<td>‘binarycomplete’</td>
<td>(2^{K-1} - 1)</td>
<td>This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.</td>
</tr>
<tr>
<td>‘denserandom’</td>
<td>Random, but approximately 10 (\log_2 K)</td>
<td>For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1532.</td>
</tr>
<tr>
<td>‘onevsall’</td>
<td>(K)</td>
<td>For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.</td>
</tr>
<tr>
<td>‘ordinal’</td>
<td>(K-1)</td>
<td>For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.</td>
</tr>
<tr>
<td>Value</td>
<td>Number of Binary Learners</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'sparserandom'</td>
<td>Random, but approximately 15 log₂K</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1532.</td>
</tr>
<tr>
<td>'ternarycomplete'</td>
<td>(3^K - 2^{(K+1)} + 1)/2</td>
<td>This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.</td>
</tr>
</tbody>
</table>

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K-by-L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in ClassNames. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of Coding(i,j), that is, the class that learner j assigns to observations in class i.

<table>
<thead>
<tr>
<th>Value</th>
<th>Dichotomous Class Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Learner j assigns observations in class i to a negative class.</td>
</tr>
<tr>
<td>0</td>
<td>Before training, learner j removes observations in class i from the data set.</td>
</tr>
<tr>
<td>1</td>
<td>Learner j assigns observations in class i to a positive class.</td>
</tr>
</tbody>
</table>

- Every column must contain at least one -1 or 1.
- For all column indices i,j such that i ≠ j, Coding(:,i) cannot equal Coding(:,j) and Coding(:,i) cannot equal -Coding(:,j).
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 32-1531.

Example: 'Coding','ternarycomplete'  

Data Types: char | string | double | single | int16 | int32 | int64 | int8

**FitPosterior** — Flag indicating whether to transform scores to posterior probabilities

false or 0 (default) | true or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of 'FitPosterior' and a true (1) or false (0).
If `FitPosterior` is `true`, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is AdaBoostM2, LPBoost, RUSBoost, RobustBoost, or TotalBoost.
- The binary learners (`Learners`) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: `'FitPosterior',true`

Data Types: `logical`

**Learners — Binary learner templates**

'`svm`' (default) | 'discriminant' | 'kernel' | 'knn' | 'linear' | 'naivebayes' | 'tree' | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of `Learners` and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use GentleBoost, LogitBoost, and RobustBoost, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'discriminant'</td>
<td>Discriminant analysis. For default options, see <code>templateDiscriminant</code>.</td>
</tr>
<tr>
<td>'kernel'</td>
<td>Kernel classification model. For default options, see <code>templateKernel</code>.</td>
</tr>
<tr>
<td>'knn'</td>
<td>k-nearest neighbors. For default options, see <code>templateKNN</code>.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Linear classification model. For default options, see <code>templateLinear</code>.</td>
</tr>
<tr>
<td>'naivebayes'</td>
<td>Naive Bayes. For default options, see <code>templateNaiveBayes</code>.</td>
</tr>
<tr>
<td>'svm'</td>
<td>SVM. For default options, see <code>templateSVM</code>.</td>
</tr>
<tr>
<td>'tree'</td>
<td>Classification trees. For default options, see <code>templateTree</code>.</td>
</tr>
</tbody>
</table>

- If `Learners` is a template object, then each binary learner trains according to the stored options. You can create a template object using:

  - `templateDiscriminant`, for discriminant analysis.
  - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the AdaBoostM2 ensemble method for binary learning.
• `templateKernel`, for kernel classification.
• `templateKNN`, for k-nearest neighbors.
• `templateLinear`, for linear classification.
• `templateNaiveBayes`, for naive Bayes.
• `templateSVM`, for SVM.
• `templateTree`, for classification trees.

• If `Learners` is a cell vector of template objects, then:
  • Cell `j` corresponds to binary learner `j` (in other words, column `j` of the coding design matrix), and the cell vector must have length `L`. `L` is the number of columns in the coding design matrix. For details, see Coding.
  • To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range `(-∞,∞)`, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
  • You cannot specify linear classification model learner templates with any other template.
  • Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: 'Learners','tree'

`NumBins` — Number of bins for numeric predictors

`[]`(empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar. This argument is valid only when `fitcecoc` uses a tree learner, that is, 'Learners' is either 'tree' or a template object created by using `templateTree`, or a template object created by using `templateEnsemble` with tree weak learners.

• If the 'NumBins' value is empty (default), then the software does not bin any predictors.
• If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.

  • If the 'NumBins' value exceeds the number (`u`) of unique values for a predictor, then `fitcecoc` bins the predictor into `u` bins.
  • `fitcecoc` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: 'NumBins',50

Data Types: `single` | `double`
NumConcurrent — Number of binary learners concurrently trained

Number of binary learners concurrently trained, specified as the comma-separated pair consisting of 'NumConcurrent' and a positive integer scalar. The default value is 1, which means fitcecoc trains the binary learners sequentially.

**Note** This option applies only when you use fitcecoc on tall arrays. See “Tall Arrays” on page 32-1533 for more information.

Data Types: single | double

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note**
- For linear classification learners, if you orient X so that observations correspond to columns and specify 'ObservationsIn','columns', then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient X so that observations correspond to rows.

Example: 'ObservationsIn','columns'

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. `Verbose` controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages every time it trains a new binary learner.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays extra diagnostic messages every time it trains a new binary learner.</td>
</tr>
</tbody>
</table>

Each binary learner has its own verbosity level that is independent of this name-value pair argument. To change the verbosity level of a binary learner, create a template object and specify the 'Verbose' name-value pair argument. Then, pass the template object to fitcecoc by using the 'Learners' name-value pair argument.
Example: 'Verbose',1
Data Types: double | single

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier
'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the CVPartition, Holdout, KFold, or Leaveout name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition
[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500, 'KFold', 5). Then, you can specify the cross-validated model by using 'CVPartition', cvp.

Holdout — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1
Data Types: double | single

KFold — Number of folds
10 (default) | positive integer value greater than 1
Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1 Randomly partition the data into k sets.
2 For each set, reserve the set as validation data, and train the model using the other k - 1 sets.
3 Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is size(Mdl.X,1), the software:

1 Reserves the observation as validation data, and trains the model using the other n - 1 observations
2 Stores the n compact, trained models in the cells of a n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: CVPartition, Holdout, KFold, or Leaveout.

**Note** Leave-one-out is not recommended for cross-validating ECOC models composed of linear or kernel classification model learners.

Example: 'Leaveout','on'

**Other Classification Options**

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
</tbody>
</table>
Value | Description
---|---
Character matrix | Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors | Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
'all' | All predictors are categorical.

Specification of `'CategoricalPredictors'` is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, SVM, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is kNN.

If you specify `'CategoricalPredictors'` for any other learner, then the software warns that it cannot train that binary learner. For example, the software cannot train linear or kernel classification model learners using categorical predictors.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See `'CategoricalPredictors'` of `fitcknn` for k-nearest learners, `'CategoricalPredictors'` of `fitcnb` for naive Bayes learners, `'CategoricalPredictors'` of `fitcsvm` for SVM learners, and `'CategoricalPredictors'` of `fitctree` for tree learners.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `'ClassNames'` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{a',b',c'}`. To train the model using observations from classes `a` and `c` only, specify `'ClassNames',{"a'","c'"}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames',{"b'","g'"}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`
Cost — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix Cost, then Cost(i,j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- The structure S, then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as Y
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default is ones(K) - eye(K), where K is the number of distinct classes.

Example: 'Cost',[0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

Options — Parallel computing options
[] (default) | structure array returned by statset

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. These options require Parallel Computing Toolbox. fitcecoc uses 'Streams','UseParallel', and 'UseSubstreams' fields.

This table summarizes the available options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Streams'</td>
<td>A RandStream object or cell array of such objects. If you do not specify Streams, the software uses the default stream or streams. If you specify Streams, use a single object except when the following are true:</td>
</tr>
<tr>
<td></td>
<td>- You have an open parallel pool.</td>
</tr>
<tr>
<td></td>
<td>- UseParallel is true.</td>
</tr>
<tr>
<td></td>
<td>- UseSubstreams is false.</td>
</tr>
<tr>
<td></td>
<td>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and Streams must supply a single random number stream.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'UseParallel'</td>
<td>If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting 'UseParallel',true. The fitcecoc function sends each binary learner to a worker in the pool. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster. For details on Intel TBB, see <a href="https://software.intel.com/en-us/intel-tbb">https://software.intel.com/en-us/intel-tbb</a>.</td>
</tr>
<tr>
<td>'UseSubstreams'</td>
<td>Set to true to compute in parallel using the stream specified by 'Streams'. Default is false. For example, set Streams to a type allowing substreams, such as 'mlfg6331_64' or 'mrg32k3a'.</td>
</tr>
</tbody>
</table>

A best practice to ensure more predictable results is to use parpool and explicitly create a parallel pool before you invoke parallel computing using fitcecoc.

Example: 'Options',statset('UseParallel',true)

Data Types: struct

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

 Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcecoc uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
**Prior** — Prior probabilities

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 32-1531.

Example: struct('ClassNames',
{['setosa','versicolor','virginica']},
'ClassProbs',1:3)  

Data Types: single | double | char | string | struct

**ResponseName** — Response variable name

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar:

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'  
Data Types: char | string

**ScoreTransform** — Score transformation

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

32-1518
This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1 - x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'               | -1 for $x < 0$  
                        | 0 for $x = 0$  
                        | 1 for $x > 0$                                        |
| 'symmetric'          | $2x - 1$                                                                    |
| 'symmetricismax'     | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit'     | $2/(1 + e^{x}) - 1$                                                         |

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones($n,1$), where $n$ is the number of observations in X or Tbl.

Data Types: double | single | char | string

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects
Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Coding'} along with the default parameters for the specified Learners:
  - Learners = 'svm' (default) — {'BoxConstraint','KernelScale'}
  - Learners = 'discriminant' — {'Delta','Gamma'}
  - Learners = 'kernel' — {'KernelScale','Lambda'}
  - Learners = 'knn' — {'Distance','NumNeighbors'}
  - Learners = 'linear' — {'Lambda','Learner'}
  - Learners = 'naivebayes' — {'DistributionNames','Width'}
  - Learners = 'tree' — {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitcecoc by varying the parameters. For information about cross-validation loss in a different context, see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcecoc are:

- Coding — fitcecoc searches among 'onevsall' and 'onevsone'.
- The eligible hyperparameters for the chosen Learners, as specified in this table.

<table>
<thead>

Alternatively, use hyperparameters with your chosen Learners, such as

```matlab
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcecoc', meas, species, 'svm');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcecoc', meas, species, 'svm');
params(2).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize ECOC Classifier” on page 32-1500.

Example: ‘auto’

`HyperparameterOptimizationOptions — Options for optimization`  
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters
BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. HyperparameterOptimizationResults is nonempty when the OptimizeHyperparameters name-value pair argument is nonempty and the Learners name-value pair argument designates linear or kernel binary learners. The value depends on the setting of the HyperparameterOptimizationOptions name-value pair argument:

- 'bayesopt' (default) — Object of class BayesianOptimization
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observation from smallest (best) to highest (worst)

Data Types: table
Limitations

- For training linear or kernel classification models, fitcecoc does not support tables. That is, if Learners is 'linear' or 'kernel', contains a linear classification model learner template (see templateLinear), or contains a kernel classification model learner template (see templateKernel), then you cannot supply Tbl, ResponseVarName, or formula. Supply a matrix of predictor data (X) and an array of responses (Y) instead.

- fitcecoc supports sparse matrices for training linear classification models only. For all other models, supply a full matrix of predictor data instead.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- \( m_{kj} \) is element \((k,j)\) of the coding design matrix \( M \) (that is, the code corresponding to class \( k \) of binary learner \( j \)).
- \( s_j \) is the score of binary learner \( j \) for an observation.
- \( g \) is the binary loss function.
- \( \hat{k} \) is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-189, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \sum_{j=1}^L m_{kj} g(m_{kj}, s_j).
\]

In loss-weighted decoding [Escalera et al.] on page 18-189, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

\[
\hat{k} = \arg\min_k \frac{\sum_{j=1}^L m_{kj} g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.
\]

Allwein et al. on page 18-189 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where \( y_j \) is a class label for a particular binary learner (in the set \{-1,1,0\}), \( s_j \) is the score for observation \( j \), and \( g(y_j, s_j) \).

<table>
<thead>

</tr>
</tbody>
</table>

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-189.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the loss and predict object functions), which measures how well an ECOC classifier performs as a whole.

**Coding Design**

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design, for a particular column (or binary learner):

- A row containing 1 directs the binary learner to group all observations in the corresponding class into a positive class.
- A row containing -1 directs the binary learner to group all observations in the corresponding class into a negative class.
- A row containing 0 directs the binary learner to ignore all observations in the corresponding class.

Coding design matrices with large, minimal, pairwise row distances based on the Hamming measure are optimal. For details on the pairwise row distance, see “Random Coding Design Matrices” on page 32-1532 and [4].

This table describes popular coding designs.

<table>

</thead>
<tbody>
<tr>
<td>sparse random</td>
<td>For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1532.</td>
<td>Random, but approximately $15 \log_2 K$</td>
<td>Variable</td>
</tr>
</tbody>
</table>

This plot compares the number of binary learners for the coding designs with increasing $K$.

#### Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classification problems.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.
Assume the following:

- The classification problem has three classes.
- The coding design is one-versus-one. For three classes, this coding design is

<table>
<thead>
<tr>
<th>Learner 1</th>
<th>Learner 2</th>
<th>Learner 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class 1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Class 2</td>
<td>-1</td>
<td>0</td>
</tr>
<tr>
<td>Class 3</td>
<td>0</td>
<td>-1</td>
</tr>
</tbody>
</table>

- The decoding scheme uses loss $g$.
- The learners are SVMs.

To build this classification model, the ECOC algorithm follows these steps.

1. Learner 1 trains on observations in Class 1 or Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly.

2. Let $M$ be the coding design matrix with elements $m_{kl}$, and $s_l$ be the predicted classification score for the positive class of learner $l$. The algorithm assigns a new observation to the class ($\hat{k}$) that minimizes the aggregation of the losses for the $L$ binary learners.

$$
\hat{k} = \arg\min_k \sum_{l=1}^L m_{kl} g(m_{kl}, s_l) / \sum_{l=1}^L |m_{kl}|
$$

ECOC models can improve classification accuracy, compared to other multiclass models [2].

**Tips**

- The number of binary learners grows with the number of classes. For a problem with many classes, the binarycomplete and ternarycomplete coding designs are not efficient. However:
  - If $K \leq 4$, then use ternarycomplete coding design rather than sparserandom.
  - If $K \leq 5$, then use binarycomplete coding design rather than denserandom.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionchart`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use $k$-fold cross-validation (`KFold`).
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.
**Algorithms**

**Custom Coding Design Matrices**

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors \( u \) and \( v \), \( u \neq v \) and \( u \neq -v \).
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
  - You can move vertically from 1 to -1 or -1 to 1.
  - You can move horizontally from a nonzero element to another nonzero element.
  - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row \( i \) to row \( j \) using these rules, then classes \( i \) and \( j \) cannot be separated by the design. For example, in the coding design

\[
\begin{bmatrix}
1 & 0 \\
-1 & 0 \\
0 & 1 \\
0 & -1
\end{bmatrix}
\]

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

**Parallel Computing**

If you use parallel computing (see Options), then fitcecoc trains binary learners in parallel.

**Prior Probabilities and Cost**

- Prior probabilities — The software normalizes the specified class prior probabilities (Prior) for each binary learner. Let \( M \) be the coding design matrix and \( I(A,c) \) be an indicator matrix. The indicator matrix has the same dimensions as \( A \). If the corresponding element of \( A \) is \( c \), then the indicator matrix has elements equaling one, and zero otherwise. Let \( M_{+1} \) and \( M_{-1} \) be \( K \)-by-\( L \) matrices such that:
  - \( M_{+1} = M \odot I(M,1) \), where \( \odot \) is element-wise multiplication (that is, \( M_{\text{plus}} = M \odot (M == 1) \)). Also, let \( m_l^{(+1)} \) be column vector \( l \) of \( M_{+1} \).
  - \( M_{-1} = -M \odot I(M,-1) \) (that is, \( M_{\text{minus}} = -M \odot (M == -1) \)). Also, let \( m_l^{(-1)} \) be column vector \( l \) of \( M_{-1} \).

Let \( m_l^{(+1)} \pi \) and \( m_l^{(-1)} \pi \), where \( \pi \) is the vector of specified, class prior probabilities (Prior).

Then, the positive and negative, scalar class prior probabilities for binary learner \( l \) are
\[ \bar{H}_l^{(j)} = \frac{\|H_l^{(j)}\|_1}{\|H_l^{(j+1)}\|_1 + \|H_l^{(j-1)}\|_1}, \]

where \( j = \{-1,1\} \) and \( \|a\|_1 \) is the one-norm of \( a \).

- **Cost** — The software normalizes the K-by-K cost matrix \( C \) (Cost) for each binary learner. For binary learner \( l \), the cost of classifying a negative-class observation into the positive class is

\[ c_l^{-+} = (\bar{H}_l^{(-1)})^T C n_l^{(+1)}. \]

Similarly, the cost of classifying a positive-class observation into the negative class is

\[ c_l^{+-} = (\bar{H}_l^{(+1)})^T C n_l^{(-1)}. \]

The cost matrix for binary learner \( l \) is

\[
C_l = \begin{bmatrix}
0 & c_l^{-+} \\
c_l^{+-} & 0
\end{bmatrix}.
\]

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify Prior and Cost, then the software adjusts the class prior probabilities as follows:

\[
\bar{n}_l^{-1} = \frac{c_l^{-+} + \bar{n}_l^{-1}}{c_l^{-+} + \bar{n}_l^{-1} + c_l^{+-} - \bar{n}_l^{+1}}
\]

\[
\bar{n}_l^{+1} = \frac{c_l^{+-} - \bar{n}_l^{+1}}{c_l^{+-} - \bar{n}_l^{+1} + c_l^{-+} - \bar{n}_l^{-1}}.
\]

**Random Coding Design Matrices**

For a given number of classes \( K \), the software generates random coding design matrices as follows.

1. The software generates one of these matrices:
   - **Dense random** — The software assigns 1 or –1 with equal probability to each element of the \( K \)-by-\( L_d \) coding design matrix, where \( L_d \approx 10\log_2 K \).
   - **Sparse random** — The software assigns 1 to each element of the \( K \)-by-\( L_s \) coding design matrix with probability 0.25, –1 with probability 0.25, and 0 with probability 0.5, where \( L_s \approx 15\log_2 K \).

2. If a column does not contain at least one 1 and at least one –1, then the software removes that column.

3. For distinct columns \( u \) and \( v \), if \( u = v \) or \( u = -v \), then the software removes \( v \) from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by
\[ \Delta(k_1, k_2) = 0.5 \sum_{l=1}^{L} |m_{k_1 l}||m_{k_2 l}| |m_{k_1 l} - m_{k_2 l}|, \]

where \( m_{kj} \) is an element of coding design matrix \( j \).

Support Vector Storage

By default and for efficiency, fitcecoc empties the Alpha, SupportVectorLabels, and SupportVectors properties for all linear SVM binary learners. fitcecoc lists Beta, rather than Alpha, in the model display.

To store Alpha, SupportVectorLabels, and SupportVectors, pass a linear SVM template that specifies storing support vectors to fitcecoc. For example, enter:

\[
\begin{align*}
&\text{t} = \text{templateSVM('SaveSupportVectors',true)} \\
&Mdl = \text{fitcecoc}(X,Y,'Learners',t);
\end{align*}
\]

You can remove the support vectors and related values by passing the resulting ClassificationECOC model to discardSupportVectors.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - \( \text{Mdl} = \text{fitcecoc}(X,Y) \)
  - \( \text{Mdl} = \text{fitcecoc}(X,Y,\text{Name},\text{Value}) \)
  - \( \text{[Mdl,FitInfo,HyperparameterOptimizationResults]} = \text{fitcecoc}(X,Y,\text{Name},\text{Value}) \) — fitcecoc returns the additional output arguments FitInfo and HyperparameterOptimizationResults when you specify the ‘OptimizeHyperparameters’ name-value pair argument.
- The FitInfo output argument is an empty structure array currently reserved for possible future use.
Options related to cross-validation are not supported. The supported name-value pair arguments are:

- 'ClassNames'
- 'Cost'
- 'Coding' — Default value is 'onevsall'.
- 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify
  \[
  \text{fitcecoc}(X,Y,\text{'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',\text{struct('Holdout',0.2))}}.
  \]
- 'Learners' — Default value is 'linear'. You can specify 'linear','kernel', a templateLinear or templateKernel object, or a cell array of such objects.
- 'OptimizeHyperparameters' — When you use linear binary learners, the value of the 'Regularization' hyperparameter must be 'ridge'.
- 'Prior'
- 'Verbose' — Default value is 1.
- 'Weights'

This additional name-value pair argument is specific to tall arrays:

- 'NumConcurrent' — A positive integer scalar specifying the number of binary learners that are trained concurrently by combining file I/O operations. The default value for 'NumConcurrent' is 1, which means fitcecoc trains the binary learners sequentially. 'NumConcurrent' is most beneficial when the input arrays cannot fit into the distributed cluster memory. Otherwise, the input arrays can be cached and speedup is negligible.

If you run your code on Apache Spark™, NumConcurrent is upper bounded by the memory available for communications. Check the 'spark.executor.memory' and 'spark.driver.memory' properties in your Apache Spark configuration. See parallel.cluster.Hadoop for more details. For more information on Apache Spark and other execution environments that control where your code runs, see “Extend Tall Arrays with Other Products” (MATLAB).

For more information, see "Tall Arrays" (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true in one of these ways:

- Set the 'UseParallel' field of the options structure to true using statset and specify the 'Options' name-value pair argument in the call to fitcecoc.
  
  For example: 'Options',statset('UseParallel',true)
  
  For more information, see the 'Options' name-value pair argument.

- Perform parallel hyperparameter optimization by using the 'HyperparameterOptions',struct('UseParallel',true) name-value pair argument in the call to fitcecoc.
  
  For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

Introduced in R2014b
fitcensemble

Fit ensemble of learners for classification

Syntax

Mdl = fitcensemble(Tbl,ResponseVarName)
Mdl = fitcensemble(Tbl,formula)
Mdl = fitcensemble(Tbl,Y)
Mdl = fitcensemble(X,Y)
Mdl = fitcensemble(___,'Name',Value)

Description

Mdl = fitcensemble(Tbl,ResponseVarName) returns the trained classification ensemble model object (Mdl) that contains the results of boosting 100 classification trees and the predictor and response data in the table Tbl. ResponseVarName is the name of the response variable in Tbl. By default, fitcensemble uses LogitBoost for binary classification and AdaBoostM2 for multiclass classification.

Mdl = fitcensemble(Tbl,formula) applies formula to fit the model to the predictor and response data in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl. For example, ‘Y~X1+X2+X3’ fits the response variable Tbl.Y as a function of the predictor variables Tbl.X1, Tbl.X2, and Tbl.X3.

Mdl = fitcensemble(Tbl,Y) treats all variables in the table Tbl as predictor variables. Y is the array of class labels that is not in Tbl.

Mdl = fitcensemble(X,Y) uses the predictor data in the matrix X and the array of class labels in Y.

Mdl = fitcensemble(___,'Name',Value) uses additional options specified by one or more Name,Value pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Classification Ensemble

Create a predictive classification ensemble using all available predictor variables in the data. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the census1994 data set.

load census1994

Train an ensemble of classification models using the entire data set and default options.
Mdl1 = fitcensemble(adultdata,'salary')

Mdl1 =
classreg.learning.classif.ClassificationEnsemble
    PredictorNames: {1x14 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
    ClassNames: [<=50K    >50K]
    ScoreTransform: 'none'
    NumObservations: 32561
    NumTrained: 100
    Method: 'LogitBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training cycles.'
    FitInfo: [100x1 double]
    FitInfoDescription: {2x1 cell}

Properties, Methods

Mdl is a ClassificationEnsemble model. Some notable characteristics of Mdl are:

- Because two classes are represented in the data, LogitBoost is the ensemble aggregation algorithm.
- Because the ensemble aggregation method is a boosting algorithm, classification trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Use the classification ensemble to predict the labels of a random set of five observations from the data. Compare the predicted labels with their true values.

rng(1) % For reproducibility
[pX,pIdx] = datasample(adultdata,5);
label = predict(Mdl1,pX);
table(label,adultdata.salary(pIdx),'VariableNames',{'Predicted','Truth'})
ans=5×2 table
  Predicted    Truth
    _____    _____
  <=50K      <=50K
  <=50K      <=50K
  <=50K      <=50K
  <=50K      <=50K
  <=50K      <=50K

Train a new ensemble using age and education only.

Mdl2 = fitcensemble(adultdata,'salary ~ age + education');

Compare the resubstitution losses between Mdl1 and Mdl2.

rsLoss1 = resubLoss(Mdl1)
rsLoss1 = 0.1058
rsLoss2 = resubLoss(Mdl2)
rsLoss2 = 0.2037

The in-sample misclassification rate for the ensemble that uses all predictors is lower.

**Speed Up Training by Binning Numeric Predictor Values**

Train an ensemble of boosted classification trees by using `fitcensemble`. Reduce training time by specifying the 'NumBins' name-value pair argument to bin numeric predictors. This argument is valid only when `fitcensemble` uses a tree learner. After training, you can reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

Generate a sample data set.

```matlab
rng('default') % For reproducibility
N = 1e6;
X = [mvnrnd([-1 -1],eye(2),N); mvnrnd([1 1],eye(2),N)];
y = [zeros(N,1); ones(N,1)];

Visualize the data set.
```

```matlab
figure
scatter(X(1:N,1),X(1:N,2),'Marker','.','MarkerEdgeAlpha',0.01)
hold on
scatter(X(N+1:2*N,1),X(N+1:2*N,2),'Marker','.','MarkerEdgeAlpha',0.01)
```

![ Scatter plot of sample data set ]
Train an ensemble of boosted classification trees using adaptive logistic regression (LogitBoost, the default for binary classification). Time the function for comparison purposes.

```matlab
tic
Mdl1 = fitcensemble(X,y);
toc
Elapsed time is 478.988422 seconds.
```

Speed up training by using the 'NumBins' name-value pair argument. If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

```matlab
tic
Mdl2 = fitcensemble(X,y,'NumBins',50);
toc
Elapsed time is 165.598434 seconds.
```

The process is about three times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the classification errors by resubstitution.

```matlab
rsLoss1 = resubLoss(Mdl1)
rLoss1 = 0.0788
rsLoss2 = resubLoss(Mdl2)
rLoss2 = 0.0788
```

In this example, binning predictor values reduces training time without loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

```matlab
X = Mdl2.X;  % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

32-1539
Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

**Estimate Generalization Error of Boosting Ensemble**

Estimate the generalization error of ensemble of boosted classification trees.

Load the ionosphere data set.

```matlab
load ionosphere
```

Cross-validate an ensemble of classification trees using AdaBoostM1 and 10-fold cross-validation. Specify that each tree should be split a maximum of five times using a decision tree template.

```matlab
rng(5); % For reproducibility
t = templateTree('MaxNumSplits',5);
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t,'CrossVal','on');
```

Mdl is a `ClassificationPartitionedEnsemble` model.

Plot the cumulative, 10-fold cross-validated, misclassification rate. Display the estimated generalization error of the ensemble.

```matlab
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold Misclassification rate');
xlabel('Learning cycle');
```
kfoldLoss returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves a misclassification rate of around 0.06 after accumulating about 50 weak learners. Then, the misclassification rate increase slightly as more weak learners enter the ensemble.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters, such as the maximum number of decision splits per tree and the number of learning cycles.

**Optimize Classification Ensemble**

Optimize hyperparameters automatically using fitensemble.

Load the ionosphere data set.

load ionosphere
You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

```matlab
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto')
```

In this example, for reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function. Also, for reproducibility of random forest algorithm, specify the 'Reproducible' name-value pair argument as true for tree learners.

```matlab
rng('default')
t = templateTree('Reproducible',true);
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto','Learners',t, ... 'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Min objective vs. Number of function evaluations

Optimization completed.
MaxObjectiveEvaluations of 30 reached.
Total function evaluations: 30
Total elapsed time: 302.4207 seconds.
Total objective function evaluation time: 270.9631

Best observed feasible point:

32-1543
The optimization searched over the ensemble aggregation methods for binary classification, over NumLearningCycles, over the LearnRate for applicable methods, and over the tree learner MinLeafSize. The output is the ensemble classifier with the minimum estimated cross-validation loss.

Optimize Classification Ensemble Using Cross-Validation

One way to create an ensemble of boosted classification trees that has satisfactory predictive performance is by tuning the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.

This example manually finds optimal parameters by using the cross-validation option (the 'KFold' name-value pair argument) and the kfoldLoss function. Alternatively, you can use the 'OptimizeHyperparameters' name-value pair argument to optimize hyperparameters automatically. See “Optimize Classification Ensemble” on page 32-1541.

Load the ionosphere data set.
To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most \( n - 1 \) splits. \( n \) is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
2. Estimate the cross-validated misclassification rate of each ensemble.
3. For tree-complexity level \( j, j = 1 \ldots J \), compare the cumulative, cross-validated misclassification rate of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
4. Choose the curve that achieves the minimal misclassification rate, and note the corresponding learning cycle and learning rate.

Cross-validate a deep classification tree and a stump. These classification trees serve as benchmarks.

```matlab
rng(1) % For reproducibility
MdlDeep = fitctree(X,Y,'CrossVal','on','MergeLeaves','off', ... 'MinParentSize',1);
MdlStump = fitctree(X,Y,'MaxNumSplits',1,'CrossVal','on');
```

Cross-validate an ensemble of 150 boosted classification trees using 5-fold cross-validation. Using a tree template, vary the maximum number of splits using the values in the sequence \( \{ 3^0, 3^1, \ldots, 3^m \} \). \( m \) is such that \( 3^m \) is no greater than \( n - 1 \). For each variant, adjust the learning rate using each value in the set \{ 0.1, 0.25, 0.5, 1 \};

```matlab
n = size(X,1);
m = floor(log(n - 1)/log(3));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 3.*([0:m]);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);
for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j));
        Mdl{j,k} = fitcensemble(X,Y,'NumLearningCycles',numTrees,... 'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

Estimate the cumulative, cross-validated misclassification rate for each ensemble and the classification trees serving as benchmarks.

```matlab
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated misclassification rate behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'.b','LineWidth',2)
    plot(h.XLim,[errorStump errorStump],'.r','LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'-k')
    h.YLim = [0 0.2];
    xlabel('Number of trees')
    ylabel('Cross-validated misclass. rate')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate,'Learning Rate = %0.2f')); ...
               'Deep Tree';'Stump';'Min. misclass. rate']);
hL.Position(1) = 0.6;

Each curve contains a minimum cross-validated misclassification rate occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest misclassification rate overall.
Min. misclass. rate = 0.05413

Optimal Parameter Values:
Num. Trees = 47
MaxNumSplits = 3
Learning Rate = 0.25

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS));
MdlFinal = fitcensemble(X,Y,'NumLearningCycles',idxNumTrees,'Learners',tFinal,'LearnRate',learnRate(idxLR))

MdlFinal is a ClassificationEnsemble. To predict whether a radar return is good given predictor data, you can pass the predictor data and MdlFinal to predict.

Instead of searching optimal values manually by using the cross-validation option ('KFold') and the kfoldLoss function, you can use the 'OptimizeHyperparameters' name-value pair argument. When you specify 'OptimizeHyperparameters', the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using 'OptimizeHyperparameters' can be different from those obtained using manual search.

mdl = fitcensemble(X,Y,'OptimizeHyperparameters',{'NumLearningCycles','LearnRate','MaxNumSplits'})

FitInfo: [87×1 double]
FitInfoDescription: {2×1 cell}

Properties, Methods
**Input Arguments**

**Tbl** — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using **formula**.
- If Tbl does not contain the response variable, then specify the response data using **Y**. The length of response variable and the number of rows of Tbl must be equal.

**Note** To save memory and execution time, supply **X** and **Y** instead of Tbl.

Data Types: **table**

**ResponseVarName** — Response variable name
name of response variable in Tbl

Response variable name, specified as the name of the response variable in Tbl.

You must specify **ResponseVarName** as a character vector or string scalar. For example, if Tbl.Y is the response variable, then specify **ResponseVarName** as 'Y'. Otherwise, **fitcensemble** treats all columns of Tbl as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the **ClassNames** name-value pair argument. Otherwise, **fitcensemble** determines the class order, and stores it in the **Mdl.ClassNames**.

Data Types: **char** | **string**

**formula** — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in **formula**.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.
You can verify the variable names in Tbl by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in Tbl are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

**X — Predictor data**

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

**Y — Response data**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or Tbl. The length of `Y` and the number of rows of `X` or Tbl must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `OptimizeHyperparameters` name-value pair argument. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair argument.

Example: `{'CrossVal','on','LearnRate',0.05}` specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.
### General Ensemble Options

**Method — Ensemble aggregation method**

`'Bag' | 'Subspace'| 'AdaBoostM1' | 'AdaBoostM2' | 'GentleBoost' | 'LogitBoost' | 'LPBoost' | 'RobustBoost' | 'RUSBoost' | 'TotalBoost'`

Ensemble aggregation method, specified as the comma-separated pair consisting of `Method` and one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Method</th>
<th>Classification Problem Support</th>
<th>Related Name-Value Pair Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'Bag'</code></td>
<td>Bootstrap aggregation (bagging, for example, random forest[2]) — If <code>Method</code> is <code>'Bag'</code>, then <code>fitcensemble</code> uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose <code>'NumVariablesToSample'</code> value is <code>'all'</code> or use discriminant analysis learners.</td>
<td>Binary and multiclass</td>
<td>N/A</td>
</tr>
<tr>
<td><code>'Subspace'</code></td>

<td>LearnRate, RatioToSmallest</td>
</tr>
<tr>
<td><code>'TotalBoost'</code></td>
<td>Totally corrective boosting — Requires Optimization Toolbox</td>
<td>Binary and multiclass</td>
<td>MarginPrecision</td>
</tr>
</tbody>
</table>

You can specify sampling options (`FResample`, `Replace`, `Resample`) for training data when you use bagging (`'Bag'`) or boosting (`'TotalBoost'`, `'RUSBoost'`, `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, `'LogitBoost'`, `'RobustBoost'`, or `'LPBoost'`).

The defaults are:

- `'LogitBoost'` for binary problems and `'AdaBoostM2'` for multiclass problems if `Learners` includes only tree learners.
• 'AdaBoostM1' for binary problems and 'AdaBoostM2' for multiclass problems if 'Learners' includes both tree and discriminant analysis learners
• 'Subspace' if 'Learners' does not include tree learners

Example: 'Method','Bag'

**NumLearningCycles — Number of ensemble learning cycles**

100 (default) | positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as the comma-separated pair consisting of 'NumLearningCycles' and a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles*numel(Learners) learners.
- If you specify 'AllPredictorCombinations', then set Method to 'Subspace' and specify one learner only for Learners. With these settings, the software trains learners for all possible combinations of predictors taken NPredToSample at a time. Consequently, the software trains nchoosek(size(X,2),NPredToSample) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-1568.

Example: 'NumLearningCycles',500

Data Types: single | double | char | string

**Learners — Weak learners to use in ensemble**

'discriminant' | 'knn' | 'tree' | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of 'Learners' and a weak-learner name, weak-learner template object, or cell vector of weak-learner template objects.

<table>
<thead>
<tr>
<th>Weak Learner</th>
<th>Weak-Learner Name</th>
<th>Template Object Creation Function</th>
<th>Method Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discriminant analysis</td>
<td>'discriminant'</td>
<td>templateDiscriminant</td>
<td>Recommended for 'Subspace'</td>
</tr>
<tr>
<td>k-nearest neighbors</td>
<td>'knn'</td>
<td>templateKNN</td>
<td>For 'Subspace' only</td>
</tr>
<tr>
<td>Decision tree</td>
<td>'tree'</td>
<td>templateTree</td>
<td>All methods except 'Subspace'</td>
</tr>
</tbody>
</table>

- Weak-learner name ('discriminant', 'knn', or 'tree') — fitcensemble uses weak learners created by a template object creation function with default settings. For example, specifying 'Learners','discriminant' is the same as specifying 'Learners',templateDiscriminant(). See the template object creation function pages for the default settings of a weak learner.
• Weak-learner template object — \texttt{fitcensemble} uses the weak learners created by a template object creation function. Use the name-value pair arguments of the template object creation function to specify the settings of the weak learners.

• Cell vector of $m$ weak-learner template objects — \texttt{fitcensemble} grows $m$ learners per learning cycle (see \texttt{NumLearningCycles}). For example, for an ensemble composed of two types of classification trees, supply \{\texttt{t1 t2}\}, where \texttt{t1} and \texttt{t2} are classification tree template objects returned by \texttt{templateTree}.

The default \texttt{'Learners'} value is \texttt{'knn'} if \texttt{'Method'} is \texttt{'Subspace'}.

The default \texttt{'Learners'} value is \texttt{'tree'} if \texttt{'Method'} is \texttt{'Bag'} or any boosting method. The default values of \texttt{templateTree()} depend on the value of \texttt{'Method'}.

• For bagged decision trees, the maximum number of decision splits (\texttt{'MaxNumSplits'}) is $n-1$, where $n$ is the number of observations. The number of predictors to select at random for each split (\texttt{'NumVariablesToSample'}) is the square root of the number of predictors. Therefore, \texttt{fitcensemble} grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.

• For boosted decision trees, \texttt{'MaxNumSplits'} is 10 and \texttt{'NumVariablesToSample'} is \texttt{'all'}. Therefore, \texttt{fitcensemble} grows shallow decision trees. You can grow deeper trees for better accuracy.

For details on the number of learners to train, see \texttt{NumLearningCycles} and “Tips” on page 32-1568.

Example: \texttt{'Learners',templateTree('MaxNumSplits',5)}

\textbf{NPrint — Printout frequency}

\texttt{'off'} (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of \texttt{'NPrint'} and a positive integer or \texttt{'off'}.

To track the number of weak learners or folds that \texttt{fitcensemble} trained so far, specify a positive integer. That is, if you specify the positive integer $m$:

• Without also specifying any cross-validation option (for example, \texttt{CrossVal}), then \texttt{fitcensemble} displays a message to the command line every time it completes training $m$ weak learners.

• And a cross-validation option, then \texttt{fitcensemble} displays a message to the command line every time it finishes training $m$ folds.

If you specify \texttt{'off'}, then \texttt{fitcensemble} does not display a message when it completes training weak learners.

\textbf{Tip} When training an ensemble of many weak learners on a large data set, specify a positive integer for \texttt{NPrint}.

Example: \texttt{'NPrint',5}

Data Types: \texttt{single} | \texttt{double} | \texttt{char} | \texttt{string}

\textbf{NumBins — Number of bins for numeric predictors}

\[\texttt{(empty) (default) | positive integer scalar}\]
Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar. This argument is valid only when fitcensemble uses a tree learner, that is, 'Learners' is either 'tree' or a template object created by using templateTree.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then fitcensemble bins the predictor into u bins.
  - fitcensemble does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the BinEdges property.

Example: 'NumBins',50

Data Types: single | double

CategoricalPredictors — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of</td>
</tr>
<tr>
<td></td>
<td>the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or</td>
</tr>
<tr>
<td></td>
<td>Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must</td>
</tr>
<tr>
<td></td>
<td>match the entries in PredictorNames. Pad the names with extra blanks so</td>
</tr>
<tr>
<td></td>
<td>each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of</td>
<td>Each element in the array is the name of a predictor variable. The names</td>
</tr>
<tr>
<td>character vectors</td>
<td>must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

Specification of 'CategoricalPredictors' is appropriate if:

- 'Learners' specifies tree learners.
- 'Learners' specifies k-nearest learners where all predictors are categorical.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See 'CategoricalPredictors' of fitcknn for k-nearest learners and 'CategoricalPredictors' of fitctree for tree learners.
Example: 'CategoricalPredictors','all'
Data Types: single | double | logical | char | string | cell

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcensemble uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.
To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval or crossval.

Example: 'Crossval','on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using 

cvp = cvpartition(500,'KFold',5)
Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

Scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:

1 Randomly partition the data into k sets.
2 For each set, reserve the set as validation data, and train the model using the other k - 1 sets.
3 Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5
Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other n – 1 observations.
2. Store the n compact, trained models in the cells of an n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

Other Classification Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

• Order the classes during training.
• Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
• Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Cost — Misclassification cost

Square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

• The square matrix Cost, then Cost(i,j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the
predicted class. To specify the class order for the corresponding rows and columns of Cost, also specify the\ClassNames\ name-value pair argument.

- The structure S, then it must have two fields:
  - \S\ClassNames, which contains the class names as a variable of the same data type as Y
  - \S\ClassificationCosts, which contains the cost matrix with rows and columns ordered as in \S\ClassNames

The default is \text{ones}(K) - \text{eye}(K), where $K$ is the number of distinct classes.

\textbf{Note} \texttt{fitcensemble} uses Cost to adjust the prior class probabilities specified in Prior. Then, \texttt{fitcensemble} uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost',[0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

\textbf{Prior — Prior probabilities}

'empirical'(default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to $1/K$, where $K$ is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure array</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>- \S\ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>- \S\ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

\texttt{fitcensemble} normalizes the prior probabilities in Prior to sum to 1.

Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)

Data Types: char | string | double | single | struct
ScoreTransform — Score transformation

'ScoreTransform' is a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>(\frac{1}{1 + e^{-2x}})</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>(\log(x / (1 - x)))</td>

<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>(\frac{1}{1 + e^{-x}})</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>(x) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'         | -1 for \(x < 0\)\)\  
                  | 0 for \(x = 0\)\  
                  | 1 for \(x > 0\)                           |
| 'symmetric'    | \(2x - 1\)                                   |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | \(\frac{2}{1 + e^{-x}} - 1\)                 |

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeovic vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string
Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement

'off' (default) | 'on'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace','off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off'(default) specifies to reweight observations at every learning iteration.
  - If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

AdaBoostM1, AdaBoostM2, LogitBoost, and GentleBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].
To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: single | double

**RUSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: single | double

**RatioToSmallest — Sampling proportion with respect to lowest-represented class**

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are `K` classes in the training data and the lowest-represented class has `m` observations in the training data.

- If you specify the positive numeric scalar `s`, then `fitcensemble` samples `s*m` observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2019.
- If you specify the numeric vector `[s1, s2, ..., sK]`, then `fitcensemble` samples `si*m` observations from class `i`, `i = 1, ..., K`. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 32-2018).

The default value is `ones(K,1)`, which specifies to sample `m` observations from each class.

Example: 'RatioToSmallest',[2,1]

Data Types: single | double

**LPBoost and TotalBoost Method Options**

**MarginPrecision — Margin precision to control convergence speed**

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of 'MarginPrecision' and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.
**Tip** To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5
Data Types: single | double

**RobustBoost Method Options**

**RobustErrorGoal — Target classification error**

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

**Tip** For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05
Data Types: single | double

**RobustMarginSigma — Classification margin distribution spread**

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on RobustBoost, for example, [19].

Example: `'RobustMarginSigma',0.5
Data Types: single | double

**RobustMaxMargin — Maximal classification margin**

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1
Data Types: single | double

**Random Subspace Method Options**

**NPredToSample — Number of predictors to sample**

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval $1,...,p$, where $p$ is the number of predictor variables ($size(X,2)$ or $size(Tbl,2)$).

Data Types: single | double
Hyperparameter Optimization Options

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Method','NumLearningCycles','LearnRate'} along with the default parameters for the specified Learners:
  - Learners = 'tree' (default) — {'MinLeafSize'}
  - Learners = 'discriminant' — {'Delta','Gamma'}
  - Learners = 'knn' — {'Distance','NumNeighbors'}

**Note** For hyperparameter optimization, Learners must be a single argument, not a string array or cell array.

- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitcensemble by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcensemble are:

- **Method** — Depends on the number of classes.
  - Two classes — Eligible methods are 'Bag', 'GentleBoost', 'LogitBoost', 'AdaBoostM1', and 'RUSBoost'.
  - Three or more classes — Eligible methods are 'Bag', 'AdaBoostM2', and 'RUSBoost'.
- **NumLearningCycles** — fitcensemble searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — fitcensemble searches among positive reals, by default log-scaled with range [1e-3,1].
- The eligible hyperparameters for the chosen Learners:
Alternatively, use hyperparameters with your chosen Learners. Note that you must specify the predictor data and response when creating an optimizableVariable object.

load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');

To see the eligible and default hyperparameters, examine params.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');
params(4).Range = [1,30];

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is
log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control
the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Classification Ensemble” on page 32-1541.

Example: 'OptimizeHyperparameters',
{ Method', 'NumLearningCycles', 'LearnRate', 'MinLeafSize', 'MaxNumSplits'}

HyperparameterOptimizationOptions — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of
'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of
the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| Optimizer                | • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt.  
• 'gridsearch' — Use grid search with NumGridDivisions values per dimension.  
• 'randomsearch' — Search at random among MaxObjectiveEvaluations points.  
'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command sortrows(Mdl.HyperparameterOptimizationResults). | 'bayesopt' |
| AcquisitionFunctionName | • 'expected-improvement-per-second-plus'  
• 'expected-improvement'  
• 'expected-improvement-plus'  
• 'expected-improvement-per-second'  
• 'lower-confidence-bound'  
• 'probability-of-improvement'  
Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3. | 'expected-improvement-per-second-plus' |
<table>

<td></td>
</tr>
<tr>
<td>UseParallel</td>
<td>Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.</td>
<td>false</td>
</tr>
</tbody>
</table>
**Field Name** | **Values** | **Default**
--- | --- | ---
Repartition | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization. true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false

Use no more than one of the following three field names.

| **CVPartition** | A cvpartition object, as created by cvpartition. | 'Kfold', 5 if you do not specify any cross-validation field |
| **Holdout** | A scalar in the range (0,1) representing the holdout fraction. | |
| **Kfold** | An integer greater than 1. | |

Example:

`'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)`

Data Types: struct

**Output Arguments**

**Mdl — Trained classification ensemble model**

ClassificationBaggedEnsemble model object | ClassificationEnsemble model object | ClassificationPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

<table>
<thead>
<tr>

<td>'off'</td>
</tr>
<tr>
<td>ClassificationPartitionedEnsemble</td>
<td>Yes</td>
<td>Any ensemble aggregation method for classification</td>
<td>'off' or 'on'</td>
</tr>
</tbody>
</table>

The name-value pair arguments that control cross-validation are CrossVal, Holdout, KFold, Leaveout, and CVPartition.

To reference properties of Mdl, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

**Tips**

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However,
you do not have to train an ensemble for that many cycles at once. You can start by growing a few
dozen learners, inspect the ensemble performance and then, if necessary, train more weak
learners using resume for classification problems.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners.
  That is, if you specify weak learners with default parameters, then the ensemble can perform
  poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak
  learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using Resample, then it is good practice to resample to entire data set.
  That is, use the default setting of 1 for FResample.

- If the ensemble aggregation method (Method) is ‘bag’ and:
  - The misclassification cost (Cost) is highly imbalanced, then, for in-bag samples, the software
    oversamples unique observations from the class that has a large penalty.
  - The class prior probabilities (Prior) are highly skewed, the software oversamples unique
    observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag
observations from the class that has a large penalty or prior probability. Consequently, the
estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large
estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced
misclassification cost matrix using Cost or a less skewed prior probability vector using Prior.

- Because the order of some input and output arguments correspond to the distinct classes in the
  training data, it is good practice to specify the class order using the ClassNames name-value pair
  argument.

  - To determine the class order quickly, remove all observations from the training data that are
    unclassified (that is, have a missing label), obtain and display an array of all the distinct
    classes, and then specify the array for ClassNames. For example, suppose the response
    variable (Y) is a cell array of labels. This code specifies the class order in the variable
    classNames.

    ```
    Ycat = categorical(Y);
    classNames = categories(Ycat)
    ```

    categorical assigns <undefined> to unclassified observations and categories excludes
    <undefined> from its output. Therefore, if you use this code for cell arrays of labels or similar
    code for categorical arrays, then you do not have to remove observations with missing labels to
    obtain a list of the distinct classes.

  - To specify that the class order from lowest-represented label to most-represented, then quickly
determine the class order (as in the previous bullet), but arrange the classes in the list by
frequency before passing the list to ClassNames. Following from the previous example, this
code specifies the class order from lowest- to most-represented in classNamesLH.

    ```
    Ycat = categorical(Y);
    classNames = categories(Ycat);
    freq = countcats(Ycat);
    [~,idx] = sort(freq);
    classNamesLH = classNames(idx);
    ```

- After training a model, you can generate C/C++ code that predicts labels for new data.
Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code
Generation” on page 31-2.
Algorithms

• For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-38.
• If you set Method to be a boosting algorithm and Learners to be decision trees, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using templateTree.
• For bagging ('Method','Bag'), fitcensemble generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
• For the RUSBoost ensemble aggregation method ('Method','RUSBoost'), the name-value pair argument RatioToSmallest specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: A and B. A has 100 observations and B has 10 observations. Suppose also that the lowest-represented class has m observations in the training data.

  • If you set 'RatioToSmallest',2, then s*m = 2*10 = 20. Consequently, fitcensemble trains every learner using 20 observations from class A and 20 observations from class B. If you set 'RatioToSmallest',[2 2], then you obtain the same result.
  • If you set 'RatioToSmallest',[2,1], then s1*m = 2*10 = 20 and s2*m = 1*10 = 10. Consequently, fitcensemble trains every learner using 20 observations from class A and 10 observations from class B.
• For dual-core systems and above, fitcensemble parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

References

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `UseParallel` option to `true`.

To perform parallel hyperparameter optimization, use the `HyperparameterOptions`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

fitcknn

Fit k-nearest neighbor classifier

Syntax

Mdl = fitcknn(Tbl,ResponseVarName)
Mdl = fitcknn(Tbl,formula)
Mdl = fitcknn(Tbl,Y)
Mdl = fitcknn(X,Y)
Mdl = fitcknn(___,Name,Value)

Description

Mdl = fitcknn(Tbl,ResponseVarName) returns a k-nearest neighbor classification model based on the input variables (also known as predictors, features, or attributes) in the table Tbl and output (response) Tbl.ResponseVarName.

Mdl = fitcknn(Tbl,formula) returns a k-nearest neighbor classification model based on the input variables in the table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl.

Mdl = fitcknn(Tbl,Y) returns a k-nearest neighbor classification model based on the predictor variables in the table Tbl and response array Y.

Mdl = fitcknn(X,Y) returns a k-nearest neighbor classification model based on the predictor data X and response Y.

Mdl = fitcknn(___,Name,Value) fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples

Train k-Nearest Neighbor Classifier

Train a k-nearest neighbor classifier for Fisher's iris data, where k, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

load fisheriris
X = meas;
Y = species;

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)

Mdl = ClassificationKNN
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    Distance: 'euclidean'
    NumNeighbors: 5

Properties, Methods

Mdl is a trained ClassificationKNN classifier, and some of its properties appear in the Command Window.

To access the properties of Mdl, use dot notation.

Mdl.ClassNames
ans = 3x1 cell
    { 'setosa'    }
    { 'versicolor'}
    { 'virginica' }

Mdl.Prior
ans = 1x3
    0.3333    0.3333    0.3333

Mdl.Prior contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in fitcknn. The order of the class prior probabilities corresponds to the order of the classes in Mdl.ClassNames. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

Mdl.Prior = [0.5 0.2 0.3];

You can pass Mdl to predict to label new measurements or crossval to cross-validate the classifier.

Train a k-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

load fisheriris
X = meas;
Y = species;
X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

\[
\text{Mdl} = \text{fitcknn}(X,Y,'\text{NumNeighbors}',3,...
\text{\hspace{1cm}}'\text{NSMethod}',\text{\textquoteleft}\text{exhaustive}'\text{\textquoteleft},'\text{Distance}',\text{\textquoteleft}\text{minkowski}'\text{\textquoteleft},...
\text{\hspace{1cm}}'\text{Standardize}',1);
\]

Mdl is a ClassificationKNN classifier.

You can examine the properties of Mdl by double-clicking Mdl in the Workspace window. This opens the Variable Editor.

Train a \( k \)-Nearest Neighbor Classifier Using a Custom Distance Metric

Train a \( k \)-nearest neighbor classifier using the chi-square distance.
Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between \( j \)-dimensional points \( x \) and \( z \) is

\[
\chi(x, z) = \sqrt{\sum_{j=1}^{J} w_j (x_j - z_j)^2},
\]

where \( w_j \) is a weight associated with dimension \( j \).

Specify the chi-square distance function. The distance function must:

- Take one row of \( X \), e.g., \( x \), and the matrix \( Z \).
- Compare \( x \) to each row of \( Z \).
- Return a vector \( D \) of length \( n_z \), where \( n_z \) is the number of rows of \( Z \). Each element of \( D \) is the distance between the observation corresponding to \( x \) and the observations corresponding to each row of \( Z \).

```matlab
chiSqrDist = @(x,Z,wt)sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```matlab
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

\( \text{KNNMdl} \) is a \text{ClassificationKNN} classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.

```matlab
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)
classError = 0.0600
```

\( \text{CVKNNMdl} \) is a \text{ClassificationPartitionedModel} classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

```matlab
w2 = [0.2; 0.2; 0.3; 0.3];
CVKNNMdl2 = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w2),...
    'NumNeighbors',k,'KFold',10,'Standardize',1);
classError2 = kfoldLoss(CVKNNMdl2)
classError2 = 0.0400
```

The second weighting scheme yields a classifier that has better out-of-sample performance.
Optimize Fitted KNN Classifier

This example shows how to optimize hyperparameters automatically using `fitcknn`. The example uses the Fisher iris data.

Load the data.

```matlab
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```matlab
rng(1)
Mdl = fitcknn(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',
              struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name

name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.
The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If \( Y \) is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value pair argument.

**Data Types:** char | string

**formula — Explanatory model of response variable and subset of predictor variables**

Character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, \( Y \) represents the response variable, and \( X1, X2, \) and \( X3 \) represent the predictor variables.

To specify a subset of variables in \( Tbl \) as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in \( Tbl \) that do not appear in `formula`.

The variable names in the formula must be both variable names in \( Tbl \) (\( Tbl.Properties.VariableNames \)) and valid MATLAB identifiers.

You can verify the variable names in \( Tbl \) by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in \( Tbl \) are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

**Data Types:** char | string

**Y — Class labels**

Categorical array | Character array | String array | Logical vector | Numeric vector | Cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of \( Y \) represents the classification of the corresponding row of \( X \).

The software considers NaN, `'` (empty character vector), `''` (empty string), `<missing>`, and `<undefined>` values in \( Y \) to be missing values. Consequently, the software does not train using observations with a missing response.

**Data Types:** categorical | char | string | logical | single | double | cell

**X — Predictor data**

Numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of \( Y \) and the number of rows of \( X \) must be equal.
To specify the names of the predictors in the order of their appearance in \( X \), use the \texttt{PredictorNames} name-value pair argument.

Data Types: \texttt{double} | \texttt{single}

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of \textit{Name}, \textit{Value} arguments. \textit{Name} is the argument name and \textit{Value} is the corresponding value. \textit{Name} must appear inside quotes. You can specify several name and value pair arguments in any order as \texttt{Name1,Value1,...,NameN,ValueN}.

**Note** You cannot use any cross-validation name-value pair argument along with the \texttt{'OptimizeHyperparameters'} name-value pair argument. You can modify the cross-validation for \texttt{'OptimizeHyperparameters'} only by using the \texttt{'HyperparameterOptimizationOptions'} name-value pair argument.

Example: \texttt{'NumNeighbors',3,'NSMethod','exhaustive','Distance','minkowski'} specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

**Model Parameters**

\textbf{BreakTies — Tie-breaking algorithm}

\texttt{'smallest' (default) | 'nearest' | 'random'}

Tie-breaking algorithm used by the predict method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of \texttt{'BreakTies'} and one of the following:

- \texttt{'smallest'} — Use the smallest index among tied groups.
- \texttt{'nearest'} — Use the class with the nearest neighbor among tied groups.
- \texttt{'random'} — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the \( K \) nearest neighbors.

Example: \texttt{'BreakTies','nearest'}

\textbf{BucketSize — Maximum data points in node}

\texttt{50} (default) | positive integer value

Maximum number of data points in the leaf node of the \( kd \)-tree, specified as the comma-separated pair consisting of \texttt{'BucketSize'} and a positive integer value. This argument is meaningful only when \texttt{NSMethod} is \texttt{'kdtree'}.

Example: \texttt{'BucketSize',40}

Data Types: \texttt{single} | \texttt{double}

\textbf{CategoricalPredictors — Categorical predictor flag}

\texttt{[] | 'all'}

Categorical predictor flag, specified as the comma-separated pair consisting of \texttt{'CategoricalPredictors'} and one of the following:
- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

The predictor data for fitcknn must be either all continuous or all categorical.

- If the predictor data is in a table (Tbl), fitcknn assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If Tbl includes both continuous and categorical values, then you must specify the value of 'CategoricalPredictors' so that fitcknn can determine how to treat all predictors, as either continuous or categorical variables.
- If the predictor data is a matrix (X), fitcknn assumes that all predictors are continuous. To identify all predictors in X as categorical, specify 'CategoricalPredictors' as 'all'.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

Example: 'CategoricalPredictors','all'

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:
- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:
- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.
The default is \( \text{Cost}(i,j) = 1 \) if \( i \neq j \), and \( \text{Cost}(i,j) = 0 \) if \( i = j \).

**Data Types:** single | double | struct

**Cov** — Covariance matrix

*nancov(X) (default) | positive definite matrix of scalar values*

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

**Data Types:** single | double

**Distance** — Distance metric

*’cityblock’ | ’chebychev’ | ’correlation’ | ’cosine’ | ’euclidean’ | ’hamming’ | function handle | ...*

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

<table>
<thead>
<tr>
<th><strong>NSMethod</strong></th>
<th><strong>Distance Metric Names</strong></th>
</tr>

<tbody>
<tr>
<td>exhaustive</td>
<td>Any distance metric of ExhaustiveSearcher</td>
</tr>
<tr>
<td>kdtree</td>
<td>’cityblock’, ’chebychev’, ’euclidean’, or ’minkowski’</td>
</tr>
</tbody>
</table>

This table includes valid distance metrics of ExhaustiveSearcher.

<table>
<thead>
<tr>
<th><strong>Distance Metric Names</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>’cityblock’</td>
<td>City block distance.</td>
</tr>
<tr>
<td>’chebychev’</td>
<td>Chebychev distance (maximum coordinate difference).</td>
</tr>
<tr>
<td>’correlation’</td>
<td>One minus the sample linear correlation between observations (treated as sequences of values).</td>
</tr>
<tr>
<td>’cosine’</td>
<td>One minus the cosine of the included angle between observations (treated as vectors).</td>
</tr>
<tr>
<td>’euclidean’</td>
<td>Euclidean distance.</td>
</tr>
<tr>
<td>’hamming’</td>
<td>Hamming distance, percentage of coordinates that differ.</td>
</tr>
<tr>
<td>’jaccard’</td>
<td>One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.</td>
</tr>
<tr>
<td>’mahalanobis’</td>
<td>Mahalanobis distance, computed using a positive definite covariance matrix ( C ). The default value of ( C ) is the sample covariance matrix of ( X ), as computed by ( \text{nancov}(X) ). To specify a different value for ( C ), use the ‘Cov’ name-value pair argument.</td>
</tr>
<tr>
<td>’minkowski’</td>
<td>Minkowski distance. The default exponent is 2. To specify a different exponent, use the ‘Exponent’ name-value pair argument.</td>
</tr>
<tr>
<td>Distance Metric Names</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'seuclidean'</td>
<td>Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, S = nanstd(X). To specify another value for S, use the Scale name-value pair argument.</td>
</tr>
<tr>
<td>'spearman'</td>
<td>One minus the sample Spearman's rank correlation between observations (treated as sequences of values).</td>
</tr>
</tbody>
</table>
| @distfun              | Distance function handle. distfun has the form 
  \[
  \text{function } D2 = \text{distfun}(ZI,ZJ)
  \text{\% calculation of distance}
  \]
  where
  - ZI is a 1-by-N vector containing one row of X or Y.
  - ZJ is an M2-by-N matrix containing multiple rows of X or Y.
  - D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k,:). |

If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-11.

Example: 'Distance','minkowski'

Data Types: char | string | function_handle

DistanceWeight — Distance weighting function

'default' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'equal'</td>
<td>No weighting</td>
</tr>
<tr>
<td>'inverse'</td>
<td>Weight is 1/distance</td>
</tr>
<tr>
<td>'squaredinverse'</td>
<td>Weight is 1/distance^2</td>
</tr>
<tr>
<td>@fcn</td>
<td>fcn is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).</td>
</tr>
</tbody>
</table>

Example: 'DistanceWeight','inverse'

Data Types: char | string | function_handle

Exponent — Minkowski distance exponent

2 (default) | positive scalar value
Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3
Data Types: single | double

IncludeTies — Tie inclusion flag
type (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies',true
Data Types: logical

NSMethod — Nearest neighbor search method
'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a kd-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebychev'
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point xnew, the software computes the distance values from all points in X to xnew to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod','exhaustive'

NumNeighbors — Number of nearest neighbors to find
1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3
Data Types: single | double

PredictorNames — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.
• If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.

• The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.

• By default, PredictorNames is {'x1','x2',...}.

• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcknn uses only the predictor variables in PredictorNames and the response variable in training.

• PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.

• By default, PredictorNames contains the names of all predictor variables.

• A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'
Data Types: char | string | single | double | struct

**ResponseName** — Response variable name

'S' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char, 'response'

**Scale** — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

**ScoreTransform** — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>$1/(1 + e^{-2x})$</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>$\log(x / (1 - x))$</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>$1/(1 + e^{-x})$</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>$x$ (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'         | -1 for $x < 0$  
                  | 0 for $x = 0$  
                  | 1 for $x > 0$  |
| 'symmetric'    | $2x - 1$                                           |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | $2/(1 + e^{-x}) - 1$                             |
For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**Standardize — Flag to standardize predictors**

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize',1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize',true

Data Types: logical

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

**Cross Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.
To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'CrossVal','on'

**CVP** — Cross-validation partition

```
[] (default) | cvpartition partition object
```

Cross-validation partition, specified as the comma-separated pair consisting of 'CVP' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVP, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using 'CVP',cvp.

**Holdout** — Fraction of data for holdout validation

```
scalar value in the range (0,1)
```

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVP, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold** — Number of folds

```
10 (default) | positive integer value greater than 1
```

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:

1. Randomly partition the data into k sets.
2. For each set, reserve the set as validation data, and train the model using the other k − 1 sets.
3. Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVP, Holdout, KFold, or Leaveout.

Example: 'KFold',5
Data Types: `single` | `double`

**Leaveout — Leave-one-out cross-validation flag**

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the $n$ observations (where $n$ is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other $n-1$ observations.
2. Store the $n$ compact, trained models in the cells of an $n$-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. Example: `'Leaveout','on'`

**Hyperparameter Optimization Options**

**OptimizeHyperparameters — Parameters to optimize**

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{’Distance’,’NumNeighbors’}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcknn` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcknn` are:

- **Distance** — `fitcknn` searches among `'cityblock'`, `'chebychev'`, `'correlation'`, `'cosine'`, `'euclidean'`, `'hamming'`, `'jaccard'`, `'mahalanobis'`, `'minkowski'`, `'seuclidean'`, and `'spearman'`.
- **DistanceWeight** — `fitcknn` searches among `'equal'`, `'inverse'`, and `'squaredinverse'`.
- **Exponent** — `fitcknn` searches among positive real values, by default in the range $[0.5,3]$. 

32-1590
• **NumNeighbors** — `fitcknn` searches among positive integer values, by default log-scaled in the range \([1, \max(2, \text{round}(\text{NumObservations}/2))]\).

• **Standardize** — `fitcknn` searches among the values 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitcknn',meas,species);
params(1).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \(\log(1 + \text{cross-validation loss})\) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Fitted KNN Classifier” on page 32-1576.

Example: 'auto'

### HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

`'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

**Data Types:** struct

### Output Arguments

**Mdl — Trained k-nearest neighbor classification model**

ClassificationKNN model object | ClassificationPartitionedModel cross-validated model object

Trained k-nearest neighbor classification model, returned as a ClassificationKNN model object or a ClassificationPartitionedModel cross-validated model object.

If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationKNN model object.
To reference properties of Mdl, use dot notation. For example, to display the distance metric at the Command Window, enter Mdl.Distance.

More About

Prediction

ClassificationKNN predicts the classification of a point xnew using a procedure equivalent to this:

1. Find the NumNeighbors points in the training set X that are nearest to xnew.
2. Find the NumNeighbors response values Y to those nearest points.
3. Assign the classification label ynew that has the largest posterior probability among the values in Y.

For details, see “Posterior Probability” on page 32-4144 in the predict documentation.

Tips

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- NaNs or <undefined>s indicate missing observations. The following describes the behavior of fitcknn when the data set or weights contain missing observations.
  - If any value of Y or any weight is missing, then fitcknn removes those values from Y, the weights, and the corresponding rows of X from the data. The software renormalizes the weights to sum to 1.
  - If you specify to standardize predictors ('Standardize',1) or the standardized Euclidean distance ('Distance','seuclidean') without a scale, then fitcknn removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements nanmean and nanstd on each predictor.
  - If you specify the Mahalanobis distance ('Distance','mahalanbois') without its covariance matrix, then fitcknn removes rows of X that contain at least one missing value. In other words, the software implements nancov on the predictor matrix X.
  - Suppose that you set 'Standardize',1.
    - If you also specify Prior or Weights, then the software takes the observation weights into account. Specifically, the weighted mean of predictor j is
      \[ \bar{x}_j = \sum_{B_j} w_k x_{jk} \]
      and the weighted standard deviation is
      \[ s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j), \]
      where \( B_j \) is the set of indices k for which \( x_{jk} \) and \( w_k \) are not missing.
• If you also set ‘Distance’, 'mahalanobis' or 'Distance', 'seuclidean', then you cannot specify Scale or Cov. Instead, the software:

1 Computes the means and standard deviations of each predictor
2 Standardizes the data using the results of step 1
3 Computes the distance parameter values using their respective default.

• If you specify Scale and either of Prior or Weights, then the software scales observed distances by the weighted standard deviations.

• If you specify Cov and either of Prior or Weights, then the software applies the weighted covariance matrix to the distances. In other words,

\[
\text{Cov} = \frac{\sum B w_j}{\left(\sum B w_j\right)^2 - \sum B w_j^2} \sum B w_j (x_j - \bar{x})(x_j - \bar{x}),
\]

where \( B \) is the set of indices \( j \) for which the observation \( x_j \) does not have any missing values and \( w_j \) is not missing.

**Alternatives**

Although fitcknn can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using fitcecoc.

**Extended Capabilities**

**Automatic Parallel Support**

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the ‘UseParallel’ option to true.

To perform parallel hyperparameter optimization, use the ‘HyperparameterOptions’, struct(‘UseParallel’,true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2014a**
fitclinear

Fit linear classification model to high-dimensional data

Syntax

Mdl = fitclinear(X,Y)
Mdl = fitclinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitclinear(__)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(__)

Description

fitclinear trains linear classification models for two-class (binary) learning with high-dimensional, full or sparse predictor data. Available linear classification models include regularized support vector machines (SVM) and logistic regression models. fitclinear minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables, train a linear classification model by using fitclinear. For low- through medium-dimensional predictor data sets, see "Alternatives for Lower-Dimensional Data" on page 32-1625.

To train a linear classification model for multiclass learning by combining SVM or logistic regression binary classifiers using error-correcting output codes, see fitcecoc.

Mdl = fitclinear(X,Y) returns a trained linear classification model object that contains the results of fitting a binary support vector machine to the predictors X and class labels Y.

Mdl = fitclinear(X,Y,Name,Value) returns a trained linear classification model with additional options specified by one or more Name,Value pair arguments. For example, you can specify that the columns of the predictor matrix correspond to observations, implement logistic regression, or specify to cross-validate. It is good practice to cross-validate using the Kfold Name,Value pair argument. The cross-validation results determine how well the model generalizes.

[Mdl,FitInfo] = fitclinear(__) also returns optimization details using any of the previous syntaxes. You cannot request FitInfo for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(__) also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair.

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.
load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

rng(1); % For reproducibility
[Mdl,FitInfo] = fitclinear(X,Ystats)

Mdl = ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
  ScoreTransform: 'none'
      Beta: [34023x1 double]
      Bias: -1.0059
      Lambda: 3.1674e-05
      Learner: 'svm'

Properties, Methods

FitInfo = struct with fields:
  Lambda: 3.1674e-05
  Objective: 5.3783e-04
  PassLimit: 10
  NumPasses: 10
  BatchLimit: []
  NumIterations: 238561
  GradientNorm: NaN
  GradientTolerance: 0
  RelativeChangeInBeta: 0.0562
  BetaTolerance: 1.0000e-04
  DeltaGradient: 1.4582
  DeltaGradientTolerance: 1
  TerminationCode: 0
  TerminationStatus: {'Iteration limit exceeded.'}
      Alpha: [31572x1 double]
      History: []
      FitTime: 0.2391
      Solver: {'dual'}

Mdl is a ClassificationLinear model. You can pass Mdl and the training or new data to loss to inspect the in-sample classification error. Or, you can pass Mdl and new predictor data to predict to predict class labels for new observations.

FitInfo is a structure array containing, among other things, the termination status (TerminationStatus) and how long the solver took to fit the model to the data (FitTime). It is
good practice to use FitInfo to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like DeltaGradient.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

load nlpdata

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

Ystats = Y == 'stats';

Create a set of 11 logarithmically-spaced regularization strengths from $10^{-6}$ through $10^{-0.5}$.

Lambda = logspace(-6,-0.5,11);

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpaRSA. Lower the tolerance on the gradient of the objective function to $10^{-8}$.

X = X';% For reproducibility
rng(10);% For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
    NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'

Properties, Methods

numCLModels = numel(CVMdl.Trained)

numCLModels = 5
CVMdl is a ClassificationPartitionedLinear model. Because fitclinear implements 5-fold cross-validation, CVMdl contains 5 ClassificationLinear models that the software trains on each fold.

Display the first trained linear classification model.

Mdl1 = CVMdl.Trained{1}

Mdl1 =  
ClassificationLinear  
ResponseName: 'Y'  
ClassNames: [0 1]  
ScoreTransform: 'logit'  
Beta: [34023×11 double]  
Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04 0.0020 0.0071 0.0251 0.0891 0.3162]  
Learner: 'logistic'

Properties, Methods

Mdl1 is a ClassificationLinear model object. fitclinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in Lambda.

Estimate the cross-validated classification error.

ce = kfoldLoss(CVMdl);

Because there are 11 regularization strengths, ce is a 1-by-11 vector of classification error rates.

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
'Lambda',Lambda,'GradientTolerance',1e-8);

numNZCoeff = sum(Mdl.Beta~=0);

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between $10^{-4}$ to $10^{-1}$ should suffice.

```matlab
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```matlab
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

### Optimize Linear Classifier

This example shows how to minimize the cross-validation error in a linear classifier using `fitclinear`. The example uses the NLP data set.

Load the NLP data set.

```matlab
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.
The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. Identify the relevant labels.

\[
X = X'; \\
Y_{\text{stats}} = Y == 'stats';
\]

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

\[
\text{rng default} \\
\text{Mdl} = \text{fitclinear}(X,Y_{\text{stats}},'ObservationsIn','columns','Solver','sparsa',... \\
'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',... \\
\text{struct('AcquisitionFunctionName','expected-improvement-plus'))}
\]

Properties, Methods

Input Arguments

X — Predictor data
    full matrix | sparse matrix

Predictor data, specified as an n-by-p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Class labels
    categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the classification model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- fitclinear only supports binary classification. Either Y must contain exactly two distinct classes, or you must specify two classes for training using the 'ClassNames' name-value pair argument. For multiclass learning, see fitcecoc.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.
• It is good practice to specify the class order using the ClassNames name-value pair argument.

Data Types: char | string | cell | categorical | logical | single | double

**Note**  fitclinear removes missing observations, that is, observations with any of these characteristics:

• NaN, empty character vector (''), empty string ('"'), <missing>, and <undefined> elements in the response (Y or ValidationData(2))
• At least one NaN value in a predictor observation (row in X or ValidationData(1))
• NaN value or 0 weight (Weights or ValidationData(3))

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note**  You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'ObservationsIn','columns','Learner','logistic','CrossVal','on' specifies that the columns of the predictor matrix corresponds to observations, to implement logistic regression, to implement 10-fold cross-validation.

**Linear Classification Options**

**Lambda — Regularization term strength**

`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

• For 'auto', Lambda = 1/n.
  • If you specify a cross-validation, name-value pair argument (e.g., CrossVal), then n is the number of in-fold observations.
  • Otherwise, n is the training sample size.
• For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in Lambda in ascending order.
  • If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-1625 for the next optimization iteration. Otherwise, the software uses warm starts.
• If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: `‘Lambda’, 10.^(10:-2:2)`

Data Types: `char` | `string` | `double` | `single`

**Learner — Linear classification model type**

`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `‘Learner’` and `'svm'` or `'logistic'`.

In this table, \( f(x) = x\beta + b \).

- \( \beta \) is a vector of \( p \) coefficients.
- \( x \) is an observation from \( p \) predictor variables.
- \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Algorithm</th>
<th>Response Range</th>
<th>Loss Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'svm'</code></td>
<td>Support vector machine</td>
<td>( y \in {-1,1}; 1 ) for the positive class and (-1) otherwise</td>
<td>Hinge: ( \ell = \max[0, 1 - yf(x)] )</td>
</tr>
<tr>
<td><code>'logistic'</code></td>
<td>Logistic regression</td>
<td>Same as <code>'svm'</code></td>
<td>Deviance (logistic): ( \ell = \log(1 + \exp(-yf(x))) )</td>
</tr>
</tbody>
</table>

Example: `‘Learner’`, `'logistic'`

**ObservationsIn — Predictor data observation dimension**

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `‘ObservationsIn’` and `'columns'` or `'rows'`.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify `‘ObservationsIn’`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

**Regularization — Complexity penalty type**

`'lasso'` | `'ridge'`

Complexity penalty type, specified as the comma-separated pair consisting of `‘Regularization’` and `'lasso'` or `'ridge'`.

The software composes the objective function for minimization from the sum of the average loss function (see `Learner`) and the regularization term in this table.
Value | Description
--- | ---
'lasso' | Lasso (L1) penalty: \( \lambda \sum_{j=1}^{p} |\beta_j| \)
'ridge' | Ridge (L2) penalty: \( \frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2 \)

To specify the regularization term strength, which is \( \lambda \) in the expressions, use **Lambda**.

The software excludes the bias term (\( \beta_0 \)) from the regularization penalty.

If **Solver** is 'sparsa', then the default value of **Regularization** is 'lasso'. Otherwise, the default is 'ridge'.

**Tip**
- For predictor variable selection, specify 'lasso'. For more on variable selection, see "Introduction to Feature Selection" on page 15-49.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization','lasso'

**Solver** — **Objective function minimization technique**
'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sgd'</td>
<td>Stochastic gradient descent (SGD) [5][3]</td>
<td></td>
</tr>
<tr>
<td>'asgd'</td>
<td>Average stochastic gradient descent (ASGD) [8]</td>
<td></td>
</tr>
</tbody>
</table>
| 'dual' | Dual SGD for SVM [2][7] | **Regularization** must be 'ridge' and **Learner** must be 'svm'.
| 'bfgs' | Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4] | Inefficient if \( X \) is very high-dimensional. |
| 'lbfgs' | Limited-memory BFGS (LBFGS) [4] | **Regularization** must be 'ridge'. |
| 'sparsa' | Sparse Reconstruction by Separable Approximation (SpaRSA) [6] | **Regularization** must be 'lasso'. |
• A ridge penalty (see Regularization) and $X$ contains 100 or fewer predictor variables, then the default solver is 'bfgs'.

• An SVM model (see Learner), a ridge penalty, and $X$ contains more than 100 predictor variables, then the default solver is 'dual'.

• A lasso penalty and $X$ contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each $\Lambda$.

For more details on which solver to choose, see “Tips” on page 32-1626.

Example: 'Solver', {'sgd', 'lbfgs'}

**Beta — Initial linear coefficient estimates**

zeros($p$,1) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates ($\beta$), specified as the comma-separated pair consisting of 'Beta' and a $p$-dimensional numeric vector or a $p$-by-$L$ numeric matrix. $p$ is the number of predictor variables in $X$ and $L$ is the number of regularization-strength values (for more details, see $\Lambda$).

• If you specify a $p$-dimensional vector, then the software optimizes the objective function $L$ times using this process.

  1 The software optimizes using $\text{Beta}$ as the initial value and the minimum value of $\Lambda$ as the regularization strength.

  2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-1625, and the next smallest value in $\Lambda$ as the regularization strength.

  3 The software implements step 2 until it exhausts all values in $\Lambda$.

• If you specify a $p$-by-$L$ matrix, then the software optimizes the objective function $L$ times. At iteration $j$, the software uses $\text{Beta}(; ,j)$ as the initial value and, after it sorts $\Lambda$ in ascending order, uses $\Lambda(j)$ as the regularization strength.

If you set 'Solver', 'dual', then the software ignores $\text{Beta}$.

Data Types: single | double

**Bias — Initial intercept estimate**

numeric scalar | numeric vector

Initial intercept estimate ($b$), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an $L$-dimensional numeric vector. $L$ is the number of regularization-strength values (for more details, see $\Lambda$).

• If you specify a scalar, then the software optimizes the objective function $L$ times using this process.

  1 The software optimizes using $\text{Bias}$ as the initial value and the minimum value of $\Lambda$ as the regularization strength.

  2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in $\Lambda$ as the regularization strength.
The software implements step 2 until it exhausts all values in \( \Lambda \).

- If you specify an \( L \)-dimensional vector, then the software optimizes the objective function \( L \) times. At iteration \( j \), the software uses \( \text{Bias}(j) \) as the initial value and, after it sorts \( \Lambda \) in ascending order, uses \( \Lambda(j) \) as the regularization strength.

- By default:
  - If \( \text{Learner} \) is 'logistic', then let \( g_j \) be 1 if \( Y(j) \) is the positive class, and -1 otherwise. \( \text{Bias} \) is the weighted average of the \( g \) for training or, for cross-validation, in-fold observations.
  - If \( \text{Learner} \) is 'svm', then \( \text{Bias} \) is 0.

Data Types: single | double

**FitBias — Linear model intercept inclusion flag**

*true* (default) | *false*

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The software includes the bias term ( b ) in the linear model, and then estimates it.</td>
</tr>
<tr>
<td>false</td>
<td>The software sets ( b = 0 ) during estimation.</td>
</tr>
</tbody>
</table>

Example: 'FitBias',false

Data Types: logical

**PostFitBias — Flag to fit linear model intercept after optimization**

*false* (default) | *true*

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>The software estimates the bias term ( b ) and the coefficients ( \beta ) during optimization.</td>
</tr>
<tr>
<td>true</td>
<td>To estimate ( b ), the software:</td>
</tr>
<tr>
<td></td>
<td>1. Estimates ( \beta ) and ( b ) using the model</td>
</tr>
<tr>
<td></td>
<td>2. Estimates classification scores</td>
</tr>
<tr>
<td></td>
<td>3. Refits ( b ) by placing the threshold on the classification scores that attains maximum accuracy</td>
</tr>
</tbody>
</table>

If you specify true, then FitBias must be true.

Example: 'PostFitBias',true

Data Types: logical

**Verbose — Verbosity level**

*0* (default) | nonnegative integer
Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitclinear` displays at the command line.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>fitclinear</code> does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td><code>fitclinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
<tr>
<td>Any other positive integer</td>
<td><code>fitclinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
</tbody>
</table>

Example: `'Verbose',1`  
Data Types: `double` | `single`

**SGD and ASGD Solver Options**

**BatchSize — Mini-batch size**

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If `X` is a numeric matrix, then the default value is 10.
- If `X` is a sparse matrix, then the default value is \( \max([10, \text{ceil}(\sqrt{ff})]) \), where \( ff = \frac{\text{numel}(X)}{\text{nnz}(X)} \) (the fullness factor of `X`).

Example: `'BatchSize',100`  
Data Types: `single` | `double`

**LearnRate — Learning rate**

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. `LearnRate` specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If `Regularization` is 'ridge', then `LearnRate` specifies the initial learning rate \( y_0 \). The software determines the learning rate for iteration \( t \), \( y_t \), using

  \[
  y_t = \frac{y_0}{(1 + \lambda y_0 t)^c}.
  \]

- \( \lambda \) is the value of `Lambda`.
- If `Solver` is 'sgd', then \( c = 1 \).
If Solver is 'asgd', then c is 0.75 [7].
If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\sqrt{1+\max((\text{sum}(X.^2,\text{obsDim})))}$, where obsDim is 1 if the observations compose the columns of the predictor data X, and 2 otherwise.

Example: 'LearnRate', 0.01
Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate
true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:
1. For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true
Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs
10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient $j$ using

$$
\hat{\beta}_j^* = \begin{cases} 
\hat{\beta}_j - u_t & \text{if } |\hat{\beta}_j| > u_t, \\
0 & \text{if } |\hat{\beta}_j| \leq u_t, \\
\hat{\beta}_j + u_t & \text{if } |\hat{\beta}_j| < -u_t.
\end{cases}
$$

- For SGD, $\hat{\beta}_j$ is the estimate of coefficient $j$ after processing $k$ mini-batches. $u_t = k\gamma_t \lambda$. $\gamma_t$ is the learning rate at iteration $t$. $\lambda$ is the value of Lambda.
- For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient $j$ after processing $k$ mini-batches, $u_t = k\lambda$.

If Regularization is 'ridge', then the software ignores TruncationPeriod.

Example: 'TruncationPeriod', 100
Data Types: single | double
Other Classification Options

ClassNames — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:
- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure.

- If you specify the square matrix cost ('Cost',cost), then cost(i,j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of cost, use the ClassNames name-value pair argument.
- If you specify the structure S ('Cost',S), then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as Y
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default value for Cost is ones(K) – eye(K), where K is the number of distinct classes.

fitclinear uses Cost to adjust the prior class probabilities specified in Prior. Then, fitclinear uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost',[0 2; 1 0]

Data Types: single | double | struct

Prior — Prior probabilities
'empirical' (default) | 'uniform' | numeric vector | structure array
Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to their order in Y. If you specify the order using the 'ClassNames' name-value pair argument, then order the elements accordingly.</td>
</tr>
</tbody>
</table>
| structure array | A structure S with two fields:  
|               | • S.ClassNames contains the class names as a variable of the same type as Y. 
|               | • S.ClassProbs contains a vector of corresponding prior probabilities. |

`fitclinear` normalizes the prior probabilities in Prior to sum to 1.

Example: 'Prior',struct('ClassNames', {{'setosa','versicolor'}}, 'ClassProbs',1:2)

Data Types: char | string | double | single | struct

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>1/(1 + e^2x)</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>log(x / (1 - x))</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>1/(1 + e^x)</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'      | -1 for x < 0  
0 for x = 0  
1 for x > 0       |
<p>| 'symmetric' | 2x - 1                                           |</p>
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{-x}} - 1 )</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

**Weights — Observation weights**

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `fitclinear` weights the observations in `X` with the corresponding value in `Weights`. The size of `Weights` must equal the number of observations in `X`.

`fitclinear` normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X`.

Data Types: `double` | `single`

**Cross-Validation Options**

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'CrossVal','on'`

**CVPartition — Cross-validation partition**

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)
Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', \( p \), then the software:

1. Randomly reserves \( p \times 100\% \) of the data as validation data, and trains the model using the rest of the data.
2. Stores the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'Holdout', 0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', \( k \), then the software:

1. Randomly partitions the data into \( k \) sets.
2. For each set, reserves the set as validation data, and trains the model using the other \( k - 1 \) sets.
3. Stores the \( k \) compact, trained models in the cells of a \( k \)-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold', 8

Data Types: single | double

**SGD and ASGD Convergence Controls**

**BatchLimit — Maximal number of batches**

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes BatchLimit batches, it terminates optimization.

- By default:
  - The software passes through the data PassLimit times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is \( \text{ceil}(1e6/BatchSize) \). BatchSize is the value of the 'BatchSize' name-value pair argument.
  - If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
  - If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit', 100

Data Types: single | double
**BetaTolerance — Relative tolerance on linear coefficients and bias term**
1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration $t$. If

$$\left| \frac{B_t - B_{t-1}}{B_t} \right|_2 < \text{BetaTolerance},$$

then optimization terminates.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6
Data Types: single | double

**NumCheckConvergence — Number of batches to process before next convergence check**
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see BatchSize.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence',100
Data Types: single | double

**PassLimit — Maximal number of passes**
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

fitclinear processes all observations when it completes one pass through the data.

When fitclinear passes through the data PassLimit times, it terminates optimization.

If you specify 'BatchLimit' and 'PassLimit', then fitclinear chooses the argument that results in processing the fewest observations.

Example: 'PassLimit',5
Data Types: single | double

**ValidationData — Validation data for optimization convergence detection**
cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see "Algorithms" on page 32-1627. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.
• `ValidationData(1)` must contain an \(m\)-by-\(p\) or \(p\)-by-\(m\) full or sparse matrix of predictor data that has the same orientation as \(X\). The predictor variables in the training data \(X\) and `ValidationData{1}` must correspond. The number of observations in both sets can vary.

• `ValidationData{2}` and \(Y\) must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of \(Y\).

• Optionally, `ValidationData(3)` can contain an \(m\)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

**Dual SGD Convergence Controls**

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let \(B_t = [\beta_t; b_t]\), that is, the vector of the coefficients and the bias term at optimization iteration \(t\). If \(\frac{\|B_t - B_{t-1}\|_2}{B_t} < \text{BetaTolerance}\), then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

**DeltaGradientTolerance — Gradient-difference tolerance**

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'DeltaGradientTolerance',1e-2`

Data Types: `double` | `single`
NumCheckConvergence — Number of passes through entire data set to process before next convergence check
5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence',100

Data Types: single | double

PassLimit — Maximal number of passes
10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data PassLimit times, it terminates optimization.

Example: 'PassLimit',5

Data Types: single | double

ValidationData — Validation data for optimization convergence detection
cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see "Algorithms" on page 32-1627. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an m-by-p or p-by-m full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData{2} and Y must be the same data type. The set of all distinct labels of ValidationData{2} must be a subset of all distinct labels of Y.
- Optionally, ValidationData(3) can contain an m-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpaRSA Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term
1e-4 (default) | nonnegative scalar
Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t, b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration $t$. If $\frac{\|B_t - B_{t-1}\|_2}{B_t} < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

**GradientTolerance — Absolute gradient tolerance**

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration $t$. If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'GradientTolerance',1e-5

Data Types: single | double

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize',10

Data Types: single | double

**IterationLimit — Maximal number of optimization iterations**

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500
Data Types: `single` | `double`

**ValidationData — Validation data for optimization convergence detection**

- **cell array**

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1627. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- **ValidationData(1)** must contain an \( m \)-by-\( p \) or \( p \)-by-\( m \) full or sparse matrix of predictor data that has the same orientation as \( X \). The predictor variables in the training data \( X \) and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- **ValidationData(2)** and \( Y \) must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of \( Y \).
- Optionally, **ValidationData(3)** can contain an \( m \)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

**Hyperparameter Optimization**

**OptimizeHyperparameters — Parameters to optimize**

- `'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{ `'Lambda'`, `'Learner'` }.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitclinear` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.
The eligible parameters for `fitclinear` are:

- **Lambda** — *fitclinear* searches among positive values, by default log-scaled in the range $[10^{-5}/\text{NumObservations}, 10^5/\text{NumObservations}]$.
- **Learner** — *fitclinear* searches among 'svm' and 'logistic'.
- **Regularization** — *fitclinear* searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitclinear', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `HyperparameterOptimizationOptions` name-value pair argument. To control the plots, set the `ShowPlots` field of the `HyperparameterOptimizationOptions` name-value pair argument.

For an example, see “Optimize Linear Classifier” on page 32-1600.

Example: 'OptimizeHyperparameters', 'auto'

### HyperparameterOptimizationOptions — Options for optimization

Structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th><strong>Field Name</strong></th>
<th><strong>Values</strong></th>
<th><strong>Default</strong></th>
</tr>
</thead>
</table>
| **Optimizer** | • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls `bayesopt`.
• 'gridsearch' — Use grid search with `NumGridDivisions` values per dimension.
• 'randomsearch' — Search at random among `MaxObjectiveEvaluations` points.
'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)` | 'bayesopt' |
<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| AcquisitionFunctionName | • 'expected-improvement-per-second-plus'  
• 'expected-improvement'  
• 'expected-improvement-plus'  
• 'expected-improvement-per-second'  
• 'lower-confidence-bound'  
• 'probability-of-improvement' | 'expected-improvement-per-second-plus'      |
|                         | Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see "Acquisition Function Types" on page 10-3. |
| MaxObjectiveEvaluations | Maximum number of objective function evaluations.                                                                                                                                                      | 30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch' |
| MaxTime                 | Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.                              | Inf                                          |
| NumGridDivisions        | For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.   | 10                                           |
| ShowPlots               | Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters. | true                                         |
| SaveIntermediateResults | Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object. | false                                        |
### Field Name | Values | Default
---|---|---
Verbose | Display to the command line.  
• 0 — No iterative display  
• 1 — Iterative display  
• 2 — Iterative display with extra information  
For details, see the `bayesopt` Verbose name-value pair argument. | 1 |
UseParallel | Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see "Parallel Bayesian Optimization" on page 10-7. | false |
Repartition | Logical value indicating whether to repartition the cross-validation at every iteration. If false, the optimizer uses a single partition for the optimization.  
true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations. | false |

Use no more than one of the following three field names.

| Field Name | Values | Default |
---|---|---|
CVPartition | A `cvpartition` object, as created by `cvpartition`. | 'Kfold',5 if you do not specify any cross-validation field |
Holdout | A scalar in the range (0,1) representing the holdout fraction. | |
Kfold | An integer greater than 1. | |

Example:  
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

### Output Arguments

**Mdl — Trained linear classification model**  
`ClassificationLinear` model object | `ClassificationPartitionedLinear` cross-validated model object

Trained linear classification model, returned as a `ClassificationLinear` model object or `ClassificationPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `ClassificationLinear` model object.
To reference properties of Mdl, use dot notation. For example, enter Mdl.Beta in the Command Window to display the vector or matrix of estimated coefficients.

**Note** Unlike other classification models, and for economical memory usage, ClassificationLinear and ClassificationPartitionedLinear model objects do not store the training data or training process details (for example, convergence history).

**FitInfo — Optimization details**
structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, Objective is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of Lambda and columns correspond to values of Solver.

This table describes some notable fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TerminationStatus</td>
<td>• Reason for optimization termination</td>
</tr>
<tr>
<td></td>
<td>• Corresponds to a value in TerminationCode</td>
</tr>
<tr>
<td>FitTime</td>
<td>Elapsed, wall-clock time in seconds</td>
</tr>
<tr>
<td>History</td>
<td>A structure array of optimization information for each iteration. The field Solver stores solver types using integer coding.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Integer</th>
<th>Solver</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SGD</td>
</tr>
<tr>
<td>2</td>

<td>Dual SGD for SVM</td>
</tr>
<tr>
<td>4</td>
<td>LBFGS</td>
</tr>
<tr>
<td>5</td>
<td>BFGS</td>
</tr>
<tr>
<td>6</td>
<td>SpaRSA</td>
</tr>
</tbody>
</table>

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter FitInfo.History.Objective.

It is good practice to examine FitInfo to assess whether convergence is satisfactory.

**HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters**
BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the Optimizer field value of the 'HyperparameterOptimizationOptions' name-value pair argument.
### Value of Optimizer Field

<table>

<td>Object of class BayesianOptimization</td>
</tr>
<tr>
<td>'gridsearch' or 'randomsearch'</td>
<td>Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)</td>
</tr>
</tbody>
</table>

### More About

#### Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

#### Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

<table>
<thead>
<tr>
<th>Model to Fit</th>
<th>Function</th>
<th>Notable Algorithmic Differences</th>
</tr>
</thead>
</table>
| SVM          | • Binary classification: fitcsvm  
• Multiclass classification: fitcecoc  
• Regression: fitrsvm | • Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations.  
• Solves dual problem using SMO, ISDA, or $L_1$ minimization via quadratic programming using quadprog. |
| Linear regression | • Least-squares without regularization: fitlm  
• Regularized least-squares using a lasso penalty: lasso  
• Ridge regression: ridge or lasso | • lasso implements cyclic coordinate descent. |
| Logistic regression | • Logistic regression without regularization: fitglm.  
• Regularized logistic regression using a lasso penalty: lassoglm | • fitglm implements iteratively reweighted least squares.  
• lassoglm implements cyclic coordinate descent. |
**Tips**

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn','columns'`. As a result, you can experience a significant reduction in optimization-execution time.

- For better optimization accuracy if $X$ is high-dimensional and **Regularization** is `'ridge'`, set any of these combinations for **Solver**:
  - `'sgd'`
  - `'asgd'`
  - `'dual'` if Learner is `'svm'`
  - `{ 'sgd', 'lbfgs' }`
  - `{ 'asgd', 'lbfgs' }`
  - `{ 'dual', 'lbfgs' }` if Learner is `'svm'`

  Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if $X$ is moderate- through low-dimensional and **Regularization** is `'ridge'`, set **Solver** to `'bfgs'`.

- If **Regularization** is `'lasso'`, set any of these combinations for **Solver**:
  - `'sgd'`
  - `'asgd'`
  - `'sparsa'`
  - `{ 'sgd', 'sparsa' }`
  - `{ 'asgd', 'sparsa' }`

  When choosing between SGD and ASGD, consider that:
  - SGD takes less time per iteration, but requires more iterations to converge.
  - ASGD requires fewer iterations to converge, but takes more time per iteration.

- If $X$ has few observations, but many predictor variables, then:
  - Specify `'PostFitBias',true.``
  - For SGD or ASGD solvers, set **PassLimit** to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.

- For SGD and ASGD solvers, **BatchSize** affects the rate of convergence.
  - If **BatchSize** is too small, then `fitclinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  - If **BatchSize** is too large, then `fitclinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.

  Large learning rates (see **LearnRate**) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.

- When using lasso penalties, experiment with various values of **TruncationPeriod**. For example, set **TruncationPeriod** to 1, 10, and then 100.

- For efficiency, `fitclinear` does not standardize predictor data. To standardize $X$, enter
The code requires that you orient the predictors and observations as the rows and columns of \(X\), respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

### Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
  - `fitclinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
  - When `fitclinear` estimates a validation loss, it compares the estimate to the minimal estimate.
  - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitclinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (CrossVal, CVPartition, Holdout, or KFold), then:
  1. `fitclinear` randomly partitions \(X\) and \(Y\) according to the cross-validation routine that you choose.
  2. `fitclinear` trains the model using the training-data partition. During objective-function optimization, `fitclinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
  3. Once `fitclinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
     - If you implement \(k\)-fold cross-validation, and `fitclinear` has not exhausted all training-set folds, then `fitclinear` returns to Step 2 to train using the next training-set fold.
     - Otherwise, `fitclinear` terminates training, and then returns the cross-validated model.
  4. You can determine the quality of the cross-validated model. For example:
     - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
     - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

### References

**Extended Capabilities**

**Tall Arrays**

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory *fitclinear* function. Supported name-value pair arguments, and any differences, are:
  - 'ObservationsIn' — Supports only 'rows'.
  - 'Lambda' — Can be 'auto' (default) or a scalar.
  - 'Learner'
  - 'Regularization' — Supports only 'ridge'.
  - 'Solver' — Supports only 'lbfgs'.
  - 'FitBias' — Supports only true.
  - 'Verbose' — Default value is 1.
  - 'Beta'
  - 'Bias'
  - 'ClassNames'
  - 'Cost'
  - 'Prior'
  - 'Weights' — Value must be a tall array.
  - 'HessianHistorySize'
  - 'BetaTolerance' — Default value is relaxed to 1e–3.
  - 'GradientTolerance' — Default value is relaxed to 1e–3.
  - 'IterationLimit' — Default value is relaxed to 20.
  - 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
  - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify *fitclinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
• For tall arrays, `fitclinear` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for Beta and Bias are not given, `fitclinear` refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2016a**
fitcnb

Train multiclass naive Bayes model

Syntax

Mdl = fitcnb(Tbl,ResponseVarName)
Mdl = fitcnb(Tbl,formula)
Mdl = fitcnb(Tbl,Y)
Mdl = fitcnb(X,Y)
Mdl = fitcnb(___,Name,Value)

Description

Mdl = fitcnb(Tbl,ResponseVarName) returns a multiclass naive Bayes model (Mdl), trained by the predictors in table Tbl and class labels in the variable Tbl.ResponseVarName.

Mdl = fitcnb(Tbl,formula) returns a multiclass naive Bayes model (Mdl), trained by the predictors in table Tbl. formula is an explanatory model of the response and a subset of predictor variables in Tbl used to fit Mdl.

Mdl = fitcnb(Tbl,Y) returns a multiclass naive Bayes model (Mdl), trained by the predictors in the table Tbl and class labels in the array Y.

Mdl = fitcnb(X,Y) returns a multiclass naive Bayes model (Mdl), trained by predictors X and class labels Y.

Mdl = fitcnb(___,Name,Value) returns a naive Bayes classifier with additional options specified by one or more Name,Value pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)

<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>setosa</td>
<td>50</td>
<td>33.33%</td>
</tr>
<tr>
<td>versicolor</td>
<td>50</td>
<td>33.33%</td>
</tr>
<tr>
<td>virginica</td>
<td>50</td>
<td>33.33%</td>
</tr>
</tbody>
</table>

The software can classify data with more than two classes using naive Bayes methods.
Train a naive Bayes classifier. It is good practice to specify the class order.

Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})

Mdl =
    ClassificationNaiveBayes
      ResponseName: 'Y'
      CategoricalPredictors: []
      ClassNames: {'setosa'  'versicolor'  'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150
      DistributionNames: {'normal'  'normal'}
      DistributionParameters: {3x2 cell}

Properties, Methods

Mdl is a trained ClassificationNaiveBayes classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within setosa.

setosaIndex = strcmp(Mdl.ClassNames,'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}
estimates = 2x1
    1.4620
    0.1737

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

figure
    gscatter(X(:,1),X(:,2),Y);
h = gca;
cxlim = h.XLim;
cylim = h.YLim;
hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)).^2; % Create diagonal covariance matrix
    xlim = Mu(j,1) + 4*[1 -1]*sqrt(Sigma(1,1,j));
    ylim = Mu(j,2) + 4*[1 -1]*sqrt(Sigma(2,2,j));
    f = @(x1,x2)reshape(mvnpdf([x1(:),x2(:)],Mu(:,j),Sigma(:,:,j)),size(x1));
    fcontour(f,[xlim ylim]) % Draw contours for the multivariate normal distributions
end
h.XLim = cxlim;
h.YLim = cylim;
title('Naive Bayes Classifier -- Fisher''s Iris Data')
xlabel('Petal Length (cm)')
You can change the default distribution using the name-value pair argument 'DistributionNames'. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using 'DistributionNames','mvmn'.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'}; % Class order
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set, which in this case is 33% for each species. However, suppose you know that in the
population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

```matlab
classNames = {'setosa','versicolor','virginica'};
prior = [0.5 0.2 0.3];
Mdl = fitcnb(X,Y,'ClassNames',classNames,'Prior',prior)
```

Mdl = `ClassificationNaiveBayes`
- ResponseName: 'Y'
- CategoricalPredictors: []
- ClassNames: {'setosa'  'versicolor'  'virginica'}
- ScoreTransform: 'none'
- NumObservations: 150
- DistributionNames: {'normal'  'normal'  'normal'  'normal'}
- DistributionParameters: {3x4 cell}

Properties, Methods

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses `prior`.

Create a new naive Bayes model based on `Mdl`, and specify that the prior class probability distribution is an empirical class distribution.

```matlab
defaultPriorMdl = Mdl;
FreqDist = cell2table(tabulate(Y));
defaultPriorMdl.Prior = FreqDist{:3};
```

The software normalizes the prior class probabilities to sum to 1.

Estimate the cross-validation error for both models using 10-fold cross-validation.

```matlab
rng(1); % For reproducibility
defaultCVMdl = crossval(defaultPriorMdl);
defaultLoss = kfoldLoss(defaultCVMdl)
defaultLoss = 0.0533
```

```matlab
CVMdl = crossval(Mdl);
Loss = kfoldLoss(CVMdl)
Loss = 0.0340
```

`Mdl` performs better than `defaultPriorMdl`. 

32-1633
Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```matlab
Mdl1 = fitcnb(X,Y,...
   'ClassNames',{'setosa','versicolor','virginica'})
```

```matlab
Mdl1 = ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal'  'normal'  'normal'  'normal'}
    DistributionParameters: {3x4 cell}
```

```matlab
Mdl1.DistributionParameters
ans=3x4 cell array
{2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
{2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
{2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
```

```matlab
Mdl1.DistributionParameters{1,2}
ans = 2x1
3.4280
0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `Mdl1.DistributionParameters` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for `Mdl1`.

```matlab
isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionchart(Y,isLabels1);
```
Element \((j, k)\) of the confusion matrix chart represents the number of observations that the software classifies as \(k\), but are truly in class \(j\) according to the data.

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

\[
\text{Mdl2} = \text{fitcnb}(X,Y,...
\quad \text{'DistributionNames'},\{'\text{normal}',\'\text{normal}',\'\text{kernel}',\'\text{kernel}'\},...
\quad \text{'ClassNames'},\{'\text{setosa}',\'\text{versicolor}',\'\text{virginica}'\});
\]

\[
\text{Mdl2.DistributionParameters}\{1,2\}
\]

\[
\begin{bmatrix}
3.4280 \\
0.3791 \\
\end{bmatrix}
\]

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the ‘\text{Width}’ name-value pair argument.

Estimate the confusion matrix for \text{Mdl2}.

\[
\text{isLabels2} = \text{resubPredict}(\text{Mdl2});
\]

\[
\text{ConfusionMat2} = \text{confusionchart}(Y,\text{isLabels2});
\]
Based on the confusion matrices, the two classifiers perform similarly in the training sample.

**Compare Classifiers Using Cross-Validation**

Load Fisher's iris data set.

```matlab
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Train and cross-validate a naive Bayes classifier using the default options and k-fold cross-validation. It is good practice to specify the class order.

```matlab
CVMdl1 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'CrossVal','on');
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. CVMdl1 is a ClassificationPartitionedModel model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.
t = templateNaiveBayes();
CVMdl2 = fitcecoc(X,Y,'CrossVal','on','Learners',t);

CVMdl2 is a ClassificationPartitionedECOC model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for fitcnb.

Compare the out-of-sample $k$-fold classification error (proportion of misclassified observations).

```matlab
classErr1 = kfoldLoss(CVMdl1,'LossFun','ClassifErr')
classErr1 = 0.0533

classErr2 = kfoldLoss(CVMdl2,'LossFun','ClassifErr')
classErr2 = 0.0467
```

Md2 has a lower generalization error.

### Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

#### Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to $y$ for each email.

```matlab
n = 1000;                       % Sample size
rng(1);                         % For reproducibility
Y = randsample([-1 1],n,true);  % Random labels

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```matlab
tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
0.4 0.1 0.3 0.05 0.15];             % Token relative frequencies
tokensPerEmail = 20;                    % Fixed for convenience
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

#### Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```matlab
Mdl = fitcnb(X,Y,'DistributionNames','mn');
```

Mdl is a trained ClassificationNaiveBayes classifier.

Assess the in-sample performance of Mdl by estimating the misclassification error.
isGenRate = resubLoss(Mdl,'LossFun','ClassifErr')

isGenRate = 0.0200

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

newN = 500;
newY = randsample([-1 1],newN,true);
newX = zeros(newN,5);
newX(newY == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...                     sum(newY == 1));
newX(newY == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...                     sum(newY == -1));

Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier Mdl, and determine whether the algorithm generalizes.

oosGenRate = loss(Mdl,newX,newY)

oosGenRate = 0.0261

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Optimize Naive Bayes Classifier

This example shows how to use the OptimizeHyperparameters name-value pair to minimize cross-validation loss in a naive Bayes classifier fitcnb. The example uses Fisher's iris data.

Load Fisher's iris data.

load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'};

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

rng default
Mdl = fitcnb(X,Y,'ClassNames',classNames,'OptimizeHyperparameters','auto',...                     'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...                     'expected-improvement-plus'))

Warning: It is recommended that you first standardize all numeric predictors when optimizing the Naive Bayes 'Width' parameter. Ignore this warning if you have done that.

Properties, Methods

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.
A good practice is to specify the order of the classes by using the ClassNames name-value pair argument.

Data Types: char | string

**formula — Explanatory model of response variable and subset of predictor variables**

char vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

```
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

Data Types: char | string

**Y — Class labels**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each element of Y defines the class membership of the corresponding row of X. Y supports K class levels.

If Y is a character array, then each row must correspond to one class label.

The length of Y and the number of rows of X must be equivalent.

Data Types: categorical | char | string | logical | single | double | cell

**X — Predictor data**

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equivalent.

Data Types: double
**Note:** The software treats NaN, empty character vector (''), empty string ('"'), <missing>, and <undefined> elements as missing data values.

- If Y contains missing values, then the software removes them and the corresponding rows of X.
- If X contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of Y.
- If X contains missing values and you set 'DistributionNames','mn', then the software removes those rows of X and the corresponding elements of Y.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'DistributionNames','mn','Prior','uniform','KSWidth',0.5 specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

**Naive Bayes Options**

**DistributionNames — Data distributions**

`'kernel'` | `'mn'` | `'mvmn'` | `'normal'` | string array | cell array of character vectors

Data distributions fitcnb uses to model the data, specified as the comma-separated pair consisting of 'DistributionNames' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'kernel'</code></td>
<td>Kernel smoothing density estimate.</td>
</tr>
<tr>
<td><code>'mn'</code></td>
<td>Multinomial distribution. If you specify mn, then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 32-1657.</td>
</tr>
<tr>
<td><code>'mvmn'</code></td>
<td>Multivariate multinomial distribution. For details, see “Algorithms” on page 32-1657.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>'normal'</td>
<td>Normal (Gaussian) distribution.</td>
</tr>
</tbody>
</table>

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by-P string array or cell array of character vectors, then the software models feature \( j \) using the distribution in element \( j \) of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvmn'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'DistributionNames','mn'
Example: 'DistributionNames',{'kernel','normal','kernel'}

**Kernel — Kernel smoother type**

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let \( I\{u\} \) denote the indicator function.

<table>
<thead>
<tr>
<th>Value</th>
<th>Kernel</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'box'</td>
<td>Box (uniform)</td>
<td>( f(x) = 0.5 I{</td>
</tr>
<tr>
<td>'epanechnikov'</td>
<td>Epanechnikov</td>
<td>( f(x) = 0.75 (1 - x^2) I{</td>
</tr>
<tr>
<td>'normal'</td>
<td>Gaussian</td>
<td>( f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2) )</td>
</tr>
<tr>
<td>'triangle'</td>
<td>Triangular</td>
<td>( f(x) = (1 -</td>
</tr>
</tbody>
</table>

If you specify a 1-by-P string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element \( j \) for feature \( j \) in \( X \). The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Kernel',{ 'epanechnikov', 'normal' }

**Support — Kernel smoothing density support**

'unbounded' (default) | 'positive' | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'Support' and 'positive', 'unbounded', a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.
1-by-2 numeric row vector | For example, \([L, U]\), where \(L\) and \(U\) are the finite lower and upper bounds, respectively, for the density support.

'positive' | The density support is all positive real values.

'unbounded' | The density support is all real values.

If you specify a 1-by-\(P\) string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software ignores elements of \(\text{Kernel}\) not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify \(\text{Kernel, Support, or Width}\).

Example: 'KSSupport',\([-10,20]\), 'unbounded'

Data Types: char | string | cell | double

**Width** | Kernel smoothing window width
---|---
matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are \(K\) class levels and \(P\) predictors. This table summarizes the available options for setting the kernel smoothing window width.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(K)-by-(P) matrix of numeric values</td>
<td>Element ((k,j)) specifies the width for predictor (j) in class (k).</td>
</tr>
<tr>
<td>(K)-by-1 numeric column vector</td>
<td>Element (k) specifies the width for all predictors in class (k).</td>
</tr>
<tr>
<td>1-by-(P) numeric row vector</td>
<td>Element (j) specifies the width in all class levels for predictor (j).</td>
</tr>
<tr>
<td>scalar</td>
<td>Specifies the bandwidth for all features in all classes.</td>
</tr>
</tbody>
</table>

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify \(\text{Width}\) and it contains \(\text{NaN}\)s, then the software selects widths for the elements containing \(\text{NaN}\)s.

You must specify that at least one predictor has distribution 'kernel' to additionally specify \(\text{Kernel, Support, or Width}\).

Example: 'Width', [\(\text{NaN} \ \text{NaN}\)]

Data Types: double | struct

**Cross-Validation Options**

**CrossVal** | Cross-validation flag
---|---
'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.
To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'CrossVal','on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using 

cvp = cvpartition(500,'KFold',5).

Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1 Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.

2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:

1 Randomly partition the data into k sets.

2 For each set, reserve the set as validation data, and train the model using the other k – 1 sets.

3 Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5
Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'label' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other n - 1 observations.
2. Store the n compact, trained models in the cells of an n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

**Other Classification Options**

**CategoricalPredictors — Categorical predictors list**

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitcnb assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fitcnb assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

For the identified categorical predictors, fitcnb uses multivariate multinomial distributions. For details, see DistributionNames and “Algorithms” on page 32-1657.

Example: 'CategoricalPredictors', 'all'
Data Types: single | double | logical | char | string | cell

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i,j)=1 if i~=j, and Cost(i,j)=0 if i=j.

Example: 'Cost',struct('ClassNames',{'b','g'},'ClassificationCosts',[0 0.5; 1 0])

Data Types: single | double | struct

**PredictorNames — Predictor variable names**
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.
• If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.

• The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.

• By default, PredictorNames is {'x1','x2',...}.

• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcnb uses only the predictor variables in PredictorNames and the response variable in training.

• PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.

• By default, PredictorNames contains the names of all predictor variables.

• A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior','uniform'
Data Types: char | string | single | double | struct

**ResponseName — Response variable name**
'
Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar:

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

**ScoreTransform — Score transformation**
'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>1/(1 + e^{-2x})</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>log(x / (1 – x))</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>1/(1 + e^{x})</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for x &lt; 0; 0 for x = 0; 1 for x &gt; 0</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>2x – 1</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>2/(1 + e^{x}) – 1</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'
Data Types: char | string | function_handle

**Weights — Observation weights**
numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each
row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

• 'none' — Do not optimize.
• 'auto' — Use {'DistributionNames','Width'}.
• 'all' — Optimize all eligible parameters.
• String array or cell array of eligible parameter names.
• Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitcnb by varying the parameters. For information about cross-validation loss (albeit in a different context), see "Classification Loss" on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair:

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcnb are:

• DistributionNames — fitcnb searches among 'normal' and 'kernel'.
• Width — fitcnb searches among real values, by default log-scaled in the range [MinPredictorDiff/4,max(MaxPredictorRange,MinPredictorDiff)].
• Kernel — fitcnb searches among 'normal', 'box', 'epanechnikov', and 'triangle'.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,
load fisheriris
params = hyperparameters('fitcnb', meas, species);
params(2).Range = [1e-2, 1e2];

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see "Optimize Naive Bayes Classifier" on page 32-1638.

Example: 'auto'

**HyperparameterOptimizationOptions — Options for optimization**

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Output Arguments

Mdl — Trained naive Bayes classification model
ClassificationNaiveBayes model object | ClassificationPartitionedModel cross-validated model object

Trained naive Bayes classification model, returned as a ClassificationNaiveBayes model object or a ClassificationPartitionedModel cross-validated model object.

If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationNaiveBayes model object.
To reference properties of Mdl, use dot notation. For example, to access the estimated distribution parameters, enter `Mdl.DistributionParameters`.

**More About**

**Bag-of-Tokens Model**

In the bag-of-tokens model, the value of predictor $j$ is the nonnegative number of occurrences of token $j$ in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

**Naive Bayes**

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

1. Estimates the densities of the predictors within each class.
2. Models posterior probabilities according to Bayes rule. That is, for all $k = 1,...,K$,

   $$
   \hat{P}(Y = k | X_1, ..., X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P(X_j | Y=k)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P(X_j | Y=k)},
   $$

   where:
   - $Y$ is the random variable corresponding to the class index of an observation.
   - $X_1,...,X_P$ are the random predictors of an observation.
   - $\pi(Y = k)$ is the prior probability that a class index is $k$.
3. Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability

$$
\hat{P}(Y = k | X_1, ..., X_P) \propto \pi(Y = k) P_{mn}(X_1, ..., X_P | Y = k),
$$

where $P_{mn}(X_1, ..., X_P | Y = k)$ is the probability mass function of a multinomial distribution.

**Tips**

- For classifying count-based data, such as the bag-of-tokens model on page 32-1656, use the multinomial distribution (e.g., set `'DistributionNames','mn'`).
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.
Algorithms

- If you specify 'DistributionNames', 'mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-1656. The software stores the probability that token \( j \) appears in class \( k \) in the property DistributionParameters\( \{k, j\} \). Using additive smoothing [2], the estimated probability is

\[
P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},
\]

where:

- \( c_{j|k} = \sum_{i: y_i \in \text{class } k} x_{ij} w_i \); which is the weighted number of occurrences of token \( j \) in class \( k \).
- \( n_k \) is the number of observations in class \( k \).
- \( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.
- \( c_k = \sum_{j=1}^{P} c_{j|k} \); which is the total weighted number of occurrences of all tokens in class \( k \).

- If you specify 'DistributionNames', 'mvmn' when training Mdl using fitcnb, then:

1. For each predictor, the software collects a list of the unique levels, stores the sorted list in CategoricalLevels, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
2. For predictor \( j \) in class \( k \), the software counts instances of each categorical level using the list stored in CategoricalLevels\( \{j\} \).
3. The software stores the probability that predictor \( j \), in class \( k \), has level \( L \) in the property DistributionParameters\( \{k, j\} \), for all levels in CategoricalLevels\( \{j\} \). Using additive smoothing [2], the estimated probability is

\[
P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},
\]

where:

- \( m_{j|k}(L) = \sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i \); which is the weighted number of observations for which predictor \( j \) equals \( L \) in class \( k \).
- \( n_k \) is the number of observations in class \( k \).
- \( I\{x_{ij} = L\} = 1 \) if \( x_{ij} = L \), 0 otherwise.
- \( w_i \) is the weight for observation \( i \). The software normalizes weights within a class such that they sum to the prior probability for that class.
- \( m_j \) is the number of distinct levels in predictor \( j \).
- \( m_k \) is the weighted number of observations in class \( k \).
References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- Supported syntaxes are:
  - `Mdl = fitcnb(Tbl,Y)`
  - `Mdl = fitcnb(X,Y)`
  - `Mdl = fitcnb(___,Name,Value)`
- Options related to kernel densities, cross-validation, and hyperparameter optimization are not supported. The supported name-value pair arguments are:
  - `'DistributionNames' — 'kernel' value is not supported.
  - `'CategoricalPredictors'
  - `'Cost'
  - `'PredictorNames'
  - `'Prior'
  - `'ResponseName'
  - `'ScoreTransform'
  - `'Weights' — Value must be a tall array.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics
“Naive Bayes Classification” on page 21-2
“Grouping Variables” on page 2-45

Introduced in R2014b
**fitcsvm**

Train support vector machine (SVM) classifier for one-class and binary classification

**Syntax**

```matlab
Mdl = fitcsvm(Tbl,ResponseVarName)
Mdl = fitcsvm(Tbl,formula)
Mdl = fitcsvm(Tbl,Y)
Mdl = fitcsvm(X,Y)
Mdl = fitcsvm(____,Name,Value)
```

**Description**

`fitcsvm` trains or cross-validates a support vector machine (SVM) model for one-class and two-class (binary) classification on a low-dimensional or moderate-dimensional predictor data set. `fitcsvm` supports mapping the predictor data using kernel functions, and supports sequential minimal optimization (SMO), iterative single data algorithm (ISDA), or $L_1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM model for binary classification on a high-dimensional data set, that is, a data set that includes many predictor variables, use `fitclinear` instead.

For multiclass learning with combined binary SVM models, use error-correcting output codes (ECOC). For more details, see `fitcecoc`.

To train an SVM regression model, see `fitrsvm` for low-dimensional and moderate-dimensional predictor data sets, or `fitrlinear` for high-dimensional data sets.

```matlab
Mdl = fitcsvm(Tbl,ResponseVarName) returns a support vector machine (SVM) classifier on page 32-1690 Mdl trained using the sample data contained in the table `Tbl`. `ResponseVarName` is the name of the variable in `Tbl` that contains the class labels for one-class or two-class classification.
```

```matlab
Mdl = fitcsvm(Tbl,formula) returns an SVM classifier trained using the sample data contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of the predictor variables in `Tbl` used to fit `Mdl`.
```

```matlab
Mdl = fitcsvm(Tbl,Y) returns an SVM classifier trained using the predictor variables in the table `Tbl` and the class labels in vector `Y`.
```

```matlab
Mdl = fitcsvm(X,Y) returns an SVM classifier trained using the predictors in the matrix `X` and the class labels in vector `Y` for one-class or two-class classification.
```

```matlab
Mdl = fitcsvm(____,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the type of cross-validation, the cost for misclassification, and the type of score transformation function.
```

**Examples**
Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```matlab
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```matlab
SVMMModel = fitcsvm(X,y)
```

```
SVMMModel = ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 100
        Alpha: [24x1 double]
        Bias: -14.4149
    KernelParameters: [1x1 struct]
    BoxConstraints: [100x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [100x1 logical]
    Solver: 'SMO'
```

Properties, Methods

`SVMMModel` is a trained `ClassificationSVM` classifier. Display the properties of `SVMMModel`. For example, to determine the class order, use dot notation.

```matlab
classOrder = SVMMModel.ClassNames
```

```
classOrder = 2x1 cell
    {'versicolor'}
    {'virginica'}
```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```matlab
sv = SVMMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
```
The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

**Train and Cross-Validate SVM Classifier**

Load the ionosphere data set.

```matlab
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. Standardize the predictors.

```matlab
SVMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',... 'KernelScale','auto');
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Cross-validate the SVM classifier. By default, the software uses 10-fold cross-validation.

```matlab
CVSVMModel = crossval(SVMModel); 
```

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated classifier.
Estimate the out-of-sample misclassification rate.

```matlab
classLoss = kfoldLoss(CVSVMModel)
classLoss = 0.0484
```

The generalization rate is approximately 5%.

### Detect Outliers Using SVM and One-Class Learning

Modify Fisher's iris data set by assigning all the irises to the same class. Detect outliers in the modified data set, and confirm the expected proportion of the observations that are outliers.

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```matlab
load fisheriris
X = meas(:,1:2);
y = ones(size(X,1),1);
```

Train an SVM classifier using the modified data set. Assume that 5% of the observations are outliers. Standardize the predictors.

```matlab
rng(1);
SVMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...
    'OutlierFraction',0.05);
SVMModel
```

`SVMModel` is a trained `ClassificationSVM` classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```matlab
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));
figure
plot(X(:,1),X(:,2),'k.'
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{f Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```
The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```matlab
CVSVMModel = crossval(SVMModel);
 [~,scorePred] = kfoldPredict(CVSVMModel);
 outlierRate = mean(scorePred<0)
outlierRate = 0.0467
```

### Find Multiple Class Boundaries Using Binary SVM

Create a scatter plot of the `fisheriris` data set. Treat coordinates of a grid within the plot as new observations from the distribution of the data set, and find class boundaries by assigning the coordinates to one of the three classes in the data set.

Load Fisher's iris data set. Use the petal lengths and widths as the predictors.

```matlab
load fisheriris
X = meas(:,3:4);
Y = species;

Examine a scatter plot of the data.

```
h = gca;
lims = [h.XLim h.YLim]; % Extract the x and y axis limits
title('{\bf Scatter Diagram of Iris Measurements}');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location','Northwest');

The data contains three classes, one of which is linearly separable from the others.

For each class:

1. Create a logical vector (indx) indicating whether an observation is a member of the class.
2. Train an SVM classifier using the predictor data and indx.
3. Store the classifier in a cell of a cell array.

Define the class order.

SVMMModels = cell(3,1);
classes = unique(Y);
rng(1); % For reproducibility

for j = 1:numel(cases)
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'
    Standardize',true,...
    'KernelFunction','rbf','BoxConstraint',1);
end
SVMMModels is a 3-by-1 cell array, with each cell containing a ClassificationSVM classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier:

\[
d = 0.02; \\
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),... \\
\quad min(X(:,2)):d:max(X(:,2))); \\
xGrid = [x1Grid(:),x2Grid(:)]; \\
N = size(xGrid,1); \\
Scores = zeros(N,numel(classes));
\]

\[
\text{for } j = 1:\text{numel(classes)} \\
\text{\quad }[-,score] = \text{predict(SVMModels}{j}\text{,xGrid);} \\
\text{\quad Scores(:,j) = score(:,2); % Second column contains positive-class scores}
\text{end}
\]

Each row of Scores contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

\[
[-,maxScore] = \text{max(Scores,[]),2);}
\]

Color in the regions of the plot based on the class to which the corresponding new observation belongs.

\[
\text{figure} \\
\text{h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...} \\
\text{\quad [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);} \\
\text{hold on} \\
\text{h(4:6) = gscatter(X(:,1),X(:,2),Y);} \\
\text{title('{\bf Iris Classification Regions}');} \\
\text{xlabel('Petal Length (cm)');} \\
\text{ylabel('Petal Width (cm)');} \\
\text{legend(h,{'setosa region','versicolor region','virginica region','...} \\
\text{\quad observed setosa','observed versicolor','observed virginica'},...} \\
\text{\quad 'Location','Northwest'});} \\
\text{axis tight} \\
\text{hold off}
\]
Optimize SVM Classifier

Optimize hyperparameters automatically using `fitcsvm`.

Load the `ionosphere` data set.

```matlab
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```matlab
rng default
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto',
     'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.
You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable \( Y \) is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including \( Y \), as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If \( Y \) is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar
Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, \( Y \) represents the response variable, and \( X1 \), \( X2 \), and \( X3 \) represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers.

You can verify the variable names in `Tbl` by using the `isvarname` function. The following code returns logical `1` (`true`) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,Tbl.Properties.VariableNames)
```

If the variable names in `Tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);
```

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors
Class labels to which the SVM model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- \( Y \) must contain at most two distinct classes. For multiclass learning, see `fitcecoc`.
- If \( Y \) is a character array, then each element of the class labels must correspond to one row of the array.
- The length of \( Y \) and the number of rows in `Tbl` or `X` must be equal.
- It is a good practice to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`
**X — Predictor data**
matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor (also known as a feature).

The length of Y and the number of rows in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the 'PredictorNames' name-value pair argument.

Data Types: double | single

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: fitcsvm(X,Y,'KFold',10,'Cost',[0 2;1 0],'ScoreTransform','sign') performs 10-fold cross-validation, applies double the penalty to false positives compared to false negatives, and transforms scores using the sign function.

**SVM Options**

**BoxConstraint — Box constraint**
1 (default) | positive scalar

Box constraint on page 32-1689, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see "Algorithms" on page 32-1693.

Example: 'BoxConstraint',100

Data Types: double | single

**KernelFunction — Kernel function**
'linear' | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the elements of the Gram matrix on page 32-1689, specified as the comma-separated pair consisting of 'KernelFunction' and a kernel function name. Suppose \(G(x_j, x_k)\) is element \((j,k)\) of the Gram matrix, where \(x_j\) and \(x_k\) are \(p\)-dimensional vectors representing observations \(j\) and \(k\) in \(X\). This table describes supported kernel function names and their functional forms.

<table>
<thead>
<tr>
<th>Kernel Function Name</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'gaussian' or 'rbf'</td>
<td>Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning</td>
<td>(G(x_j, x_k) = \exp(-|x_j - x_k|^2))</td>
</tr>
</tbody>
</table>
### Kernel Function Name

<table>
<thead>
<tr>
<th>Kernel Function Name</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>'linear'</td>
<td>Linear kernel, default for two-class learning</td>
<td>$G(x_j, x_k) = x_j'x_k$</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>Polynomial kernel. Use 'PolynomialOrder', $q$ to specify a polynomial kernel of order $q$.</td>
<td>$G(x_j, x_k) = (1 + x_j'x_k)^q$</td>
</tr>
</tbody>
</table>

You can set your own kernel function, for example, `kernel`, by setting `KernelFunction`, 'kernel'. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- $U$ is an $m$-by-$p$ matrix. Columns correspond to predictor variables, and rows correspond to observations.
- $V$ is an $n$-by-$p$ matrix. Columns correspond to predictor variables, and rows correspond to observations.
- $G$ is an $m$-by-$n$ Gram matrix on page 32-1689 of the rows of $U$ and $V$.

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: `char` | `string`

### KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix $X$ by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within `kernel`.

Example: 'KernelScale', 'auto'

Data Types: `double` | `single` | `char` | `string`

### PolynomialOrder — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.
If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software throws an error.
Example: 'PolynomialOrder',2
Data Types: double | single

**KernelOffset — Kernel offset parameter**

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:
• 0 if the solver is SMO (that is, you set 'Solver','SMO')
• 0.1 if the solver is ISDA (that is, you set 'Solver','ISDA')

Example: 'KernelOffset',0
Data Types: double | single

**Standardize — Flag to standardize predictor data**

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:
• The software centers and scales each predictor variable (X or Tbl) by the corresponding weighted column mean and standard deviation. For details on weighted standardizing, see “Algorithms” on page 32-1693. MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
• The software trains the classifier using the standardized predictors, but stores the unstandardized predictors as a matrix or table in the classifier property X.

Example: 'Standardize',true
Data Types: logical

**Solver — Optimization routine**

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ISDA'</td>
<td>Iterative Single Data Algorithm (see [30])</td>
</tr>
<tr>
<td>'L1QP'</td>
<td>Uses quadprog to implement L1 soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>'SMO'</td>
<td>Sequential Minimal Optimization (see [17])</td>
</tr>
</tbody>
</table>

The default value is 'ISDA' if you set 'OutlierFraction' to a positive value for two-class learning, and 'SMO' otherwise.

Example: 'Solver','ISDA'

**Alpha — Initial estimates of alpha coefficients**

numeric vector of nonnegative values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector of nonnegative values. The length of Alpha must be equal to the number of rows in X.

- Each element of 'Alpha' corresponds to an observation in X.
- 'Alpha' cannot contain any NaNs.
- If you specify 'Alpha' and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and 'Alpha' that correspond to the missing values. That is, enter:

```matlab
idx = ~isundefined(categorical(Y));
Y = Y(idx,:);
X = X(idx,:);
alpha = alpha(idx);
```

Then pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The default values are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

Example: 'Alpha',0.1*ones(size(X,1),1)

Data Types: double | single

**CacheSize — Cache size**

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n-by-n Gram matrix on page 32-1689.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of memory for training the model.

Example: 'CacheSize','maximal'

Data Types: double | single | char | string
**ClipAlphas — Flag to clip alpha coefficients**

true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation $j$ is $\alpha_j$ and the box constraint of observation $j$ is $C_j$, $j = 1,...,n$, where $n$ is the training sample size.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>At each iteration, if $\alpha_j$ is near 0 or near $C_j$, then MATLAB sets $\alpha_j$ to 0 or to $C_j$, respectively.</td>
</tr>
<tr>
<td>false</td>
<td>MATLAB does not change the alpha coefficients during optimization.</td>
</tr>
</tbody>
</table>

MATLAB stores the final values of $\alpha$ in the Alpha property of the trained SVM model object.

ClipAlphas can affect SMO and ISDA convergence.

Example: 'ClipAlphas',false

Data Types: logical

**Nu — $\nu$ parameter for one-class learning**

0.5 (default) | positive scalar

$\nu$ parameter for "One-Class Learning" on page 32-1690, specified as the comma-separated pair consisting of 'Nu' and a positive scalar. Nu must be greater than 0 and at most 1.

Set Nu to control the tradeoff between ensuring that most training examples are in the positive class and minimizing the weights in the score function.

Example: 'Nu',0.25

Data Types: double | single

**NumPrint — Number of iterations between optimization diagnostic message output**

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint',500

Data Types: double | single

**OutlierFraction — Expected proportion of outliers in training data**

0 (default) | numeric scalar in the interval (0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval (0,1).

Suppose that you set 'OutlierFraction',outlierfraction, where outlierfraction is a value greater than 0.
For two-class learning, the software implements robust learning. In other words, the software attempts to remove 100*outlierfraction% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

For one-class learning, the software finds an appropriate bias term such that outlierfraction of the observations in the training set have negative scores.

Example: 'OutlierFraction',0.01
Data Types: double | single

RemoveDuplicates — Flag to replace duplicate observations with single observations

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If RemoveDuplicates is true, then fitcsvm replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see Weights).

Tip If your data set contains many duplicate observations, then specifying 'RemoveDuplicates',true can decrease convergence time considerably.

Data Types: logical

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of Verbose controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to Mdl.ConvergenceInfo.History.

This table summarizes the available verbosity level options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The software does not display or save convergence information.</td>
</tr>
<tr>
<td>1</td>
<td>The software displays diagnostic messages and saves convergence criteria every numprint iterations, where numprint is the value of the name-value pair argument 'NumPrint'.</td>
</tr>
<tr>
<td>2</td>
<td>The software displays diagnostic messages and saves convergence criteria at every iteration.</td>
</tr>
</tbody>
</table>

Example: 'Verbose',1
Data Types: double | single

Other Classification Options

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'
Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tb1), fitcsvm assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fitcsvm assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

For the identified categorical predictors, fitcsvm creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}
Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify the square matrix Cost and the true class of an observation is $i$, then $Cost(i,j)$ is the cost of classifying a point into class $j$. That is, rows correspond to the true classes and columns correspond to predicted classes. To specify the class order for the corresponding rows and columns of Cost, also specify the ClassNames name-value pair argument.
- If you specify the structure $S$, then $S$ must have two fields:
  - $S.ClassNames$, which contains the class names as a variable of the same data type as $Y$
  - $S.ClassificationCosts$, which contains the cost matrix with rows and columns ordered as in $S.ClassNames$

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Consequently, the cost matrix resets to the default. For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see “Algorithms” on page 32-1693.

The default values are:
- $Cost = 0$ for one-class learning
- $Cost(i,j) = 1$ if $i \neq j$ and $Cost(i,j) = 0$ if $i = j$ for two-class learning
Example: 'Cost',[0,1;2,0]

Data Types: double | single | struct

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply $X$ and $Y$, then you can use 'PredictorNames' to give the predictor variables in $X$ names.
  - The order of the names in PredictorNames must correspond to the column order of $X$. That is, PredictorNames{1} is the name of $X(:,1)$, PredictorNames{2} is the name of $X(:,2)$, and so on. Also, size($X,2$) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2','...'}.
- If you supply $Tbl$, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcsvm uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of $Tbl.Properties.VariableNames$ and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
• A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in Y.</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to 1/K, where K is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element in the vector is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements to sum to 1.</td>
</tr>
<tr>
<td>structure</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>• S.ClassNames contains the class names as a variable of the same type as Y.</td>
</tr>
<tr>
<td></td>
<td>• S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements of the vector to sum to 1.</td>
</tr>
</tbody>
</table>

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see "Algorithms" on page 32-1693.

Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)
Data Types: char | string | double | single | struct

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar:

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string
**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-2x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log(x / (1 - x)) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>x (no transformation)</td>
</tr>
<tr>
<td>'sign'</td>
<td>-1 for ( x &lt; 0 ) 0 for ( x = 0 ) 1 for ( x &gt; 0 )</td>
</tr>
<tr>
<td>'symmetric'</td>
<td>( 2x - 1 )</td>
</tr>
<tr>
<td>'symmetricismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1</td>
</tr>
<tr>
<td>'symmetriclogit'</td>
<td>( \frac{2}{1 + e^{x}} - 1 )</td>
</tr>
</tbody>
</table>

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

**Weights — Observation weights**

numeric vector | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or the name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response variable when training the model.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

The software normalizes Weights to sum up to the value of the prior probability in the respective class. For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see “Algorithms” on page 32-1693.

Data Types: double | single | char | string
Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the CVPartition, Holdout, KFold, or Leaveout name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single
**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k, then the software completes these steps:

1. Randomly partition the data into k sets.
2. For each set, reserve the set as validation data, and train the model using the other k – 1 sets.
3. Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout','on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other n – 1 observations.
2. Store the n compact, trained models in the cells of an n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Convergence Control Options**

**DeltaGradientTolerance — Tolerance for gradient difference**

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

If DeltaGradientTolerance is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- 1e-3 if the solver is SMO (for example, you set 'Solver','SMO')
- 0 if the solver is ISDA (for example, you set 'Solver','ISDA')

Example: 'DeltaGradientTolerance',1e-2
**Data Types: double | single**

**GapTolerance — Feasibility gap tolerance**

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If GapTolerance is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: 'GapTolerance',1e-2
Data Types: double | single

**IterationLimit — Maximal number of numerical optimization iterations**

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. Mdl.ConvergenceInfo contains convergence information.

Example: 'IterationLimit',1e8
Data Types: double | single

**KKTTolerance — Karush-Kuhn-Tucker complementarity conditions violation tolerance**

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690 violation tolerance, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar.

If KKTTolerance is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:
- 0 if the solver is SMO (for example, you set 'Solver','SMO')
- 1e-3 if the solver is ISDA (for example, you set 'Solver','ISDA')

Example: 'KKTTolerance',1e-2
Data Types: double | single

**ShrinkagePeriod — Number of iterations between reductions of active set**

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000
Data Types: double | single
Hyperparameter Optimization Options

**OptimizeHyperparameters — Parameters to optimize**

- Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:
  - 'none' — Do not optimize.
  - 'auto' — Use {'BoxConstraint','KernelScale'}.
  - 'all' — Optimize all eligible parameters.
  - String array or cell array of eligible parameter names.
  - Vector of optimizableVariable objects, typically the output of hyperparameters.

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

- 'none' — Do not optimize.
- 'auto' — Use {'BoxConstraint','KernelScale'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitcsvm by varying the parameters. For information about cross-validation loss see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair argument.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcsvm are:

- **BoxConstraint** — fitcsvm searches among positive values, by default log-scaled in the range [1e-3,1e3].
- **KernelScale** — fitcsvm searches among positive values, by default log-scaled in the range [1e-3,1e3].
- **KernelFunction** — fitcsvm searches among 'gaussian', 'linear', and 'polynomial'.
- **PolynomialOrder** — fitcsvm searches among integers in the range [2,4].
- **Standardize** — fitcsvm searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example:

```matlab
load fisheriris
params = hyperparameters('fitcsvm',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the **Verbose** field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the **ShowPlots** field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize SVM Classifier” on page 32-1667.
Example: 'auto'

**HyperparameterOptimizationOptions — Options for optimization structure**

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

Data Types: struct

Output Arguments

**Mdl** — Trained SVM classification model

ClassificationSVM model object | ClassificationPartitionedModel cross-validated model object

Trained SVM classification model, returned as a ClassificationSVM model object or ClassificationPartitionedModel cross-validated model object.

If you set any of the name-value pair arguments KFold, Holdout, Leaveout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated classifier. Otherwise, Mdl is a ClassificationSVM classifier.

To reference properties of Mdl, use dot notation. For example, enter Mdl.Alpha in the Command Window to display the trained Lagrange multipliers.

Limitations

- *fitcsvm* trains SVM classifiers for one-class or two-class learning applications. To train SVM classifiers using data with more than two classes, use *fitcecoc*.
- *fitcsvm* supports low-dimensional and moderate-dimensional data sets. For high-dimensional data sets, use *fitclinear* instead.

More About

**Box Constraint**

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

**Gram Matrix**

The Gram matrix of a set of *n* vectors \( \{x_1, \ldots, x_n; \ x_j \in \mathbb{R}^p\} \) is an *n*-by-*n* matrix with element \((j,k)\) defined as \(G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle\), an inner product of the transformed predictors using the kernel function \(\phi\).

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data \(X\). The dual formalization replaces the inner product of the observations in \(X\) with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.
Karush-Kuhn-Tucker (KKT) Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

\[
\begin{align*}
\alpha_j y_j f(x_j) - 1 + \xi_j &= 0 \\
\xi_j (C - \alpha_j) &= 0
\end{align*}
\]

for all \( j = 1, \ldots, n \), where \( f(x_j) = \phi(x_j)\beta + b \), \( \phi \) is a kernel function (see Gram matrix on page 32-1689), and \( \xi_j \) is a slack variable. If the classes are perfectly separable, then \( \xi_j = 0 \) for all \( j = 1, \ldots, n \).

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-1690. The objective is to minimize the dual expression

\[
0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)
\]

with respect to \( \alpha_1, \ldots, \alpha_n \), subject to

\[
\sum \alpha_j = n \nu
\]

and \( 0 \leq \alpha_j \leq 1 \) for all \( j = 1, \ldots, n \). The value of \( G(x_j, x_k) \) is in element \((j,k)\) of the Gram matrix on page 32-1689.

A small value of \( \nu \) leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of \( \nu \) leads to more support vectors and, therefore, a curvy, flexible decision boundary. The optimal value of \( \nu \) should be large enough to capture the data complexity and small enough to avoid overtraining. Also, \( 0 < \nu \leq 1 \).

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of \( \alpha_1, \ldots, \alpha_n \).

SVM classifiers that yield fewer support vectors for a given training set are preferred.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is
\[ f(x) = x'\beta + b, \]

where:

- \( x \) is an observation (corresponding to a row of \( X \)).
- The vector \( \beta \) contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to \( \text{Mdl.Beta} \)). For separable data, the optimal margin length is \( 2/\|\beta\| \).
- \( b \) is the bias term (corresponding to \( \text{Mdl.Bias} \)).

The root of \( f(x) \) for particular coefficients defines a hyperplane. For a particular hyperplane, \( f(z) \) is the distance from point \( z \) to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive (\( y = 1 \)) and negative (\( y = -1 \)) classes separate.

- For separable classes, the objective is to minimize \( \|\beta\| \) with respect to the \( \beta \) and \( b \) subject to \( y_j f(x_j) \geq 1 \), for all \( j = 1,..,n \). This is the primal formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (\( \xi_j \)) to penalize the objective function for observations that cross the margin boundary for their class. \( \xi_j = 0 \) for observations that do not cross the margin boundary for their class, otherwise \( \xi_j \geq 0 \).

The objective is to minimize \( 0.5\|\beta\|^2 + C \sum \xi_j \) with respect to the \( \beta \), \( b \), and \( \xi_j \) subject to \( y_j f(x_j) \geq 1 - \xi_j \) and \( \xi_j \geq 0 \) for all \( j = 1,..,n \), and for a positive scalar box constraint on page 32-1689 \( C \). This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces \( n \) coefficients \( a_1,..,a_n \) (corresponding to \( \text{Mdl.Alpha} \)). The dual formalizations for linear SVM are as follows:

- For separable classes, minimize

\[
0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} a_j a_k y_j y_k x_j x_k - \sum_{j=1}^{n} a_j
\]

with respect to \( a_1,..,a_n \), subject to \( \sum a_j y_j = 0 \), \( a_j \geq 0 \) for all \( j = 1,..,n \), and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition \( 0 \leq a_j \leq C \) for all \( j = 1,..,n \).

The resulting score function is

\[
\hat{f}(x) = \sum_{j=1}^{n} \hat{a}_j y_j x_j' x_j + \hat{b}.
\]

\( \hat{b} \) is the estimate of the bias and \( \hat{a}_j \) is the \( j \)th estimate of the vector \( \hat{\alpha}, j = 1,..,n \). Written this way, the score function is free of the estimate of \( \beta \) as a result of the primal formalization.

The SVM algorithm classifies a new observation \( z \) using \( \text{sign} \{ \hat{f}(z) \} \).
In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^{n} \alpha_j$$

with respect to \( \alpha_1, \ldots, \alpha_n \), subject to \( \sum \alpha_j y_j = 0 \), \( 0 \leq \alpha_j \leq C \) for all \( j = 1, \ldots, n \), and the KKT complementarity conditions. \( G(x_k, x_j) \) are elements of the Gram matrix on page 32-1689. The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^{n} \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-145, [1], and [3].

**Tips**

- Unless your data set is large, always try to standardize the predictors (see Standardize). Standardization makes predictors insensitive to the scales on which they are measured.
- It is a good practice to cross-validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- For one-class learning:
  - The default setting for the name-value pair argument Alpha can lead to long training times. To speed up training, set Alpha to a vector mostly composed of 0s.
  - Set the name-value pair argument Nu to a value closer to 0 to yield fewer support vectors and, therefore, a smoother but crude decision boundary.
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set BoxConstraint to a large value. This action increases the training time.
- For optimal training time, set CacheSize as high as the memory limit your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active set using the name-value pair argument 'ShrinkagePeriod'. It is a good practice to specify 'ShrinkagePeriod', 1000.
- Duplicate observations that are far from the decision boundary do not affect convergence. However, just a few duplicate observations that occur near the decision boundary can slow down convergence considerably. To speed up convergence, specify 'RemoveDuplicates', true if:
  - Your data set contains many duplicate observations.
  - You suspect that a few duplicate observations fall near the decision boundary.

To maintain the original data set during training, fitcsvm must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify true for data sets containing few duplicates, then fitcsvm consumes close to double the memory of the original data.

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.
Algorithms

• For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-1690 and “Understanding Support Vector Machines” on page 18-145.

• NaN, <undefined>, empty character vector (''), empty string ('"'), and <missing> values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.

• `fitcsvm` removes observations that have zero weight or prior probability.

• For two-class learning, if you specify the cost matrix C (see `Cost`), then the software updates the class prior probabilities \( p \) (see `Prior`) to \( p_c \) by incorporating the penalties described in C. Specifically, `fitcsvm` completes these steps:

1. Compute \( p_c^* = pC \).

2. Normalize \( p_c^* \) so that the updated prior probabilities sum to 1.

\[
p_c = \frac{1}{\sum_{j=1}^{K} p_{c,j}^*} p_{c,j}^*.
\]

\( K \) is the number of classes.

3. Reset the cost matrix to the default

\[
C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.
\]

4. Remove observations from the training data corresponding to classes with zero prior probability.

• For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation \( j \) in class \( k \) is

\[
w_j^* = \frac{w_j}{\sum_{j \in \text{Class } k} w_j} p_{c,k}.
\]

\( w_j \) is the normalized weight for observation \( j \); \( p_{c,k} \) is the updated prior probability of class \( k \) (see previous bullet).

• For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation \( j \) is

\[
C_j = n C_0 w_j^*.
\]

\( n \) is the training sample size, \( C_0 \) is the initial box constraint (see the `BoxConstraint` name-value pair argument), and \( w_j^* \) is the total weight of observation \( j \) (see previous bullet).
• If you set 'Standardize', true and the 'Cost', 'Prior', or 'Weights' name-value pair argument, then fitcsvm standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, fitcsvm standardizes predictor \( j \) (\( x_j \)) using

\[
x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.
\]

\[
\mu_j^* = \frac{1}{\sum_k w_k x_{jk}} \sum_k w_k x_{jk}.
\]

\( x_{jk} \) is observation \( k \) (row) of predictor \( j \) (column).

\[
(\sigma_j^*)^2 = \frac{v_1}{v_1 - v_2} \sum_k w_k (x_{jk} - \mu_j^*)^2.
\]

\[
v_1 = \sum_j w_j^*.
\]

\[
v_2 = \sum_j (w_j^*)^2.
\]

• Assume that \( p \) is the proportion of outliers that you expect in the training data, and that you set 'OutlierFraction', \( p \).

• For one-class learning, the software trains the bias term such that 100\( p \)% of the observations in the training data have negative scores.

• The software implements robust learning for two-class learning. In other words, the software attempts to remove 100\( p \)% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

• If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.

• The PredictorNames property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then PredictorNames is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.

• The ExpandedPredictorNames property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then ExpandedPredictorNames is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

• Similarly, the Beta property stores one beta coefficient for each predictor, including the dummy variables.

• The SupportVectors property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are \( m \) support vectors and three predictors, one of which is a categorical variable with three levels. Then SupportVectors is an \( n \)-by-5 matrix.

• The X property stores the training data as originally input and does not include the dummy variables. When the input is a table, X contains only the columns used as predictors.
• For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
  
• For a variable with \( k \) ordered levels, the software creates \( k - 1 \) dummy variables. The \( j \)th dummy variable is -1 for levels up to \( j \), and +1 for levels \( j + 1 \) through \( k \).

• The names of the dummy variables stored in the \texttt{ExpandedPredictorNames} property indicate the first level with the value +1. The software stores \( k - 1 \) additional predictor names for the dummy variables, including the names of levels 2, 3, ..., \( k \).

• All solvers implement \( L_1 \) soft-margin minimization.

• For one-class learning, the software estimates the Lagrange multipliers, \( \alpha_1, \ldots, \alpha_n \), such that

\[
\sum_{j=1}^{n} \alpha_j = n\nu.
\]

\section*{Extended Capabilities}

\textbf{Automatic Parallel Support}

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the \texttt{’UseParallel’} option to \texttt{true}.

To perform parallel hyperparameter optimization, use the \texttt{’HyperparameterOptions’}, \texttt{struct(’UseParallel’,true)} name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.
For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**GPU Arrays**
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'KernelFunction' option must not specify a custom kernel.
- The 'Solver' option can be set to only 'SMO'.
- The 'OutlierFraction' option is not supported.
- The 'Alpha' option must specify a feasible starting point.
- The 'OptimizeHyperparameters' option is not supported.
- One-class classification is not supported. The labels must contain two different classes.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

**Introduced in R2014a**
**fitctree**

Fit binary decision tree for multiclass classification

**Syntax**

```
tree = fitctree(Tbl,ResponseVarName)
tree = fitctree(Tbl,formula)
tree = fitctree(Tbl,Y)
tree = fitctree(X,Y)
tree = fitctree(____,Name,Value)
```

**Description**

- `tree = fitctree(Tbl,ResponseVarName)` returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `Tbl.ResponseVarName`. The returned binary tree splits branching nodes based on the values of a column of `Tbl`.

- `tree = fitctree(Tbl,formula)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

- `tree = fitctree(Tbl,Y)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

- `tree = fitctree(X,Y)` returns a fitted binary classification decision tree based on the input variables contained in matrix `X` and output `Y`. The returned binary tree splits branching nodes based on the values of a column of `X`.

- `tree = fitctree(____,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

**Examples**

**Grow a Classification Tree**

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)
```

```
tc =
    ClassificationTree
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'b'  'g'}
```
ScoreTransform: 'none'
NumObservations: 351

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the MaxNumSplits, MinLeafSize, or MinParentSize name-value pair parameters. fitctree grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the ionosphere data set.

load ionosphere

The default values of the tree depth controllers for growing classification trees are:

- \( n - 1 \) for MaxNumSplits. \( n \) is the training sample size.
- 1 for MinLeafSize.
- 10 for MinParentSize.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross-validate the model by using 10-fold cross-validation.

rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
view(MdlDefault.Trained{1}, 'Mode', 'graph')
The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model by using 10-fold cross-validation.

```matlab
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```
Compare the cross-validation classification errors of the models.

```matlab
classErrorDefault = kfoldLoss(MdlDefault)
classErrorDefault = 0.1140
classError7 = kfoldLoss(Mdl7)
classError7 = 0.1254
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

**Optimize Classification Tree**

This example shows how to optimize hyperparameters automatically using `fitctree`. The example uses Fisher's iris data.

Load Fisher's iris data.

```matlab
load fisheriris
```
Optimize the cross-validation loss of the classifier, using the data in `meas` to predict the response in `species`.

```matlab
X = meas;
Y = species;
Mdl = fitctree(X,Y,'OptimizeHyperparameters','auto')
```

- Max: 4356
hours_per_week: 32561x1 double

Values:

Min   1
Median 40
Max   99

salary: 32561x1 categorical

Values:

<=50K 24720
>50K 7841

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

Mdl = fitctree(X, 'salary', 'PredictorSelection', 'curvature', ...
                'Surrogate', 'on');

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
In this case, `capital_gain` is the most important predictor, followed by `education_num`.

**Optimize Classification Tree on Tall Array**

This example shows how to optimize hyperparameters of a classification tree automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat ‘NA’ values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.

```matlab
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek','DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

![Predictor Importance Estimates](image)

Predictors

In this case, `capital_gain` is the most important predictor, followed by `education_num`.

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

Y = tt.DepDelay > 10 % Class labels

Y =

Remove rows in X and Y that contain missing data.
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);

Standardize the predictor variables.
Z = zscore(X);

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'MinLeafSize' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'MinLeafSize'). For reproducibility, use the 'expected-improvement-plus' acquisition function and set the seeds of the random number generators using rng and tallrng. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

rng('default')

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If Tbl contains the response variable, and you want to use all remaining variables in Tbl as predictors, then specify the response variable by using ResponseVarName.

If Tbl contains the response variable, and you want to use only a subset of the remaining variables in Tbl as predictors, then specify a formula by using formula.

If Tbl does not contain the response variable, then specify a response variable by using Y. The length of the response variable and the number of rows in Tbl must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the ClassNames name-value pair argument.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.
The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

`cellfun(@isvarname,Tbl.Properties.VariableNames)`

If the variable names in Tbl are not valid, then convert them by using the `matlab.lang.makeValidName` function.

`Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);`

Data Types: char | string

**Y — Class labels**

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

When fitting the tree, `fitctree` considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. `fitctree` does not use observations with missing values for Y in the fit.

For numeric Y, consider fitting a regression tree using `fitrtree` instead.

Data Types: single | double | categorical | logical | char | string | cell

**X — Predictor data**

numeric matrix

Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

`fitctree` considers NaN values in X as missing values. `fitctree` does not use observations with all missing values for X in the fit. `fitctree` uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Note** You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.
Example: ‘CrossVal','on','MinLeafSize',40 specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

Model Parameters

AlgorithmForCategorical — Algorithm for best categorical predictor split

’Exact’ | ’PullLeft’ | ’PCA’ | ’OVAbyClass’

Algorithm to find the best split on a categorical predictor with C categories for data and K ≥ 3 classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Exact'</td>
<td>Consider all 2^{C-1} - 1 combinations.</td>
</tr>
<tr>
<td>’PullLeft’</td>
<td>Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.</td>
</tr>
<tr>
<td>’PCA’</td>
<td>Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all C - 1 splits.</td>
</tr>
<tr>
<td>’OVAbyClass’</td>
<td>Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.</td>
</tr>
</tbody>
</table>

fitctree automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For K = 2 classes, fitctree always performs the exact search. To specify a particular algorithm, use the 'AlgorithmForCategorical' name-value pair argument.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-25.

Example: ‘AlgorithmForCategorical’,’PCA'

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of ‘CategoricalPredictors' and one of the values in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A true entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must match the entries in PredictorNames. Pad the names with extra blanks so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
<td>Each element in the array is the name of a predictor variable. The names must match the entries in PredictorNames.</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (Tbl), fitctree assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (X), fitctree assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

**ClassNames — Names of classes to use for training**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Cost of misclassification**
square matrix | structure
Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $\text{Cost}(i,j)$ is the cost of classifying a point into class $j$ if its true class is $i$ (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of $\text{Cost}$, also specify the $\text{ClassNames}$ name-value pair argument.
- Structure $S$ having two fields: $S\text{.ClassNames}$ containing the group names as a variable of the same data type as $Y$, and $S\text{.ClassificationCosts}$ containing the cost matrix.

The default is $\text{Cost}(i,j)=1$ if $i\neq j$, and $\text{Cost}(i,j)=0$ if $i=j$.

Data Types: single | double | struct

**MaxDepth — Maximum tree depth**

positive integer

Maximum tree depth, specified as the comma-separated pair consisting of 'MaxDepth' and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of fitctree takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

**Note** This option applies only when you use fitctree on tall arrays. See Tall Arrays on page 32-1794 for more information.

**MaxNumCategories — Maximum category levels**

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. fitctree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxNumCategories levels in the split node. Otherwise, fitctree finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: 'MaxNumCategories',8

**MaxNumSplits — Maximal number of decision splits**

$\text{size}(X,1) - 1$ (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. fitctree splits MaxNumSplits or fewer branch nodes. For more details on splitting behavior, see Algorithms on page 32-1791.

Example: 'MaxNumSplits',5

Data Types: single | double

**MergeLeaves — Leaf merge flag**

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

32-1777
If MergeLeaves is 'on', then fitctree:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node.
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree.

Otherwise, fitctree does not merge leaves.

Example: 'MergeLeaves','off'

MinLeafSize — Minimum number of leaf node observations
1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize, 2*MinLeafSize).

Example: 'MinLeafSize',3

Data Types: single | double

MinParentSize — Minimum number of branch node observations
10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitctree uses the setting that gives larger leaves: MinParentSize = max(MinParentSize, 2*MinLeafSize).

Example: 'MinParentSize',8

Data Types: single | double

NumBins — Number of bins for numeric predictors
[](empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then fitctree bins the predictor into u bins.
  - fitctree does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the BinEdges property.

Example: 'NumBins',50
Data Types: single | double

**NumVariablesToSample — Number of predictors to select at random for each split**

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' as 'all'. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify 'Reproducible',true.

Example: 'NumVariablesToSample',3
Data Types: char | string | single | double

**PredictorNames — Predictor variable names**

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitctree uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

**PredictorSelection — Algorithm used to select the best split predictor**

'allsplits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'allsplits'</td>
<td>Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].</td>
</tr>
<tr>
<td>'curvature'</td>
<td>Curvature test on page 32-1788 — Selects the split predictor that minimizes the p-value of chi-square tests of independence between each predictor and the response [4]. Training speed is similar to standard CART.</td>
</tr>
<tr>
<td>'interaction-curvature'</td>
<td>Interaction test on page 32-1790 — Chooses the split predictor that minimizes the p-value of chi-square tests of independence between each predictor and the response, and that minimizes the p-value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.</td>
</tr>
</tbody>
</table>

For 'curvature' and 'interaction-curvature', if all tests yield p-values greater than 0.05, then fitctree stops splitting nodes.

**Tip**

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance` and “Introduction to Feature Selection” on page 15-49.
  - Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
  - Prediction speed is unaffected by the value of 'PredictorSelection'.

For details on how fitctree selects split predictors, see “Node Splitting Rules” on page 32-1791 and “Choose Split Predictor Selection Technique” on page 19-14.

Example: 'PredictorSelection','curvature'

**Prior — Prior probabilities**

- 'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- Character vector or string scalar.
  
- 'empirical' determines class probabilities from class frequencies in the response variable in Y or Tbl. If you pass observation weights, fitctree uses the weights to compute the class probabilities.
• 'uniform' sets all class probabilities to be equal.
• Vector (one scalar value for each class). To specify the class order for the corresponding elements of 'Prior', also specify the ClassNames name-value pair argument.
• Structure S with two fields.
  • S.ClassNames contains the class names as a variable of the same type as the response variable in Y or Tbl.
  • S.ClassProbs contains a vector of corresponding probabilities.

If you set values for both 'Weights' and 'Prior', fitctree normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Example: 'Prior','uniform'

Data Types: char | string | single | double | struct

Prune — Flag to estimate optimal sequence of pruned subtrees
'on' (default) | 'off'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If Prune is 'on', then fitctree grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, fitctree grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained ClassificationTree model, pass it to prune.

Example: 'Prune','off'

PruneCriterion — Pruning criterion
'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'error' or 'impurity'.

If you specify 'impurity', then fitctree uses the impurity measure specified by the 'SplitCriterion' name-value pair argument.

For details, see "Impurity and Node Error" on page 32-1789.

Example: 'PruneCriterion','impurity'

Reproducible — Flag to enforce reproducibility
false (logical 0) (default) | true (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of 'Reproducible' and either false or true.

If 'NumVariablesToSample' is not 'all', then the software selects predictors at random for each split. To reproduce the random selections, you must specify 'Reproducible',true and set the seed of the random number generator by using rng. Note that setting 'Reproducible' to true can slow down training.

Example: 'Reproducible',true

Data Types: logical
**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar representing the name of the response variable.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName','IrisType'

Data Types: char | string

**ScoreTransform — Score transformation**

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'doublelogit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'invlogit'</td>
<td>( \log\left(\frac{x}{1-x}\right) )</td>
</tr>
<tr>
<td>'ismax'</td>
<td>Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0</td>
</tr>
<tr>
<td>'logit'</td>
<td>( \frac{1}{1 + e^{-x}} )</td>
</tr>
<tr>
<td>'none' or 'identity'</td>
<td>( x ) (no transformation)</td>
</tr>
</tbody>
</table>
| 'sign'        | -1 for \( x < 0 \)  
               | 0 for \( x = 0 \)  
               | 1 for \( x > 0 \)              |
| 'symmetric'   | \( 2x - 1 \)                                    |
| 'symmetricismax' | Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1 |
| 'symmetriclogit' | \( \frac{2}{1 + e^{-x}} - 1 \)            |

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform','logit'

Data Types: char | string | function_handle

**SplitCriterion — Split criterion**

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

For details, see “Impurity and Node Error” on page 32-1789.

Example: 'SplitCriterion','deviance'
**Surrogate — Surrogate decision splits flag**

'Surrogate' is specified as a comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- **'on'**: fitctree finds at most 10 surrogate splits at each branch node.
- **'all'**: fitctree finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- **Positive integer value**: fitctree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 32-1791.

Example: 'Surrogate','on'

Data Types: single | double | char | string

**Weights — Observation weights**

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in Tbl. The software weights the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors when training the model.

fitctree normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: single | double | char | string

**Cross-Validation Options**

**CrossVal — Flag to grow cross-validated decision tree**

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If 'on', fitctree grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the crossval method.

Example: 'CrossVal','on'

**CVPartition — Partition for cross-validated tree**

cvpartition object
Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Holdout — Fraction of data for holdout validation**

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: ‘Holdout’, 0.1

Data Types: single | double

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', 5, then the software:

1. Randomly partitions the data into 5 sets
2. For each set, reserves the set as validation data, and trains the model using the other 5 - 1 sets
3. Stores the 5 compact, trained models in the cells of a 5-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: CVPartition, Holdout, KFold, or Leaveout.

Example: ‘KFold’, 8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Specify 'on' to use leave-one-out cross-validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: ‘Leaveout’, 'on'

Hyperparameter Optimization Options

**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects
Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of optimizableVariable objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for fitctree by varying the parameters. For information about cross-validation loss (albeit in a different context), see "Classification Loss" on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitctree are:

- **MaxNumSplits** — fitctree searches among integers, by default log-scaled in the range \([1, \max(2, \text{NumObservations}-1)]\).
- **MinLeafSize** — fitctree searches among integers, by default log-scaled in the range \([1, \max(2, \text{floor(NumObservations/2)})]\).
- **SplitCriterion** — For two classes, fitctree searches among 'gdi' and 'deviance'. For three or more classes, fitctree also searches among 'twoing'.
- **NumVariablesToSample** — fitctree does not optimize over this hyperparameter. If you pass NumVariablesToSample as a parameter name, fitctree simply uses the full number of predictors. However, fitcensemble does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitctree',meas,species);
params(1).Range = [1,30];
```

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see "Optimize Classification Tree" on page 32-1701.

*Example: 'auto'*

HyperparameterOptimizationOptions — Options for optimization
structure
Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
</table>
| **Optimizer**               | • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt.  
• 'gridsearch' — Use grid search with NumGridDivisions values per dimension.  
• 'randomsearch' — Search at random among MaxObjectiveEvaluations points.  
'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command sortrows(Mdl.HyperparameterOptimizationResults). | 'bayesopt'       |
| **AcquisitionFunctionName** | • 'expected-improvement-per-second-plus'  
• 'expected-improvement'  
• 'expected-improvement-plus'  
• 'expected-improvement-per-second'  
• 'lower-confidence-bound'  
• 'probability-of-improvement'  
Acquisition functions whose names include per-second do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include plus modify their behavior when they are overexploiting an area. For more details, see "Acquisition Function Types" on page 10-3. | 'expected-improvement-per-second-plus' |
<p>| <strong>MaxObjectiveEvaluations</strong> | Maximum number of objective function evaluations.                     | 30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch' |
| <strong>MaxTime</strong>                 | Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations. | Inf              |
| <strong>NumGridDivisions</strong>        | For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables. | 10               |</p>

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct
Output Arguments

tree — Classification tree
classification tree object

Classification tree, returned as a classification tree object.

Using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method. Instead, use kfoldPredict to predict responses for observations not used for training.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

More About

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

1. If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2. For each level in the partitioned predictor \( j = 1, \ldots, J \) and class in the response \( k = 1, \ldots, K \), compute the weighted proportion of observations in class k

\[
\hat{\pi}_{jk} = \frac{1}{n} \sum_{i=1}^{n} I\{y_i = k\} w_i.
\]

\( w_i \) is the weight of observation \( i \), \( \sum w_i = 1 \), \( I \) is the indicator function, and \( n \) is the sample size. If all observations have the same weight, then \( \hat{\pi}_{jk} = \frac{n_{jk}}{n} \), where \( n_{jk} \) is the number of observations in level \( j \) of the predictor that are in class \( k \).

3. Compute the test statistic

\[
t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \left( \frac{\hat{\pi}_{jk} - \hat{\pi}_{j+k}}{\hat{\pi}_{j+k}} \right)^2
\]

\( \hat{\pi}_{j+k} = \sum_{k} \hat{\pi}_{jk} \), that is, the marginal probability of observing the predictor at level \( j \). \( \hat{\pi}_{+k} = \sum_{j} \hat{\pi}_{jk} \), that is the marginal probability of observing class \( k \). If \( n \) is large enough, then \( t \) is distributed as a \( \chi^2 \) with \( (K-1)(J-1) \) degrees of freedom.

4. If the \( p \)-value for the test is less than 0.05, then reject the null hypothesis that there is no association between \( x \) and \( y \).

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.
The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant p-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

**Note** If levels of a predictor are pure for a particular class, then fitctree merges those levels. Therefore, in step 3 of the algorithm, J can be less than the actual number of levels in the predictor. For example, if x has 4 levels, and all observations in bins 1 and 2 belong to class 1, then those levels are pure for class 1. Consequently, fitctree merges the observations in bins 1 and 2, and J reduces to 3.

For more details on how the curvature test applies to growing classification trees, see “Node Splitting Rules” on page 32-1791 and [4].

**Impurity and Node Error**

ClassificationTree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the SplitCriterion name-value pair argument:

- **Gini's Diversity Index (gdi)** — The Gini index of a node is
  \[ 1 - \sum_i p^2(i), \]
  where the sum is over the classes i at the node, and p(i) is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- **Deviance ('deviance')** — With p(i) defined the same as for the Gini index, the deviance of a node is
  \[ -\sum_i p(i) \log_2 p(i). \]
  A pure node has deviance 0; otherwise, the deviance is positive.

- **Twoing rule ('twoing')** — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let \( L(i) \) denote the fraction of members of class i in the left child node after a split, and \( R(i) \) denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize
  \[ P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2, \]
  where \( P(L) \) and \( P(R) \) are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- **Node error** — The node error is the fraction of misclassified classes at a node. If \( j \) is the class with the largest number of training samples at a node, the node error is
  \[ 1 - p(j). \]
**Interaction Test**

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables $x_1$ and $x_2$ with respect to $y$ is conducted using this process.

1. If $x_1$ or $x_2$ is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.

2. Create the nominal variable $z$ with $J = J_1 J_2$ levels that assigns an index to observation $i$ according to which levels of $x_1$ and $x_2$ it belongs. Remove any levels of $z$ that do not correspond to any observations.

3. Conduct a curvature test on page 32-1788 between $z$ and $y$.

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-1788, “Node Splitting Rules” on page 32-1791 and [3].

**Predictive Measure of Association**

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-1791 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose $x_j$ and $x_k$ are predictor variables $j$ and $k$, respectively, and $j \neq k$. At node $t$, the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$
\lambda_{jk} = \frac{\min(P_L, P_R) - \left(1 - P_{LjLk} - P_{RjRk}\right)}{\min(P_L, P_R)}.
$$

- $P_L$ is the proportion of observations in node $t$, such that $x_j < u$. The subscript $L$ stands for the left child of node $t$.
- $P_R$ is the proportion of observations in node $t$, such that $x_j \geq u$. The subscript $R$ stands for the right child of node $t$.
- $P_{LjLk}$ is the proportion of observations at node $t$, such that $x_j < u$ and $x_k < v$.
- $P_{RjRk}$ is the proportion of observations at node $t$, such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for $x_j$ or $x_k$ do not contribute to the proportion calculations.

$\lambda_{jk}$ is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$. 
**Surrogate Decision Splits**

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-1791.

**Tip**

- By default, Prune is ‘on’. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to prune.
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

**Node Splitting Rules**

fitctree uses these processes to determine how to split node \( t \).

- For standard CART (that is, if PredictorSelection is ‘allpairs’) and for all predictors \( x_i, i = 1, \ldots, p \):
  1. fitctree computes the weighted impurity of node \( t, i \). For supported impurity measures, see SplitCriterion.
  2. fitctree estimates the probability that an observation is in node \( t \) using

\[
P(T) = \sum_{j \in T} w_j.
\]

\( w_j \) is the weight of observation \( j \), and \( T \) is the set of all observation indices in node \( t \). If you do not specify Prior or Weights, then \( w_j = 1/n \), where \( n \) is the sample size.

- fitctree sorts \( x_i \) in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. fitctree stores any indices corresponding to missing values in the set \( T_\cup \), which is the unsplit set.

- fitctree determines the best way to split node \( t \) using \( x_i \) by maximizing the impurity gain (\( \Delta I \)) over all splitting candidates. That is, for all splitting candidates in \( x_i \):
  
  a. fitctree splits the observations in node \( t \) into left and right child nodes (\( t_L \) and \( t_R \), respectively).
  b. fitctree computes \( \Delta I \). Suppose that for a particular splitting candidate, \( t_L \) and \( t_R \) contain observation indices in the sets \( T_L \) and \( T_R \), respectively.

- If \( x_i \) does not contain any missing values, then the impurity gain for the current splitting candidate is
\[ \Delta I = P(T)_{it} - P(T_L)_{itL} - P(T_R)_{itR}. \]

- If \( x_i \) contains missing values then, assuming that the observations are missing at random, the impurity gain is

\[ \Delta I_U = P(T - T_U)_{it} - P(T_L)_{itL} - P(T_R)_{itR}. \]

\( T - T_U \) is the set of all observation indices in node \( t \) that are not missing.

- If you use surrogate decision splits on page 32-1791, then:
  1. \texttt{fitctree} computes the predictive measures of association on page 32-1790 between the decision split \( x_j < u \) and all possible decision splits \( x_k < v, j \neq k \).
  2. \texttt{fitctree} sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
  3. \texttt{fitctree} decides the child node assignments for observations with a missing value for \( x_i \) using the surrogate split. If the surrogate predictor also contains a missing value, then \texttt{fitctree} uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for \texttt{fitctree} to split two different observations at node \( t \) using two different surrogate splits. For example, suppose the predictors \( x_1 \) and \( x_2 \) are the best and second best surrogates, respectively, for the predictor \( x_i \) \( i \notin \{1,2\} \), at node \( t \). If observation \( m \) of predictor \( x_i \) is missing (i.e., \( x_{mi} \) is missing), but \( x_{m1} \) is not missing, then \( x_1 \) is the surrogate predictor for observation \( x_{mi} \). If observations \( x_{(m+1)1} \) and \( x_{(m+1)2}, I \) are missing, but \( x_{(m+1)2} \) is not missing, then \( x_2 \) is the surrogate predictor for observation \( m + 1 \).
  4. \texttt{fitctree} uses the appropriate impurity gain formula. That is, if \texttt{fitctree} fails to assign all missing observations in node \( t \) to children nodes using surrogate splits, then the impurity gain is \( \Delta I_U \). Otherwise, \texttt{fitctree} uses \( \Delta I \) for the impurity gain.

\texttt{fitctree} chooses the candidate that yields the largest impurity gain.

\texttt{fitctree} splits the predictor variable at the cut point that maximizes the impurity gain.

- For the curvature test (that is, if \texttt{PredictorSelection} is 'curvature'):
  1. \texttt{fitctree} conducts curvature tests on page 32-1788 between each predictor and the response for observations in node \( t \).

  - If all \( p \)-values are at least 0.05, then \texttt{fitctree} does not split node \( t \).
  - If there is a minimal \( p \)-value, then \texttt{fitctree} chooses the corresponding predictor to split node \( t \).
  - If more than one \( p \)-value is zero due to underflow, then \texttt{fitctree} applies standard CART to the corresponding predictors to choose the split predictor.

  2. If \texttt{fitctree} chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

- For the interaction test (that is, if \texttt{PredictorSelection} is 'interaction-curvature'):
  1. For observations in node \( t \), \texttt{fitctree} conducts curvature tests on page 32-1788 between each predictor and the response and interaction tests on page 32-1790 between each pair of predictors and the response.
• If all \( p \)-values are at least 0.05, then \texttt{fitctree} does not split node \( t \).
• If there is a minimal \( p \)-value and it is the result of a curvature test, then \texttt{fitctree} chooses the corresponding predictor to split node \( t \).
• If there is a minimal \( p \)-value and it is the result of an interaction test, then \texttt{fitctree} chooses the split predictor using standard CART on the corresponding pair of predictors.
• If more than one \( p \)-value is zero due to underflow, then \texttt{fitctree} applies standard CART to the corresponding predictors to choose the split predictor.

2 If \texttt{fitctree} chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

• If \texttt{MergeLeaves} is 'on' and \texttt{PruneCriterion} is 'error' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.
• To accommodate \texttt{MaxNumSplits}, \texttt{fitctree} splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds \texttt{MaxNumSplits}, \texttt{fitctree} follows this procedure:

1 Determine how many branch nodes in the current layer must be unsplit so that there are at most \texttt{MaxNumSplits} branch nodes.
2 Sort the branch nodes by their impurity gains.
3 Unsplit the number of least successful branches.
4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.
• The software splits branch nodes layer by layer until at least one of these events occurs:

  • There are \texttt{MaxNumSplits} branch nodes.
  • A proposed split causes the number of observations in at least one branch node to be fewer than \texttt{MinParentSize}.
  • A proposed split causes the number of observations in at least one leaf node to be fewer than \texttt{MinLeafSize}.
  • The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see \texttt{PruneCriterion}), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
  • For values 'curvature' or 'interaction-curvature' of \texttt{PredictorSelection}, all tests yield \( p \)-values greater than 0.05.

\texttt{MaxNumSplits} and \texttt{MinLeafSize} do not affect splitting at their default values. Therefore, if you set '\texttt{MaxNumSplits}', splitting might stop due to the value of \texttt{MinParentSize}, before \texttt{MaxNumSplits} splits occur.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `tree = fitctree(Tbl,Y)
  - `tree = fitctree(X,Y)
  - `tree = fitctree(___,Name,Value)
  - `[tree,FitInfo,HyperparameterOptimizationResults] = fitctree(___,Name,Value)` — `fitctree` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the 'OptimizeHyperparameters' name-value pair argument.

- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.

- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

  `HyperparameterOptimizationResults` is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty at the time you create the model. The values in 'HyperparameterOptimizationResults' depend on the value you specify for the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model.

- If you specify 'bayesopt' (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.

- If you specify 'gridsearch' or 'randomsearch', then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

- Supported name-value pair arguments, and any differences, are:
  - 'AlgorithmForCategorical'
CategoricalPredictors'
'ClassNames'
'Cost'
'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitctree(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
'MaxNumCategories'
'MaxNumSplits' — for tall optimization, fitctree searches among integers, by default log-scaled in the range \([1,\max(2,\min(10000,\text{NumObservations}-1))]\).
'MergeLeaves'
'MinLeafSize'
'MinParentSize'
'NumVariablesToSample'
'OptimizeHyperparameters'
'PredictorNames'
'Prior'
'ResponseName'
'ScoreTransform'
'SplitCriterion'
'Weights'
This additional name-value pair argument is specific to tall arrays:
'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of fitctree takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics
"Splitting Categorical Predictors in Classification Trees" on page 19-25

Introduced in R2014a
**fitglm**

Create generalized linear regression model

**Syntax**

```matlab
mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm(____,modelspec)
mdl = fitglm(____,Name,Value)
```

**Description**

`mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(____,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(____,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

**Examples**

**Fit a Logistic Regression Model**

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```matlab
load hospital
dsa = hospital;
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```matlab
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```matlab
mdl = fitglm(dsa,modelspec,'Distribution','binomial')
```

```matlab
mdl = Generalized linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
```
Distribution = Binomial

Estimated Coefficients:

<table>
<thead>
<tr>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>-6.0492</td>
<td>19.749</td>
<td>-0.3063</td>
</tr>
<tr>

<td>-2.2859</td>
<td>12.424</td>
<td>-0.18399</td>
</tr>
<tr>
<td>Age</td>
<td>0.11691</td>
<td>0.50977</td>
<td>0.22934</td>
</tr>
<tr>
<td>Weight</td>
<td>0.031109</td>
<td>0.15208</td>
<td>0.20455</td>
</tr>
<tr>
<td>Sex_Male:Age</td>
<td>0.020734</td>
<td>0.20681</td>
<td>0.10025</td>
</tr>
<tr>
<td>Sex_Male:Weight</td>
<td>0.01216</td>
<td>0.053168</td>
<td>0.22871</td>
</tr>
<tr>
<td>Age:Weight</td>
<td>-0.00071959</td>
<td>0.0038964</td>
<td>-0.18468</td>
</tr>
</tbody>
</table>

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large p-value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```matlab
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6])*.4+.2+.3 + 1);
y = poissrnd(mu);

mdl = fitglm(X,y,'linear','Distribution','poisson')
mdl =
Generalized linear regression model:  
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7  
Distribution = Poisson

Estimated Coefficients:

<table>
<thead>
<tr>
<th>Estimate</th>

<td>0.34267</td>
<td>0.056778</td>
<td>6.0352</td>
</tr>
<tr>
<td>x7</td>
<td>0.04316</td>
<td>0.06146</td>
<td>0.70225</td>
</tr>
</tbody>
</table>
```
100 observations, 92 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22

The p-values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables x1, x3, and |x6| are statistically significant.

**Input Arguments**

**tbl** — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

- By default, `fitglm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

**X** — Predictor variables

matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.
By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in \( X \).

Data Types: `single` | `double`

**\( y \) — Response variable**  
vector | matrix

Response variable, specified as a vector or matrix.

- If `'Distribution'` is not `'binomial'`, then \( y \) must be an \( n \)-by-1 vector, where \( n \) is the number of observations. Each entry in \( y \) is the response for the corresponding row of \( X \). The data type must be single or double.
- If `'Distribution'` is `'binomial'`, then \( y \) can be an \( n \)-by-1 vector or \( n \)-by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

**modelspec — Model specification**  
'linear' (default) | character vector or string scalar naming the model | t-by-(\( p + 1 \)) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification, specified as one of these values.

- A character vector or string scalar naming the model.

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear term for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear term for each predictor; and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept term and linear and squared terms for each predictor.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept term, linear and squared terms for each predictor; and all products of pairs of distinct predictors.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree ( i ) in the first predictor, degree ( j ) in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and ( x_1 ), ( x_2 ), ( x_1^2 ), ( x_2^2 ), ( x_1 \cdot x_2 ), and ( x_1^3 \cdot x_2^2 ) terms, where ( x_1 ) and ( x_2 ) are the first and second predictors, respectively.</td>
</tr>
</tbody>
</table>

- A t-by-(\( p + 1 \)) matrix, or a "Terms Matrix" on page 32-1805, specifying terms in the model, where \( t \) is the number of terms and \( p \) is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
• A character vector or string scalar representing a “Formula” on page 32-1806 in the form
  \[ Y \sim \text{terms} \],
  where the terms are in “Wilkinson Notation” on page 32-1806. The variable names in the formula
  must be valid MATLAB identifiers.

  The software determines the order of terms in a fitted model by using the order of terms in \( tbl \) or \( X \). Therefore, the order of terms in the model can be different from the order of terms in the
  specified formula.

Example: 'quadratic'

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and
**Value** is the corresponding value. You can specify several name and
value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

Example: 'Distribution','normal','link','probit','Exclude',[23,59] specifies that
the distribution of the response is normal, and instructs \texttt{fitglm} to use the probit link function and
exclude the 23rd and 59th observations from the fit.

**BinomialSize — Number of trials for binomial distribution**

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated
pair consisting of 'BinomialSize' and the variable name in \( tbl \), a numeric scalar, or a numeric
vector of the same length as the response. This is the parameter \( n \) for the fitted binomial distribution.
**BinomialSize** applies only when the Distribution parameter is 'binomial'.

If **BinomialSize** is a scalar value, that means all observations have the same number of trials.

As an alternative to **BinomialSize**, you can specify the response as a two-column matrix with counts
in column 1 and **BinomialSize** in column 2.

Data Types: single | double | char | string

**CategoricalVars — Categorical variable list**

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars'
and either a string array or cell array of character vectors containing categorical variable names in
the table or dataset array \( tbl \), or a logical or numeric index vector indicating which columns are
categorical.

• If data is in a table or dataset array \( tbl \), then, by default, \texttt{fitglm} treats all categorical values,
  logical values, character arrays, string arrays, and cell arrays of character vectors as categorical
  variables.

• If data is in matrix \( X \), then the default value of 'CategoricalVars' is an empty matrix [ ]. That
  is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the
following examples.

Example: 'CategoricalVars',[2,3]

Example: 'CategoricalVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**DispersionFlag — Indicator to compute dispersion parameter**

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

| true      | Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE). |
| false     | Default. Use the theoretical value when computing standard errors. |

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

**Distribution — Distribution of the response variable**

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

| 'normal'    | Normal distribution |
| 'binomial'  | Binomial distribution |
| 'poisson'   | Poisson distribution |
| 'gamma'     | Gamma distribution |
| 'inverse gaussian' | Inverse Gaussian distribution |

Example: 'Distribution', 'gamma'

**Exclude — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]
Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Intercept — Indicator for constant term**

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

**Link — Link function**

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

<table>
<thead>
<tr>
<th>Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>( f(\mu) = \mu )</td>
<td>( \mu = Xb )</td>
</tr>
<tr>
<td>'log'</td>
<td>( f(\mu) = \log(\mu) )</td>
<td>( \mu = \exp(Xb) )</td>
</tr>
<tr>
<td>'logit'</td>
<td>( f(\mu) = \log(\mu/(1-\mu)) )</td>
<td>( \mu = \exp(Xb) / (1 + \exp(Xb)) )</td>
</tr>
<tr>
<td>'probit'</td>
<td>( f(\mu) = \Phi^{-1}(\mu) )</td>
<td>( \mu = \Phi(Xb) )</td>
</tr>
<tr>
<td>'comploglog'</td>
<td>( f(\mu) = \log(-\log(1 - \mu)) )</td>
<td>( \mu = 1 - \exp(-\exp(Xb)) )</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>( f(\mu) = 1/\mu )</td>
<td>( \mu = 1/(Xb) )</td>
</tr>
<tr>
<td>( p ) (a number)</td>
<td>( f(\mu) = \mu^p )</td>
<td>( \mu = Xb^{1/p} )</td>
</tr>
</tbody>
</table>
| \( S \) (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:  
  - \( S\.Link \) — The link function  
  - \( S\.Inverse \) — The inverse link function  
  - \( S\.Derivative \) — The derivative of the link function | \( f(\mu) = S\.Link(\mu) \) | \( \mu = S\.Inverse(Xb) \) |

The link function defines the relationship \( f(\mu) = X^*b \) between the mean response \( \mu \) and the linear combination of predictors \( X^*b \).

For more information on the canonical link functions, see “Canonical Link Function” on page 32-1807.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

**Offset — Offset variable**

[ ] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and the variable name in tbl or a numeric vector with the same length as the response.

fitglm uses Offset as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

\[ f(\mu) = \text{Offset} + X^*b, \]

where \( f \) is the link function, \( \mu \) is the mean response, and \( X^*b \) is the linear combination of predictors \( X \). The Offset predictor has coefficient 1.

32-1803
For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor $A$. By using the log link function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char | string

**PredictorVars — Predictor variables**
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in $X$, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**
last column in tbl (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 0 1 0 0])
Data Types: single | double | logical | char | string

**VarNames — Names of variables**
{'x1','x2',...,'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of $X$ first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.
The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

Before specifying 'VarNames', `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```matlab
cellfun(@isvarname, varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```matlab
varNames = matlab.lang.makeValidName(varNames);
```

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: `string` | `cell`

**Weights — Observation weights**

`ones(n,1)` (default) | `n`-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an `n`-by-1 vector of nonnegative scalar values, where `n` is the number of observations.

Data Types: `single` | `double`

### Output Arguments

**mdl — Generalized linear regression model**

`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

### More About

**Terms Matrix**

A terms matrix `T` is a `t`-by-(`p` + 1) matrix specifying terms in a model, where `t` is the number of terms, `p` is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `A`, `B`, and `C` and the response variable `Y` in the order `A`, `B`, `C`, and `Y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `B`; equivalently, `A^0 * B^1 * C^0`
- `[1 0 1 0]` — `A*C`
The $\theta$ at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include $\theta$ for the response variable in the last column of each row.

**Formula**

A formula for model specification is a character vector or string scalar of the form `$Y \sim terms$'.

- $Y$ is the response name.
- `terms` represents the predictor terms in a model using Wilkinson notation.

For example:

- `$Y \sim A + B + C$' specifies a three-variable linear model with intercept.
- `$Y \sim A + B + C - 1$' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include $-1$ in the formula.

**Wilkinson Notation**

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `-` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `( )` groups terms.

This table shows typical examples of Wilkinson notation.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Term in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>$A^k$, where $k$ is a positive integer</td>
<td>$A, A^2, ..., A^k$</td>
</tr>
<tr>
<td>$A + B$</td>
<td>$A, B$</td>
</tr>
<tr>
<td>$A*B$</td>
<td>$A, B, A*B$</td>
</tr>
<tr>
<td>$A:B$</td>
<td>$A*B$ only</td>
</tr>
<tr>
<td>$-B$</td>
<td>Do not include $B$</td>
</tr>
<tr>
<td>$A*B + C$</td>
<td>$A, B, C, A*B$</td>
</tr>
<tr>
<td>$A + B + C + A:B$</td>
<td>$A, B, C, A*B$</td>
</tr>
</tbody>
</table>
Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using –1.

For more details, see “Wilkinson Notation” on page 11-90.

### Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Canonical Link Function Name</th>
<th>Link Function</th>
<th>Mean (Inverse) Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'normal'</td>
<td>'identity'</td>
<td>$f(\mu) = \mu$</td>
<td>$\mu = Xb$</td>
</tr>
<tr>
<td>'binomial'</td>
<td>'logit'</td>
<td>$f(\mu) = \log(\mu/(1 - \mu))$</td>
<td>$\mu = \exp(Xb) / (1 + \exp(Xb))$</td>
</tr>
<tr>
<td>'poisson'</td>
<td>'log'</td>
<td>$f(\mu) = \log(\mu)$</td>
<td>$\mu = \exp(Xb)$</td>
</tr>
<tr>
<td>'gamma'</td>
<td>-1</td>
<td>$f(\mu) = 1/\mu$</td>
<td>$\mu = 1/(Xb)$</td>
</tr>
<tr>
<td>'inverse gaussian'</td>
<td>-2</td>
<td>$f(\mu) = 1/\mu^2$</td>
<td>$\mu = (Xb)^{-1/2}$</td>
</tr>
</tbody>
</table>

### Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

### Algorithms

- `fitglm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has $L$ levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
  - `fitglm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor $X$, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with $L$ levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
• Interaction terms between two categorical predictors with $L$ and $M$ levels consist of the $(L - 1)(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
• You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
• `fitglm` considers NaN, '', (empty character vector), '', (empty string), <missing>, and <undefined> values in `tbl`, `X`, and `Y` to be missing values. `fitglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitglm` uses each observation in the fit.

Alternative Functionality
• Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

References

Extended Capabilities

**Tall Arrays**
Calculate with arrays that have more rows than `fit` in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• If any input argument to `fitglm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights', 'Exclude', 'Offset', and 'BinomialSize' name-value pairs.
• The default number of iterations is 5. You can change the number of iterations using the 'Options' name-value pair to pass in an options structure. Create an options structure using `statset` to specify a different value for MaxIter.
• For tall data, `fitglm` returns a `CompactGeneralizedLinearModel` object that contains most of the same properties as a `GeneralizedLinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `GeneralizedLinearModel` properties:
  • Diagnostics
  • Fitted
  • Offset
  • ObservationInfo
  • ObservationNames
  • Residuals
You can compute the residuals directly from the compact object returned by \texttt{GLM = fitglm(X,Y)} using
\begin{verbatim}
RES = Y - predict(GLM,X);
S = sqrt(GLM.SSE/GLM.DFE);
histogram(RES,linspace(-3*S,3*S,51))
\end{verbatim}

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

**Introduced in R2013b**
fitglme

Fit generalized linear mixed-effects model

Syntax

glme = fitglme(tbl,formula)
glme = fitglme(tbl,formula,Name,Value)

Description

glme = fitglme(tbl,formula) returns a generalized linear mixed-effects model, glme. The model is specified by formula and fitted to the predictor variables in the table or dataset array, tbl.

glme = fitglme(tbl,formula,Name,Value) returns a generalized linear mixed-effects model using additional options specified by one or more Name,Value pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

load mfr

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

• Flag to indicate whether the batch used the new process (newprocess)
• Processing time for each batch, in hours (time)
• Temperature of the batch, in degrees Celsius (temp)
• Categorical variable indicating the supplier of the chemical used in the batch (supplier)
• Number of defects in the batch (defects)

The data also includes time_dev and temp_dev, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using newprocess, time_dev, temp_dev, and supplier as fixed-effects predictors. Include a random-effects term for intercept grouped by factory, to account for quality differences that might exist due to factory-specific variations. The response variable defects has a Poisson distribution, and the appropriate link function for this
model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as ‘effects’, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

\[
defects_{ij} \sim \text{Poisson}(\mu_{ij}).
\]

This corresponds to the generalized linear mixed-effects model

\[
\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time}_\text{dev}_{ij} + \beta_3 \text{temp}_\text{dev}_{ij} + \beta_4 \text{supplier}_C_{ij} + \beta_5 \text{supplier}_B_{ij} + b_i,
\]

where

- \(\text{defects}_{ij}\) is the number of defects observed in the batch produced by factory \(i\) during batch \(j\).
- \(\mu_{ij}\) is the mean number of defects corresponding to factory \(i\) (where \(i = 1, 2, \ldots, 20\)) during batch \(j\) (where \(j = 1, 2, \ldots, 5\)).
- \(\text{newprocess}_{ij}, \text{time}_\text{dev}_{ij}\), and \(\text{temp}_\text{dev}_{ij}\) are the measurements for each variable that correspond to factory \(i\) during batch \(j\). For example, \(\text{newprocess}_{ij}\) indicates whether the batch produced by factory \(i\) during batch \(j\) used the new process.
- \(\text{supplier}_C_{ij}\) and \(\text{supplier}_B_{ij}\) are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory \(i\) during batch \(j\).
- \(b_i \sim N(0, \sigma^2_b)\) is a random-effects intercept for each factory \(i\) that accounts for factory-specific variation in quality.

\[
glme = \text{fitglme(mfr,} \text{'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)'}, ..., \text{'Distribution'}, \text{'Poisson'}, \text{'Link'}, \text{'log'}, \text{'FitMethod'}, \text{'Laplace'}, ..., \text{'DummyVarCoding'}, \text{'effects'})\);
\]

Display the model.

\[
disp(glme)
\]

Generalized linear mixed-effects model fit by ML

Model information:

- Number of observations: 100
- Fixed effects coefficients: 6
- Random effects coefficients: 20
- Covariance parameters: 1
- Distribution: Poisson
- Link: Log
- FitMethod: Laplace

Formula:

\[
defects \sim 1 + \text{newprocess} + \text{time}_\text{dev} + \text{temp}_\text{dev} + \text{supplier} + (1 \mid \text{factory})
\]

Model fit statistics:

<table>
<thead>
<tr>
<th>AIC</th>
<th>BIC</th>
<th>LogLikelihood</th>
<th>Deviance</th>
</tr>
</thead>
<tbody>
<tr>
<td>416.35</td>
<td>434.58</td>
<td>-201.17</td>
<td>402.35</td>
</tr>
</tbody>
</table>

Fixed effects coefficients (95% CIs):
The Model information table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

Formula indicates the model specification using Wilkinson’s notation.

The Model fit statistics table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The Fixed effects coefficients table indicates that fitglme returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (Name) contains the name of each fixed-effects coefficient, column 2 (Estimate) contains its estimated value, and column 3 (SE) contains the standard error of the coefficient. Column 4 (tStat) contains the t-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (DF) and column 6 (pValue) contain the degrees of freedom and p-value that correspond to the t-statistic, respectively. The last two columns (Lower and Upper) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only factory), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, std indicates that fitglme returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by fitglme does not provide confidence intervals for the random-effects parameters. To compute and display these values, use covarianceParameters.
Input Arguments

**tbl — Input data**

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using formula.

**formula — Formula for model specification**

character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. The formula is case sensitive. For a full description, see “Formula” on page 32-1822.

Example: '
y ~ treatment + (1|block)'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:

'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects'

specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

**BinomialSize — Number of trials for binomial distribution**

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. BinomialSize applies only when the Distribution parameter is 'binomial'.

If BinomialSize is a scalar value, that means all observations have the same number of trials.

Data Types: single | double

**CheckHessian — Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

32-1813
If you specify 'FitMethod' as 'MPL' or 'REML', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CheckHessian',true

**CovarianceMethod — Method to compute covariance of estimated parameters**

'conditional' (default) | 'JointHessian'

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of 'CovarianceMethod' and either 'conditional' or 'JointHessian'. If you specify 'conditional', then fitglme computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify 'JointHessian', then fitglme computes the joint covariance of fixed effects and covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify 'FitMethod' as 'MPL' or 'REML', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CovarianceMethod','JointHessian'

**CovariancePattern — Pattern of covariance matrix**

'FullCholesky' | 'Isotropic' | 'Full' | 'Diagonal' | 'CompSymm' | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and 'FullCholesky', 'Isotropic', 'Full', 'Diagonal', 'CompSymm', a square symmetric logical matrix, a string array, or a cell array containing character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FullCholesky'</td>
<td>Full covariance matrix using the Cholesky parameterization. fitglme estimates all elements of the covariance matrix.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 'Isotropic' | Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like:<br>\[
\begin{pmatrix}
\sigma_b^2 & 0 & 0 \\
0 & \sigma_b^2 & 0 \\
0 & 0 & \sigma_b^2
\end{pmatrix}
\]
where \(\sigma_b^2\) is the common variance of the random-effects terms. |
| 'Full'      | Full covariance matrix, using the log-Cholesky parameterization. fitlme estimates all elements of the covariance matrix.                                                                                                                                                                                                                         |
| 'Diagonal'  | Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.                                                                -------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'CompSymm'  | Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like:<br>\[
\begin{pmatrix}
\sigma_b^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_b^2 & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_b^2
\end{pmatrix}
\]
where \(\sigma_b^2\) is the common variance of the random-effects terms and \(\sigma_{b1,b2}\) is the common covariance between any two random-effects term. |
| PAT         | Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \(\text{PAT}(a,b) = \text{false}\), then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.                                                                                       |
For scalar random-effects terms, the default is ‘Isotropic’. Otherwise, the default is ‘FullCholesky’.

Example: ‘CovariancePattern’, 'Diagonal'
Example: ‘CovariancePattern’, {'Full', 'Diagonal'}

Data Types: char | string | logical | cell

**DispersionFlag** — Indicator to compute dispersion parameter
false for ‘binomial’ and ‘poisson’ distributions (default) | true

Indicator to compute dispersion parameter for ‘binomial’ and ‘poisson’ distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Estimate a dispersion parameter when computing standard errors</td>
</tr>
<tr>
<td>false</td>
<td>Use the theoretical value of 1.0 when computing standard errors</td>
</tr>
</tbody>
</table>

'DispersionFlag' only applies if 'FitMethod' is 'MPL' or 'REML'.

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

**Distribution** — Distribution of the response variable
'Normal' (default) | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Normal'</td>
<td>Normal distribution</td>
</tr>
<tr>
<td>'Binomial'</td>
<td>Binomial distribution</td>
</tr>
<tr>
<td>'Poisson'</td>
<td>Poisson distribution</td>
</tr>
<tr>
<td>'Gamma'</td>
<td>Gamma distribution</td>
</tr>
<tr>
<td>'InverseGaussian'</td>
<td>Inverse Gaussian distribution</td>
</tr>
</tbody>
</table>

Example: 'Distribution', 'Binomial'

**DummyVarCoding** — Coding to use for dummy variables
'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'

**EBMethod — Method used to approximate empirical Bayes estimates of random effects**

'Auto' (default) | 'LineSearchNewton' | 'TrustRegion2D' | 'fsolve'

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of 'EBMethod' and one of the following.

- 'Auto'
- 'LineSearchNewton'
- 'TrustRegion2D'
- 'fsolve'

'AUTO' is similar to 'LineSearchNewton' but uses a different convergence criterion and does not display iterative progress. 'Auto' and 'LineSearchNewton' may fail for non-canonical link functions. For non-canonical link functions, 'TrustRegion2D' or 'fsolve' are recommended. You must have Optimization Toolbox to use 'fsolve'.

Example: 'EBMethod','LineSearchNewton'

**EBOptOptions — Options for empirical Bayes optimization**

Structure

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of 'EBOptOptions' and a structure containing the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'TolFun'</td>
<td>Relative tolerance on the gradient norm. Default is 1e-6.</td>
</tr>
<tr>
<td>'TolX'</td>
<td>Absolute tolerance on the step size. Default is 1e-8.</td>
</tr>
<tr>
<td>'MaxIter'</td>
<td>Maximum number of iterations. Default is 100.</td>
</tr>
<tr>
<td>'Display'</td>
<td>'off', 'iter', or 'final'. Default is 'off'.</td>
</tr>
</tbody>
</table>

If 'EBMethod' is 'Auto' and 'FitMethod' is 'Laplace', TolFun is the relative tolerance on the linear predictor of the model, and the 'Display' option does not apply.

If 'EBMethod' is 'fsolve', then 'EBOptOptions' must be specified as an object created by optimoptions('fsolve').

Data Types: struct

**Exclude — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.
Example: 'Exclude', [13, 67]

Data Types: single | double | logical

**FitMethod** — Method for estimating model parameters

'MPL' (default) | 'REPL' | 'Laplace' | 'ApproximateLaplace'

Method for estimating model parameters, specified as the comma-separated pair consisting of 'FitMethod' and one of the following:

- 'MPL' — Maximum pseudo likelihood
- 'REPL' — Restricted maximum pseudo likelihood
- 'Laplace' — Maximum likelihood using Laplace approximation
- 'ApproximateLaplace' — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: 'FitMethod', 'REPL'

**InitPLIterations** — Initial number of pseudo likelihood iterations

10 (default) | integer value in the range $[1, +\infty)$

Initial number of pseudo likelihood iterations used to initialize parameters for ApproximateLaplace and Laplace fit methods, specified as the comma-separated pair consisting of 'InitPLIterations' and an integer value greater than or equal to 1.

Data Types: single | double

**Link** — Link function

'identity' | 'log' | 'logit' | 'probit' | 'complloglog' | 'reciprocal' | scalar value | structure

Link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'identity'</td>
<td>$g(\mu) = \mu$</td>
</tr>
<tr>
<td></td>
<td>This is the default for the normal distribution.</td>
</tr>
<tr>
<td>'log'</td>
<td>$g(\mu) = \log(\mu)$</td>
</tr>
<tr>
<td></td>
<td>This is the default for the Poisson distribution.</td>
</tr>
<tr>
<td>'logit'</td>
<td>$g(\mu) = \log(\mu/(1-\mu))$</td>
</tr>
<tr>
<td></td>
<td>This is the default for the binomial distribution.</td>
</tr>
<tr>
<td>'loglog'</td>
<td>$g(\mu) = \log(-\log(\mu))$</td>
</tr>
<tr>
<td>'probit'</td>
<td>$g(\mu) = \text{norminv}(\mu)$</td>
</tr>
<tr>
<td>'complloglog'</td>
<td>$g(\mu) = \log(-\log(1-\mu))$</td>
</tr>
<tr>
<td>'reciprocal'</td>
<td>$g(\mu) = \mu.\text{^(-1)}$</td>
</tr>
<tr>
<td>Scalar value P</td>
<td>$g(\mu) = \mu.\text{^P}$</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
Structure S | A structure containing four fields whose values are function handles with the following names:
  - S.Link — Link function
  - S.Derivative — Derivative
  - S.SecondDerivative — Second derivative
  - S.Inverse — Inverse of link

Specification of S.SecondDerivative can be omitted if FitMethod is MPL or REMPL, or if S is the canonical link for the specified distribution.

The default link function used by fitglme is the canonical link that depends on the distribution of the response.

<table>
<thead>
<tr>
<th>Response Distribution</th>
<th>Canonical Link Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Normal'</td>
<td>'identity'</td>
</tr>
<tr>
<td>'Binomial'</td>
<td>'logit'</td>
</tr>
<tr>
<td>'Poisson'</td>
<td>'log'</td>
</tr>
<tr>
<td>'Gamma'</td>
<td>-1</td>
</tr>
<tr>
<td>'InverseGaussian'</td>
<td>-2</td>
</tr>
</tbody>
</table>

Example: 'Link','log'

Data Types: char | string | single | double | struct

**MuStart — Starting value for conditional mean**

scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of 'MuStart' and a scalar value. Valid values are as follows.

<table>
<thead>
<tr>
<th>Response Distribution</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Normal'</td>
<td>(-Inf,Inf)</td>
</tr>
<tr>
<td>'Binomial'</td>
<td>(0,1)</td>
</tr>
<tr>
<td>'Poisson'</td>
<td>(0,Inf)</td>
</tr>
<tr>
<td>'Gamma'</td>
<td>(0,Inf)</td>
</tr>
<tr>
<td>'InverseGaussian'</td>
<td>(0,Inf)</td>
</tr>
</tbody>
</table>

Data Types: single | double

**Offset — Offset**

zeros(n,1) (default) | n-by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an n-by-1 vector of scalar values, where n is the length of the response vector. You can also specify the variable name of an n-by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.
Data Types: single | double

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'quasinewton'</td>
<td>Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using <code>statset('fitglme')</code>. If you do not specify the options, then <code>fitglme</code> uses the default options of <code>statset('fitglme')</code>.</td>
</tr>
<tr>
<td>'fminsearch'</td>
<td>Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using <code>optimset('fminsearch')</code>. If you do not specify the options, then <code>fitglme</code> uses the default options of <code>optimset('fminsearch')</code>.</td>
</tr>
<tr>
<td>'fminunc'</td>
<td>Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using <code>optimoptions('fminunc')</code>. If you do not specify the options, then <code>fitglme</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.</td>
</tr>
</tbody>
</table>

Example: 'Optimizer','fminsearch'

OptimizerOptions — Options for optimization algorithm
structure returned by `statset` | structure returned by `optimset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('fitglme')`, a structure created by `optimset('fminsearch')`, or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminsearch', then use `optimset('fminsearch')` to change the options of the algorithm. If 'Optimizer' is 'fminsearch' and you do not supply 'OptimizerOptions', then the defaults used in `fitglme` are the default options created by `optimset('fminsearch')`.
- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the defaults used in `fitglme` are the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use `statset('fitglme')` to change the optimization parameters. If 'Optimizer' is 'quasinewton' and you do not change the optimization parameters using `statset`, then `fitglme` uses the default options created by `statset('fitglme')`. 

32-1820
The 'quasinewton' optimizer uses the following fields in the structure created by
`statset('fitglmme')`.

**TolFun — Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**PLIterations — Maximum number of pseudo likelihood iterations**

100 (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of 'PLIterations' and a positive integer value. PL is used for fitting the model if 'FitMethod' is 'MPL' or 'REMPL'. For other 'FitMethod' values, PL iterations are used to initialize parameters for subsequent optimization.

Example: 'PLIterations', 200

Data Types: single | double

**PLTolerance — Relative tolerance factor for pseudo likelihood iterations**

1e-08 (default) | positive scalar value

Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of 'PLTolerance' and a positive scalar value.

Example: 'PLTolerance', 1e-06

Data Types: single | double

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod', 'random'
UseSequentialFitting — Initial fitting type
false (default) | true

, specified as the comma-separated pair consisting of 'UseSequentialFitting' and either false or true. If 'UseSequentialFitting' is false, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If 'UseSequentialFitting' is true, the initial values from pseudo likelihood iterations are refined using 'ApproximateLaplace' for 'Laplace' fitting.

Example: 'UseSequentialFitting',true

Verbose — Indicator to display optimization process on screen
0 (default) | 1 | 2

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. If 'Verbose' is specified as 1 or 2, then fitglme displays the progress of the iterative model-fitting process. Specifying 'Verbose' as 2 displays iterative optimization information from the individual pseudo likelihood iterations. Specifying 'Verbose' as 1 omits this display.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',1

Weights — Observation weights
vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: single | double

Output Arguments

glme — Generalized linear mixed-effects model
GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table tbl contains the following:

- A response variable, y
- Predictor variables, X_j, which can be continuous or grouping variables
• Grouping variables, \( g_1, g_2, \ldots, g_R \),

where the grouping variables in \( X_j \) and \( g_r \) can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, \( 'y \sim \text{fixed} + (\text{random}_1 | g_1) + \ldots + (\text{random}_R | g_R)' \), the term \( \text{fixed} \) corresponds to a specification of the fixed-effects design matrix \( X \), \( \text{random}_1 \) is a specification of the random-effects design matrix \( Z_1 \) corresponding to grouping variable \( g_1 \), and similarly \( \text{random}_R \) is a specification of the random-effects design matrix \( Z_R \) corresponding to grouping variable \( g_R \). You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>( X^k ), where ( k ) is a positive integer</td>
<td>( X, X^2, \ldots, X^k )</td>
</tr>
<tr>
<td>( X1 + X2 )</td>
<td>( X1, X2 )</td>
</tr>
<tr>
<td>( X1*X2 )</td>
<td>( X1, X2, X1.*X2 ) (elementwise multiplication of ( X1 ) and ( X2 ))</td>
</tr>
<tr>
<td>( X1:X2 )</td>
<td>( X1.*X2 ) only</td>
</tr>
<tr>
<td>- ( X2 )</td>
<td>Do not include ( X2 )</td>
</tr>
<tr>
<td>( X1*X2 + X3 )</td>
<td>( X1, X2, X3, X1*X2 )</td>
</tr>
<tr>
<td>( X1 + X2 + X3 + X1:X2 )</td>
<td>( X1, X2, X3, X1*X2 )</td>
</tr>
<tr>
<td>( X1<em>X2</em>X3 - X1:X2:X3 )</td>
<td>( X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3 )</td>
</tr>
<tr>
<td>( X1*(X2 + X3) )</td>
<td>( X1, X2, X3, X1<em>X2, X1</em>X3 )</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using \(-1\). Here are some examples for generalized linear mixed-effects model specification.

**Examples:**

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 'y \sim X1 + X2' )</td>
<td>Fixed effects for the intercept, ( X1 ) and ( X2 ). This is equivalent to ( 'y \sim 1 + X1 + X2' ).</td>
</tr>
<tr>
<td>( 'y \sim -1 + X1 + X2' )</td>
<td>No intercept and fixed effects for ( X1 ) and ( X2 ). The implicit intercept term is suppressed by including (-1).</td>
</tr>
<tr>
<td>( 'y \sim 1 + (1</td>
<td>g_1)' )</td>
</tr>
<tr>
<td>( 'y \sim X1 + (1</td>
<td>g_1)' )</td>
</tr>
<tr>
<td>( 'y \sim X1 + (X1</td>
<td>g_1)' )</td>
</tr>
<tr>
<td>Formula</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>
</tbody>
</table>

**Topics**
“Fit a Generalized Linear Mixed-Effects Model” on page 12-57
“Generalized Linear Mixed-Effects Models” on page 12-48

**Introduced in R2014b**
**fitgmdist**

Fit Gaussian mixture model to data

**Syntax**

```
GMMModel = fitgmdist(X,k)
GMMModel = fitgmdist(X,k,Name,Value)
```

**Description**

`GMMModel = fitgmdist(X,k)` returns a Gaussian mixture distribution model (`GMMModel`) with `k` components fitted to data (`X`).

`GMMModel = fitgmdist(X,k,Name,Value)` returns a Gaussian mixture distribution model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a regularization value or the covariance type.

**Examples**

**Cluster Data Using a Gaussian Mixture Model**

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 2];
Sigma1 = [2 0; 0 0.5];
mu2 = [-3 -5];
Sigma2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure
y = [zeros(1000,1);ones(1000,1)];
h = gscatter(X(:,1),X(:,2),y);
hold on
gmPDF = @(x1,x2)reshape(pdf(GMMModel,[x1(:) x2(:)]),size(x1));
g = gca;
fcontour(gmPDF,[g.XLim g.YLim])
title('Scatter Plot and Fitted Gaussian Mixture Contours')
legend(h,'Model 0','Model1')
hold off
```
Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

\[
\begin{align*}
\text{mu1} &= [1 \ 2]; \\
\text{Sigma}1 &= [1 \ 0; \ 0 \ 1]; \\
\text{mu2} &= [3 \ 4]; \\
\text{Sigma}2 &= [0.5 \ 0; \ 0 \ 0.5];
\end{align*}
\]

\text{rng}(3); % For reproducibility
\text{X1} = \text{[mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];}
\text{X} = \text{[X1;X1(:,1)+X1(:,2)];}

The columns of \text{X} are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use \text{try/catch} statements to help manage error messages.

\text{rng(1);} % Reset seed for common start values
\text{try}
\hspace{1em} \text{GMMModel} = \text{fitgmdist(X,2)}
\text{catch exception}
\hspace{1em} \text{disp('There was an error fitting the Gaussian mixture model')}\hspace{1em}
\hspace{1em} \text{error} = \text{exception.message}
\text{end}
There was an error fitting the Gaussian mixture model:

```
error =
'Ill-conditioned covariance created at iteration 2.'
```

The covariance estimates are ill-conditioned. Consequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization:

```
rng(3); % Reset seed for common start values
GMModel = fitgmdist(X,2,'RegularizationValue',0.1)
```

```
GMModel =
Gaussian mixture distribution with 2 components in 3 dimensions
Component 1:
Mixing proportion: 0.536725
Mean:    2.8831    3.9506    6.8338
Component 2:
Mixing proportion: 0.463275
Mean:    0.8813    1.9758    2.8571
```

In this case, the algorithm converges to a solution due to regularization.

### Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set:

```
load fisheriris
classes = unique(species)
```

```
classes = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization:

```
[~,score] = pca(meas,'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMModels = cell(3,1); % Preallocation
options = statset('MaxIter',1000);
```
rng(1); % For reproducibility

for j = 1:3
    GMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('GM Mean for %i Component(s)
',j)
    Mu = GMModels{j}.mu
end

GM Mean for 1 Component(s)
Mu = 1x2
10^-14 x
    -0.2743   -0.0870

GM Mean for 2 Component(s)
Mu = 2x2
    1.3212   -0.0954
    -2.6424    0.1909

GM Mean for 3 Component(s)
Mu = 3x2
    0.4856   -0.1287
    1.4484   -0.0904
    -2.6424    0.1909

GMModels is a cell array containing three, fitted gmdistribution models. The means in the three
component models are different, suggesting that the model distinguishes among the three iris
species.

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels,
use gscatter to distinguish between the true number of components.

figure
for j = 1:3
    subplot(2,2,j)
    h1 = gscatter(score(:,1),score(:,2),species);
    h = gca;
    hold on
    gmPDF = @(x1,x2)arrayfun(@(x1,x2)pdf(GMModels{j},[x1(:) x2(:)]),x1,x2);
    fcontour(gmPDF,[h.XLim h.YLim],'MeshDensity',100)
    title(sprintf('GM Model - %i Component(s)',j));
    xlabel('1st principal component');
    ylabel('2nd principal component');
    if(j ~= 3)
        legend off;
    end
end
hold off
end
g = legend(h1);
g.Position = [0.7 0.25 0.1 0.1];
The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

**Determine the Best Gaussian Mixture Fit Using AIC**

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```matlab
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
```
Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```matlab
gmModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);```

11 iterations, log-likelihood = -4787.38

`gmmModel` is a fitted `gmdistribution` model.
Examine the AIC over varying numbers of components.

```matlab
AIC = zeros(1,4); GMModels = cell(1,4); options = statset('MaxIter',500);
for k = 1:4
    GMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k)= GMModels{k}.AIC;
end

[minAIC,numComponents] = min(AIC);
numComponents = 2

BestModel = GMModels{numComponents}
```

BestModel =

`Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.501719
Mean: 1.9824 4.0013

Component 2:
Mixing proportion: 0.498281
Mean: 0.9880 1.0511`

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

### Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```matlab
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify `k = 3` components.

```matlab
rng(10); % For reproducibility
GMModel1 = fitgmdist(X,3);
```

By default, the software:

1. Implements the “k-means++ Algorithm for Initialization” on page 32-1838 to choose `k = 3` initial cluster centers.
2. Sets the initial covariance matrices as diagonal, where element (j, j) is the variance of `X(:,j)`.
3. Treats the initial mixing proportions as uniform.

Fit a Gaussian mixture model by connecting each observation to its label.
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;

GMMModel2 = fitgmdist(X,3,'Start',y);

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);

GMMModel3 = fitgmdist(X,3,'Start',S);

Use gscatter to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
haxis = gca;
xlim = haxis.XLim;
ylim = haxis.YLim;
d = (max([xlim ylim])-min([xlim ylim]))/1000;
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel1,X1Grid(:),X2Grid(:)),size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Random Initial Values}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel2,X1Grid(:),X2Grid(:)),size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from Labels}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel3,X1Grid(:),X2Grid(:)),size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from the Structure}');
xlabel('Sepal length');
ylabel('Sepal width');
According to the contours, GMModel2 seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```
ans=3×3 table
   Model1        Model2        Model3
    ______________________    ________________    ________________
   5.2115     2.0119    4.2857    1.3339    1.4604    0.2429
  1.4610    0.24423     1.4620     0.2460    4.7509    1.4629
  4.6829     1.4429    5.5507    2.0316    5.0158    1.8592
```

GMModel2 seems to distinguish between the iris species the best.

**Input Arguments**

- **X** — Data
  numeric matrix
Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

The rows of X correspond to observations, and the columns of X correspond to variables. The number of observations must be larger than each of the following: the number of variables and the number of components.

NaNs indicate missing values. The software removes rows of X containing at least one NaN before fitting, which decreases the effective sample size.

Data Types: single | double

k — Number of components
positive integer

Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify k = 3, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (X).

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'RegularizationValue',0.1,'CovarianceType','diagonal' specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

CovarianceType — Type of covariance matrix
'full' (default) | 'diagonal'

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of 'CovarianceType' and either 'diagonal' or 'full'.

If you set 'diagonal', then the software fits diagonal covariance matrices. In this case, the software estimates k*d covariance parameters, where d is the number of columns in X (i.e., d = size(X,2)).

Otherwise, the software fits full covariance matrices. In this case, the software estimates k*d*(d +1)/2 covariance parameters.

Example: 'CovarianceType','diagonal'

Options — Iterative EM algorithm optimization options
statset options structure

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of 'Options' and a statset options structure.

This table describes the available name-value pair arguments.
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Display'</td>
<td>'final': Display the final output.</td>
</tr>
<tr>
<td></td>
<td>'iter': Display iterative output to the Command Window for some functions; otherwise display the final output.</td>
</tr>
<tr>
<td></td>
<td>'off': Do not display optimization information.</td>
</tr>
<tr>
<td>'MaxIter'</td>
<td>Positive integer indicating the maximum number of iterations allowed. The default is 100.</td>
</tr>
<tr>
<td>'TolFun'</td>
<td>Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is 1e-6.</td>
</tr>
</tbody>
</table>

Example: 'Options', statset('Display', 'final', 'MaxIter', 1500, 'TolFun', 1e-5)

**ProbabilityTolerance** — Tolerance for posterior probabilities

1e-8 (default) | nonnegative scalar value in range [0, 1e-6]

Tolerance for posterior probabilities, specified as the comma-separated pair consisting of **ProbabilityTolerance** and a nonnegative scalar value in the range [0, 1e-6].

In each iteration, after the estimation of posterior probabilities, fitgmdist sets any posterior probability that is not larger than the tolerance value to zero. Using a nonzero tolerance might speed up fitgmdist.

Example: 'ProbabilityTolerance', 0.0000025

Data Types: single | double

**RegularizationValue** — Regularization parameter value

0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of **RegularizationValue** and a nonnegative scalar.

Set **RegularizationValue** to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: 'RegularizationValue', 0.01

Data Types: single | double

**Replicates** — Number of times to repeat EM algorithm

1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of **Replicates** and a positive integer.

If **Replicates** is greater than 1, then:

- The name-value pair argument **Start** must be **plus** (the default) or **randSample**.
- **GMModel** is the fit with the largest loglikelihood.

Example: 'Replicates', 10
Data Types: single | double

**SharedCovariance** — Flag indicating whether all covariance matrices are identical

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCovariance' and either logical value false or true.

If `SharedCovariance` is true, then all k covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of k.

**Start** — Initial value setting method

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', 'plus', a vector of integers, or a structure array.

The value of `Start` determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'randSample'</td>
<td>The software selects k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j).</td>
</tr>
<tr>
<td>'plus'</td>
<td>The software selects k observations from X using the k-means++ algorithm on page 32-1838. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of X(:,j).</td>
</tr>
<tr>
<td>Vector of integers</td>
<td>A vector of length n (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to k, which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.</td>
</tr>
</tbody>
</table>
### Value | Description
--- | ---
Structure array | Suppose that there are \(d\) variables (i.e., \(d = \text{size}(X,2)\)). The structure array, e.g., \(S\), must have three fields:

- \(S \mu\): A \(k\)-by-\(d\) matrix specifying the initial mean of each component.
- \(S \Sigma\): A numeric array specifying the covariance matrix of each component. \(\Sigma\) is one of the following:
  - A \(d\)-by-\(d\)-by-\(k\) array. \(\Sigma(:,:,j)\) is the initial covariance matrix of component \(j\).
  - A \(1\)-by-\(d\)-by-\(k\) array. \(\text{diag}(\Sigma(:,:,j))\) is the initial covariance matrix of component \(j\).
  - A \(d\)-by-\(d\) matrix. \(\Sigma\) is the initial covariance matrix for all components.
  - A \(1\)-by-\(d\) vector. \(\text{diag}(\Sigma)\) is the initial covariance matrix for all components.
- \(S \cdot \text{ComponentProportion}\): A \(1\)-by-\(k\) vector of scalars specifying the initial mixing proportions of each component. The default is uniform.

Example: 'Start', \(\text{ones}(n,1)\)

Data Types: single | double | char | string | struct

### Output Arguments

**GMMModel — Fitted Gaussian mixture model**

gmdistribution model

Fitted Gaussian mixture model, returned as a gmdistribution model.

Access properties of **GMMModel** using dot notation. For example, display the AIC by entering **GMMModel.AIC**.

### Tips

**fitgmdist** might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

- The number of dimensions of your data is relatively high and there are not enough observations.
- Some of the predictors (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:
• Preprocess your data to remove correlated features.
• Set 'SharedCovariance' to true to use an equal covariance matrix for every component.
• Set 'CovarianceType' to 'diagonal'.
• Use 'RegularizationValue' to add a very small positive number to the diagonal of every covariance matrix.
• Try another set of initial values.
• Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

fitgmdist fits GMMs to data using the iterative Expectation-Maximization (EM) algorithm. Using initial values for component means, covariance matrices, and mixing proportions, the EM algorithm proceeds using these steps.

1 For each observation, the algorithm computes posterior probabilities of component memberships. You can think of the result as an n-by-k matrix, where element (i,j) contains the posterior probability that observation i is from component j. This is the E-step of the EM algorithm.
2 Using the component-membership posterior probabilities as weights, the algorithm estimates the component means, covariance matrices, and mixing proportions by applying maximum likelihood. This is the M-step of the EM algorithm.

The algorithm iterates over these steps until convergence. The likelihood surface is complex, and the algorithm might converge to a local optimum. Also, the resulting local optimum might depend on the initial conditions. fitgmdist has several options for choosing initial conditions, including random component assignments for the observations and the k-means ++ algorithm.

k-means++ Algorithm for Initialization

The k-means++ algorithm uses an heuristic to find centroid seeds for k-means clustering. fitgmdist can apply the same principle to initialize the EM algorithm by using the k-means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The k-means++ algorithm assumes the number of clusters is k and chooses the initial parameter values as follows.

1 Select the component mixture probability to be the uniform probability \( p_i = \frac{1}{k}, \) where \( i = 1, ..., k \).
2 Select the covariance matrices to be diagonal and identical, where \( \sigma_i = \text{diag}(a_1, a_2, ..., a_k) \) and \( a_j = \text{var}(X_j) \).
3 Select the first initial component center \( \mu_1 \) uniformly from all data points in \( X \).
4 To choose center \( j \):
   a Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.
For $m = 1, \ldots, n$ and $p = 1, \ldots, j - 1$, select centroid $j$ at random from $X$ with probability

$$\frac{d^2(x_m, \mu_p)}{\sum_{h : x_h \in M_p} d^2(x_h, \mu_p)}$$

where $d(x_m, \mu_p)$ is the distance between observation $m$ and $\mu_p$, and $M_p$ is the set of all observations closest to centroid $\mu_p$ and $x_m$ belongs to $M_p$.

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5. Repeat step 4 until $k$ centroids are chosen.

Topics

“Tune Gaussian Mixture Models” on page 16-57
“Cluster Using Gaussian Mixture Model” on page 16-39

Introduced in R2014a
**fitlm**

Fit linear regression model

**Syntax**

mdl = fitlm(tbl)
mdl = fitlm(X,y)
mdl = fitlm(____,modelspec)
mdl = fitlm(____,Name,Value)

**Description**

mdl = fitlm(tbl) returns a linear regression model fit to variables in the table or dataset array tbl. By default, fitlm takes the last variable as the response variable.

mdl = fitlm(X,y) returns a linear regression model of the responses y, fit to the data matrix X.

mdl = fitlm(____,modelspec) defines the model specification using any of the input argument combinations in the previous syntaxes.

mdl = fitlm(____,Name,Value) specifies additional options using one or more name-value pair arguments. For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

**Examples**

**Fit Linear Regression Using Data in Matrix**

Fit a linear regression model using a matrix input data set.

Load the carsmall data set, a matrix input data set.

load carsmall
X = [Weight,Horsepower,Acceleration];

Fit a linear regression model by using fitlm.

mdl = fitlm(X,MPG)

mdl =
Linear regression model:
  y ~ 1 + x1 + x2 + x3

Estimated Coefficients:
  Estimate    SE    tStat    pValue
  ________    ______    ______    ______
  (Intercept)    47.977    3.8785    12.37    4.8957e-21
  x1     -0.0065416    0.0011274    -5.8023    9.8742e-08
  x2     -0.042943    0.024313    -1.7663    0.08078
Number of observations: 93, Error degrees of freedom: 89
Root Mean Squared Error: 4.09
R-squared: 0.752, Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, \( y \sim 1 + x_1 + x_2 + x_3 \), corresponds to
\[ y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \epsilon. \]

The model display also shows the estimated coefficient information, which is stored in the Coefficients property. Display the Coefficients property.

```plaintext
mdl.Coefficients
ans=4×4 table
        Estimate        SE          tStat        pValue
    ________    _________    _________    __________
(Intercept)        47.977       3.8785        12.37    4.8957e-21
    x1            -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2            -0.042943     0.024313      -1.7663       0.08078
    x3            -0.011583      0.19333    -0.059913       0.95236
```

The Coefficient property includes these columns:

- **Estimate** — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (intercept) is 47.977.
- **SE** — Standard error of the coefficients.
- **tStat** — t-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that tStat = Estimate/SE. For example, the t-statistic for the intercept is 47.977/3.8785 = 12.37.
- **pValue** — p-value for the t-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the p-value of the t-statistic for \( x_2 \) is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- **Number of observations** — Number of rows without any NaN values. For example, Number of observations is 93 because the MPG data vector has six NaN values and the Horsepower data vector has one NaN value for a different observation, where the number of rows in \( X \) and MPG is 100.
- **Error degrees of freedom** — \( n - p \), where \( n \) is the number of observations, and \( p \) is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the Error degrees of freedom is 93 - 4 = 89.
- **Root mean squared error** — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
• **R-squared** and **Adjusted R-squared** — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the R-squared value suggests that the model explains approximately 75% of the variability in the response variable MPG.

• **F-statistic vs. constant model** — Test statistic for the F-test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.

• **p-value** — p-value for the F-test on the model. For example, the model is significant with a p-value of 7.3816e-27.

You can find these statistics in the model properties (NumObservations, DFE, RMSE, and Rsquared) and by using the anova function.

\[
\text{anova(mdl, 'summary')}
\]

\[
\begin{array}{cccc}
\text{SumSq} & \text{DF} & \text{MeanSq} & \text{F} & \text{pValue} \\
\hline
\text{Total} & 6004.8 & 92 & 65.269 & \\
\text{Model} & 4516 & 3 & 1505.3 & 89.987 & 7.3816e-27 \\
\text{Residual} & 1488.8 & 89 & 16.728 & \\
\end{array}
\]

### Fit Linear Regression Using Data in Table

Load the sample data.

\[
\text{load carsmall}
\]

Store the variables in a table.

\[
\text{tbl = table(Weight, Acceleration, MPG, 'VariableNames', {'Weight', 'Acceleration', 'MPG'})}
\]

Display the first five rows of the table.

\[
\text{tbl(1:5,:)}
\]

\[
\begin{array}{ccc}
\text{Weight} & \text{Acceleration} & \text{MPG} \\
3504 & 12 & 18 \\
3693 & 11.5 & 15 \\
3436 & 11 & 18 \\
3433 & 12 & 16 \\
3449 & 10.5 & 17 \\
\end{array}
\]

Fit a linear regression model for miles per gallon (MPG). Specify the model formula by using Wilkinson notation.

\[
\text{lm = fitlm(tbl, 'MPG~Weight+Acceleration')}
\]

\[
\text{lm = Linear regression model:}
\]
MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>45.155</td>
<td>3.4659</td>
<td>13.028</td>
<td>1.6266e-22</td>
</tr>
<tr>
<td>Weight</td>
<td>-0.0082475</td>
<td>0.00059836</td>
<td>-13.783</td>
<td>5.3165e-24</td>
</tr>
<tr>
<td>Acceleration</td>
<td>0.19694</td>
<td>0.14743</td>
<td>1.3359</td>
<td>0.18493</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743, Adjusted R-Squared: 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27

The model 'MPG~Weight+Acceleration' in this example is equivalent to set the model specification as 'linear'. For example,

```matlab
lm2 = fitlm(tbl,'linear');
```

If you use a character vector for model specification and you do not specify the response variable, then `fitlm` accepts the last variable in `tbl` as the response variable and the other variables as the predictor variables.

---

### Fit Linear Regression Using Specified Model Formula

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

```matlab
load carsmall
```

Store the variables in a table.

```matlab
tbl = table(Weight,Acceleration,Model_Year,MPG,'VariableNames',{'Weight','Acceleration','Model_Year','MPG'});
```

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

```matlab
lm = fitlm(tbl,'MPG~Weight+Acceleration')
```

```
lm = Linear regression model: MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>45.155</td>
<td>3.4659</td>
<td>13.028</td>
<td>1.6266e-22</td>
</tr>
<tr>
<td>Weight</td>
<td>-0.0082475</td>
<td>0.00059836</td>
<td>-13.783</td>
<td>5.3165e-24</td>
</tr>
<tr>
<td>Acceleration</td>
<td>0.19694</td>
<td>0.14743</td>
<td>1.3359</td>
<td>0.18493</td>
</tr>
</tbody>
</table>
```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743, Adjusted R-Squared: 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27

The p-value of 0.18493 indicates that Acceleration does not have a significant impact on MPG.

Remove Acceleration from the model, and try improving the model by adding the predictor variable Model_Year. First define Model_Year as a categorical variable.

```matlab
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl,'MPG~Weight+Model_Year')
```

```
lm =
Linear regression model:
    MPG ~ 1 + Weight + Model_Year

estimated Coefficients:
                          Estimate     SE         tStat      pValue
    ______________________    __________    _______    __________
    (Intercept)                   40.11       1.5418     26.016    1.2024e-43
    Weight                      -0.0066475  0.00042802    -15.531    3.3639e-27
    Model_Year_76          1.9291       0.74761     2.5804      0.011488
    Model_Year_82          7.9093       0.84975     9.3078    7.8681e-15
```

Number of observations: 94, Error degrees of freedom: 90
Root Mean Squared Error: 2.92
R-squared: 0.873, Adjusted R-Squared: 0.868
F-statistic vs. constant model: 206, p-value = 3.83e-40

Specifying modelspec using Wilkinson notation enables you to update the model without having to change the design matrix. fitlm uses only the variables that are specified in the formula. It also creates the necessary two dummy indicator variables for the categorical variable Model_Year.

**Fit Linear Regression Using Terms Matrix**

Fit a linear regression model using a terms matrix.

**Terms Matrix for Table Input**

If the model variables are in a table, then a column of 0s in a terms matrix represents the position of the response variable.

Load the hospital data set.

```matlab
load hospital
```

Store the variables in a table.

```matlab
t = table(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,hospital.Smoker, ...
    'VariableNames',
    {'Sex','BloodPressure', 'Age', 'Smoker'});
```
Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' using a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of 0s for the response variable.

\[
T = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}
\]

Fit a linear model.

mdl1 = fitlm(t,T)

mdl1 =

Linear regression model:
  BloodPressure ~ 1 + Sex + Age + Smoker

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>

<td>116.14</td>
<td>2.6107</td>
<td>44.485</td>
<td>7.1287e-66</td>
</tr>
<tr>
<td>Sex_Male</td>
<td>0.050106</td>
<td>0.98364</td>
<td>0.050939</td>
<td>0.95948</td>
</tr>
<tr>
<td>Age</td>
<td>0.085276</td>
<td>0.066945</td>
<td>1.2738</td>
<td>0.2058</td>
</tr>
<tr>
<td>Smoker_1</td>
<td>9.87</td>
<td>1.0346</td>
<td>9.5395</td>
<td>1.4516e-15</td>
</tr>
</tbody>
</table>

Number of observations: 100, Error degrees of freedom: 96
Root Mean Squared Error: 4.78
R-squared: 0.507,  Adjusted R-Squared: 0.492
F-statistic vs. constant model: 33, p-value = 9.91e-15

Terms Matrix for Matrix Input

If the predictor and response variables are in a matrix and column vector, then you must include 0 for the response variable at the end of each row in a terms matrix.

Load the carsmall data set and define the matrix of predictors.

load carsmall
X = [Acceleration,Weight];

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a terms matrix. This model includes the main effect and two-way interaction terms for the variables Acceleration and Weight, and a second-order term for the variable Weight.

\[
T = \begin{bmatrix} 0 & 0 & 0; 1 & 0 & 0; 0 & 1 & 0; 1 & 1 & 0; 0 & 0 & 2 \end{bmatrix}
\]

\[
T = 5 \times 3
\]

0 0 0
1 0 0
0 1 0

Fit a linear model.

mdl2 = fitlm(X,MPG,T)

mdl2 =
Linear regression model:
y ~ 1 + x1*x2 + x2^2

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>

<td>0.54418</td>
<td>0.57125</td>
<td>0.95261</td>
<td>0.34337</td>
</tr>
<tr>
<td>x2</td>
<td>-0.012781</td>
<td>0.0060312</td>
<td>-2.1192</td>
<td>0.036857</td>
</tr>
<tr>
<td>x1:x2</td>
<td>-0.00010892</td>
<td>0.00017925</td>
<td>-0.6076</td>
<td>0.545</td>
</tr>
<tr>
<td>x2^2</td>
<td>9.7518e-07</td>
<td>7.5389e-07</td>
<td>1.2935</td>
<td>0.19917</td>
</tr>
</tbody>
</table>

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 4.1
R-squared: 0.751, Adjusted R-Squared: 0.739
F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which corresponds to the Weight variable, are significant at the 5% significance level.

**Linear Regression with Categorical Predictor**

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use anova to test the significance of the categorical variable.

**Model with Categorical Predictor**

Load the carsmall data set and create a linear regression model of MPG as a function of Model_Year. To treat the numeric vector Model_Year as a categorical variable, identify the predictor using the 'CategoricalVars' name-value pair argument.

load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})

mdl =
Linear regression model:
MPG ~ 1 + Model_Year

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Intercept)</td>
<td>17.69</td>
<td>1.0328</td>
<td>17.127</td>
<td>3.2371e-30</td>
</tr>
<tr>
<td>Model_Year_76</td>
<td>3.8839</td>
<td>1.4059</td>
<td>2.7625</td>
<td>0.0069402</td>
</tr>
</tbody>
</table>
The model formula in the display, $\text{MPG} \sim 1 + \text{Model\_Year}$, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of $\text{Model\_Year}$ is 76 and 82, respectively. The $\text{Model\_Year}$ variable includes three distinct values, which you can check by using the `unique` function.

unique($\text{Model\_Year}$)

ans = 3×1

70
76
82

`fitlm` chooses the smallest value in $\text{Model\_Year}$ as a reference level (‘70’) and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

**Model with Full Indicator Variables**

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```matlab
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

mdl =

Linear regression model:
$\text{MPG} \sim \text{Model\_Year\_70} + \text{Model\_Year\_76} + \text{Model\_Year\_82}$

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model_Year_70</td>
<td>17.69</td>
<td>1.0328</td>
<td>17.127</td>
<td>3.2371e-30</td>
</tr>
<tr>
<td>Model_Year_76</td>
<td>21.574</td>
<td>0.95387</td>
<td>22.617</td>
<td>4.0156e-39</td>
</tr>
</tbody>
</table>
Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```matlab
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```matlab
categories(Year)
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category '70' as a reference level. Reorder `Year` by using the `reordercats` function.

```matlab
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

The first category of `Year_reordered` is '76'. Create a linear regression model of MPG as a function of `Year_reordered`.

```matlab
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```matlab
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year
```

```matlab
Estimated Coefficients:
                Estimate     SE         tStat      pValue
    __________    _______    _______    __________
    (Intercept)   21.574     0.95387     22.617    4.0156e-39
    Model_Year_70 -3.8839     1.4059     -2.7625     0.0069402
    Model_Year_82 10.136     1.3812      7.3385    8.7634e-11
```

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15

`mdl2` uses '76' as a reference level and includes two indicator variables $I_{\text{Year} = 70}$ and $I_{\text{Year} = 82}$. 

32-1848
Evaluate Categorical Predictor

The model display of `mdl2` includes a `p`-value of each term to test whether or not the corresponding coefficient is equal to zero. Each `p`-value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the `'components'` (default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```matlab
anova(mdl2,'components')
```

```
ans=2×5 table
          SumSq     DF    MeanSq      F        pValue
        ______    __    ______    _____    __________
Model_Year    3190.1     2    1595.1    51.56    1.0694e-15
Error         2815.2    91    30.936
```

The component ANOVA table includes the `p`-value of the `Model_Year` variable, which is smaller than the `p`-values of the indicator variables.

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```matlab
load hospital
```

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.

```matlab
mdl = fitlm(hospital,'interactions','ResponseVar','Weight',... 'PredictorVars',{'Sex','Age','Smoker'},... 'CategoricalVar',{'Sex','Smoker'})
```

```matlab
mdl =
Linear regression model:
    Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker

Estimated Coefficients:
                     Estimate      SE        tStat        pValue
    ______    _______    ________    __________
(Intercept)             118.7     7.0718      16.785     6.821e-30
Sex_Male               68.336     9.7153      7.0339    3.3386e-10
Age                   0.31068    0.18531      1.6765      0.096991
Smoker_1               3.0425     10.446     0.29127       0.77149
Sex_Male:Age         -0.49094    0.24764     -1.9825      0.050377
Sex_Male:Smoker_1      0.9509     3.8031     0.25003       0.80312
Age:Smoker_1         -0.07288    0.26275    -0.27737       0.78211
```

Number of observations: 100, Error degrees of freedom: 93
The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

**Fit Robust Linear Regression Model**

Load the hald data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables ingredients and heat. The matrix ingredients contains the percent composition of four chemicals present in the cement. The vector heat contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl = 
Linear regression model (robust fit):
  y ~ 1 + x1 + x2 + x3 + x4
Estimated Coefficients:
                 Estimate     SE      tStat       pValue
  ________    _______    ________    ________
   (Intercept)       60.09     75.818     0.79256      0.4509
     x1               1.5753    0.80585      1.9548    0.086346
     x2               0.5322    0.78315     0.67957     0.51596
     x3              0.13346     0.8166     0.16343     0.87424
     x4             -0.12052     0.7672    -0.15709     0.87906
```

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-103, which compares the results of a robust fit to a standard least-squares fit.

**Input Arguments**

- **tbl** — Input data
table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.
By default, `fitlm` takes the last variable as the response variable and the others as the predictor variables.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument.

To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.

```plaintext
cellfun(@isvarname,tbl.Properties.VariableNames)
```

If the variable names in `tbl` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```plaintext
tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);
```

**X — Predictor variables**

*matrix*

Predictor variables, specified as an `n`-by-`p` matrix, where `n` is the number of observations and `p` is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

**y — Response variable**

*vector*

Response variable, specified as an `n`-by-`1` vector, where `n` is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical`

**modelspec — Model specification**

*character vector or string scalar naming the model | `t`-by-(`p` + 1) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'*

Model specification, specified as one of these values.
• A character vector or string scalar naming the model.

<table>
<thead>
<tr>
<th>Value</th>
<th>Model Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>Model contains only a constant (intercept) term.</td>
</tr>
<tr>
<td>'linear'</td>
<td>Model contains an intercept and linear term for each predictor.</td>
</tr>
<tr>
<td>'interactions'</td>
<td>Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).</td>
</tr>
<tr>
<td>'purequadratic'</td>
<td>Model contains an intercept term and linear and squared terms for each predictor.</td>
</tr>
<tr>
<td>'quadratic'</td>
<td>Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.</td>
</tr>
<tr>
<td>'polyijk'</td>
<td>Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and $x_1$, $x_2$, $x_2^2$, $x_3$, $x_1x_2$, and $x_1x_2^2$ terms, where $x_1$ and $x_2$ are the first and second predictors, respectively.</td>
</tr>
</tbody>
</table>

• A $t$-by-$(p + 1)$ matrix, or a “Terms Matrix” on page 32-1856, specifying terms in the model, where $t$ is the number of terms and $p$ is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.

• A character vector or string scalar representing a “Formula” on page 32-1857 in the form 'Y ~ terms', where the terms are in “Wilkinson Notation” on page 32-1857. The variable names in the formula must be valid MATLAB identifiers.

The software determines the order of terms in a fitted model by using the order of terms in tbl or X. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

Example: 'quadratic'
Example: 'y ~ X1 + X2^2 + X1:X2'
Data Types: single | double | char | string

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Intercept',false,'PredictorVars', [1,3], 'ResponseVar',5,'RobustOpts','logistic' specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning
constant, first and third variables are the predictor variables, and fifth variable is the response variable.

**CategoricalVars — Categorical variable list**
string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitlm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]
Example: `'CategoricalVars',logical([0 1 1 0 0 0])
Data Types: single | double | logical | string | cell

**Exclude — Observations to exclude**
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]
Example: `'Exclude',logical([0 1 1 0 0 0])
Data Types: single | double | logical

**Intercept — Indicator for constant term**
ture (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false

**PredictorVars — Predictor variables**
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.
The string values or character vectors should be among the names in \texttt{tbl}, or the names you specify using the \texttt{'VarNames'} name-value pair argument.

The default is all variables in \texttt{X}, or all variables in \texttt{tbl} except for \texttt{ResponseVar}.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: \texttt{'PredictorVars',[2,3]}
Example: \texttt{'PredictorVars',logical([0 1 0 0 0])}

Data Types: \texttt{single} | \texttt{double} | \texttt{logical} | \texttt{string} | \texttt{cell}

**ResponseVar — Response variable**

last column in \texttt{tbl} (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of \texttt{'ResponseVar'} and either a character vector or string scalar containing the variable name in the table or dataset array \texttt{tbl}, or a logical or numeric index vector indicating which column is the response variable. You typically need to use \texttt{'ResponseVar'} when fitting a table or dataset array \texttt{tbl}.

For example, you can specify the fourth variable, say \texttt{yield}, as the response out of six variables, in one of the following ways.

Example: \texttt{'ResponseVar','yield'}
Example: \texttt{'ResponseVar',[4]}
Example: \texttt{'ResponseVar',logical([0 0 1 0 0])}

Data Types: \texttt{single} | \texttt{double} | \texttt{logical} | \texttt{char} | \texttt{string}

**RobustOpts — Indicator of robust fitting type**

\texttt{'off'} (default) | \texttt{'on'} | character vector | string scalar | structure

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of \texttt{'RobustOpts'} and one of these values.

- \texttt{'off'} — No robust fitting. \texttt{fitlm} uses ordinary least squares.
- \texttt{'on'} — Robust fitting using the \texttt{'bisquare'} weight function with the default tuning constant.
- Character vector or string scalar — Name of a robust fitting weight function from the following table. \texttt{fitlm} uses the corresponding default tuning constant specified in the table.
- Structure with the two fields \texttt{RobustWgtFun} and \texttt{Tune}.
  - The \texttt{RobustWgtFun} field contains the name of a robust fitting weight function from the following table or a function handle of a custom weight function.
  - The \texttt{Tune} field contains a tuning constant. If you do not set the \texttt{Tune} field, \texttt{fitlm} uses the corresponding default tuning constant.

<table>

</tbody>
</table>

- The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- The value \( r \) in the weight functions is

\[
r = \text{resid}/(\text{tune} \cdot \text{s} \cdot \sqrt{1 - h}),
\]

where \( \text{resid} \) is the vector of residuals from the previous iteration, \( \text{tune} \) is the tuning constant, \( h \) is the vector of leverage values from a least-squares fit, and \( s \) is an estimate of the standard deviation of the error term given by

\[
\text{s} = \text{MAD}/0.6745.
\]

\( \text{MAD} \) is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If \( X \) has \( p \) columns, the software excludes the smallest \( p \) absolute deviations when computing the median.

For robust fitting, \texttt{fitlm} uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).

Example: 'RobustOpts','andrews'

\textbf{VarNames — Names of variables}

\{'x1','x2',...,'xn','y'\} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of \( X \) first, and the name for the response variable \( y \) last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:
You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.

You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments 'Lower' and 'Upper', respectively.

Before specifying 'VarNames', `varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. The following code returns logical 1 (true) for each variable that has a valid variable name.

```
cellfun(@isvarname, varNames)
```

If the variable names in `varNames` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
varNames = matlab.lang.makeValidName(varNames);
```

Example: 'VarNames',{"'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: `string` | `cell`

**Weights — Observation weights**

`ones(n,1)` (default) | n-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n-by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

**Output Arguments**

**mdl — Linear model**

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not [], or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

**More About**

**Terms Matrix**

A terms matrix `T` is a t-by-(`p` + 1) matrix specifying terms in a model, where `t` is the number of terms, `p` is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `A`, `B`, and `C` and the response variable `Y` in the order `A`, `B`, `C`, and `Y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — B; equivalently, `A^0 * B^1 * C^0`
\begin{itemize}
\item \([1 \ 0 \ 1 \ 0]\) — \(A*C\)
\item \([2 \ 0 \ 0 \ 0]\) — \(A^2\)
\item \([0 \ 1 \ 2 \ 0]\) — \(B*(C^2)\)
\end{itemize}

The \(\theta\) at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include \(\theta\) for the response variable in the last column of each row.

**Formula**

A formula for model specification is a character vector or string scalar of the form '\(Y \sim terms\)'.

- \(Y\) is the response name.
- \(terms\) represents the predictor terms in a model using Wilkinson notation.

For example:

- '\(Y \sim A + B + C\)' specifies a three-variable linear model with intercept.
- '\(Y \sim A + B + C - 1\)' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include \(-1\) in the formula.

**Wilkinson Notation**

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- () groups terms.

This table shows typical examples of Wilkinson notation.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Term in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>(A^k), where (k) is a positive integer</td>
<td>(A, A^2, \ldots, A^k)</td>
</tr>

<td>Do not include (B)</td>
</tr>
<tr>
<td>(A*B + C)</td>
<td>(A, B, C, A*B)</td>
</tr>
<tr>
<td>(A + B + C + A:B)</td>
<td>(A, B, C, A*B)</td>
</tr>
</tbody>
</table>
Wilkinson Notation | Term in Standard Notation
---|---

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

For more details, see “Wilkinson Notation” on page 11-90.

**Tips**
- To access the model properties of the `LinearModel` object `mdl`, you can use dot notation. For example, `mdl.Residuals` returns a table of the raw, Pearson, Studentized, and standardized residual values for the model.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**
- The main fitting algorithm is QR decomposition. For robust fitting, `fitlm` uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).
- `fitlm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has $L$ levels (categories) includes $L-1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
  - `fitlm` treats the group of $L-1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor $X$, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with $L$ levels consist of the element-wise product of the $L-1$ indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with $L$ and $M$ levels consist of the $(L-1)*(M-1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
- `fitlm` considers `NaN`, `' ' (empty character vector), " " (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `fitlm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitlm` uses each observation in the fit.
Alternative Functionality

• For reduced computation time on high-dimensional data sets, fit a linear regression model using the fitrlinear function.
• To regularize a regression, use fitrlinear, lasso, ridge, or plsregress.
  • fitrlinear regularizes a regression for high-dimensional data sets using lasso or ridge regression.
  • lasso removes redundant predictors in linear regression using lasso or elastic net.
  • ridge regularizes a regression with correlated terms using ridge regression.
  • plsregress regularizes a regression with correlated terms using partial least squares.

References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

• If any input argument to fitlm is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights' and 'Exclude' name-value pairs.
• The 'RobustOpts' name-value pair is not supported with tall arrays.
• For tall data, fitlm returns a CompactLinearModel object that contains most of the same properties as a LinearModel object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these LinearModel properties:
  • Diagnostics
  • Fitted
  • ObservationInfo
  • ObservationNames
  • Residuals
  • Steps
Variables

You can compute the residuals directly from the compact object returned by \( \text{LM} = \text{fitlm}(X,Y) \) using

\[
\text{RES} = Y - \text{predict(LM,X);} \\
S = \text{LM.RMSE;} \\
\text{histogram(RES,linspace(-3*S,3*S,51))}
\]

- If the \texttt{CompactLinearModel} object is missing lower order terms that include categorical factors:
  - The \texttt{plotEffects} and \texttt{plotInteraction} methods are not supported.
  - The \texttt{anova} method with the 'components' option is not supported.

For more information, see “Tall Arrays for Out-of-Memory Data” (MATLAB).

Introduced in R2013b
**fitlme**

Fit linear mixed-effects model

**Syntax**

lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)

**Description**

lme = fitlme(tbl,formula) returns a linear mixed-effects model, specified by formula, fitted to the variables in the table or dataset array tbl.

lme = fitlme(tbl,formula,Name,Value) returns a linear mixed-effects model with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

**Examples**

**Fit Linear Mixed-Effects Model**

Load the sample data.

load imports-85

Store the variables in a table.

tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{'Horsepower','CityMPG','EngineType'});

Display the first five rows of the table.

tbl(1:5,:)

<table>

<tr>
<td>115</td>
<td>18</td>
<td>35</td>
</tr>
</tbody>
</table>

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

lme = fitlme(tbl,'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
In this model, CityMPG is the response variable, horsepower is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to 1 + Horsepower, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a –1 to eliminate the intercept from the second random-effect term.

Display the model.

```matlab
lme
```

32-1862
Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

\[
lme2 = \text{fitlme(tbl,'CityMPG-Horsepower+(Horsepower|EngineType)' );}
\]

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to \((1 + \text{Horsepower}|\text{EngineType})\).

Display the model.

\[
lme2
\]

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

Fit Random Intercept LME Model

Load the sample data.

load flu

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the new response variable FluRate, the nominal variable Region that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.

flu2 = stack(flu,2:10,'NewDataVarName','FluRate', ...'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

Display the first six rows of flu2.

flu2(1:6,:)

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, WtdILI, and a random intercept that varies by Date. The model corresponds to

\[ y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \epsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma_b^2), \]

and the error term has the distribution,
\( \epsilon_{im} \sim N(0, \sigma^2) \).

```matlab
lme = fitlme(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =  
Linear mixed-effects model fit by ML

<td>0.30201</td>
<td>0.28217</td>
<td>0.32324</td>
</tr>
</tbody>
</table>

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of \( \sigma_b \) is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

32-1865
\[
\hat{y}_{28} = \hat{\beta}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{\beta}_{10/30/2005}
\]
\[
= 0.1639 + 0.7236 \times (1.343) + 0.3318
\]
\[
= 1.46749,
\]

where \( \hat{\beta} \) is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```matlab
beta = fixedEffects(lme); % Compute the fixed-effects components
[-,-,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

\( y_{hat} = 1.4674 \)

You can display the fitted value using the `fitted` method.

```matlab
F = fitted(lme);
F(28)
```

\( ans = 1.4674 \)

---

**LME Model for Randomized Block Design**

Load the sample data.

```matlab
load('shift.mat')
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a fixed effects design matrix to describe the effect of shift. This matrix has two columns, Shift_Evening and Shift_Morning, where

\[
\begin{align*}
\text{Shift}_\text{Evening} &= \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\end{align*}
\]

\[
\text{Shift}_\text{Morning} = \begin{cases} 
1, & \text{if Morning}
\end{cases}
\]

The model corresponds to

32-1866
Morning Shift: \( QCDev_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im}, \)

Evening Shift: \( QCDev_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \epsilon_{im}, \)

Night Shift: \( QCDev_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im}, \)

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, ..., 15, \) and \( m = 1, 2, ..., 5. \) The random effects and the observation error have the following distributions:

\( b_{0m} \sim N(0, \sigma_B^2) \)

and

\( \epsilon_{im} \sim N(0, \sigma^2). \)

```matlab
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)',...
             'FitMethod','REML','DummyVarCoding','effects')

lme =
   Linear mixed-effects model fit by REML

Model information:
   Number of observations              15
   Fixed effects coefficients           3
   Random effects coefficients          5
   Covariance parameters                2

Formula:
   QCDev ~ 1 + Shift + (1 | Operator)

Model fit statistics:
   AIC       BIC       LogLikelihood    Deviance
   58.913    61.337    -24.456          48.913

Fixed effects coefficients (95% CIs):
   Name                     Estimate    SE         tStat    DF    pValue
   {'(Intercept)'}          3.6525     0.94109    3.8812    12    0.0021832
   {'Shift\_Evening'}      -0.53293   0.31206    -1.7078    12      0.11339
   {'Shift\_Morning'}       -0.91973   0.31206    -2.9473    12     0.012206

       Lower      Upper
   1.6021       5.703
   -1.2129     0.14699
   -1.5997    -0.23981

Random effects covariance parameters (95% CIs):
   Group: Operator (5 Levels)
   Name1                  Name2                  Type           Estimate
   {'(Intercept)'}        {'(Intercept)'}        {'std'}        2.0457

       Lower      Upper
   0.98207      4.2612

Group: Error
   Name                     Estimate    Lower    Upper
```

32-1867
Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[ B = \text{randomEffects}(lme) \]

\[
B = \begin{bmatrix}
0.5775 \\
1.1757 \\
-2.1715 \\
2.3655 \\
-1.9472
\end{bmatrix}
\]

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

\[
\hat{y}_{\text{Evening, Operator3}} = \beta_0 + \beta_1 \text{Shift_Evening} + \hat{b}_{03} \\
= 3.6525 - 0.53293 - 2.1715 \\
= 0.94807.
\]

You can also display this value as follows.

\[
F = \text{fitted}(lme); \\
F(\text{shift.Shift=='Evening' & shift.Operator=='3'}) \\
\text{ans} = 0.9481
\]

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

\[
\hat{y}_{\text{Morning, Operator3}} = \beta_0 + \beta_2 \text{Shift_Morning} + \hat{b}_{03} \\
= 3.6525 - 0.91973 - 2.1715 \\
= 0.56127.
\]

You can also display this value as follows.

\[
F(\text{shift.Shift=='Morning' & shift.Operator=='3'}) \\
\text{ans} = 0.5613
\]

The operator tends to make a smaller magnitude of error during the morning shift.

**LME Model for Split-Plot Experiment**

Load the sample data.

\[
\text{load('fertilizer.mat')}
\]

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of...
tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```matlab
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

\[
y_{imjk} = \beta_0 + \sum_{m=2}^{4} \beta_{1m} I[F]_{im} + \sum_{j=2}^{5} \beta_{2j} I[T]_{ij} + \sum_{j=2}^{5} \sum_{m=2}^{4} \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S \ast T)_{jk} + \epsilon_{imjk},
\]

where \(i = 1, 2, \ldots, 60\), index \(m\) corresponds to the fertilizer types, \(j\) corresponds to the tomato types, and \(k = 1, 2, 3\) corresponds to the blocks (soil). \(S_k\) represents the \(k\)th soil type, and \((S \ast T)_{jk}\) represents the \(j\)th tomato type nested in the \(k\)th soil type. \(I[F]_{im}\) is the dummy variable representing level \(m\) of the fertilizer. Similarly, \(I[T]_{ij}\) is the dummy variable representing level \(j\) of the tomato type.

The random effects and observation error have these prior distributions: \(b_{0k} \sim N(0, \sigma_S^2)\), \(b_{0jk} \sim N(0, \sigma_{S \ast T}^2)\), and \(\epsilon_{imjk} \sim N(0, \sigma^2)\).

```matlab
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

```
lme = 
Linear mixed-effects model fit by ML
```

**Model information:**
- Number of observations: 60
- Fixed effects coefficients: 20
- Random effects coefficients: 18
- Covariance parameters: 3

**Formula:**
\[\text{Yield} \sim 1 + \text{Tomato} \ast \text{Fertilizer} + (1 \mid \text{Soil}) + (1 \mid \text{Soil:Tomato})\]

**Model fit statistics:**
- AIC: 522.57
- BIC: 570.74
- LogLikelihood: -238.29
- Deviance: 476.57

Group: Error
The \( p \)-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the \texttt{anova} method after refitting the model using ‘effects’ contrasts.

The confidence interval for the standard deviations of the random-effects terms (\( \sigma^2 \)), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term \texttt{Tomato:Fertilizer} and the random-effects term \((1 \mid \text{Soil})\).

You can compare the two models using the compare method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

### Longitudinal Study with a Covariate

Load the sample data.

```matlab
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```matlab
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables `I[.]`. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the ‘reference’ method of coding dummy variables.

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 I_{W_i} + \beta_2 I_{Wk_i} + \beta_3 I_{[PB]_i} + \beta_4 I_{[PC]_i} + \beta_5 I_{[PD]_i} \\
+ \beta_6 (Week_i \ast I_{[PB]_i}) + \beta_7 (Week_i \ast I_{[PC]_i}) + \beta_8 (Week_i \ast I_{[PD]_i}) \\
+ b_{0m} + b_{1m} Week_{im} + \epsilon_{im},
\]

where \( i = 1, 2, \ldots, 120 \), and \( m = 1, 2, \ldots, 20 \). \( \beta_j \) are the fixed-effects coefficients, \( j = 0, 1, \ldots, 8 \), and \( b_{0m} \) and \( b_{1m} \) are random effects. \( I_{W} \) stands for initial weight and \( I[\cdot] \) is a dummy variable representing a type of program. For example, \( I_{[PB]} \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2) \\
b_{1m} \sim N(0, \sigma_1^2)
\]
\[ \epsilon_{im} \sim N(0, \sigma^2). \]

```matlab
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

Group: Error
The p-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

### Input Arguments

**tbl** — Input data
table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see "Grouping Variables" on page 2-45). You must specify the model for the variables using `formula`.

Data Types: table

**formula** — Formula for model specification
character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. The formula is case sensitive. For a full description, see "Formula" on page 32-1878.

Example: 'y ~ treatment + (1|block)'

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `CovariancePattern','Diagonal','Optimizer','fminunc','OptimizerOptions',opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

**CovariancePattern** — Pattern of covariance matrix
'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are $R$ random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length $R$, where each element $r$ of the array specifies the pattern of the covariance matrix...
matrix of the random-effects vector associated with the $r$th random-effects term. The options for each element follow.

- **'FullCholesky'**
  Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

- **'Full'**
  Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

- **'Diagonal'**
  Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

\[
\begin{pmatrix}
\sigma_{b1}^2 & 0 & 0 \\
0 & \sigma_{b2}^2 & 0 \\
0 & 0 & \sigma_{b3}^2
\end{pmatrix}
\]

- **'Isotropic'**
  Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_{b1}^2 & 0 & 0 \\
0 & \sigma_{b2}^2 & 0 \\
0 & 0 & \sigma_{b3}^2
\end{pmatrix}
\]

where $\sigma_{b1}^2$ is the common variance of the random-effects terms.

- **'CompSymm'**
  Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2
\end{pmatrix}
\]

where $\sigma_{b1}^2$ is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term.
PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \( PAT(a,b) = \text{false} \), then the \((a, b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern',
{'Full','Diagonal'}
Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'
Default. Maximum likelihood estimation
'REML'
Restricted maximum likelihood estimation

Example: 'FitMethod','REML'

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]
Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding','effects'
Optimizer — Optimization algorithm

'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinewton'

Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using \texttt{statset('LinearMixedModel')}.

If you don't specify the options, then \texttt{LinearMixedModel} uses the default options of \texttt{statset('LinearMixedModel')}.

'fminunc'

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using \texttt{optimoptions('fminunc')}.

If you don't specify the options, then \texttt{LinearMixedModel} uses the default options of \texttt{optimoptions('fminunc')} with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

OptimizerOptions — Options for optimization algorithm

structure returned by \texttt{statset} | object returned by \texttt{optimoptions}

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by \texttt{statset('LinearMixedModel')} or an object returned by \texttt{optimoptions('fminunc')}.

- If 'Optimizer' is 'fminunc', then use \texttt{optimoptions('fminunc')} to change the options of the optimization algorithm. See \texttt{optimoptions} for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for \texttt{LinearMixedModel} is the default options created by \texttt{optimoptions('fminunc')} with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use \texttt{statset('LinearMixedModel')} to change the optimization parameters. If you don't change the optimization parameters, then \texttt{LinearMixedModel} uses the default options created by \texttt{statset('LinearMixedModel')}.

The 'quasinewton' optimizer uses the following fields in the structure created by \texttt{statset('LinearMixedModel')}:

TolFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

TolX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value
Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true

**CheckHessian — Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

**Output Arguments**

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

**More About**

**Formula**

In general, a formula for model specification is a character vector or string scalar of the form '

$y \sim terms$'. For the linear mixed-effects models, this formula is in the form '$y \sim fixed + (random1|$
grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table tbl contains the following:
- A response variable, y
- Predictor variables, Xj, which can be continuous or grouping variables
- Grouping variables, g1, g2, ..., gR,

where the grouping variables in Xj and gj can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random1|g1) + ... + (randomR|gR)', the term fixed corresponds to a specification of the fixed-effects design matrix X, random1 is a specification of the random-effects design matrix Z1 corresponding to grouping variable g1, and similarly randomR is a specification of the random-effects design matrix ZR corresponding to grouping variable gR. You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>X^k, where k is a positive integer</td>
<td>X, X^2, ..., X^k</td>
</tr>
<tr>
<td>X1 + X2</td>
<td>X1, X2</td>
</tr>
<tr>
<td>X1*X2</td>
<td>X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)</td>
</tr>
<tr>
<td>X1:X2</td>
<td>X1.*X2 only</td>
</tr>
<tr>
<td>- X2</td>
<td>Do not include X2</td>
</tr>
<tr>
<td>X1*X2 + X3</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1 + X2 + X3 + X1:X2</td>
<td>X1, X2, X3, X1*X2</td>
</tr>
<tr>
<td>X1<em>X2</em>X3 - X1:X2:X3</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3, X2*X3</td>
</tr>
<tr>
<td>X1*(X2 + X3)</td>
<td>X1, X2, X3, X1<em>X2, X1</em>X3</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

<table>
<thead>
<tr>
<th>Formula</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'y ~ X1 + X2'</td>
<td>Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.</td>
</tr>
<tr>
<td>'y ~ -1 + X1 + X2'</td>
<td>No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.</td>
</tr>
<tr>
<td>Formula</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (X1</td>
<td>g1)'</td>
</tr>
<tr>
<td>'y ~ X1 + (1</td>
<td>g1) + (-1 + X1</td>
</tr>
<tr>
<td>'y ~ 1 + (1</td>
<td>g1) + (1</td>
</tr>
</tbody>
</table>

**Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[ b \sim N(0, \sigma^2 D(\theta)), \]

where \( D \) is a \( q \)-by-\( q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the observation error variance. Since the covariance matrix of the random effects, \( D \), is symmetric, it has \( q(q+1)/2 \) free parameters. Suppose \( L \) is the lower triangular Cholesky factor of \( D(\theta) \) such that

\[ D(\theta) = L(\theta)L(\theta)^T, \]

then the \( q*(q+1)/2 \)-by-1 unconstrained parameter vector \( \theta \) is formed from elements in the lower triangular part of \( L \).

For example, if

\[ L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix}, \]

then

\[ \theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}. \]

**Log-Cholesky Parameterization**

When the diagonal elements of \( L \) in Cholesky parameterization are constrained to be positive, then the solution for \( L \) is unique. Log-Cholesky parameterization is the same as Cholesky parameterization.
except that the logarithm of the diagonal elements of $L$ are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$
\begin{bmatrix}
\log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33})
\end{bmatrix}
$$

**Alternatives**

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

**Introduced in R2013b**
fitlmematrix

Fit linear mixed-effects model

Syntax

lme = fitlmematrix(X,y,Z,[])
lme = fitlmematrix(X,y,Z,G)
lme = fitlmematrix(____,Name,Value)

Description

lme = fitlmematrix(X,y,Z,[]) creates a linear mixed-effects model of the responses y using the fixed-effects design matrix X and random-effects design matrix or matrices in Z.

[] implies that there is one group. That is, the grouping variable G is ones(n,1), where n is the number of observations. Using fitlmematrix(X,Y,Z,[]) without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design Z and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

lme = fitlmematrix(X,y,Z,G) creates a linear mixed-effects model of the responses y using the fixed-effects design matrix X and random-effects design matrix Z or matrices in Z, and the grouping variable or variables in G.

lme = fitlmematrix(____,Name,Value) also creates a linear mixed-effects model with additional options specified by one or more Name,Value pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

load carsmall

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)

lme =

Now, fit the same model by building the grouping into the Z matrix.

\[ Z = \text{double}([\text{Model Year==70, Model Year==76, Model Year==82}]); \]
\[ \text{lme} = \text{fitlmematrix}(X,y,Z,[],'\text{Covariancepattern','Isotropic'}) \]

Now, fit the same model by building the grouping into the Z matrix.

\[ Z = \text{double}([\text{Model Year==70, Model Year==76, Model Year==82}]); \]
\[ \text{lme} = \text{fitlmematrix}(X,y,Z,[],'\text{Covariancepattern','Isotropic'}) \]
Load the sample data.

```matlab
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 [PB]_i + \beta_4 [PC]_i + \beta_5 [PD]_i \\
+ \beta_6 (Week_i \times [PB]_i) + \beta_7 (Week_i \times [PC]_i) + \beta_8 (Week_i \times [PD]_i) \\
+ b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
\]

where \(i = 1, 2, ..., 120\), and \(m = 1, 2, ..., 20\). \(\beta_j\) are the fixed-effects coefficients, \(j = 0, 1, ..., 8\), and \(b_{0m}\) and \(b_{1m}\) are random effects. IW stands for initial weight and \([ \cdot ]\) is a dummy variable representing a type of program. For example, \([PB]_i\) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[
b_{0m} \sim N(0, \sigma_0^2)
\]

\[
b_{1m} \sim N(0, \sigma_1^2)
\]

\[
\varepsilon_{im} \sim N(0, \sigma^2).
\]

```matlab
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
```
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...  
    D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];  
Z = [ones(120,1), Week];  
G = Subject;

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using fitlmematrix with the defined design matrices and grouping variables.

```matlab
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...  
    {'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD'},...  
    'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'});
```

```matlab
lme =

Random effects covariance parameters (95% CIs):  
Group: Subject (20 Levels)
Name1          Name2          Type            Estimate
{'Intercept'}  {'Intercept'}  {'std'}       0.18407

32-1885
Examine the fixed effects coefficients table. The row labeled 'InitWeight' has a p-value of 0.0228, and the row labeled 'Week' has a p-value of 0.0115. These p-values indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.

**Random Intercept Model**

Load the sample data.

```matlab
load flu
```

The flu dataset array has a Date variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, FluRate, and a nominal variable, Region, the nationwide estimate WtdILI, that shows which region each estimate is from, and the grouping variable Date.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

\[ y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52, \]

where \( y_{im} \) is the observation \( i \) for level \( m \) of grouping variable Date, \( b_{0m} \) is the random effect for level \( m \) of the grouping variable Date, and \( \varepsilon_{im} \) is the observation error for observation \( i \). The random effect has the prior distribution,

\[ b_{0m} \sim N(0, \sigma_b^2), \]

and the error term has the distribution,
\[ \varepsilon_{im} \sim N(0, \sigma^2). \]

```matlab
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;

Fit the linear mixed-effects model.
```

```matlab
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},...
'RandomEffectPredictors',{{'Intercept'}},'RandomEffectGroups',{['Date']})
```

```matlab
lme =
Linear mixed-effects model fit by ML
```

Model information:
- Number of observations: 468
- Fixed effects coefficients: 2
- Random effects coefficients: 52
- Covariance parameters: 2

Formula:
y ~ Intercept + NationalRate + (Intercept | Date)

Model fit statistics:
- AIC: 286.24
- BIC: 302.83
- LogLikelihood: -139.12
- Deviance: 278.24

Fixed effects coefficients (95% CIs):
- `'Intercept'`: Estimate: 0.16385, SE: 0.057525, tStat: 2.8484, DF: 466, pValue: 0.0045885
- `'NationalRate'`: Estimate: 0.7236, SE: 0.032219, tStat: 22.459, DF: 466, pValue: 3.0502e-76

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>
<th>DF</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'Intercept'</code></td>
<td>0.16385</td>
<td>0.057525</td>
<td>2.8484</td>
<td>466</td>
<td>0.0045885</td>
</tr>
<tr>
<td><code>'NationalRate'</code></td>
<td>0.7236</td>
<td>0.032219</td>
<td>22.459</td>
<td>466</td>
<td>3.0502e-76</td>

</tbody>
</table>

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)
- `'Intercept'`: Name1: `'Intercept'`, Name2: `'Intercept'`, Type: `'std'`, Estimate: 0.17146, Lower: 0.13227
- Upper: 0.22226

Group: Error
- `'Res Std'`: Name: `'Res Std'`, Estimate: 0.30201, Lower: 0.28217, Upper: 0.32324

The confidence limits of the standard deviation of the random-effects term \( \sigma_b \), do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.
The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

\[ \hat{y}_{28} = \hat{b}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{b}_{10/30/2005} \]
\[ = 0.1639 + 0.7236 \times (1.343) + 0.3318 \]
\[ = 1.46749, \]

where \( \hat{b} \) is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```matlab
beta = fixedEffects(lme); % compute the fixed effects
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

\[ y_{hat} = 1.4674 \]

You can simply display the fitted value using the `fitted(lme)` method.

```matlab
F = fitted(lme);
F(28)
an = 1.4674
```

**Randomized Block Design**

Load the sample data.

```matlab
load('shift.mat');
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. ‘effects’ contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

\[
\text{Shift\_Evening} = \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

\[
\text{Shift\_Morning} = \begin{bmatrix} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{bmatrix}
\]

The model corresponds to
Morning Shift: \[ Q_{Dev_i} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im}, \]

Evening Shift: \[ Q_{Dev_i} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \epsilon_{im}, \]

Night Shift: \[ Q_{Dev_i} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im}, \]

where \( i \) represents the observations, and \( m \) represents the operators, \( i = 1, 2, \ldots, 15 \), and \( m = 1, 2, \ldots, 5 \). The random effects and the observation error have the following distributions:

\[ b_{0m} \sim N(0, \sigma^2_b) \]

and

\[ \epsilon_{im} \sim N(0, \sigma^2). \]

\[ S = \text{shift.Shift}; \]
\[ X1 = (S=='Morning') - (S=='Night'); \]
\[ X2 = (S=='Evening') - (S=='Night'); \]
\[ X = [\text{ones}(15,1), X1, X2]; \]
\[ y = \text{shift.QCDev}; \]
\[ Z = \text{ones}(15,1); \]
\[ G = \text{shift.Operator}; \]

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```r
lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
                      {'Intercept','S_Morning','S_Evening'},
                      'RandomEffectGroups',{'Operator'},
                      'DummyVarCoding','effects')
```

lme =

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

\[
B = \text{randomEffects}(\text{lme})
\]

\[
B = \begin{pmatrix} 0.5775 \\ 1.1757 \\ -2.1715 \\ 2.3655 \\ -1.9472 \end{pmatrix}
\]

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

\[
\hat{y}_{\text{Evening, Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift}_{\text{Evening}} + \hat{b}_{03}
\]

\[
= 3.6525 - 0.53293 - 2.1715
\]

\[
= 0.94807
\]

You can also display this value as follows.

\[
F = \text{fitted}(\text{lme});
F(\text{shift.Shift=='Evening' & shift.Operator=='3'})
\]

\[
\text{ans} = 0.9481
\]

**Correlated and Uncorrelated Random-Effects Terms**

Load the sample data.

\[
\text{load carbig}
\]

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

\[
\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \epsilon_{im}, \quad m = 1, 2, 3,
\]

with the random-effects terms having the following prior distributions:
\[ b_{0m} \sim N(0, \sigma_0^2), \]
\[ b_{1m} \sim N(0, \sigma_1^2), \]

where \( m \) represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

\[
X = \begin{bmatrix} \text{ones(406,1)}, \text{Acceleration}, \text{Horsepower} \end{bmatrix};
\]

\[
Z = \{ \text{ones(406,1)}, \text{Acceleration} \};
\]

\[
G = \{ \text{Model}_\text{Year}, \text{Model}_\text{Year} \};
\]

\[
\text{Model}_\text{Year} = \text{nominal}(\text{Model}_\text{Year});
\]

Now, fit the model using \texttt{fitlmematrix} with the defined design matrices and grouping variables.

\[
\text{lme} = \text{fitlmematrix}(X, \text{MPG}, Z, G, '\text{FixedEffectPredictors}', ... \{ '\text{Intercept}', '\text{Acceleration}', '\text{Horsepower}' \}, '\text{RandomEffectPredictors}', ... \{ \{ '\text{Intercept}' \}, \{ '\text{Acceleration}' \} \}, '\text{RandomEffectGroups}', \{ '\text{Model}_\text{Year}', '\text{Model}_\text{Year}' \})
\]

\[
\text{lme} = \text{Linear mixed-effects model fit by ML}
\]

Model information:
- Number of observations: 392
- Fixed effects coefficients: 3

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the compare method.

**Specify the Covariance Pattern**

Load the sample data.

```matlab
load('weight.mat');
```

*weight* contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define *Subject* and *Program* as categorical variables.

```matlab
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```matlab
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

\[
y_{im} = \beta_0 + \beta_1 W_i + \beta_2 \text{Week}_i + \beta_3 [PB]_i + \beta_4 [PC]_i + \beta_5 [PD]_i \\
+ b_{0m} + b_{1m} \text{Week2}_{im} + b_{2m} \text{Week4}_{im} + b_{3m} \text{Week6}_{im} + b_{4m} \text{Week8}_{im} \\
+ b_{5m} \text{Week10}_{im} + b_{6m} \text{Week12}_{im} + \epsilon_{im},
\]
where $i = 1, 2, ..., 120$, and $m = 1, 2, ..., 20$.

$\beta_j$ are the fixed-effects coefficients, $j = 0, 1, ..., 8$, and $b_{0m}$ and $b_{1m}$ are random effects. IW stands for initial weight and $[.]$ is a dummy variable representing a type of program. For example, $I[PB]$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```matlab
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},... 'RandomEffectPredictors',{{'Intercept','Week'}},... 'RandomEffectGroups','Subject','CovariancePattern','Isotropic')
```

```
lme =
Linear mixed-effects model fit by ML

Random effects covariance parameters (95% CIs):
Input Arguments

X — Fixed-effects design matrix
n-by-p matrix

Fixed-effects design matrix, specified as an n-by-p matrix, where n is the number of observations, and p is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

Data Types: single | double

y — Response values
n-by-1 vector

Response values, specified as an n-by-1 vector, where n is the number of observations.

Data Types: single | double

Z — Random-effects design
n-by-q matrix | cell array of R n-by-q(r) matrices, r = 1, 2, ..., R

Random-effects design, specified as either of the following.

• If there is one random-effects term in the model, then Z must be an n-by-q matrix, where n is the number of observations and q is the number of variables in the random-effects term.
• If there are R random-effects terms, then Z must be a cell array of length R. Each cell of Z contains an n-by-q(r) design matrix Z{r}, r = 1, 2, ..., R, corresponding to each random-effects term. Here, q(r) is the number of random effects term in the rth random effects design matrix, Z{r}.

Data Types: single | double | cell

G — Grouping variable or variables
n-by-1 vector | cell array of R n-by-1 vectors

Grouping variable or variables on page 2-45, specified as either of the following.

• If there is one random-effects term, then G must be an n-by-1 vector corresponding to a single grouping variable with M levels or groups.

    G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.
• If there are multiple random-effects terms, then \( G \) must be a cell array of length \( R \). Each cell of \( G \) contains a grouping variable \( G{r} \), \( r = 1, 2, ..., R \), with \( M(r) \) levels.

\( G{r} \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: categorical | logical | single | double | char | string | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:
'CovariancePattern','Diagonal','DummyVarCoding','full','Optimizer','fminunc'
specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the fminunc optimization algorithm.

FixedEffectPredictors — Names of columns in fixed-effects design matrix

\{'x1', 'x2', ..., 'xP'\} (default) | string array or cell array of length \( p \)

Names of columns in the fixed-effects design matrix \( X \), specified as the comma-separated pair consisting of 'FixedEffectPredictors' and a string array or cell array of length \( p \).

For example, if you have a constant term and two predictors, say TimeSpent and Gender, where Female is the reference level for Gender, as the fixed effects, then you can specify the names of your fixed effects in the following way. Gender_Male represents the dummy variable you must create for category Male. You can choose different names for these variables.

Example: ['FixedEffectPredictors','{'Intercept','TimeSpent','Gender_Male'}],

Data Types: string | cell

RandomEffectPredictors — Names of columns in random-effects design matrix or cell array

string array or cell array of length \( q \) | cell array of length \( R \) with elements of length \( q(r) \), \( r = 1, 2, ..., R \)

Names of columns in the random-effects design matrix or cell array \( Z \), specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

• A string array or cell array of length \( q \) when \( Z \) is an \( n \)-by-\( q \) design matrix. In this case, the default is \{'z1', 'z2', ..., 'zQ'\}.

• A cell array of length \( R \), when \( Z \) is a cell array of length \( R \) with each element \( Z{r} \) of length \( q(r) \), \( r = 1, 2, ..., R \). In this case, the default is \{'z11', 'z12', ..., 'z1Q(1)'\},...,\{'zr1', 'zr2', ..., 'zrQ(r)'\}.

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors','{'Intercept','Acceleration'}'

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable g1, and the second for the intercept, grouped by the variable g2, then you specify the random-effects predictor names as follows.
Example: ‘RandomEffectPredictors’,{{'Intercept','Acceleration'},{'Intercept'}}
Data Types: string | cell

**ResponseVarName — Name of response variable**

'y' (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a character vector or string scalar.

For example, if your response variable name is **score**, then you can specify it as follows.
Example: 'ResponseVarName','score'
Data Types: char | string

**RandomEffectGroups — Names of random effects grouping variables**

'g' or {'g1','g2',...,'gR'} (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if **G** is a vector, then the value of 'RandomEffectGroups' is the name for the grouping variable **G**. The default is 'g'.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if **G** is a cell array of length **R**, then the value of 'RandomEffectGroups' is a string array or cell array of length **R**, where each element is the name for the grouping variable **G{r}**. The default is {'g1','g2',...,'gR'}.

For example, if you have two random-effects terms, **z1** and **z2**, grouped by the grouping variables **sex** and **subject**, then you can specify the names of your grouping variables as follows.
Example: 'RandomEffectGroups',{'sex','subject'}
Data Types: char | string | cell

**CovariancePattern — Pattern of covariance matrix**

'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are **R** random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length **R**, where each element **r** of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the **r**th random-effects term. The options for each element follow.

'FullCholesky' Default. Full covariance matrix using the Cholesky parameterization. **fitlme** estimates all elements of the covariance matrix.
'Full' Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal' Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

\[
\begin{bmatrix}
\sigma_{b1}^2 & 0 & 0 \\
0 & \sigma_{b2}^2 & 0 \\
0 & 0 & \sigma_{b3}^2
\end{bmatrix}
\]

'Isotropic' Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{bmatrix}
\sigma_b^2 & 0 & 0 \\
0 & \sigma_b^2 & 0 \\
0 & 0 & \sigma_b^2
\end{bmatrix}
\]

where \( \sigma_b^2 \) is the common variance of the random-effects terms.

'CompSymm' Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{bmatrix}
\sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\
\sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2
\end{bmatrix}
\]

where \( \sigma_{b1}^2 \) is the common variance of the random-effects terms and \( \sigma_{b1,b2} \) is the common covariance between any two random-effects term.

PAT Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'
Example: 'CovariancePattern',
{'Full', 'Diagonal'}
Data Types: char | string | logical | cell

**FitMethod — Method for estimating parameters**

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

- 'ML' Default. Maximum likelihood estimation
- 'REML' Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

**Weights — Observation weights**

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n, where n is the number of observations.

Data Types: single | double

**Exclude — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13, 67]

Data Types: single | double | logical

**DummyVarCoding — Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding', 'effects'

**Optimizer — Optimization algorithm**

'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.
'quasinewton'

Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using \texttt{statset('LinearMixedModel')}. If you don't specify the options, then \texttt{LinearMixedModel} uses the default options of \texttt{statset('LinearMixedModel')}.

'fminunc'

You must have Optimization Toolbox to specify this option. Change the options of the algorithm using \texttt{optimoptions('fminunc')}. If you don't specify the options, then \texttt{LinearMixedModel} uses the default options of \texttt{optimoptions('fminunc')} with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

\textbf{OptimizerOptions — Options for optimization algorithm}

structure returned by \texttt{statset} | object returned by \texttt{optimoptions}

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by \texttt{statset('LinearMixedModel')} or an object returned by \texttt{optimoptions('fminunc')}.

- If 'Optimizer' is 'fminunc', then use \texttt{optimoptions('fminunc')} to change the options of the optimization algorithm. See \texttt{optimoptions} for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for \texttt{LinearMixedModel} is the default options created by \texttt{optimoptions('fminunc')} with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use \texttt{statset('LinearMixedModel')} to change the optimization parameters. If you don’t change the optimization parameters, then \texttt{LinearMixedModel} uses the default options created by \texttt{statset('LinearMixedModel')}:

The 'quasinewton' optimizer uses the following fields in the structure created by \texttt{statset('LinearMixedModel')}:

\textbf{TolFun — Relative tolerance on gradient of objective function}

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

\textbf{TolX — Absolute tolerance on step size}

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

\textbf{MaxIter — Maximum number of iterations allowed}

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

\textbf{Display — Level of display}

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

32-1900
**StartMethod —** Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose —** Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true

**CheckHessian —** Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

**Output Arguments**

**lme —** Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

**More About**

**Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[ b \sim N(0, \sigma^2 D(\theta)), \]

where \( D \) is a \( q \times q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the observation error variance. Since the covariance matrix of the random effects, \( D \), is symmetric, it has \( q(q+1)/2 \) free parameters. Suppose \( L \) is the lower triangular Cholesky factor of \( D(\theta) \) such that
\[ D(\theta) = L(\theta)L(\theta)^T, \]
then the \( q(q+1)/2 \)-by-1 unconstrained parameter vector \( \theta \) is formed from elements in the lower triangular part of \( L \).

For example, if
\[
L = \begin{bmatrix}
L_{11} & 0 & 0 \\
L_{21} & L_{22} & 0 \\
L_{31} & L_{32} & L_{33}
\end{bmatrix},
\]
then
\[
\theta = \begin{bmatrix}
L_{11} \\
L_{21} \\
L_{31} \\
L_{22} \\
L_{32} \\
L_{33}
\end{bmatrix}.
\]

**Log-Cholesky Parameterization**

When the diagonal elements of \( L \) in Cholesky parameterization are constrained to be positive, then the solution for \( L \) is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of \( L \) are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing \( L_{ii} \geq 0 \),
\[
\theta = \begin{bmatrix}
\log(L_{11}) \\
L_{21} \\
L_{31} \\
\log(L_{22}) \\
L_{32} \\
\log(L_{33})
\end{bmatrix}.
\]

**Alternative Functionality**

You can also fit a linear mixed-effects model using `fitlme(tbl,formula)`, where `tbl` is a table or dataset array containing the response \( y \), the predictor variables \( X \), and the grouping variables, and `formula` is of the form \( 'y \sim fixed + (random_1|g_1) + \ldots + (random_R|g_R)' \).

**See Also**

LinearMixedModel | compare | fitlme

*Introduced in R2013b*
fitrgp

Fit a Gaussian process regression (GPR) model

Syntax

gprMdl = fitrgp(Tbl,ResponseVarName)
gprMdl = fitrgp(Tbl,formula)
gprMdl = fitrgp(Tbl,y)
gprMdl = fitrgp(X,y)
gprMdl = fitrgp(___,'Name',Value)

Description

gprMdl = fitrgp(Tbl,ResponseVarName) returns a Gaussian process regression (GPR) model trained using the sample data in Tbl, where ResponseVarName is the name of the response variable in Tbl.

gprMdl = fitrgp(Tbl,formula) returns a Gaussian process regression (GPR) model, trained using the sample data in Tbl, for the predictor variables and response variables identified by formula.

gprMdl = fitrgp(Tbl,y) returns a GPR model for the predictors in table Tbl and continuous response vector y.

gprMdl = fitrgp(X,y) returns a GPR model for predictors X and continuous response vector y.

gprMdl = fitrgp(___,'Name',Value) returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.

gprMdl is a RegressionGP object. For methods and properties of this class, see RegressionGP class page.

If you train a cross-validated model, then gprMdl is a RegressionPartitionedModel object. For further analysis on the cross-validated object, use the methods of RegressionPartitionedModel class. For the methods of this class, see the RegressionPartitionedModel class page.

Examples

Train GPR Model Using Data in Table

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name abalone.data.

Store the data into a table. Display the first seven rows.
tbl = readtable('abalone.data','Filetype','text',... 'ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height',... 'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
ans =

    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRings
   ___    ______    ________    ______    _______    _______    _______    ________    ____________

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Fit a GPR model using the subset of regressors method for parameter estimation and fully independent conditional method for prediction. Standardize the predictors.

gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',... 'FitMethod','sr','PredictMethod','fic','Standardize',1)
grMdl =

RegressionGP
    PredictorNames: {1x8 cell}

    ActiveSetHistory: [1x1 struct]
    BCDInformation: []

Predict the responses using the trained model.

ypred = resubPredict(gprMdl);
Plot the true response and the predicted responses.

```matlab
figure();
plot(tbl.NoShellRings,'r.');
hold on
plot(ypred,'b');
xlabel('x');
ylabel('y');
legend({'data','predictions'},'Location','Best');
axis([0 4300 0 30]);
hold off;
```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```matlab
L = resubLoss(gprMdl)
L =
4.0064
```

**Train GPR Model and Plot Predictions**

Generate sample data.

```matlab
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```
Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

```matlab
gprMdl = fitrgp(x,y,'Basis','linear',...  
    'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of `x` (resubstitution predictions) using the trained model.

```matlab
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```matlab
plot(x,y,'b.');  
hold on;  
plot(x,ypred,'r','LineWidth',1.5);  
xlabel('x');  
ylabel('y');  
legend('Data','GPR predictions');  
hold off
```

**Impact of Specifying Initial Kernel Parameter Values**

Load the sample data.
load('gprdata2.mat')

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');

Now, fit a second model, where you specify the initial values for the kernel parameters.

sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',
               'KernelParameters',kparams0,'Sigma',sigma0);

Compute the resubstitution predictions from both models.

ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);

Plot the response predictions from both models and the responses in training data.

figure();
plot(x,y,'r.');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters','kparams0 = [3.5,6.2], sigma0 = 0.2'},
       'Location','Best');
title('Impact of initial kernel parameter values');
hold off
The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

**Use Separate Length Scales for Predictors**

Load the sample data.

```matlab
load('gprdata.mat')
```

There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

\[
k_{ij} \theta = \sigma_f^2 \exp \left[ -\frac{1}{2} \sum_{m=1}^{d} \frac{(x_{im} - x_{jm})^2}{\sigma_m^2} \right].
\]

where \( \sigma_m \) represents the length scale for predictor \( m \), \( m = 1, 2, ..., d \) and \( \sigma_f \) is the signal standard deviation. The unconstrained parametrization \( \theta \) is...
\[ \theta_m = \log \sigma_m, \text{ for } m = 1, 2, \ldots, d \]
\[ \theta_{d+1} = \log \sigma_f. \]

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

\[
\begin{align*}
\text{sigma0} &= \text{std}(y\text{train}); \\
\text{sigmaF0} &= \text{sigma0}; \\
\text{d} &= \text{size}(X\text{train},2); \\
\text{sigmaM0} &= 10^*\text{ones}(d,1);
\end{align*}
\]

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

\[
\text{gprMdl} = \text{fitrgp}(X\text{train}, y\text{train}, [\text{Basis}, 'constant', \text{FitMethod}, 'exact', ... \\
'\text{PredictMethod}', 'exact', '\text{KernelFunction}', '\text{ardsquaredexponential}', ... \\
'\text{KernelParameters}', [\text{sigmaM0}; \text{sigmaF0}], '\text{Sigma}', \text{sigma0}, '\text{Standardize}', 1);
\]

Compute the regression loss on the test data.

\[
L = \text{loss(gprMdl, X\text{test}, y\text{test})}
\]

\[
L = 0.6919
\]

Access the kernel information.

\[
\text{gprMdl.KernelInformation}
\]

\[
\begin{align*}
\text{ans} &= \text{struct with fields:} \\
&\hspace{1cm}\text{Name: 'ARDSquaredExponential'} \\
&\hspace{1cm}\text{KernelParameters: [7x1 double]} \\
&\hspace{1cm}\text{KernelParameterNames: [7x1 cell]}
\end{align*}
\]

Display the kernel parameter names.

\[
\text{gprMdl.KernelInformation.KernelParameterNames}
\]

\[
\begin{align*}
\text{ans} &= 7\times1 \text{ cell} \\
&\hspace{1cm}\{'\text{LengthScale1}'\} \\
&\hspace{1cm}\{'\text{LengthScale2}'\} \\
&\hspace{1cm}\{'\text{LengthScale3}'\} \\
&\hspace{1cm}\{'\text{LengthScale4}'\} \\
&\hspace{1cm}\{'\text{LengthScale5}'\} \\
&\hspace{1cm}\{'\text{LengthScale6}'\} \\
&\hspace{1cm}\{'\text{SigmaF}'\}
\end{align*}
\]

Display the kernel parameters.

\[
\text{sigmaM} = \text{gprMdl.KernelInformation.KernelParameters}(1:end-1,1)
\]

\[
\begin{align*}
\text{sigmaM} &= 6\times1 \\
&\hspace{1cm}10^4 \times \\
&\hspace{1cm}0.0004 \\
&\hspace{1cm}0.0007 \\
&\hspace{1cm}0.0004
\end{align*}
\]
4.1731
0.1018
0.0056

\[
\begin{align*}
\sigma_F &= \text{gprMdl.KernelInformation.KernelParameters}(\text{end}) \\
\sigma_F &= 28.1718 \\
\sigma &= \text{gprMdl.Sigma} \\
\sigma &= 0.8162
\end{align*}
\]

Plot the log of learned length scales.

```matlab
figure()
plot((1:d)',log(sigmaM),'ro-');
xlabel('Length scale number');
ylabel('Log of length scale');
```

The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```matlab
X = [Xtrain(:,1:3) Xtrain(:,6)];
sigma0 = std(ytrain);
sigmaF0 = sigma0;
```
d = size(X,2);
sigmaM0 = 10*ones(d,1);

```
gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',... 'PredictMethod','exact','KernelFunction','ardsquaredexponential',... 'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression error on the test data.

```
xtest = [Xtest(:,1:3) Xtest(:,6)];
L = loss(gprMdl,xtest,ytest)
L = 0.6928
```

The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

```
ypred = predict(gprMdl,xtest);
```

Plot the original response along with the fitted values.

```
figure;
plot(ytest,'r');
hold on;
plot(ypred,'b');
legend('True response','GPR predicted values','Location','Best');
hold off
```
Optimize GPR Regression

This example shows how to optimize hyperparameters automatically using `fitrgp`. The example uses the `gprdata2` data that ships with your software.

Load the data.

```matlab
load('gprdata2.mat')
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```matlab
gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```matlab
rng default

gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'));
```

Train GPR Model Using Cross-Validation

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name abalone.data.

Store the data into a table. Display the first seven rows.

```matlab
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height','WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
```

```plaintext
ans =
    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRings
    ___    ______    ________    ______    _______    _______    _______    ________    ____________

    'I'    0.425       0.3       0.095     0.3515      0.141     0.0775      0.12        8
    'F'     0.53     0.415        0.15     0.7775      0.237     0.1415      0.33       20
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Train a cross-validated GPR model using the 25% of the data for validation.

```matlab
rng('default') % For reproducibility
cvgprMdl = fitrgp(tbl,'NoShellRings','Standardize',1,'Holdout',0.25);
```

Compute the average loss on folds using models trained on out-of-fold observations.

```matlab
kfoldLoss(cvgprMdl)
```

```plaintext
ans =
    4.6409
```

Predict the responses for out-of-fold data.

```matlab
ypred = kfoldPredict(cvgprMdl);
```

Plot the true responses used for testing and the predictions.

```matlab
figure();
plot(ypred(cvgprMdl.Partition.test));
hold on;
y = table2array(tbl(:,end));
plot(y(cvgprMdl.Partition.test),'r.');
axis([0 1050 0 30]);
xlabel('x')
ylabel('y')
hold off;
```
Fit GPR Model Using Custom Kernel Function

Generate the sample data.

```matlab
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as

\[ k(x_i, x_j \mid \theta) = \sigma_f^2 \exp \left( -\frac{1}{2} \frac{(x_i - x_j)^T(x_i - x_j)}{\sigma_l^2} \right) \]

where \( \sigma_f \) is the signal standard deviation, \( \sigma_l \) is the length scale. Both \( \sigma_f \) and \( \sigma_l \) must be greater than zero. This condition can be enforced by the unconstrained parametrization, \( \sigma_l = \exp(\theta(1)) \) and \( \sigma_f = \exp(\theta(2)) \), for some unconstrained parametrization vector \( \theta \).

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

```matlab
kfcn = @(XN,XM,theta) (exp(theta(2))^2)*exp(-( pdist2(XN,XM).^2 )/(2*exp(theta(1))^2));
```
Here \( \text{pdist2}(XN, XM)^2 \) computes the distance matrix.

Fit a GPR model using the custom kernel function, \( \text{kfcn} \). Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, \( \text{theta} \)).

\[
\text{theta0} = [1.5, 0.2];
\]

\[
gprMdl = \text{fitrgp}(x, y, 'KernelFunction', \text{kfcn}, 'KernelParameters', \text{theta0});
\]

\( \text{fitrgp} \) uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

\[
L = \text{resubLoss}(gprMdl)
\]

\[
L = 0.0391
\]

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

\[
sigmaL0 = \exp(1.5);
\]

\[
sigmaF0 = \exp(0.2);
\]

\[
gprMdl2 = \text{fitrgp}(x, y, 'KernelFunction', 'squaredexponential', 'KernelParameters', [sigmaL0, sigmaF0]);
\]

Compute the resubstitution loss for this model.

\[
L2 = \text{resubLoss}(gprMdl2)
\]

\[
L2 = 0.0391
\]

The two loss values are the same as expected.

**Specify Initial Step Size for LBFGS Optimization**

Train a GPR model on generated data with many predictors. Specify the initial step size for the LBFGS optimizer.

Set the seed and type of the random number generator for reproducibility of the results.

\[
\text{rng}(0, 'twister'); \quad \% \text{For reproducibility}
\]

Generate sample data with 300 observations and 3000 predictors, where the response variable depends on the 4th, 7th, and 13th predictors.

\[
N = 300;
P = 3000;
X = \text{rand}(N, P);
y = \cos(X(:, 7)) + \sin(X(:, 4).*X(:, 13)) + 0.1*\text{randn}(N, 1);
\]

Set initial values for the kernel parameters.

\[
sigmaL0 = \text{sqrt}(P)\times\text{ones}(P, 1); \quad \% \text{Length scale for predictors}
sigmaF0 = 1; \quad \% \text{Signal standard deviation}
\]
Set initial noise standard deviation to 1.

\[ \sigma_{N0} = 1; \]

Specify \( 1e-2 \) as the termination tolerance for the relative gradient norm.

\[
\text{opts} = \text{statset('fitrgp');}
\text{opts.TolFun = 1e-2;}
\]

Fit a GPR model using the initial kernel parameter values, initial noise standard deviation, and an automatic relevance determination (ARD) squared exponential kernel function.

Specify the initial step size as 1 for determining the initial Hessian approximation for an LBFGS optimizer.

\[
gpr = \text{fitrgp}(X,y,'KernelFunction','ardsquaredexponential','Verbose',1,...
'Optimizer','lbfgs','OptimizerOptions',opts,...
'KernelParameters',[sigmaL0;sigmaF0],'Sigma',sigmaN0,'InitialStepSize',1);
\]

Parameter estimation: FitMethod = Exact, Optimizer = lbfgs

Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
Because the GPR model uses an ARD kernel with many predictors, using an LBFGS approximation to the Hessian is more memory efficient than storing the full Hessian matrix. Also, using the initial step size to determine the initial Hessian approximation may help speed up optimization.

Find the predictor weights by taking the exponential of the negative learned length scales. Normalize the weights.

\begin{verbatim}
sigmaL = gpr.KernelInformation.KernelParameters(1:end-1); % Learned length scales
weights = exp(-sigmaL); % Predictor weights
weights = weights/sum(weights); % Normalized predictor weights
\end{verbatim}

Plot the normalized predictor weights.

\begin{verbatim}
figure;
semilogx(weights,'ro');
xlabel('Predictor index');
ylabel('Predictor weight');
\end{verbatim}
The trained GPR model assigns the largest weights to the 4th, 7th, and 13th predictors. The irrelevant predictors have weights close to zero.

**Input Arguments**

**Tbl — Sample data**

`table`  
Sample data used to train the model, specified as a `table`. Each row of `Tbl` corresponds to one observation, and each column corresponds to one variable. `Tbl` contains the predictor variables, and optionally it can also contain one column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all the remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the predictors in training the model, then specify the response variable and the predictor variables using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable using `y`. The length of the response variable and the number of rows in `Tbl` must be equal.

For more information on the `table` data type, please see `table`.

If your predictor data contains categorical variables, then the software uses full dummy coding for these variables. The software creates one dummy variable for each level of the categorical variable.
Data Types: table

**ResponseVarName — Response variable name**
name of a variable in Tbl

Response variable name, specified as the name of a variable in Tbl. You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable y is stored in Tbl (as Tbl.y), then specify it as 'y'. Otherwise, the software treats all the columns of Tbl, including y, as predictors when training the model.

Data Types: char | string

**formula — Response and predictor variables to use in model training**
character vector or string scalar in the form of 'y~x1+x2+x3'

Response and predictor variables to use in model training, specified as a character vector or string scalar in the form of 'y~x1+x2+x3'. In this form, y represents the response variable; x1, x2, x3 represent the predictor variables to use in training the model.

Use a formula if you want to specify a subset of variables in Tbl as predictors to use when training the model. If you specify a formula, then any variables that do not appear in formula are not used to train the model.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

The formula does not indicate the form of the BasisFunction.

Example: 'PetalLength~PetalWidth+Species' identifies the variable PetalLength as the response variable, and PetalWidth and Species as the predictor variables.

Data Types: char | string

**X — Predictor data for the GPR model**
n-by-d matrix

Predictor data for the GPR model, specified as an n-by-d matrix. n is the number of observations (rows), and d is the number of predictors (columns).

The length of y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: double

**y — Response data for the GPR model**
n-by-1 vector
Response data for the GPR model, specified as an n-by-1 vector. You can omit y if you provide the Tbl training data that also includes y. In that case, use ResponseVarName to identify the response variable or use formula to identify the response and predictor variables.

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note. You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'FitMethod','fic' trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

Fitting

FitMethod — Method to estimate parameters of the GPR model

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

<table>
<thead>
<tr>
<th>Fit Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'none'</td>
<td>No estimation, use the initial parameter values as the known parameter values.</td>
</tr>
<tr>
<td>'exact'</td>
<td>Exact Gaussian process regression. Default if ( n \leq 2000 ), where ( n ) is the number of observations.</td>
</tr>
<tr>
<td>'sd'</td>
<td>Subset of data points approximation. Default if ( n &gt; 2000 ), where ( n ) is the number of observations.</td>
</tr>
<tr>
<td>'sr'</td>
<td>Subset of regressors approximation.</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully independent conditional approximation.</td>
</tr>
</tbody>
</table>

Example: 'FitMethod','fic'

BasisFunction — Explicit basis in the GPR model

'constant' (default) | 'none' | 'linear' | 'pureQuadratic' | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of 'BasisFunction' and one of the following. If \( n \) is the number of observations, the basis function adds the term \( H^T\beta \) to the model, where \( H \) is the basis matrix and \( \beta \) is a \( p \)-by-1 vector of basis coefficients.
Explicit Basis | Basis Matrix
--- | ---
'none' | Empty matrix.
'constant' | \[ H = 1 \] (n-by-1 vector of 1s, where \( n \) is the number of observations)
'linear' | \[ H = [1, X] \]
'pureQuadratic' | \[ H = [1, X, X_2], \] where
\[
X_2 = \begin{bmatrix}
    x_{11}^2 & x_{12}^2 & \ldots & x_{1d}^2 \\
    x_{21}^2 & x_{22}^2 & \ldots & x_{2d}^2 \\
    \vdots & \vdots & \ddots & \vdots \\
    x_{n1}^2 & x_{n2}^2 & \ldots & x_{nd}^2
\end{bmatrix}.
\]
Function handle | Function handle, \( hfcn \), that \texttt{fitrgp} calls as:
\[ H = hfcn(X), \] where \( X \) is an \( n \)-by-\( d \) matrix of predictors and \( H \) is an \( n \)-by-\( p \) matrix of basis functions.

Example: 'BasisFunction', 'pureQuadratic'
Data Types: char | string | function_handle

**Beta — Initial value of the coefficients**
p-by-1 vector
Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of 'Beta' and \( p \)-by-1 vector, where \( p \) is the number of columns in the basis matrix \( H \).

The basis matrix depends on the choice of the explicit basis function as follows (also see \texttt{BasisFunction}).

\texttt{fitrgp} uses the coefficient initial values as the known coefficient values, only when \texttt{FitMethod} is 'none'.

Data Types: double

**Sigma — Initial value for the noise standard deviation of the Gaussian process model**
\( \text{std}(y)/\sqrt{2} \) (default) | positive scalar value

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of 'Sigma' and a positive scalar value.

Example: 'Sigma', 2
Data Types: double

**ConstantSigma — Constant value of Sigma for the noise standard deviation of the Gaussian process model**
false (default) | true
Constant value of \( \Sigma \) for the noise standard deviation of the Gaussian process model, specified as a logical scalar. When \( \text{ConstantSigma} \) is true, \textit{fitrgp} does not optimize the value of \( \Sigma \), but instead takes the initial value as the value throughout its computations.

Example: 'ConstantSigma',true

Data Types: logical

\textbf{SigmaLowerBound — Lower bound on the noise standard deviation}

\( 1e^{-2} \cdot \text{std}(y) \) (default) | positive scalar value

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of \('\text{SigmaLowerBound}'\) and a positive scalar value.

Example: 'SigmaLowerBound',0.02

Data Types: double

\textbf{CategoricalPredictors — Categorical predictors list}

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of \('\text{CategoricalPredictors}'\) and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
<td>Each entry in the vector is an index value corresponding to the column of</td>
</tr>
<tr>
<td></td>
<td>the predictor data (( X ) or ( Tbl )) that contains a categorical variable.</td>
</tr>
<tr>
<td>Logical vector</td>
<td>A ( \text{true} ) entry means that the corresponding column of predictor data (( X ) or ( Tbl )) is a categorical variable.</td>
</tr>
<tr>
<td>Character matrix</td>
<td>Each row of the matrix is the name of a predictor variable. The names must</td>
</tr>
<tr>
<td></td>
<td>match the entries in ( \text{PredictorNames} ). Pad the names with extra blanks</td>
</tr>
<tr>
<td></td>
<td>so each row of the character matrix has the same length.</td>
</tr>
<tr>
<td>String array or cell array of</td>
<td>Each element in the array is the name of a predictor variable. The names</td>
</tr>
<tr>
<td>character vectors</td>
<td>must match the entries in ( \text{PredictorNames} ).</td>
</tr>
<tr>
<td>'all'</td>
<td>All predictors are categorical.</td>
</tr>
</tbody>
</table>

By default, if the predictor data is in a table (\( Tbl \)), \textit{fitrgp} assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (\( X \)), \textit{fitrgp} assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the \('\text{CategoricalPredictors}'\) name-value pair argument.

For the identified categorical predictors, \textit{fitrgp} creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

\textbf{Standardize — Indicator to standardize data}

\( 0 \) (false) (default) | logical value
Indicator to standardize data, specified as the comma-separated pair consisting of 'Standardize' and a logical value.

If you set 'Standardize',1, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: 'Standardize',1
Example: 'Standardize',true
Data Types: logical

**Regularization — Regularization standard deviation**

\[ 1e-2 \times \text{std}(y) \text{ (default)} | \text{positive scalar value} \]

Regularization standard deviation for sparse methods subset of regressors ('sr') and fully independent conditional ('fic'), specified as the comma-separated pair consisting of 'Regularization' and a positive scalar value.

Example: 'Regularization',0.2
Data Types: double

**ComputationMethod — Method for computing log likelihood and gradient**

'qr' (default) | 'v'

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors ('sr') and fully independent conditional ('fic') approximation methods, specified as the comma-separated pair consisting of 'ComputationMethod' and one of the following.

- 'qr' — Use QR factorization based approach, this option provides better accuracy.
- 'v' — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: 'ComputationMethod','v'

**Kernel (Covariance) Function**

**KernelFunction — Form of the covariance function**

'squaredexponential' (default) | 'exponential' | 'matern32' | 'matern52' | 'rationalquadratic' | 'ardsquaredexponential' | 'ardexponential' | 'ardmatern32' | 'ardmatern52' | 'ardrationalquadratic' | function handle

Form of the covariance function, specified as the comma-separated pair consisting of 'KernelFunction' and one of the following.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exponential'</td>
<td>Exponential kernel.</td>
</tr>
<tr>
<td>'squaredexponential'</td>
<td>Squared exponential kernel.</td>
</tr>
<tr>
<td>'matern32'</td>
<td>Matern kernel with parameter 3/2.</td>
</tr>
<tr>
<td>'matern52'</td>
<td>Matern kernel with parameter 5/2.</td>
</tr>
<tr>
<td>'rationalquadratic'</td>
<td>Rational quadratic kernel.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>'ardexponential'</td>
<td>Exponential kernel with a separate length scale per predictor.</td>
</tr>
<tr>
<td>'ardsquaredexponential'</td>
<td>Squared exponential kernel with a separate length scale per predictor.</td>
</tr>
<tr>
<td>'ardmatern32'</td>
<td>Matern kernel with parameter 3/2 and a separate length scale per predictor.</td>
</tr>
<tr>
<td>'ardmatern52'</td>
<td>Matern kernel with parameter 5/2 and a separate length scale per predictor.</td>
</tr>
<tr>
<td>'ardrationalquadratic'</td>
<td>Rational quadratic kernel with a separate length scale per predictor.</td>
</tr>
</tbody>
</table>

Function handle
A function handle that can be called like this:

\[ Kmn = kfcn(Xm,Xn,\theta) \]

where \( Xm \) is an \( m \)-by-\( d \) matrix, \( Xn \) is an \( n \)-by-\( d \) matrix and \( Kmn \) is an \( m \)-by-\( n \) matrix of kernel products such that \( Kmn(i,j) \) is the kernel product between \( Xm(i,:) \) and \( Xn(j,:) \).

\( \theta \) is the \( r \)-by-1 unconstrained parameter vector for \( kfcn \).

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-5.

Example: ‘KernelFunction’, ‘matern32’

Data Types: char | string | function_handle

**KernelParameters — Initial values for the kernel parameters**

vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of ‘KernelParameters’ and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the KernelFunction name-value pair argument.

<table>
<thead>
<tr>
<th>'KernelFunction'</th>
<th>'KernelParameters'</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exponential' or 'squaredexponential' or 'matern32' or 'matern52'</td>
<td>2-by-1 vector ( \phi ), where ( \phi(1) ) contains the length scale and ( \phi(2) ) contains the signal standard deviation. Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is, ( \phi = [\text{mean}(\text{std}(X));\text{std}(y) / \sqrt{2}] )</td>
</tr>
</tbody>
</table>
For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-5.

Example: 'KernelParameters', theta

Data Types: double

**DistanceMethod — Method for computing inter-point distances**

- ‘fast’ (default) | ‘accurate’

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of 'DistanceMethod' and either 'fast' or 'accurate'.

32-1929
fitrgp computes \((x - y)^2\) as \(x^2 + y^2 - 2xy\) when you choose the fast option and as \((x - y)^2\) when you choose the accurate option.

Example: 'DistanceMethod','accurate'

**Active Set Selection**

**ActiveSet — Observations in the active set**

[] (default) | \(m\)-by-1 vector of integers ranging from 1 to \(n\) \((m \leq n)\) | logical vector of length \(n\)

Observations in the active set, specified as the comma-separated pair consisting of 'ActiveSet' and an \(m\)-by-1 vector of integers ranging from 1 to \(n\) \((m \leq n)\) or a logical vector of length \(n\) with at least one true element. \(n\) is the total number of observations in the training data.

fitrgp uses the observations indicated by ActiveSet to train the GPR model. The active set cannot have duplicate elements.

If you supply ActiveSet, then:

* fitrgp does not use ActiveSetSize and ActiveSetMethod.
* You cannot perform cross-validation on this model.

Data Types: double | logical

**ActiveSetSize — Size of the active set for sparse methods**

an integer \(m\) \((1 \leq m \leq n)\)

Size of the active set for sparse methods ('sd', 'sr', 'fic'), specified as the comma-separated pair consisting of 'ActiveSetSize' and an integer \(m\), \(1 \leq m \leq n\), where \(n\) is the number of observations.

Default is \(\min(1000,n)\) when FitMethod is 'sr' or 'fic', and \(\min(2000,n)\), otherwise.

Example: 'ActiveSetSize',100

Data Types: double

**ActiveSetMethod — Active set selection method**

'random' (default) | 'sgma' | 'entropy' | 'likelihood'

Active set selection method, specified as the comma-separated pair consisting of 'ActiveSetMethod' and one of the following.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'random'</td>
<td>Random selection</td>
</tr>
<tr>
<td>'sgma'</td>
<td>Sparse greedy matrix approximation</td>
</tr>
<tr>
<td>'entropy'</td>
<td>Differential entropy-based selection</td>
</tr>
<tr>
<td>'likelihood'</td>
<td>Subset of regressors log likelihood-based selection</td>
</tr>
</tbody>
</table>

All active set selection methods (except 'random') require the storage of an \(n\)-by-\(m\) matrix, where \(m\) is the size of the active set and \(n\) is the number of observations.

Example: 'ActiveSetMethod','entropy'
**RandomSearchSetSize** — Random search set size

59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of 'RandomSearchSetSize' and an integer value.

Example: 'RandomSearchSetSize', 30

Data Types: double

**ToleranceActiveSet** — Relative tolerance for terminating active set selection

1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of 'ToleranceActiveSet' and a positive scalar value.

Example: 'ToleranceActiveSet', 0.0002

Data Types: double

**NumActiveSetRepeats** — Number of repetitions

3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation on page 32-1940 when ActiveSetMethod is not 'random', specified as the comma-separated pair consisting of 'NumActiveSetRepeats' and an integer value.

Example: 'NumActiveSetRepeats', 5

Data Types: double

**Prediction**

**PredictMethod** — Method used to make predictions

'exact' | 'bcd' | 'sd' | 'sr' | 'fic'

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of 'PredictMethod' and one of the following.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'exact'</td>
<td>Exact Gaussian process regression method. Default, if ( n \leq 10000 ).</td>
</tr>
<tr>
<td>'bcd'</td>
<td>Block Coordinate Descent. Default, if ( n &gt; 10000 ).</td>
</tr>
<tr>
<td>'sd'</td>
<td>Subset of Datapoints approximation.</td>
</tr>
<tr>
<td>'sr'</td>
<td>Subset of Regressors approximation.</td>
</tr>
<tr>
<td>'fic'</td>
<td>Fully Independent Conditional approximation.</td>
</tr>
</tbody>
</table>

Example: 'PredictMethod', 'bcd'

**BlockSizeBCD** — Block size

minimum of 1000 or \( n \) (default) | integer in the range from 1 to \( n \)

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to \( n \), where \( n \) is the number of observations.
Example: 'BlockSizeBCD',1500
Data Types: double

**NumGreedyBCD — Number of greedy selections**
minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.
Example: 'NumGreedyBCD',150
Data Types: double

**ToleranceBCD — Relative tolerance on gradient norm**
1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.
Example: 'ToleranceBCD',0.002
Data Types: double

**StepToleranceBCD — Absolute tolerance on step size**
1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.
Example: 'StepToleranceBCD',0.002
Data Types: double

**IterationLimitBCD — Maximum number of BCD iterations**
1000000 (default) | integer value

Maximum number of block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'IterationLimitBCD' and an integer value.
Example: 'IterationLimitBCD',10000
Data Types: double

**Optimization**

**Optimizer — Optimizer to use for parameter estimation**
'quasinewton' (default) | 'lbfgs' | 'fminsearch' | 'fminunc' | 'fmincon'

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of 'Optimizer' and one of the values in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'quasinewton'</td>
<td>Dense, symmetric rank-1-based, quasi-Newton approximation to the Hessian</td>
</tr>
<tr>
<td>'lbfgs'</td>
<td>LBFGS-based quasi-Newton approximation to the Hessian</td>
</tr>
</tbody>
</table>
Value | Description
--- | ---
'fminsearch' | Unconstrained nonlinear optimization using the simplex search method of Lagarias et al. [5]
'fminunc' | Unconstrained nonlinear optimization (requires an Optimization Toolbox license)
'fmincon' | Constrained nonlinear optimization (requires an Optimization Toolbox license)

For more information on the optimizers, see Algorithms on page 32-1941.

Example: 'Optimizer','fmincon'

**OptimizerOptions — Options for the optimizer**

structure | object

Options for the optimizer you choose using the `Optimizer` name-value pair argument, specified as the comma-separated pair consisting of `OptimizerOptions` and a structure or object created by `optimset`, `statset('fitrgp')`, or `optimoptions`.

<table>
<thead>
<tr>
<th>Optimizer</th>
<th>Create Optimizer Options Using</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fminsearch'</td>
<td><code>optimset</code> (structure)</td>
</tr>
<tr>
<td>'quasinewton' or 'lbfgs'</td>
<td><code>statset('fitrgp')</code> (structure)</td>
</tr>
<tr>
<td>'fminunc' or 'fmincon'</td>
<td><code>optimoptions</code> (object)</td>
</tr>
</tbody>
</table>

The default options depend on the type of optimizer.

Example: `OptimizerOptions`,opt

**InitialStepSize — Initial step size**

[] (default) | real positive scalar | 'auto'

Initial step size, specified as the comma-separated pair consisting of `InitialStepSize` and a real positive scalar or `auto`.

'InitialStepSize' is the approximate maximum absolute value of the first optimization step when the optimizer is 'quasinewton' or 'lbfgs'. The initial step size can determine the initial Hessian approximation during optimization.

By default, `fitrgp` does not use the initial step size to determine the initial Hessian approximation. To use the initial step size, set a value for the 'InitialStepSize' name-value pair argument, or specify 'InitialStepSize','auto' to have `fitrgp` determine a value automatically. For more information on 'auto', see Algorithms on page 32-1941.

Example: 'InitialStepSize','auto'

**Cross-Validation**

**CrossVal — Indicator for cross-validation**

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of `CrossVal` and either 'off' or 'on'. If it is 'on', then `fitrgp` returns a GPR model cross-validated with 10 folds.
You can use one of the KFold, Holdout, Leaveout or CVPartition name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the crossval method for your model.

Example: 'CrossVal','on'

CVPartition — Random partition for a stratified k-fold cross-validation
cvpartition object

Random partition for a stratified k-fold cross-validation, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object.

Example: 'CVPartition', cvp uses the random partition defined by cvp.

If you specify CVPartition, then you cannot specify Holdout, KFold, or Leaveout.

Holdout — Fraction of data to use for testing
scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p, then the software:
1. Randomly reserves around p*100% of the data as validation data, and trains the model using the rest of the data.
2. Stores the compact, trained model in cvgprMdl.Trained.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify Holdout, then you cannot specify CVPartition, KFold, or Leaveout.

Data Types: double

KFold — Number of folds
10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. KFold must be greater than 1. If you specify 'KFold', k then the software:
1. Randomly partitions the data into k sets.
2. For each set, reserves the set as test data, and trains the model using the other k - 1 sets.
3. Stores the k compact, trained models in the cells of a k-by-1 cell array in cvgprMdl.Trained.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify KFold, then you cannot specify CVPartition, Holdout, or Leaveout.

Data Types: double

Leaveout — Indicator for leave-one-out cross-validation
'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and either 'off' or 'on'.

If you specify 'Leaveout', 'on', then, for each of the n observations, the software:
1. Reserves the observation as test data, and trains the model using the other \( n - 1 \) observations.  
2. Stores the compact, trained model in a cell in the \( n \)-by-1 cell array `cvgprMdl.Trained`.

Example: `Leaveout`, `'on'`

If you specify Leaveout, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Hyperparameter Optimization

**OptimizeHyperparameters — Parameters to optimize**

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `OptimizeHyperparameters` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{`'Sigma'`}`.
- `'all'` — Optimize all eligible parameters, equivalent to `{`'BasisFunction', 'KernelFunction', 'KernelScale', 'Sigma', 'Standardize'`}`.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitrgp` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-2756. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** `OptimizeHyperparameters` values override any values you set using other name-value pair arguments. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrgp` are:

- **BasisFunction** — `fitrgp` searches among `'constant'`, `'none'`, `'linear'`, and `'pureQuadratic'`.
- **KernelFunction** — `fitrgp` searches among `'ardexponential'`, `'ardmatern32'`, `'ardmatern52'`, `'ardrationalquadratic'`, `'ardsquaredexponential'`, `'exponential'`, `'matern32'`, `'matern52'`, `'rationalquadratic'`, and `'squaredexponential'`.
- **KernelScale** — `fitrgp` uses the `KernelParameters` argument to specify the value of the kernel scale parameter, which is held constant during fitting. In this case, all input dimensions are constrained to have the same `KernelScale` value. `fitrgp` searches among real value in the range \([1e-3*\text{MaxPredictorRange}, \text{MaxPredictorRange}]\), where

\[
\text{MaxPredictorRange} = \max(\max(X) - \min(X)).
\]

`KernelScale` cannot be optimized for any of the ARD kernels.

- **Sigma** — `fitrgp` searches among real value in the range \([1e-4, \max(1e-3, 10*\text{ResponseStd})]\), where

\[
\text{ResponseStd} = \text{std}(y).
\]
Internally, `fitrgp` sets the `ConstantSigma` name-value pair to `true` so the value of `Sigma` is constant during the fitting.

- **Standardize** — `fitrgp` searches among `true` and `false`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load fisheriris
params = hyperparameters('fitrgp',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is \( \log(1 + \text{cross-validation loss}) \) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize GPR Regression” on page 32-1912.

**Example:** `'auto'`

**HyperparameterOptimizationOptions — Options for optimization**

Structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Example:
'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)

Data Types: struct

Other

**PredictorNames — Predictor variable names**

String array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and y, then you can use 'PredictorNames' to give the predictor variables in X names.
• The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
• By default, `PredictorNames` is `{'x1','x2',...}`.
• If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrgp` uses the predictor variables in `PredictorNames` and the response only in training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - It is good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames', {'PedalLength','PedalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

• If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
• If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Verbose` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

• `0` — `fitrgp` suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of `'Display'` in `OptimizerOptions`.
• `1` — `fitrgp` displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: `'Verbose',1`

`CacheSize` — Cache size in megabytes

`1000 MB` (default) | positive scalar

Cache size in megabytes (MB), specified as the comma-separated pair consisting of `'CacheSize'` and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. `fitrgp` uses `CacheSize` to:

• Decide whether interpoint distances should be cached when estimating parameters.
• Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: ‘CacheSize’, 2000

Data Types: double

Output Arguments

gprMdl — Gaussian process regression model
RegressionGP object | RegressionPartitionedModel object

Gaussian process regression model, returned as a RegressionGP or a RegressionPartitionedModel object.

• If you cross-validate, that is, if you use one of the ‘Crossval’, ‘KFold’, ‘Holdout’, ‘Leaveout’, or ‘CVPartition’ name-value pairs, then gprMdl is a RegressionPartitionedModel object. You cannot use a RegressionPartitionedModel object to make predictions using predict. For more information on the methods and properties of this object, see RegressionPartitionedModel.

• If you do not cross-validate, then gprMdl is a RegressionGP object. You can use this object for predictions using the predict method. For more information on the methods and properties of this object, see RegressionGP.

More About

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to 'sd', 'sr', or 'fic'), if you do not provide the active set, fitrgp selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector \( \eta_0 = [\beta_0, \sigma_0, \theta_0] \) to select an active set \( A_1 \). It maximizes the GPR marginal log likelihood or its approximation using \( \eta_0 \) as the initial values and \( A_1 \) to compute the new parameter estimates \( \eta_1 \). Next, it computes the new log likelihood value \( L_1 \) using \( \eta_1 \) and \( A_1 \).

In the second iteration, the software selects the active set \( A_2 \) using the parameter values in \( \eta_1 \). Then, using \( \eta_1 \) as the initial values and \( A_2 \), it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values \( \eta_2 \). Then using \( \eta_2 \) and \( A_2 \), computes the new log likelihood value \( L_2 \).

The following table summarizes the iterations and what is computed at each iteration.

<table>
<thead>
<tr>
<th>Iteration Number</th>
<th>Active Set</th>
<th>Parameter Vector</th>
<th>Log Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( A_1 )</td>
<td>( \eta_1 )</td>
<td>( L_1 )</td>
</tr>
<tr>
<td>2</td>
<td>( A_2 )</td>
<td>( \eta_2 )</td>
<td>( L_2 )</td>
</tr>
<tr>
<td>3</td>
<td>( A_3 )</td>
<td>( \eta_3 )</td>
<td>( L_3 )</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the NumActiveSetRepeats name-value pair argument.
Tips

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.

- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of character vectors.

- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors.

- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.

- The `X` property stores the training data as originally input. It does not include the dummy variables.

- The default approach to initializing the Hessian approximation in `fitrgp` can be slow when you have a GPR model with many kernel parameters, such as when using an ARD kernel with many predictors. In this case, consider specifying `'auto'` or a value for the initial step size.

You can set `'Verbose'`, 1 for display of iterative diagnostic messages, and begin training a GPR model using an LBFGS or quasi-Newton optimizer with the default `fitrgp` optimization. If the iterative diagnostic messages are not displayed after a few seconds, it is possible that initialization of the Hessian approximation is taking too long. In this case, consider restarting training and using the initial step size to speed up optimization.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2..

Algorithms

- Fitting a GPR model involves estimating the following model parameters from the data:
  - Covariance function \( k(x_i, x_j | \theta) \) parameterized in terms of kernel parameters in vector \( \theta \) (see “Kernel (Covariance) Function Options” on page 6-5)
  - Noise variance, \( \sigma^2 \)
  - Coefficient vector of fixed basis functions, \( \beta \)

The value of the `'KernelParameters'` name-value pair argument is a vector that consists of initial values for the signal standard deviation \( \sigma_f \) and the characteristic length scales \( \sigma_l \). The `fitrgp` function uses these values to determine the kernel parameters. Similarly, the `'Sigma'` name-value pair argument contains the initial value for the noise standard deviation \( \sigma \).

- During optimization, `fitrgp` creates a vector of unconstrained initial parameter values \( \eta_0 \) by using the initial values for the noise standard deviation and the kernel parameters.

- `fitrgp` analytically determines the explicit basis coefficients \( \beta \), specified by the `'Beta'` name-value pair argument, from estimated values of \( \theta \) and \( \sigma^2 \). Therefore, \( \beta \) does not appear in the \( \eta_0 \) vector when `fitrgp` initializes numerical optimization.
Note If you specify no estimation of parameters for the GPR model, \texttt{fitrgp} uses the value of the 'Beta' name-value pair argument and other initial parameter values as the known GPR parameter values (see Beta). In all other cases, the value of the 'Beta' argument is optimized analytically from the objective function.

- The quasi-Newton optimizer uses a trust-region method with a dense, symmetric rank-1-based (SR1), quasi-Newton approximation to the Hessian, while the LBFGS optimizer uses a standard line-search method with a limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton approximation to the Hessian. See Nocedal and Wright [6].

- If you set the 'InitialStepSize' name-value pair argument to 'auto', \texttt{fitrgp} determines the initial step size, $\|s_0\|_\infty$, by using $\|s_0\|_\infty = 0.5\|\eta_0\|_\infty + 0.1$.

$s_0$ is the initial step vector, and $\eta_0$ is the vector of unconstrained initial parameter values.

- During optimization, \texttt{fitrgp} uses the initial step size, $\|s_0\|_\infty$, as follows:

  If you use 'Optimizer','quasinewton' with the initial step size, then the initial Hessian approximation is $\frac{\|g_0\|_\infty}{\|s_0\|_\infty}I$.

  If you use 'Optimizer','lbfgs' with the initial step size, then the initial inverse-Hessian approximation is $\frac{\|s_0\|_\infty}{\|g_0\|_\infty}I$.

$g_0$ is the initial gradient vector, and $I$ is the identity matrix.

Extended Capabilities

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2015b
fitrlinear

Fit linear regression model to high-dimensional data

Syntax

Mdl = fitrlinear(X,Y)
Mdl = fitrlinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitrlinear(__)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(__)

Description

fitrlinear efficiently trains linear regression models with high-dimensional, full or sparse
predictor data. Available linear regression models include regularized support vector machines (SVM)
and least-squares regression methods. fitrlinear minimizes the objective function using
techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables,
train a linear regression model by using fitrlinear. For low- through medium-dimensional
predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 32-1974.

Mdl = fitrlinear(X,Y) returns a trained regression model object that contains the results of
fitting a support vector machine regression model to the predictors X and response Y.

Mdl = fitrlinear(X,Y,Name,Value) returns a trained linear regression model with additional
options specified by one or more Name,Value pair arguments. For example, you can specify
implement least-squares regression, specify to cross-validate, or specify the type of regularization. It
is good practice to cross-validate using the Kfold Name,Value pair argument. The cross-validation
results determine how well the model generalizes.

[Mdl,FitInfo] = fitrlinear(__) also returns optimization details using any of the previous
syntaxes. You cannot request FitInfo for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(__) also returns
hyperparameter optimization details when you pass an OptimizeHyperparameters name-value
pair.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model
\[ y = x_{100} + 2x_{200} + e. \]

• \( X = x_1, \ldots, x_{1000} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
• $e$ is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Train a linear regression model. By default, \texttt{fitrlinear} uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

$[\text{Mdl,FitInfo}] = \text{fitrlinear}(X,Y)$

\texttt{Mdl} =
\begin{verbatim}
   RegressionLinear
   ResponseName: 'Y'
   ResponseTransform: 'none'
       Beta: [1000x1 double]
       Bias: -0.0056
       Lambda: 1.0000e-04
       Learner: 'svm'
\end{verbatim}

\texttt{Properties, Methods}

\texttt{FitInfo = struct with fields:}
\begin{verbatim}
   Lambda: 1.0000e-04
   Objective: 0.2725
   PassLimit: 10
   NumPasses: 10
   BatchLimit: []
   NumIterations: 100000
   GradientNorm: NaN
   GradientTolerance: 0
   RelativeChangeInBeta: 0.4907
   BetaTolerance: 1.0000e-04
   DeltaGradient: 1.5816
   DeltaGradientTolerance: 0.1000
   TerminationCode: 0
   TerminationStatus: {'Iteration limit exceeded.'}
       Alpha: [10000x1 double]
       History: []
       FitTime: 0.1552
       Solver: {'dual'}
\end{verbatim}

\texttt{Mdl} is a \texttt{RegressionLinear} model. You can pass \texttt{Mdl} and the training or new data to \texttt{loss} to inspect the in-sample mean-squared error. Or, you can pass \texttt{Mdl} and new predictor data to \texttt{predict} to predict responses for new observations.

\texttt{FitInfo} is a structure array containing, among other things, the termination status (\texttt{TerminationStatus}) and how long the solver took to fit the model to the data (\texttt{FitTime}). It is good practice to use \texttt{FitInfo} to determine whether optimization-termination measurements are satisfactory. In this case, \texttt{fitrlinear} reached the maximum number of iterations. Because training
time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

**Find Good Lasso Penalty Using Cross-Validation**

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

```matlab
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
.nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from \( 10^{-5} \) through \( 10^{-1} \).

\[
\text{Lambda} = \text{logspace}(-5,-1,15);
\]

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```matlab
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

Display the first trained linear regression model.

```matlab
Mdl1 = CVMdl.Trained{1}
```

\[
\text{Mdl1} = \\
\text{RegressionLinear} \\
\text{ResponseName: 'Y'} \\
\text{ResponseTransform: 'none'} \\
\text{Beta: [1000x15 double]} \\
\text{Bias: [1x15 double]} \\
\text{Lambda: [1x15 double]} \\
\text{Learner: 'leastsquares'}
\]
Properties, Methods

Mdl1 is a RegressionLinear model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

```matlab
mse = kfoldLoss(CVMdl);
```

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```matlab
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```matlab
figure
[hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```
Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, \( \text{Lambda}(10) \)).

\[
\text{idxFinal} = 10;
\]

Extract the model with corresponding to the minimal MSE.

\[
\text{MdlFinal} = \text{selectModels}(\text{Mdl}, \text{idxFinal})
\]

\[
\text{MdlFinal} = \text{RegressionLinear}
\]

\[
\begin{align*}
\text{ResponseName} & : 'Y' \\
\text{ResponseTransform} & : 'none' \\
\text{Beta} & : [1000x1 \text{ double}] \\
\text{Bias} & : -0.0050 \\
\text{Lambda} & : 0.0037 \\
\text{Learner} & : 'leastsquares'
\end{align*}
\]

Properties, Methods

\[
\text{idxNZCoeff} = \text{find(MdlFinal.Beta} \neq 0)
\]

\[
\text{idxNZCoeff} = 2 \times 1
\]

\[
\begin{align*}
100 \\
200
\end{align*}
\]
EstCoeff = Mdl.Beta(idxNZCoeff)

EstCoeff = 2×1
1.0051
1.9965

MdlFinal is a RegressionLinear model with one regularization strength. The nonzero coefficients EstCoeff are close to the coefficients that simulated the data.

Optimize a Linear Regression

This example shows how to optimize hyperparameters automatically using fitrlinear. The example uses artificial (simulated) data for the model

\[ y = x_{100} + 2x_{200} + e. \]

- \( X = \{x_1, \ldots, x_{1000}\} \) is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- \( e \) is random normal error with mean 0 and standard deviation 0.3.

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

Find hyperparameters that minimize five-fold cross validation loss by using automatic hyperparameter optimization.

For reproducibility, use the 'expected-improvement-plus' acquisition function.

hyperopts = struct('AcquisitionFunctionName','expected-improvement-plus');
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(X,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',hyperopts)

This optimization technique is simpler than that shown in “Find Good Lasso Penalty Using Cross-Validation” on page 32-1946, but does not allow you to trade off model complexity and cross-validation loss.

**Input Arguments**

**X — Predictor data**  
full matrix | sparse matrix

Predictor data, specified as an \( n \)-by-\( p \) full or sparse matrix.

The length of \( Y \) and the number of observations in \( X \) must be equal.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify ‘ObservationsIn’, ‘columns’, then you might experience a significant reduction in optimization-execution time.

Data Types: single | double

**Y — Response data**  
numeric vector

Response data, specified as an \( n \)-dimensional numeric vector. The length of \( Y \) and the number of observations in \( X \) must be equal.

Data Types: single | double

**Note** `fitrlinear` removes missing observations, that is, observations with any of these characteristics:

- \texttt{NaN} elements in the response (\( Y \) or \texttt{ValidationData}(2))
- At least one \texttt{NaN} value in a predictor observation (row in \( X \) or \texttt{ValidationData}(1))
- \texttt{NaN} value or 0 weight (\texttt{Weights} or \texttt{ValidationData}(3))

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: Mdl = fitrlinear(X,Y,'Learner','leastsquares','CrossVal','on','Regularization','lasso') specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

Linear Regression Options

Epsilon — Half the width of epsilon-insensitive band

iqr(Y)/13.49 (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value. 'Epsilon' applies to SVM learners only.

The default Epsilon value is iqr(Y)/13.49, which is an estimate of standard deviation using the interquartile range of the response variable Y. If iqr(Y) is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon',0.3

Data Types: single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', Lambda = 1/n.
  - If you specify a cross-validation, name-value pair argument (e.g., CrossVal), then n is the number of in-fold observations.
  - Otherwise, n is the training sample size.
  - For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in Lambda in ascending order.
  - If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-1625 for the next optimization iteration. Otherwise, the software uses warm starts.
  - If Regularization is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in Lambda.

Returns coefficient estimates for all optimization iterations.
Example: ‘Lambda’,10.^(-(10:-2:2))
Data Types: char | string | double | single

**Learner — Linear regression model type**

‘svm’ (default) | ‘leastsquares’

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In this table, \( f(x) = x\beta + b \).

- \( \beta \) is a vector of \( p \) coefficients.
- \( x \) is an observation from \( p \) predictor variables.
- \( b \) is the scalar bias.

<table>
<thead>
<tr>
<th>Value</th>
<th>Algorithm</th>
<th>Response range</th>
<th>Loss function</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘leastsquares’</td>
<td>Linear regression via ordinary least squares</td>
<td>( y \in (-\infty, \infty) )</td>
<td>Mean squared error (MSE): ( \ell_y = \frac{1}{2} [y - f(x)]^2 )</td>
</tr>
<tr>
<td>‘svm’</td>
<td>Support vector machine regression</td>
<td>Same as 'leastsquares'</td>
<td>Epsilon-insensitive: ( \ell_y = \max [0,</td>
</tr>
</tbody>
</table>

Example: ‘Learner’, ‘leastsquares’

**ObservationsIn — Predictor data observation dimension**

‘rows’ (default) | ‘columns’

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

**Note** If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

**Regularization — Complexity penalty type**

‘lasso’ | ‘ridge’

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘lasso’</td>
<td>Lasso (L1) penalty: ( \lambda \sum_{j=1}^{p}</td>
</tr>
</tbody>
</table>
To specify the regularization term strength, which is $\lambda$ in the expressions, use $\text{Lambda}$. The software excludes the bias term ($\beta_0$) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

**Tip**
- For predictor variable selection, specify 'lasso'. For more on variable selection, see “Introduction to Feature Selection” on page 15-49.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization','lasso'

**Solver — Objective function minimization technique**
'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>'sgd'</td>
<td>Stochastic gradient descent (SGD) [5][3]</td>
<td></td>
</tr>
<tr>
<td>'asgd'</td>
<td>Average stochastic gradient descent (ASGD) [8]</td>
<td></td>
</tr>
<tr>
<td>'dual'</td>
<td>Dual SGD for SVM [2][7]</td>
<td>Regularization must be 'ridge' and Learner must be 'svm'.</td>
</tr>
<tr>
<td>'bfgs'</td>
<td>Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]</td>
<td>Inefficient if X is very high-dimensional.</td>
</tr>
<tr>
<td>'lbfgs'</td>
<td>Limited-memory BFGS (LBFGS) [4]</td>
<td>Regularization must be 'ridge'.</td>
</tr>
<tr>
<td>'sparsa'</td>
<td>Sparse Reconstruction by Separable Approximation (SpaRSA) [6]</td>
<td>Regularization must be 'lasso'.</td>
</tr>
</tbody>
</table>

If you specify:
- A ridge penalty (see Regularization) and size($X,1$) $\leq$ 100 (100 or fewer predictor variables), then the default solver is 'bfgs'.
• An SVM regression model (see Learner), a ridge penalty, and size(X,1) > 100 (more than 100 predictor variables), then the default solver is 'dual'.
• A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each Lambda.

For more details on which solver to choose, see "Tips" on page 32-1975.

Example: 'Solver',{'sgd','lbfgs'}

**Beta — Initial linear coefficient estimates**

zeros(p,1) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of 'Beta' and a p-dimensional numeric vector or a p-by-L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see Lambda).

• If you specify a p-dimensional vector, then the software optimizes the objective function L times using this process.
  1 The software optimizes using Beta as the initial value and the minimum value of Lambda as the regularization strength.
  2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-1625, and the next smallest value in Lambda as the regularization strength.
  3 The software implements step 2 until it exhausts all values in Lambda.

• If you specify a p-by-L matrix, then the software optimizes the objective function L times. At iteration j, the software uses Beta(:,j) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.

If you set 'Solver','dual', then the software ignores Beta.

Data Types: single | double

**Bias — Initial intercept estimate**

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L-dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

• If you specify a scalar, then the software optimizes the objective function L times using this process.
  1 The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
  2 The uses the resulting estimate as a warm start on page 32-1974 to the next optimization iteration, and uses the next smallest value in Lambda as the regularization strength.
  3 The software implements step 2 until it exhausts all values in Lambda.
• If you specify an \( L \)-dimensional vector, then the software optimizes the objective function \( L \) times. At iteration \( j \), the software uses \( \text{Bias}(j) \) as the initial value and, after it sorts \( \text{Lambda} \) in ascending order, uses \( \text{Lambda}(j) \) as the regularization strength.

• By default:
  • If \text{Learner} is 'leastsquares', then \text{Bias} is the weighted average of \text{Y} for training or, for cross-validation, in-fold responses.
  • If \text{Learner} is 'svm', then \text{Bias} is the weighted median of \text{Y} for all training or, for cross-validation, in-fold observations that are greater than \text{Epsilon}.

Data Types: single | double

**FitBias — Linear model intercept inclusion flag**

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>The software includes the bias term ( b ) in the linear model, and then estimates it.</td>
</tr>
<tr>
<td>false</td>
<td>The software sets ( b = 0 ) during estimation.</td>
</tr>
</tbody>
</table>

Example: 'FitBias',false

Data Types: logical

**PostFitBias — Flag to fit linear model intercept after optimization**

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>The software estimates the bias term ( b ) and the coefficients ( \beta ) during optimization.</td>
</tr>
<tr>
<td>true</td>
<td>To estimate ( b ), the software:</td>
</tr>
<tr>
<td></td>
<td>1. Estimates ( \beta ) and ( b ) using the model.</td>
</tr>
<tr>
<td></td>
<td>2. Computes residuals.</td>
</tr>
<tr>
<td></td>
<td>3. Refits ( b ). For least squares, ( b ) is the weighted average of the residuals. For SVM regression, ( b ) is the weighted median between all residuals with magnitude greater than \text{Epsilon}.</td>
</tr>
</tbody>
</table>

If you specify true, then \text{FitBias} must be true.

Example: 'PostFitBias',true

Data Types: logical
**Verbose** — Verbosity level

\[ \theta \text{ (default) | nonnegative integer} \]

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and a nonnegative integer. Verbosity controls the amount of diagnostic information `fitrlinear` displays at the command line.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \theta )</td>
<td><code>fitrlinear</code> does not display diagnostic information.</td>
</tr>
<tr>
<td>1</td>
<td><code>fitrlinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
<tr>
<td>Any other positive integer</td>
<td><code>fitrlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.</td>
</tr>
</tbody>
</table>

Example: `'Verbose',1`

Data Types: `double` | `single`

**SGD and ASGD Solver Options**

**BatchSize** — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using `BatchSize` observations from the training data.

- If \( X \) is a numeric matrix, then the default value is 10.
- If \( X \) is a sparse matrix, then the default value is \( \max([10, \text{ceil}(\sqrt{ff})]) \), where \( ff = \frac{\text{numel}(X)}{\text{nnz}(X)} \) (the fullness factor of \( X \)).

Example: `BatchSize',100`

Data Types: `single` | `double`

**LearnRate** — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. `LearnRate` specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If `Regularization` is 'ridge', then `LearnRate` specifies the initial learning rate \( \gamma_0 \). The software determines the learning rate for iteration \( t \), \( \gamma_t \), using

\[
\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.
\]
• $\lambda$ is the value of Lambda.
• If Solver is 'sgd', then $c = 1$.
• If Solver is 'asgd', then $c$ is:
  • $2/3$ if Learner is 'leastsquares'
  • $3/4$ if Learner is 'svm' [8]
• If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\sqrt{1+\max((\sum X.^2, \text{obsDim}))}$, where obsDim is 1 if the observations compose the columns of $X$, and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate
true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:

1. For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true

Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs
10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient $j$ using

$$
\hat{\beta}_j^* = \begin{cases} 
\hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t, \\
0 & \text{if } |\hat{\beta}_j| \leq u_t, \\
\hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t.
\end{cases}
$$

• For SGD, $\hat{\beta}_j$ is the estimate of coefficient $j$ after processing $k$ mini-batches. $u_t = k\gamma_t \lambda$. $\gamma_t$ is the learning rate at iteration $t$. $\lambda$ is the value of Lambda.
• For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient $j$ after processing $k$ mini-batches, $u_t = k\lambda$. 

32-1961
If `Regularization` is 'ridge', then the software ignores `TruncationPeriod`.

Example: 'TruncationPeriod',100

Data Types: single | double

Other Regression Options

**Weights — Observation weights**

ones \((n,1)/n\) (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `fitrlinear` weights the observations in \(X\) with the corresponding value in `Weights`. The size of `Weights` must equal \(n\), the number of observations in \(X\).

`fitrlinear` normalizes `Weights` to sum to 1.

Data Types: double | single

**ResponseName — Response variable name**

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply \(Y\), then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

**ResponseTransform — Response transformation**

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means @\((y)y\), or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as 'ResponseTransform', myfunction.

Data Types: char | string | function_handle

Cross-Validation Options

**CrossVal — Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.
To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, or KFold. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: 'Crossval','on'

CVPartition — Cross-validation partition

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p, then the software:

1. Randomly reserves p*100% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'Holdout',0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k, then the software:

1. Randomly partitions the data into k sets
2. For each set, reserves the set as validation data, and trains the model using the other k - 1 sets
3. Stores the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold',8

Data Types: single | double

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer
Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes BatchLimit batches, it terminates optimization.

- By default:
  - The software passes through the data PassLimit times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is \( \text{ceil}(1e6/\text{BatchSize}) \). BatchSize is the value of the 'BatchSize' name-value pair argument.
  - If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
  - If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100
Data Types: single | double

**BetaTolerance** — Relative tolerance on linear coefficients and bias term
1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let \( B_t = [\beta_t ' b_t] \), that is, the vector of the coefficients and the bias term at optimization iteration \( t \). If \( \| B_t - B_{t-1} \|_2 < \text{BetaTolerance} \), then optimization terminates.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6
Data Types: single | double

**NumCheckConvergence** — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see BatchSize.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence',100
Data Types: single | double

**PassLimit** — Maximal number of passes
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.
fitrlinear processes all observations when it completes one pass through the data. When fitrlinear passes through the data PassLimit times, it terminates optimization. If you specify 'BatchLimit' and PassLimit, then fitrlinear chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 32-1976.

Example: 'PassLimit',5
Data Types: single | double

ValidationData — Validation data for optimization convergence detection
cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1976. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an m-by-p or p-by-m full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData(2) must contain an array of m responses with length corresponding to the number of observations in ValidationData{1}.
- Optionally, ValidationData(3) can contain an m-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

GradientTolerance — Absolute gradient tolerance
1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar. GradientTolerance applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Let \( \nabla J_t \) be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If \( \| \nabla J_t \|_\infty = \max |\nabla J_t| < \text{GradientTolerance} \), then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when fitrlinear satisfies either stopping criterion.

If fitrlinear converges for the last solver specified in Solver, then optimization terminates. Otherwise, fitrlinear uses the next solver specified in Solver.

Example: 'GradientTolerance',eps
Data Types: single | double

**IterationLimit — Maximal number of optimization iterations**

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',1e7

Data Types: single | double

**Dual SGD Optimization Convergence Controls**

**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration $t$. If $\frac{\|B_t - B_{t-1}\|_2}{B_t} < \text{BetaTolerance}$, then optimization terminates.

If you also specify DeltaGradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

**DeltaGradientTolerance — Gradient-difference tolerance**

0.1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-1690 violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar. DeltaGradientTolerance applies to the 'dual' value of Solver only.

- If the magnitude of the KKT violators is less than DeltaGradientTolerance, then fitrlinear terminates optimization.
- If fitrlinear converges for the last solver specified in Solver, then optimization terminates. Otherwise, fitrlinear uses the next solver specified in Solver.

Example: 'DeltaGapTolerance',1e-2

Data Types: double | single

**NumCheckConvergence — Number of passes through entire data set to process before next convergence check**

5 (default) | positive integer
Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence',100

Data Types: single | double

**PassLimit** — Maximal number of passes
10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data PassLimit times, it terminates optimization.

Example: 'PassLimit',5

Data Types: single | double

**ValidationData** — Validation data for optimization convergence detection

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1976. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- ValidationData(1) must contain an m-by-p or p-by-m full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{1} must correspond. The number of observations in both sets can vary.
- ValidationData(2) must contain an array of m responses with length corresponding to the number of observations in ValidationData{1}.
- Optionally, ValidationData(3) can contain an m-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify ValidationData, then, to display validation loss at the command line, specify a value larger than 0 for Verbose.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

By default, the software does not detect convergence by monitoring validation-data loss.

**BFGS, LBFGS, and SpaRSA Convergence Controls**

**BetaTolerance** — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.
Let $B_t = [\beta_t \; b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration $t$. If
\[
\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance},
\]
then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance', 1e-6
Data Types: single | double

**GradientTolerance — Absolute gradient tolerance**

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration $t$. If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'GradientTolerance', 1e-5
Data Types: single | double

**HessianHistorySize — Size of history buffer for Hessian approximation**

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize', 10
Data Types: single | double

**IterationLimit — Maximal number of optimization iterations**

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit', 500
Data Types: single | double
**ValidationData** — Validation data for optimization convergence detection

`cell array`

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-1976. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- **ValidationData(1)** must contain an \(m\)-by-\(p\) or \(p\)-by-\(m\) full or sparse matrix of predictor data that has the same orientation as \(X\). The predictor variables in the training data \(X\) and \(\text{ValidationData}(1)\) must correspond. The number of observations in both sets can vary.
- **ValidationData(2)** must contain an array of \(m\) responses with length corresponding to the number of observations in \(\text{ValidationData}(1)\).
- Optionally, **ValidationData(3)** can contain an \(m\)-dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

**Hyperparameter Optimization**

**OptimizeHyperparameters** — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use {'Lambda','Learner'}.  
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitrlinear` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

**Note** 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrlinear` are:
• **Lambda** — `fitrlinear` searches among positive values, by default log-scaled in the range 
[\(10^{-5}/\text{NumObservations},10^5/\text{NumObservations}\)].

• **Learner** — `fitrlinear` searches among 'svm' and 'leastsquares'.

• **Regularization** — `fitrlinear` searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```matlab
load carsmall
params = hyperparameters('fitrlinear', [Horsepower, Weight], MPG);
params(1).Range = [1e-3, 2e4];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is 
\[ \log(1 + \text{cross-validation loss}) \] for regression and the 
misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize a Linear Regression” on page 32-1949.

Example: 'OptimizeHyperparameters', 'auto'

---

**HyperparameterOptimizationOptions — Options for optimization**

*structure*

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Values</th>
<th>Default</th>
</tr>

</table>
| **Optimizer**     | • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls `bayesopt`.  
• 'gridsearch' — Use grid search with NumGridDivisions values per dimension.  
• 'randomsearch' — Search at random among MaxObjectiveEvaluations points.  
  
'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`. | 'bayesopt' |

---

</table>
### Field Name | Values | Default
--- | --- | ---
Verbose | Display to the command line.  
- 0 — No iterative display  
- 1 — Iterative display  
- 2 — Iterative display with extra information  
For details, see the `bayesopt` `Verbose` name-value pair argument. | 1

#### UseParallel
Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>Logical value indicating that parallel (true) Bayesian optimization is not used.</td>
</tr>
</tbody>
</table>

#### Repartition
Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization.

- `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.

<table>

'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)  
```

Data Types: `struct`

### Output Arguments

**Mdl — Trained linear regression model**

*RegressionLinear* model object | *RegressionPartitionedLinear* cross-validated model object

Trained linear regression model, returned as a `RegressionLinear` model object or `RegressionPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `RegressionPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `RegressionLinear` model object.
To reference properties of Mdl, use dot notation. For example, enter Mdl.Beta in the Command Window to display the vector or matrix of estimated coefficients.

**Note** Unlike other regression models, and for economical memory usage, RegressionLinear and RegressionPartitionedLinear model objects do not store the training data or optimization details (for example, convergence history).

**FitInfo — Optimization details**
structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, Objective is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of Lambda and columns correspond to values of Solver.

This table describes some notable fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| TerminationStatus | • Reason for optimization termination  
                        • Corresponds to a value in TerminationCode |
| FitTime      | Elapsed, wall-clock time in seconds                                          |
| History      | A structure array of optimization information for each iteration. The field Solver stores solver types using integer coding. |

<table>
<thead>
<tr>
<th>Integer</th>
<th>Solver</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SGD</td>
</tr>
<tr>

</tr>
<tr>
<td>4</td>
<td>LBFGS</td>
</tr>
<tr>
<td>5</td>
<td>BFGS</td>
</tr>
<tr>
<td>6</td>
<td>SpaRSA</td>
</tr>
</tbody>
</table>

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter FitInfo.History.Objective.

It is good practice to examine FitInfo to assess whether convergence is satisfactory.

**HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters**
BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the Optimizer field value of the 'HyperparameterOptimizationOptions' name-value pair argument.
### Value of Optimizer Field

<table>
<thead>
<tr>
<th>Value of Optimizer Field</th>
<th>Value of HyperparameterOptimizationResults</th>
</tr>
</thead>
<tbody>
<tr>
<td>'bayesopt' (default)</td>
<td>Object of class BayesianOptimization</td>
</tr>
<tr>
<td>'gridsearch' or 'randomsearch'</td>
<td>Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)</td>
</tr>
</tbody>
</table>

**Note** If Learner is 'least squares', then the loss term in the objective function is half of the MSE. loss returns the MSE by default. Therefore, if you use loss to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by loss and optimization results in FitInfo or returned to the command line by setting a positive verbosity level usingVerbose.

### More About

#### Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

#### Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

<table>
<thead>
<tr>
<th>Model to Fit</th>
<th>Function</th>
<th>Notable Algorithmic Differences</th>
</tr>
</thead>
</table>
| SVM          | • Binary classification: fitcsvm  
• Multiclass classification: fitcecoc  
• Regression: fitrsvm | • Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations.  
• Solves dual problem using SMO, ISDA, or L1 minimization via quadratic programming using quadprog. |
| Linear regression | • Least-squares without regularization: fitlm  
• Regularized least-squares using a lasso penalty: lasso  
• Ridge regression: ridge or lasso | • lasso implements cyclic coordinate descent. |
### Model to Fit | Function | Notable Algorithmic Differences
--- | --- | ---
Logistic regression | • Logistic regression without regularization: fitglm.  
• Regularized logistic regression using a lasso penalty: lassoglm | • fitglm implements iteratively reweighted least squares.  
• lassoglm implements cyclic coordinate descent.

#### Tips
- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `ObservationsIn`, `columns`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if $X$ is high-dimensional and Regularization is `ridge`, set any of these combinations for Solver:
  - `'sgd'`
  - `'asgd'`
  - `'dual'` if Learner is `'svm'`
  - `{`sgd``,`lbfgs`}`
  - `{`asgd``,`lbfgs`}`
  - `{`dual``,`lbfgs`}` if Learner is `'svm'`

  Other combinations can result in poor optimization accuracy.
- For better optimization accuracy if $X$ is moderate- through low-dimensional and Regularization is `ridge`, set Solver to `lbfgs`.
- If Regularization is `lasso`, set any of these combinations for Solver:
  - `'sgd'`
  - `'asgd'`
  - `'sparsa'`
  - `{`sgd``,`sparsa`}`
  - `{`asgd``,`sparsa`}`

  When choosing between SGD and ASGD, consider that:
  - SGD takes less time per iteration, but requires more iterations to converge.
  - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If $X$ has few observations, but many predictor variables, then:
  - Specify `PostFitBias`, `true`.
  - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
  - If `BatchSize` is too small, then `fitrlinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
• If `BatchSize` is too large, then `fitrlinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.

• Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.

• When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to 1, 10, and then 100.

• For efficiency, `fitrlinear` does not standardize predictor data. To standardize `X`, enter

\[ X = \text{bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2))}; \]

The code requires that you orient the predictors and observations as the rows and columns of `X`, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

• After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

### Algorithms

• If you specify `ValidationData`, then, during objective-function optimization:

  • `fitrlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
  
  • When `fitrlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
  
  • When subsequent, validation loss estimates exceed the minimal estimate five times, `fitrlinear` terminates optimization.

• If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:

  1. `fitrlinear` randomly partitions `X` and `Y` according to the cross-validation routine that you choose.
  
  2. `fitrlinear` trains the model using the training-data partition. During objective-function optimization, `fitrlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
  
  3. Once `fitrlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.

    a. If you implement k-fold cross-validation, and `fitrlinear` has not exhausted all training-set folds, then `fitrlinear` returns to Step 2 to train using the next training-set fold.
    
    b. Otherwise, `fitrlinear` terminates training, and then returns the cross-validated model.

  4. You can determine the quality of the cross-validated model. For example:

    • To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
    
    • To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.
References

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults and values compared to the in-memory fitrlinear function. Supported name-value pair arguments, and any differences, are:
  - 'Epsilon'
  - 'ObservationsIn' — Supports only 'rows'.
  - 'Lambda' — Can be 'auto' (default) or a scalar.
  - 'Learner'
  - 'Regularization' — Supports only 'ridge'.
  - 'Solver' — Supports only 'lbfgs'.
  - 'Verbose' — Default value is 1
  - 'Beta'
  - 'Bias'
  - 'FitBias' — Supports only true.
  - 'Weights' — Value must be a tall array.
  - 'HessianHistorySize'
• 'BetaTolerance' — Default value is relaxed to 1e-3.
• 'GradientTolerance' — Default value is relaxed to 1e-3.
• 'IterationLimit' — Default value is relaxed to 20.
• 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
• 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify fitrlinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2)).
• For tall arrays fitrlinear implements LBFGS by distributing the calculation of the loss and the gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for Beta and Bias are not given, fitrlinear first refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

**Automatic Parallel Support**
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

**Introduced in R2016a**
fitrm

Fit repeated measures model

Syntax

\[ \text{rm} = \text{fitrm}(t, \text{modelspec}) \]
\[ \text{rm} = \text{fitrm}(t, \text{modelspec}, \text{Name,Value}) \]

Description

\[ \text{rm} = \text{fitrm}(t, \text{modelspec}) \] returns a repeated measures model, specified by \text{modelspec}, fitted to the variables in the table or dataset array \text{t}.

\[ \text{rm} = \text{fitrm}(t, \text{modelspec}, \text{Name,Value}) \] returns a repeated measures model, with additional options specified by one or more \text{Name,Value} pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

load fisheriris

The column vector \text{species} consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix \text{meas} consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

\[
\text{t} = \text{table}('\text{species}', \text{meas(:,1)}, \text{meas(:,2)}, \text{meas(:,3)}, \text{meas(:,4)}); \\
\text{Meas} = \text{table}([1 2 3 4], '\text{VariableNames}', \{'\text{Measurements}'\});
\]

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

\[ \text{rm} = \text{fitrm}(t, '\text{meas1-mea4-species}', '\text{WithinDesign}', \text{Meas}) \]

\[ \text{rm} = \text{RepeatedMeasuresModel with properties:} \]

Between Subjects:
  BetweenDesign: [150x5 table]
  ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
  BetweenFactorNames: {'species'}
    BetweenModel: '1 + species'

Within Subjects:
WithinDesign: [4x1 table]
WithinFactorNames: {'Measurements'}
WithinModel: 'separatemeans'

Estimates:
Coefficients: [3x4 table]
Covariance: [4x4 table]

Display the coefficients.

```
rm.Coefficients
ans=3x4 table

meas1     meas2     meas3     meas4
________    ________    ________    ________
(Intercept)             5.8433      3.0573     3.758      1.1993
species_setosa        -0.83733     0.37067    -2.296    -0.95333
species_versicolor    0.092667    -0.28733     0.502     0.12667
```

`fitrm` uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

\[
\begin{align*}
\text{species_setosa} &= \begin{cases} 
1 & \text{if setosa} \\
0 & \text{if versicolor} \\
-1 & \text{if virginica}
\end{cases} \\
\text{species_versicolor} &= \begin{cases} 
0 & \text{if setosa} \\
1 & \text{if versicolor} \\
-1 & \text{if virginica}
\end{cases}
\end{align*}
\]

Display the covariance matrix.

```
rm.Covariance
ans=4x4 table

meas1     meas2     meas3     meas4
________    ________    ________    ________
meas1     0.26501    0.092721     0.16751    0.038401
meas2     0.092721    0.11539    0.055244     0.03271
meas3     0.16751    0.055244     0.18519    0.042665
meas4     0.038401    0.03271    0.042665    0.041882
```

Specify the Within-Subject Hypothesis

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.
Define a variable that stores gender information.

Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];

Store the data in a proper table array format to conduct repeated measures analysis.

`t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
   'VariableNames',{'Gender','t0','t2','t4','t6','t8'});

Define the within-subjects variable.

Time = [0 2 4 6 8];

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

`rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts')`

`rm =
RepeatedMeasuresModel with properties:

Between Subjects:
   BetweenDesign: [16x6 table]
   ResponseNames: {'t0'  't2'  't4'  't6'  't8'}
   BetweenFactorNames: {'Gender'}
   BetweenModel: '1 + Gender'

Within Subjects:
   WithinDesign: [5x1 table]
   WithinFactorNames: {'Time'}
   WithinModel: 'orthogonalcontrasts'

Estimates:
   Coefficients: [2x5 table]
   Covariance: [5x5 table]

Fit a Model with Covariates

Load the sample data.

`load repeatedmeas`

The table between includes the eight repeated measurements, y1 through y8, as responses and the between-subject factors Group, Gender, IQ, and Age. IQ and Age as continuous variables. The table within includes the within-subject factors w1 and w2.

Fit a repeated measures model, where age, IQ, group, and gender are the predictor variables, and the model includes the interaction effect of group and gender. Also define the within-subject factors.

`rm = fitrm(between,'y1-y8 ~ Group*Gender+Age+IQ','WithinDesign',within)`

`rm =
RepeatedMeasuresModel with properties:

Between Subjects:
   BetweenDesign: [16x6 table]
   ResponseNames: {'y1'  'y2'  'y4'  'y6'  'y8'}
   BetweenFactorNames: {'Group'  'Gender'  'Age'  'IQ'}
   BetweenModel: '1 + Group*Gender + Age + IQ'

Within Subjects:
   WithinDesign: [5x1 table]
   WithinFactorNames: {'w1'  'w2'}
   WithinModel: 'orthogonalcontrasts'

Estimates:
   Coefficients: [3x8 table]
   Covariance: [8x8 table]
Display the coefficients.

```
rm.Coefficients
ans=8×8 table

     y1         y2         y3         y4          y5           y6         y7          y8
  ______    _______    _______    _______    _________    ________    _______    ________
(Intercept) 141.38     195.25     9.8663    -49.154       157.77     0.23762    -42.462      76.111

IQ           -1.2671    -1.1653     0.05862     0.4288     -1.4518    -0.25501    0.22867    -0.72548
Gender_Female 5.3957    -3.9719     8.5235     9.3403       6.0909     1.642      2.1212      4.8063
Group_B:Gender_Female -0.48486    -2.9202     1.1222     0.69715               -0.065945          0.079468
```

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

### Input Arguments

**t** — Input data

`table`

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

The variable names in `t` must be valid MATLAB identifiers. You can verify the variable names by using the `isvarname` function. The following code returns logical `1` (`true`) for each variable that has a valid variable name.

```
cellfun(@isvarname,t.Properties.VariableNames)
```

If the variable names in `t` are not valid, then convert them by using the `matlab.lang.makeValidName` function.

```
t.Properties.VariableNames = matlab.lang.makeValidName(t.Properties.VariableNames);
```

Data Types: `table`
modelspec — Formula for model specification

character vector or string scalar of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector or string scalar of the form 'y1-yk ~ terms'. The responses and terms are specified using Wilkinson notation on page 32-1984. *fitrm* treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or cell arrays of character vectors.

For example, if you have four repeated measures as responses and the factors x_1, x_2, and x_3 as the predictor variables, then you can define a repeated measures model as follows.

Example: 'y1-y4 ~ x1 + x2 * x3'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'WithinDesign', 'W', 'WithinModel', 'w1+w2' specifies the matrix w as the design matrix for within-subject factors, and the model for within-subject factors w_1 and w_2 is 'w1+w2'.

WithinDesign — Design for within-subject factors

numeric vector of length r (default) | r-by-k numeric matrix | r-by-k table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and one of the following:

- Numeric vector of length r, where r is the number of repeated measures.
  In this case, *fitrm* treats the values in the vector as continuous, and these are typically time values.
- r-by-k numeric matrix of the values of the k within-subject factors, w_1, w_2, ..., w_k.
  In this case, *fitrm* treats all k variables as continuous.
- r-by-k table that contains the values of the k within-subject factors.
  In this case, *fitrm* treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table *weeks* contains the values of the within-subject factors, then you can define the design table as follows.

Example: 'WithinDesign', *weeks*

Data Types: single | double | table

WithinModel — Model specifying within-subject hypothesis test

'separatemeans' (default) | 'orthogonalcontrasts' | character vector or string scalar that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.

32-1983
• 'orthogonalcontrasts' — This is valid only when the within-subject model has a single numeric factor $T$. Responses are the average, the slope of centered $T$, and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where $p$ is the number of rows in the within-subject model.

• A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the terms in **modelspec**.

For example, if there are three within-subject factors $w_1, w_2,$ and $w_3$, then you can specify a model for the within-subject factors as follows.

Example: 'WithinModel', 'w1+w2+w2*w3'

Data Types: **char** | **string**

### Output Arguments

**rm** — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

### More About

#### Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in **modelspec**.

<table>
<thead>
<tr>
<th>Wilkinson Notation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$Y_1,Y_2,Y_3$</td>
<td>Specific list of variables</td>
</tr>
<tr>
<td>$Y_1-Y_5$</td>
<td>All table variables from $Y_1$ through $Y_5$</td>
</tr>
</tbody>
</table>

The following rules specify terms in **modelspec**.

<table>
<thead>
<tr>
<th>Wilkinson notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Constant (intercept) term</td>
</tr>
<tr>
<td>$X^k$, where $k$ is a positive integer</td>
<td>$X, X^2, ..., X^k$</td>
</tr>
<tr>
<td>$X_1 + X_2$</td>
<td>$X_1, X_2$</td>
</tr>
<tr>
<td>$X_1*X_2$</td>
<td>$X_1, X_2, X_1*X_2$</td>
</tr>
<tr>
<td>$X_1:X_2$</td>
<td>$X_1*X_2$ only</td>
</tr>
<tr>
<td>-$X_2$</td>
<td>Do not include $X_2$</td>
</tr>
<tr>
<td>$X_1*X_2 + X_3$</td>
<td>$X_1, X_2, X_3, X_1*X_2$</td>
</tr>
<tr>
<td>$X_1 + X_2 + X_3 + X_1:X_2$</td>
<td>$X_1, X_2, X_3, X_1*X_2$</td>
</tr>
<tr>
<td>$X_1<em>X_2</em>X_3 - X_1:X_2:X_3$</td>
<td>$X_1, X_2, X_3, X_1<em>X_2, X_1</em>X_3, X_2*X_3$</td>
</tr>
</tbody>
</table>
## Wilkinson notation

<table>
<thead>
<tr>
<th>Wilkinson notation</th>
<th>Factors in Standard Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X_1*(X_2 + X_3)$</td>
<td>$X_1, X_2, X_3, X_1<em>X_2, X_1</em>X_3$</td>
</tr>
</tbody>
</table>

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

- `RepeatedMeasuresModel`

### Introduced in R2014a
**fitdist**

Fit probability distribution object to data

**Syntax**

\[ \text{pd} = \text{fitdist}(x, \text{distname}) \]

\[ \text{pd} = \text{fitdist}(x, \text{distname}, \text{Name,Value}) \]

\[ [\text{pdca}, \text{gn}, \text{gl}] = \text{fitdist}(x, \text{distname}, 'By', \text{groupvar}) \]

\[ [\text{pdca}, \text{gn}, \text{gl}] = \text{fitdist}(x, \text{distname}, 'By', \text{groupvar,Name,Value}) \]

**Description**

\( \text{pd} = \text{fitdist}(x, \text{distname}) \) creates a probability distribution object by fitting the distribution specified by \text{distname} to the data in column vector \( x \).

\( \text{pd} = \text{fitdist}(x, \text{distname}, \text{Name,Value}) \) creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

\( [\text{pdca}, \text{gn}, \text{gl}] = \text{fitdist}(x, \text{distname}, 'By', \text{groupvar}) \) creates probability distribution objects by fitting the distribution specified by \text{distname} to the data in \( x \) based on the grouping variable \text{groupvar}. It returns a cell array of fitted probability distribution objects, \text{pdca}, a cell array of group labels, \text{gn}, and a cell array of grouping variable levels, \text{gl}.

\( [\text{pdca}, \text{gn}, \text{gl}] = \text{fitdist}(x, \text{distname}, 'By', \text{groupvar,Name,Value}) \) returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

**Examples**

**Fit a Normal Distribution to Data**

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```matlab
pd = fitdist(x,'Normal')
```

```matlab
pd =
    NormalDistribution
    Normal distribution
    mu = 154 [148.728, 159.272]
    sigma = 26.5714 [23.3299, 30.8674]
```
The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Plot the pdf of the distribution.

```matlab
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y,'LineWidth',2)
```

![Plot of the pdf of the distribution](image)

**Fit a Kernel Distribution to Data**

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```matlab
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

```
KernelDistribution
   Kernel = epanechnikov
   Bandwidth = 14.3792
```
Support = unbounded

Plot the pdf of the distribution.

```matlab
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y)
```

**Fit Normal Distributions to Grouped Data**

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```matlab
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca=1x2 cell array
    {1x1 prob.NormalDistribution}    {1x1 prob.NormalDistribution}
```
The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two group labels. The cell array `gl` contains two group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender:

```matlab
female = pdca{1}  % Distribution for females
female =
    NormalDistribution
    Normal distribution
    mu = 130.472   [128.183, 132.76]
    sigma = 8.30339   [6.96947, 10.2736]

male = pdca{2}  % Distribution for males
male =
    NormalDistribution
    Normal distribution
    mu = 180.532   [177.833, 183.231]
    sigma = 9.19322   [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```matlab
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```matlab
figure
plot(x_values,femalepdf,'LineWidth',2)
hold on
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast')
hold off
```
Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```matlab
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```matlab
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```matlab
female = pdca{1}  % Distribution for females
female = 
    KernelDistribution
    Kernel = triangle
    Bandwidth = 4.25894
    Support = unbounded

male = pdca{2}  % Distribution for males
```
Compute the pdf of each distribution.

```matlab
x_values = 50:1:250;
femalepdf = pdf(female, x_values);
malepdf = pdf(male, x_values);

Plot the pdfs for a visual comparison of weight distribution by gender.

```matlab
figure
plot(x_values, femalepdf, 'LineWidth', 2)
hold on
plot(x_values, malepdf, 'Color', 'r', 'LineStyle', ':', 'LineWidth', 2)
legend(gn, 'Location', 'NorthEast')
hold off
```

**Input Arguments**

- `x` — Input data
  - column vector
Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector cause `fitdist` to ignore the corresponding values in `x`.

Data Types: double

### distname — Distribution name
character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by `distname` determines the type of the returned probability distribution object.

### Description

**groupvar — Grouping variable**

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variables. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender,Smoker}`

Data Types: categorical | logical | single | double | char | string | cell

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

### Censoring — Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding element is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any `NaN` values in this censoring vector. Additionally, any `NaN` values in `x` or the frequency vector cause `fitdist` to ignore the corresponding values in the censoring vector.

This argument is valid only if `distname` is 'BirnbaumSaunders', 'Burr', 'Exponential', 'ExtremeValue', 'Gamma', 'InverseGaussian', 'Kernel', 'Logistic', 'Loglogistic', 'Lognormal', 'Nakagami', 'Normal', 'Rician', 'tLocationScale', or 'Weibull'.

Data Types: logical

### Frequency — Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the...
frequency vector specifies the frequencies for the corresponding elements in \( x \). The default is a vector of 1s, indicating that each value in \( x \) only appears once.

`fitdist` ignores any NaN values in this frequency vector. Additionally, any NaN values in \( x \) or the censoring vector cause `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `single` | `double`

**Options — Control parameters**

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of `Options` and a structure you create using `statset`.

Data Types: `struct`

**N Trials — Number of trials**

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `N Trials` and a positive integer value. You must specify `distname` as `'Binomial'` to use this option.

Data Types: `single` | `double`

**Theta — Threshold parameter**

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of `Theta` and a scalar value. You must specify `distname` as `'GeneralizedPareto'` to use this option.

Data Types: `single` | `double`

**mu — Location parameter**

0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of `mu` and a scalar value. You must specify `distname` as `'HalfNormal'` to use this option.

Data Types: `single` | `double`

**Kernel — Kernel smoother type**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of `Kernel` and one of the following:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

You must specify `distname` as `'Kernel'` to use this option.

**Support — Kernel density support**

'unbounded' (default) | 'positive' | two-element vector
Kernel density support, specified as the comma-separated pair consisting of 'Support' and 'unbounded', 'positive', or a two-element vector.

- 'unbounded' — Density can extend over the whole real line.
- 'positive' — Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify distname as 'Kernel' to use this option.

Data Types: single | double | char | string

Width — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by fitdist is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

You must specify distname as 'Kernel' to use this option.

Data Types: single | double

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by distname determines the class type of the returned probability distribution object.

pdca — Probability distribution objects

cell array

Probability distribution objects of the type specified by distname, returned as a cell array.

gn — Group labels

cell array of character vectors

Group labels, returned as a cell array of character vectors.

gl — Grouping variable levels

cell array of character vectors

Grouping variable levels, returned as a cell array of character vectors containing one column for each grouping variable.

Algorithms

The fitdist function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
• For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

**Alternative Functionality**

**App**

The **Distribution Fitter** app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

**References**

**Extended Capabilities**

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• Supported syntaxes are:

  ```matlab
  pd = fitdist(x,distname)
  pd = fitdist(x,distname,Name,Value)
  ```

  Code generation does not support the syntaxes that include the grouping variable 'By', `groupvar` and the related output arguments `pdca`, `gn`, and `gl`.

• `fitdist` supports code generation for beta, exponential, extreme value, lognormal, normal, and Weibull distributions.

  • The value of `distname` can be 'Beta', 'Exponential', 'ExtremeValue', 'Lognormal', 'Normal' or 'Weibull'.
  
  • The value of `distname` must be a compile-time constant.

• The values of `x`, 'Censoring', and 'Frequency' must not contain NaN values.

• Code generation ignores the 'Frequency' value for the beta distribution. Instead of specifying the 'Frequency' value, manually add duplicated values to `x` so that the values in `x` have the frequency you want.

• Code generation does not support these input arguments: `groupvar`, `NTrials`, `Theta`, `mu`, `Kernel`, `Support`, and `Width`.

• Names in name-value pair arguments must be compile-time constants.
• These object functions of `pd` support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Probability Distribution Objects” on page 31-70.

**Introduced in R2009a**
**fitensemble**

Fit ensemble of learners for classification and regression

**Syntax**

```matlab
Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)
Mdl = fitensemble(X,Y,Method,NLearn,Learners)
Mdl = fitensemble(___,Name,Value)
```

**Description**

`fitensemble` can boost or bag decision tree learners or discriminant analysis classifiers. The function can also train random subspace ensembles of KNN or discriminant analysis classifiers.

For simpler interfaces that fit classification and regression ensembles, instead use `fitcensemble` and `fitrensemble`, respectively. Also, `fitensemble` and `fitrensemble` provide options for Bayesian optimization.

```matlab
Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
```
to returns a trained ensemble model object that contains the results of fitting an ensemble of `NLearn` classification or regression learners (`Learners`) to all variables in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. `Method` is the ensemble-aggregation method.

```matlab
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
```
to fits the model specified by `formula`.

```matlab
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)
```
treats all variables in `Tbl` as predictor variables. `Y` is the response variable that is not in `Tbl`.

```matlab
Mdl = fitensemble(X,Y,Method,NLearn,Learners)
```
trains an ensemble using the predictor data in `X` and response data in `Y`.

```matlab
Mdl = fitensemble(___,Name,Value)
```
trains an ensemble using additional options specified by one or more `Name,Value` pair arguments and any of the previous syntaxes. For example, you can specify the class order, to implement 10-fold cross-validation, or the learning rate.

**Examples**

**Estimate the Resubstitution Loss of a Boosting Ensemble**

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```matlab
load ionosphere;
```
Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

ClassTreeEns is a trained ClassificationEnsemble ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns,'Mode','Cumulative');
```

rsLoss is a 100-by-1 vector, where element \( k \) contains the resubstitution loss after the first \( k \) learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);
xlabel('Number of Learning Cycles');
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:
Randomly partitioning the data into training and cross-validation sets. Do this by specifying 'holdout', holdoutProportion when you train the ensemble using fitensemble.

Passing the trained ensemble to kfoldLoss, which estimates the generalization error.

**Train Regression Ensemble**

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors. Then, train an ensemble using fewer predictors and compare its in-sample predictive accuracy against the first ensemble.

Load the carsmall data set. Store the training data in a table.

```matlab
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```matlab
t = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```matlab
Mdl1 = fitensemble(Tbl,'MPG','LSBoost',100,t);
```

Mdl1 is a trained RegressionEnsemble regression ensemble. Because MPG is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```matlab
Mdl1 = fitensemble(Tbl,MPG,'LSBoost',100,t);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```matlab
predMPG = predict(Mdl1,[4 200 150 3000])
predMPG = 22.8462
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Train a new ensemble using all predictors in Tbl except Displacement.

```matlab
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula,'LSBoost',100,t);
```

Compare the resubstitution MSEs between Mdl1 and Mdl2.

```matlab
mse1 = resubLoss(Mdl1)
mse1 = 6.4721
mse2 = resubLoss(Mdl2)
mse2 = 7.8599
```

The in-sample MSE for the ensemble that trains on all predictors is lower.
**Estimate the Generalization Error of a Boosting Ensemble**

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```matlab
load ionosphere;
```

Train a decision tree ensemble using AdaBoostM1, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```matlab
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...  
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```matlab
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element `k` contains the generalization error after the first `k` learning cycles.

Plot the generalization error over the number of learning cycles.

```matlab
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```
The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

**Find the Optimal Number of Splits and Trees for an Ensemble**

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.
- When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```matlab
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:
1 for \( \text{MaxNumSplits} \). This option grows stumps.

- 5 for \( \text{MinLeafSize} \)
- 10 for \( \text{MinParentSize} \)

To search for the optimal number of splits:

1. Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most \( n - 1 \) splits, where \( n \) is the training sample size. Also, decrease the learning rate for each ensemble from 1 to 0.1.

2. Cross validate the ensembles.

3. Estimate the cross-validated mean-squared error (MSE) for each ensemble.

4. Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep regression tree and a stump. Specify to use surrogate splits because the data contains missing values. These serve as benchmarks.

```matlab
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence \( \{2^0, 2^1, \ldots, 2^m\} \), where \( m \) is such that \( 2^m \) is no greater than \( n - 1 \), where \( n \) is the training sample size. For each variant, adjust the learning rate to each value in the set \{0.1, 0.25, 0.5, 1\};

```matlab
n = size(X,1);
m = floor(log2(n - 1));
lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;
```

Compute the cross-validated MSE for each ensemble.

```matlab
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform','false');
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'.b','LineWidth',2);
    plot(h.XLim,[errorStump errorStump],'.r','LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'-k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hl = legend([cellstr(num2str(lr','Learning Rate = %0.2f'));...
    'Deep Tree';'Stump';'Min. MSE']);
hl.Position(1) = 0.6;

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.
[minErr, minErrIdxLin] = min(error(:));
[idxNumTrees, idxMNS, idxLR] = ind2sub(size(error), minErrIdxLin);
fprintf('
Min. MSE = %0.5f', minErr)
Min. MSE = 18.50574
fprintf('
Optimal Parameter Values:
Num. Trees = %d', idxNumTrees);
Optimal Parameter Values:
Num. Trees = 12
fprintf('
MaxNumSplits = %d
Learning Rate = %0.2f
',
    maxNumSplits(idxMNS), lr(idxLR))
MaxNumSplits = 4
Learning Rate = 0.25

For a different approach to optimizing this ensemble, see “Optimize a Boosted Regression Ensemble” on page 10-64.

Input Arguments

Tbl — Sample data
table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using ResponseVarName.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using formula.
- If Tbl does not contain the response variable, then specify the response data using Y. The length of response variable and the number of rows of Tbl must be equal.

**Note** To save memory and execution time, supply X and Y instead of Tbl.

Data Types: table

ResponseVarName — Response variable name
name of response variable in Tbl

Response variable name, specified as the name of the response variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if Tbl.Y is the response variable, then specify ResponseVarName as 'Y'. Otherwise, fitensemble treats all columns of Tbl as predictor variables.
The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the ClassNames name-value pair argument. Otherwise, fitensemble determines the class order, and stores it in the Mdl.ClassNames.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers.

You can verify the variable names in Tbl by using the isvarname function. The following code returns logical 1 (true) for each variable that has a valid variable name.

cellfun(@isvarname,Tbl.Properties.VariableNames)

If the variable names in Tbl are not valid, then convert them by using the matlab.lang.makeValidName function.

Tbl.Properties.VariableNames = matlab.lang.makeValidName(Tbl.Properties.VariableNames);

Data Types: char | string

X — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: single | double

Y — Response data
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each entry in Y is the response to or label for the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal. If
the response variable is a character array, then each element must correspond to one row of the array.

- For classification, \( Y \) can be any of the supported data types. You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.
- For regression, \( Y \) must be a numeric column vector.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

### Method — Ensemble aggregation method
`'AdaBoostM1'` | `'LogitBoost'` | `'GentleBoost'` | `'RUSBoost'` | `'Subspace'` | `'Bag'` | `'AdaBoostM2'` | `'LSBoost'` | ...  

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
  - `'AdaBoostM1'`
  - `'LogitBoost'`
  - `'GentleBoost'`
  - `'RobustBoost'` (requires Optimization Toolbox)
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For classification with three or more classes:
  - `'AdaBoostM2'`
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For regression:
  - `'LSBoost'`
  - `'Bag'`

If you specify `Method`, `'Bag'`, then specify the problem type using the `Type` name-value pair argument, because you can specify `'Bag'` for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see "Ensemble Algorithms" on page 18-38 and "Choose an Applicable Ensemble Aggregation Method" on page 18-31.

### NLearn — Number of ensemble learning cycles
positive integer | `'AllPredictorCombinations'`
Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NLearn*numel(Learners) learners.
- If you specify 'AllPredictorCombinations', then set Method to 'Subspace' and specify one learner only in Learners. With these settings, the software trains learners for all possible combinations of predictors taken NPredToSample at a time. Consequently, the software trains nchoosek(size(X,2),NPredToSample) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-2018.

Data Types: single | double | char | string

**Learners — Weak learners to use in ensemble**
weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

<table>
<thead>
<tr>
<th>Weak Learner</th>
<th>Weak-Learner Name</th>
<th>Template Object Creation Function</th>
<th>Method Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discriminant analysis</td>
<td>'Discriminant'</td>
<td>templateDiscriminant</td>
<td>Recommended for 'Subspace'</td>
</tr>
<tr>
<td>k nearest neighbors</td>
<td>'KNN'</td>
<td>templateKNN</td>
<td>For 'Subspace' only</td>
</tr>
<tr>
<td>Decision tree</td>
<td>'Tree'</td>
<td>templateTree</td>
<td>All methods except 'Subspace'</td>
</tr>
</tbody>
</table>

For more details, see NLearn and “Tips” on page 32-2018.

Example: For an ensemble composed of two types of classification trees, supply {t1 t2}, where t1 and t2 are classification tree templates.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: ‘CrossVal','on','LearnRate',0.05 specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

**General Ensemble Options**

**CategoricalPredictors — Categorical predictors list**
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.
### Value

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector of positive integers</td>
</tr>
<tr>
<td>Logical vector</td>
</tr>
<tr>
<td>Character matrix</td>
</tr>
<tr>
<td>String array or cell array of character vectors</td>
</tr>
<tr>
<td>'all'</td>
</tr>
</tbody>
</table>

### Specification of 'CategoricalPredictors'

- 'Learners' specifies tree learners.
- 'Learners' specifies k-nearest learners where all predictors are categorical.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See 'CategoricalPredictors' of fitcknn for k-nearest learners and 'CategoricalPredictors' of fitctree for tree learners.

Example: 'CategoricalPredictors','all'

Data Types: single | double | logical | char | string | cell

### NPrint — Printout frequency

- 'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of weak learners or folds that fitensemble trained so far, specify a positive integer. That is, if you specify the positive integer \( m \):

- Without also specifying any cross-validation option (for example, CrossVal), then fitensemble displays a message to the command line every time it completes training \( m \) weak learners.
- And a cross-validation option, then fitensemble displays a message to the command line every time it finishes training \( m \) folds.

If you specify 'off', then fitensemble does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for NPrint.

Example: 'NPrint',5

Data Types: single | double | char | string

### PredictorNames — Predictor variable names

- string array of unique names
- cell array of unique character vectors
Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitensemble uses only the predictor variables in PredictorNames and the response variable in training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}
Data Types: string | cell

ResponseName — Response variable name
'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.
- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'
Data Types: char | string

Type — Supervised learning type
'classification' | 'regression'

Supervised learning type, specified as the comma-separated pair consisting of 'Type' and 'classification' or 'regression'.
- If Method is 'bag', then the supervised learning type is ambiguous. Therefore, specify Type when bagging.
- Otherwise, the value of Method determines the supervised learning type.

Example: 'Type','classification'

Cross-Validation Options

CrossVal — Cross-validation flag
'off' (default) | 'on'

Data Types: char | string
Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval or crossval.

Example: 'Crossval','on'

**CVPartition — Cross-validation partition**

[] (default) | cvpartition partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object created by cvpartition. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout — Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout',p, then the software completes these steps:

1. Randomly select and reserve p*100% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout',0.1

Data Types: double | single

**KFold — Number of folds**

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold',k, then the software completes these steps:

1. Randomly partition the data into k sets.
2. For each set, reserve the set as validation data, and train the model using the other k - 1 sets.
3. Store the k compact, trained models in the cells of a k-by-1 cell vector in the Trained property of the cross-validated model.
To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

1. Reserve the observation as validation data, and train the model using the other n - 1 observations.
2. Store the n compact, trained models in the cells of an n-by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout','on'

**Other Classification or Regression Options**

**ClassNames — Names of classes to use for training**

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use 'ClassNames' to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use 'ClassNames' to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a','b','c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames',{'a','c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames',{'b','g'}

Data Types: categorical | char | string | logical | single | double | cell

**Cost — Misclassification cost**

square matrix | structure array
Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix Cost, then \( \text{Cost}(i,j) \) is the cost of classifying a point into class \( j \) if its true class is \( i \). That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, also specify the ClassNames name-value pair argument.
- The structure S, then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as \( Y \)
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default is \( \text{ones}(K) - \text{eye}(K) \), where \( K \) is the number of distinct classes.

**Note** fitensemble uses Cost to adjust the prior class probabilities specified in Prior. Then, fitensemble uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost',[0 1 2; 1 0 2; 2 2 0]

Data Types: double | single | struct

**Prior — Prior probabilities**

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'empirical'</td>
<td>The class prior probabilities are the class relative frequencies in ( Y ).</td>
</tr>
<tr>
<td>'uniform'</td>
<td>All class prior probabilities are equal to ( 1/K ), where ( K ) is the number of classes.</td>
</tr>
<tr>
<td>numeric vector</td>
<td>Each element is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements such that they sum to 1.</td>
</tr>
<tr>
<td>structure array</td>
<td>A structure S with two fields:</td>
</tr>
<tr>
<td></td>
<td>- S.ClassNames contains the class names as a variable of the same type as ( Y ).</td>
</tr>
<tr>
<td></td>
<td>- S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</td>
</tr>
</tbody>
</table>

fitensemble normalizes the prior probabilities in Prior to sum to 1.
Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)

Data Types: char | string | double | single | struct

**Weights — Observation weights**

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of `Weights` and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones(n,1), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

**Sampling Options for Boosting Methods and Bagging**

**FResample — Fraction of training set to resample**

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

**Replace — Flag indicating to sample with replacement**

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace','off'

**Resample — Flag indicating to resample**

'off' | 'on'
Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off' (default) specifies to reweight observations at every learning iteration.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

**AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**RUSBoost Method Options**

**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

**RatioToSmallest — Sampling proportion with respect to lowest-represented class**

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are $K$ classes in the training data and the lowest-represented class has $m$ observations in the training data.
If you specify the positive numeric scalar \( s \), then `fitensemble` samples \( s \cdot m \) observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2019.

If you specify the numeric vector \([s_1, s_2, \ldots, s_K]\), then `fitensemble` samples \( s_i \cdot m \) observations from class \( i, i = 1, \ldots, K \). The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 32-2018).

The default value is `ones(K,1)`, which specifies to sample \( m \) observations from each class.

Example: `'RatioToSmallest',[2,1]
Data Types: `single` | `double`

**LPBoost and TotalBoost Method Options**

**MarginPrecision — Margin precision to control convergence speed**

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

**Tip** To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5
Data Types: `single` | `double`

**RobustBoost Method Options**

**RobustErrorGoal — Target classification error**

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

**Tip** For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05
Data Types: `single` | `double`

**RobustMarginSigma — Classification margin distribution spread**

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on RobustBoost, for example, [19].

Example: `'RobustMarginSigma',0.5
Data Types: single | double

**RobustMaxMargin — Maximal classification margin**
0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of 'RobustMaxMargin' and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below RobustMaxMargin.

Example: 'RobustMaxMargin', 1

Data Types: single | double

**Random Subspace Method Options**

**NPredToSample — Number of predictors to sample**
1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of 'NPredToSample' and a positive integer in the interval 1,...,p, where p is the number of predictor variables (size(X,2) or size(Tbl,2)).

Data Types: single | double

**Output Arguments**

**Mdl — Trained ensemble model**

<table>

</tbody>
</table>
The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

**Tips**

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.

- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

- In classification problems (that is, `Type` is `'classification'`):
  - If the ensemble-aggregation method (`Method`) is `'bag'` and:
    - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
    - The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

  For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using `Cost` or a less skewed prior probability vector using `Prior`.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument.

- To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

```matlab
Ycat = categorical(Y);
classNames = categories(Ycat)
```

`categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.
• To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to ClassNames. Following from the previous example, this code specifies the class order from lowest- to most-represented in classNamesLH.

      Ycat = categorical(Y);
      classNames = categories(Ycat);
      freq = countcats(Ycat);
      [~,idx] = sort(freq);
      classNamesLH = classNames(idx);

Algorithms

• For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-38.

• If you specify Method to be a boosting algorithm and Learners to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using templateTree.

• fitensemble generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

• For the RUSBoost ensemble-aggregation method (Method), the name-value pair argument RatioToSmallest specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: A and B. A have 100 observations and B have 10 observations. Also, suppose that the lowest-represented class has m observations in the training data.

      • If you set 'RatioToSmallest',2, then s*m = 2*10 = 20. Consequently, fitensemble trains every learner using 20 observations from class A and 20 observations from class B. If you set 'RatioToSmallest',[2, 2], then you obtain the same result.

      • If you set 'RatioToSmallest',[2,1], then s1*m = 2*10 = 20 and s2*m = 1*10 = 10. Consequently, fitensemble trains every learner using 20 observations from class A and 10 observations from class B.

• For ensembles of decision trees, and for dual-core systems and above, fitensemble parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

**Topics**

“Supervised Learning Workflow and Algorithms” on page 18-2
“Framework for Ensemble Learning” on page 18-30

**Introduced in R2011a**
**fitnlm**

Fit nonlinear regression model

**Syntax**

```matlab
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm(____,modelfun,beta0,Name,Value)
```

**Description**

- `mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`. `fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

- `mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

- `mdl = fitnlm(____,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

**Examples**

**Nonlinear Model from Table**

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```matlab
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...  
        b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl = Nonlinear regression model:
    MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:
    Estimate      SE        tStat       pValue
        ______    _______    ________    ________
       b1      -49.383     119.97    -0.41164     0.68083
       b2      376.43     567.05     0.66384     0.50719
       b3    -0.78193    0.47168     -1.6578    0.098177
       b4      422.37     776.02     0.54428     0.58656
```
Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```matlab
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... + b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

mdl =
Nonlinear regression model:
  y ~ b1 + b2*x1^b3 + b4*x2^b5

R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in Nonlinear Model

Create a nonlinear model for auto mileage based on the carbig data. Strive for more accuracy by lowering the TolFun option, and observe the iterations by setting the Display option.

Load the data and create a nonlinear model.

```matlab
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ... + b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

mdl =
Nonlinear regression model:
  y ~ b1 + b2*x1^b3 + b4*x2^b5

Specify Nonlinear Regression Using Model Name Syntax

Specify a nonlinear regression model for estimation using a function handle or model syntax.

Load sample data.

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

Use a function handle to specify the Hougen-Watson model for the rate data.

mdl = fitnlm(X,y,@hougen,beta0)

mdl =
Nonlinear regression model:
  y ~ hougen(b,X)

Estimated Coefficients:
  Estimate       SE       tStat     pValue
  ______    ________    ______    _______
  b1      1.2526     0.86701    1.4447    0.18654
  b2    0.062776    0.043561    1.4411    0.18753
  b3    0.040048    0.030885    1.2967    0.23089
  b4    0.11242    0.075157    1.4957    0.17309
  b5     1.1914    0.83671     1.4239    0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use an expression to specify the Hougen-Watson model for the rate data.

```matlab
myfun = 'y-(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

mdl2 =
Nonlinear regression model:
\[ y - \frac{(b_1 \times x_2 - x_3/b_5)}{(1 + b_2 \times x_1 + b_3 \times x_2 + b_4 \times x_3)} \]

Estimated Coefficients:

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

**Estimate Nonlinear Regression Using Robust Fitting Options**

Generate sample data from the nonlinear regression model

\[ y = b_1 + b_2 \exp(-b_3 x) + \varepsilon, \]

where \( b_1, b_2, \) and \( b_3 \) are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```matlab
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);

Set robust fitting options.
```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use an expression to specify the model.
```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
```
mdl =
Nonlinear regression model (robust fit):
\[ y \sim b_1 + b_2 \exp(-b_3 x) \]

Estimated Coefficients:

<table>
<thead>
<tr>
<th></th>
<th>Estimate</th>
<th>SE</th>
<th>tStat</th>

Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```matlab
a = 1; b = 1;
weights = @(yhat) 1 ./ ((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```matlab
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

mdl =
Nonlinear regression model:
\[ y \sim hougen(b,X) \]

Estimated Coefficients:

**Nonlinear Regression Model Using Nonconstant Error Model**

Load sample data.

```matlab
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```matlab
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```matlab
mdl = 
Nonlinear regression model:
y ~ hougen(b,X)

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

**Input Arguments**

**tbl — Input data**

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable must be numeric.

- If you specify `modelfun` using a formula, the model specification in the formula specifies the predictor and response variables.
- If you specify `modelfun` using a function handle, the last variable is the response variable and the others are the predictor variables, by default. You can set a different column as the response variable by using the `ResponseVar` name-value pair argument. To select a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot specify `modelfun` using a formula.

You can verify the variable names in `tbl` by using the `isvarname` function. The following code returns logical 1 (`true`) for each variable that has a valid variable name.
cellfun(@isvarname,tbl.Properties.VariableNames)

If the variable names in tbl are not valid, then convert them by using the
matlab.lang.makeValidName function.

tbl.Properties.VariableNames = matlab.lang.makeValidName(tbl.Properties.VariableNames);

Data Types: table

X — Predictor variables

matrix

Predictor variables, specified as an n-by-p matrix, where n is the number of observations and p is the
number of predictor variables. Each column of X represents one variable, and each row represents
one observation.

Data Types: single | double

y — Response variable

vector

Response variable, specified as an n-by-1 vector, where n is the number of observations. Each entry in
y is the response for the corresponding row of X.

Data Types: single | double

modelfun — Functional form of the model

function handle | character vector or string scalar formula in the form 'y ~
f(b1,b2,...,bj,x1,x2,...,xk)'

Functional form of the model, specified as either of the following.

• Function handle @modelfun or @(b,x)modelfun, where
  
  • b is a coefficient vector with the same number of elements as beta0.
  
  • x is a matrix with the same number of columns as X or the number of predictor variable
columns of tbl.

  modelfun(b,x) returns a column vector that contains the same number of rows as x. Each row
of the vector is the result of evaluating modelfun on the corresponding row of x. In other words,
modelfun is a vectorized function, one that operates on all data rows and returns all evaluations
in one function call. modelfun should return real numbers to obtain meaningful coefficients.

• Character vector or string scalar representing a formula in the form 'y ~
f(b1,b2,...,bj,x1,x2,...,xk)', where f represents a scalar function of the scalar
coefficient variables b1,...,bj and the scalar data variables x1,...,xk. The variable names in the
formula must be valid MATLAB identifiers.

Data Types: function_handle | char | string

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its
search for optimal coefficients from beta0.

Data Types: single | double
Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'ErrorModel','combined','Exclude',2,'Options',opt specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure opt to control the iterative fitting procedure.

CoefficientNames — Names of the model coefficients
{'b1','b2',...,'bk'} (default) | string array | cell array of character vectors

Names of the model coefficients, specified as a string array or cell array of character vectors.
Data Types: string | cell

ErrorModel — Form of the error variance model
'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant' (default)</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>'proportional'</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>'combined'</td>
<td>a,b</td>
<td>[1,1]</td>
</tr>
</tbody>
</table>

The only allowed error model when using Weights is 'constant'.

Note options.RobustWgtFun must have value [] when using an error model other than 'constant'.

Example: 'ErrorModel','proportional'

ErrorParameters — Initial estimates of the error model parameters
numeric array

Initial estimates of the error model parameters for the chosen ErrorModel, specified as a numeric array.

<table>
<thead>
<tr>
<th>Error Model</th>
<th>Parameters</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>'constant'</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>'proportional'</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>'combined'</td>
<td>a,b</td>
<td>[1,1]</td>
</tr>
</tbody>
</table>

You can only use the 'constant' error model when using Weights.

Note options.RobustWgtFun must have value [] when using an error model other than 'constant'.

32 Functions
For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for \( a \) and the starting value 2 for \( b \) as follows.

Example: 'ErrorParameters',[1,2]

Data Types: single | double

**Exclude — Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]

Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

**Options — Options for controlling the iterative fitting procedure**

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by statset. The relevant fields are the nonempty fields in the structure returned by the call statset('fitnlm').

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
<th>Default</th>

Data Types: struct

**PredictorVars — Predictor variables**

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]
Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

**ResponseVar — Response variable**

last column of tbl (default) | variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable.

If you specify a model, it specifies the response variable. Otherwise, when fitting a table or dataset array, 'ResponseVar' indicates which variable fitnlm should use as the response.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'
Example: 'ResponseVar',[4]
Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char | string

**VarNames — Names of variables**

{ 'x1', 'x2', ..., 'xn', 'y' } (default) | string array | cell array of character vectors
Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

Weights — Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have `n` elements, where `n` is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by `MSE*(1/W(i))`, where MSE is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

### Introduced in R2013b
LinearMixedModel.fitmatrix

Class: LinearMixedModel

(Not Recommended) Fit linear mixed-effects model using design matrices

**Note** LinearMixedModel.fitmatrix is not recommended. Use fitlmematrix instead.

**Syntax**

```matlab
lme = LinearMixedModel.fitmatrix(X,y,Z,[])
lme = LinearMixedModel.fitmatrix(X,y,Z,G)
lme = LinearMixedModel.fitmatrix(___,Name,Value)
```

**Description**

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`. 

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(___,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

**Input Arguments**

- **X** — Fixed-effects design matrix
  
  `n`-by-`p` matrix
  
  Fixed-effects design matrix, specified as an `n`-by-`p` matrix, where `n` is the number of observations, and `p` is the number of fixed-effects predictor variables. Each row of `X` corresponds to one observation, and each column of `X` corresponds to one variable.
  
  Data Types: `single` | `double`

- **y** — Response values
  
  `n`-by-1 vector
  
  Response values.
Response values, specified as an \( n \)-by-1 vector, where \( n \) is the number of observations.

Data Types: `single` | `double`

**Z — Random-effects design**

\( n \)-by-\( q \) matrix | cell array of \( R \) \( n \)-by-\( q(r) \) matrices, \( r = 1, 2, \ldots, R \)

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then \( Z \) must be an \( n \)-by-\( q \) matrix, where \( n \) is the number of observations and \( q \) is the number of variables in the random-effects term.
- If there are \( R \) random-effects terms, then \( Z \) must be a cell array of length \( R \). Each cell of \( Z \) contains an \( n \)-by-\( q(r) \) design matrix \( Z\{r\} \), \( r = 1, 2, \ldots, R \), corresponding to each random-effects term. Here, \( q(r) \) is the number of random effects term in the \( r \)th random effects design matrix, \( Z\{r\} \).

Data Types: `single` | `double` | `cell`

**G — Grouping variable or variables**

\( n \)-by-1 vector | cell array of \( R \) \( n \)-by-1 vectors

Grouping variable or variables on page 2-45, specified as either of the following.

- If there is one random-effects term, then \( G \) must be an \( n \)-by-1 vector corresponding to a single grouping variable with \( M \) levels or groups.

  \( G \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then \( G \) must be a cell array of length \( R \). Each cell of \( G \) contains a grouping variable \( G\{r\}, r = 1, 2, \ldots, R \), with \( M(r) \) levels.

  \( G\{r\} \) can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**FixedEffectPredictors — Names of columns in fixed-effects design matrix**

\{'x1','x2',...,'xP'} (default) | string array or cell array of length \( p \)

Names of columns in the fixed-effects design matrix \( X \), specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a string array or cell array of length \( p \).

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

Example: `'FixedEffectPredictors',{'Intercept','TimeSpent','Gender_Male'}`,

Data Types: `string` | `cell`
RandomEffectPredictors — Names of columns in random-effects design matrix or cell array
string array or cell array of length q | cell array of length R with elements of length q(r), r = 1, 2, ..., R

Names of columns in the random-effects design matrix or cell array Z, specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A string array or cell array of length q when Z is an n-by-q design matrix. In this case, the default is {'z1', 'z2', ..., 'zQ'}.
- A cell array of length R, when Z is a cell array of length R with each element Z{r} of length q(r), r = 1, 2, ..., R. In this case, the default is {'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}.

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors', {'Intercept', 'Acceleration'}

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable g1, and the second for the intercept, grouped by the variable g2, then you specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors', {{'Intercept', 'Acceleration'}, {'Intercept'}}

Data Types: string | cell

ResponseVarName — Name of response variable
'y' (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a character vector or string scalar.

For example, if your response variable name is score, then you can specify it as follows.

Example: 'ResponseVarName', 'score'

Data Types: char | string

RandomEffectGroups — Names of random effects grouping variables
'g' or {'g1', 'g2', ..., 'gR'} (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is the name for the grouping variable G. The default is 'g'.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if G is a cell array of length R, then the value of 'RandomEffectGroups' is a string array or cell array of length R, where each element is the name for the grouping variable G{r}. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, z1 and z2, grouped by the grouping variables sex and subject, then you can specify the names of your grouping variables as follows.
Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | string | cell

**CovariancePattern — Pattern of covariance matrix**

'CovariancePattern' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are \( R \) random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length \( R \), where each element \( r \) of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the \( r \)th random-effects term. The options for each element follow.

-'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

-'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

-'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

\[
\begin{pmatrix}
\sigma^2_{b1} & 0 & 0 \\
0 & \sigma^2_{b2} & 0 \\
0 & 0 & \sigma^2_{b3}
\end{pmatrix}
\]

-'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_{b} & 0 & 0 \\
0 & \sigma^2_{b} & 0 \\
0 & 0 & \sigma^2_{b}
\end{pmatrix}
\]

where \( \sigma^2_{b} \) is the common variance of the random-effects terms.
'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

\[
\begin{pmatrix}
\sigma^2_{b1} & \sigma_{b1,b2} & \sigma_{b1,b3} \\
\sigma_{b1,b2} & \sigma^2_{b1} & \sigma_{b1,b3} \\
\sigma_{b1,b3} & \sigma_{b1,b3} & \sigma^2_{b1}
\end{pmatrix}
\]

where \( \sigma^2_{b1} \) is the common variance of the random-effects terms and \( \sigma_{b1,b2} \) is the common covariance between any two random-effects term.

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if \( \text{PAT}(a,b) = \text{false} \), then the \((a,b)\) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern','Diagonal'
Example: 'CovariancePattern',{"Full','Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'
Default. Maximum likelihood estimation
'REML'
Restricted maximum likelihood estimation

Example: 'FitMethod','REML'

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length \( n \), where \( n \) is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.
Example: ‘Exclude’, [13, 67]
Data Types: single | double | logical

**DummyVarCoding — Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'reference'</td>
<td>Default. Coefficient for first category set to 0.</td>
</tr>
<tr>
<td>'effects'</td>
<td>Coefficients sum to 0.</td>
</tr>
<tr>
<td>'full'</td>
<td>One dummy variable for each category.</td>
</tr>
</tbody>
</table>

Example: 'DummyVarCoding', 'effects'

**Optimizer — Optimization algorithm**

'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

- 'quasinewton'  
  Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using statset('LinearMixedModel'). If you don't specify the options, then LinearMixedModel uses the default options of statset('LinearMixedModel').

- 'fminunc'  
  You must have Optimization Toolbox to specify this option. Change the options of the algorithm using optimoptions('fminunc'). If you don't specify the options, then LinearMixedModel uses the default options of optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

**OptimizerOptions — Options for optimization algorithm**

structure returned by statset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by statset('LinearMixedModel') or an object returned by optimoptions('fminunc').

- If 'Optimizer' is 'fminunc', then use optimoptions('fminunc') to change the options of the optimization algorithm. See optimoptions for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for LinearMixedModel is the default options created by optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.
If 'Optimizer' is 'quasinewton', then use statset('LinearMixedModel') to change the optimization parameters. If you don’t change the optimization parameters, then LinearMixedModel uses the default options created by statset('LinearMixedModel').

The 'quasinewton' optimizer uses the following fields in the structure created by statset('LinearMixedModel').

**TolFun — Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**TolX — Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**MaxIter — Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**Display — Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**StartMethod — Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'default'</td>
<td>An internally defined default value</td>
</tr>
<tr>
<td>'random'</td>
<td>A random initial value</td>
</tr>
</tbody>
</table>

Example: 'StartMethod','random'

**Verbose — Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose',true

**CheckHessian — Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.
Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

**Output Arguments**

lme — Linear mixed-effects model
LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

**Examples**

No Grouping Variable Specified

Load the sample data.

```matlab
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```matlab
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =
Linear mixed-effects model fit by ML

Longitudinal Study with Covariate

Load the sample data.
weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define Subject and Program as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

\[ y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i + \beta_6 (Week_i \cdot I[PB]_i) + \beta_7 (Week_i \cdot I[PC]_i) + \beta_8 (Week_i \cdot I[PD]_i) + b_{0m} + b_{1m} Week_{im} + \epsilon_{im}, \]

where \( i = 1, 2, \ldots, 120, \) and \( m = 1, 2, \ldots, 20. \) \( \beta_j \) are the fixed-effects coefficients, \( j = 0, 1, \ldots, 8, \) and \( b_{0m} \) and \( b_{1m} \) are random effects. IW stands for initial weight and \( I[\cdot] \) is a dummy variable representing a type of program. For example, \( I[PB]_i \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[ b_{0m} \sim N(0, \sigma_0^2) \]
\[ b_{1m} \sim N(0, \sigma_1^2) \]
\[ \epsilon_{im} \sim N(0, \sigma^2). \]

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...
    D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using LinearMixedModel.fitmatrix with the defined design matrices and grouping variables.

lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...{
    'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD'},...
    'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})

lme =

The p-values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.
### Random-Intercept Model

Load the sample data.

```matlab
tload flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```matlab
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

\[
y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52,
\]

where \(y_{im}\) is the observation \(i\) for level \(m\) of grouping variable `Date`, \(b_{0m}\) is the random effect for level \(m\) of the grouping variable `Date`, and \(\epsilon_{im}\) is the observation error for observation \(i\). The random effect has the prior distribution,

\[
b_{0m} \sim N(0, \sigma_b^2),
\]

and the error term has the distribution,

\[
\epsilon_{im} \sim N(0, \sigma^2).
\]

```matlab
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;

Fit the linear mixed-effects model.

```matlab
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},
    'RandomEffectPredictors',{{'Intercept'}},'RandomEffectGroups',{'Date'});

{'Res Std'}        0.30201     0.28217    0.32324

The confidence limits of the standard deviation of the random-effects term $\sigma_0$ do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\hat{y}_{28} = \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{\beta}_{10/30/2005}$$

$$= 0.1639 + 0.7236 \times (1.343) + 0.3318$$

$$= 1.46749,$$

where $\hat{\beta}$ is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[-,-,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat = 1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
ans = 1.4674
```
**Randomized-Block Design**

Load the sample data.

```matlab
load('shift.mat');
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the ‘effects’ contrasts. ‘effects’ contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, $X_1$ and $X_2$, where

\[
\text{Shift}_\text{Evening} = \begin{cases} 
0, & \text{if Morning} \\
1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

\[
\text{Shift}_\text{Morning} = \begin{cases} 
\text{ones}(15,1), & \text{if Morning} \\
\text{arrayll}1, & \text{if Evening} \\
-1, & \text{if Night}
\end{cases}
\]

The model corresponds to

- Morning Shift: $\text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + \epsilon_{im}$
- Evening Shift: $\text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift}_\text{Evening}_i + b_{0m} + \epsilon_{im}$
- Night Shift: $\text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift}_\text{Evening}_i - \beta_2 \text{Shift}_\text{Morning}_i + b_{0m} + \epsilon_{im}$

where $i$ represents the observations, and $m$ represents the operators, $i = 1, 2, ..., 15$, and $m = 1, 2, ..., 5$. The random effects and the observation error have the following distributions:

- $b_{0m} \sim N(0, \sigma^2_B)$
- $\epsilon_{im} \sim N(0, \sigma^2)$

```matlab
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...%

B = 5x1

   0.5775
   1.1757
  -2.1715
   2.3655
  -1.9472
The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

\[ \hat{y}_{\text{Evening, Operator3}} = \hat{\beta}_0 + \hat{\beta}_1 \text{Shift}_\text{Evening} + \hat{b}_{03} \]

\[ = 3.6525 - 0.53293 - 2.1715 \]

\[ = 0.94807. \]

You can also display this value in the following way.

\[ F = \text{fitted(lme)}; \]
\[ F(\text{shift.Shift=='Evening' & shift.Operator=='3'}) \]
\[ \text{ans} = 0.9481 \]

**Correlated and Uncorrelated Random-Effects Terms**

Load the sample data.

\[ \text{load carbig} \]

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

\[ \text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \epsilon_{im}, \quad m = 1, 2, 3, \]

with the random-effects terms having the following prior distributions:

\[ b_{0m} \sim N(0, \sigma_0^2), \]
\[ b_{1m} \sim N(0, \sigma_1^2), \]

where \( m \) represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

\[ X = \{\text{ones}(406,1) \, \text{Acceleration}, \text{Horsepower}\}; \]
\[ Z = \{\text{ones}(406,1), \text{Acceleration}\}; \]
\[ G = \{\text{Model}_\text{Year}, \text{Model}_\text{Year}\}; \]
\[ \text{Model}_\text{Year} = \text{nominal(\text{Model}_\text{Year})}; \]

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

\[ \text{lme} = \text{LinearMixedModel.fitmatrix}(X, \text{MPG}, Z, G, 'FixedEffectPredictors', \ldots \]
\[ \{\text{'Intercept'}, \text{'Acceleration'}, \text{'Horsepower'}\}, \text{'RandomEffectPredictors'}, \ldots \]
\[ \{\{\text{'Intercept'}\},\{\text{'Acceleration'}\}\}, \text{'RandomEffectGroups'}, \{\text{'Model}_\text{Year'}, \text{'Model}_\text{Year'}\} \]

\[ \text{lme} = \]
\[ \text{Linear mixed-effects model fit by ML} \]

</table>

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

\[ b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right) \]

where \( m \) represents the model year.

First prepare the random-effects design matrix and grouping variable.
Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',....

{'Res Std'}        3.6874      3.4298    3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the compare method.
Specify the Covariance Pattern

Load the sample data.

```matlab
load('weight.mat');
```

*weight* contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define *Subject* and *Program* as categorical variables.

```matlab
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```matlab
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

\[ y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 [PB]_i + \beta_4 [PC]_i + \beta_5 [PD]_i + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \epsilon_{im}, \]

where \( i = 1, 2, \ldots, 120, \) and \( m = 1, 2, \ldots, 20. \)

\( \beta \) are the fixed-effects coefficients, \( j = 0, 1, \ldots, 8, \) and \( b_{0m} \) and \( b_{1m} \) are random effects. \( IW \) stands for initial weight and \( I[\cdot] \) is a dummy variable representing a type of program. For example, \( I[PB]_i \) is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

\[ b_{0m} \sim N(0, \sigma_0^2) \]
\[ b_{1m} \sim N(0, \sigma_1^2) \]
\[ \epsilon_{im} \sim N(0, \sigma^2). \]

Fit the model using *LinearMixedModel.fitmatrix* with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```matlab
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...  {'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...  'RandomEffectPredictors',{{'Intercept','Week'}},...  'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

`lme = Linear mixed-effects model fit by ML`
Model information:
Number of observations             120
Fixed effects coefficients           6

More About

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

\[ b \sim N(0, \sigma^2 D(\theta)), \]

where \( D \) is a \( q \)-by-\( q \) symmetric and positive semidefinite matrix, parameterized by a variance component vector \( \theta \), \( q \) is the number of variables in the random-effects term, and \( \sigma^2 \) is the
observation error variance. Since the covariance matrix of the random effects, $D$, is symmetric, it has $q(q+1)/2$ free parameters. Suppose $L$ is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q(q+1)/2$-by-1 unconstrained parameter vector $\theta$ is formed from elements in the lower triangular part of $L$.

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

**Log-Cholesky Parameterization**

When the diagonal elements of $L$ in Cholesky parameterization are constrained to be positive, then the solution for $L$ is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of $L$ are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

**Tips**

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using fitlmematrix.

**Alternatives**

You can also fit a linear mixed-effects model using fitlme(tbl,formula), where tbl is a table or dataset array containing the response $y$, the predictor variables $X$, and the grouping variables, and formula is of the form `$y \sim \text{fixed} + (\text{random}_1|g_1) + ... + (\text{random}_R|g_R)$`. 
If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G).

LinearMixedModel | fitlme
**fitPosterior**

Fit posterior probabilities for support vector machine (SVM) classifier

**Syntax**

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

**Description**

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 32-2065.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or the holdout sample proportion.

**Examples**

**Estimate In-Sample Posterior Probabilities of SVM Classifiers**

Load the ionosphere data set.

```matlab
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```matlab
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Fit the optimal score-to-posterior-probability transformation function.

```matlab
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

`ScoreSVMModel` is a `ClassificationSVM` with the following properties:

- `ResponseName`: 'Y'
- `CategoricalPredictors`: []
- `ClassNames`: {'b' 'g'}
- `ScoreTransform`: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
- `NumObservations`: 351
- `Alpha`: [90x1 double]
- `Bias`: -0.1343
- `KernelParameters`: [1x1 struct]
Because the classes are inseparable, the score transformation function (ScoreSVMModel.ScoreTransform) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

[label, scores] = resubPredict(SVMModel);
[-, postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10), label(1:10), scores(1:10, 2), postProbs(1:10, 2), 'VariableNames',
{ 'TrueLabel', 'PredictedLabel', 'Score', 'PosteriorProbability'})

Plot Posterior Probability Contours for Multiple Classes

Train a multiclass SVM classifier through the process of one-versus-all (OVA) classification, and then plot probability contours for each class. To implement OVA directly, see fitcecoc.

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data.

load fisheriris
X = meas(:,3:4);
Y = species;

Examine a scatter plot of the data.

figure
gscatter(X(:,1),X(:,2),Y);
title('\textbf{Scatter Diagram of Iris Measurements}');
xlabel('Petal length');
Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. Define the class order.

```matlab
classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j});  % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...
                         'Standardize',true,'KernelFunction','rbf','KernelScale','auto');
end
```

`fitcsvm` uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```matlab
for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end
```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

\[
d = 0.02; \\
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),... \\
\quad min(X(:,2)):d:max(X(:,2))); \\
xGrid = [x1Grid(:),x2Grid(:)];
\]

\[
\text{posterior} = \text{cell}(3,1); \\
\text{for } j = 1: \text{numClasses} \\
\quad [-,\text{posterior}_j] = \text{predict(SVMModel}_j,xGrid); \\
\text{end}
\]

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

\[
\text{figure} \\
\text{h} = \text{zeros(}\text{numClasses} + 1,1); % \text{Preallocation for graphics handles} \\
\text{for } j = 1: \text{numClasses} \\
\quad \text{subplot(}2,2,j\text{)} \\
\quad \text{contourf(x1Grid,x2Grid,}\text{reshape(posterior}_j(:,2),\text{size(x1Grid,1)},\text{size(x1Grid,2))}); \\
\quad \text{hold on} \\
\quad \text{h(1:} \text{numClasses}) = \text{gscatter(X(:,1),X(:,2),Y);} \\
\quad \text{title(}'\text{Posteriors for %s Class}',\text{classNames}_j\text{);} \\
\quad \text{xlabel('Petal length')} \\
\quad \text{ylabel('Petal width')} \\
\quad \text{legend off} \\
\quad \text{axis tight} \\
\quad \text{hold off} \\
\text{end} \\
\text{h(}\text{numClasses} + 1\text{)} = \text{colorbar(}'\text{Location}',\text{'EastOutside'},... \\
\quad '\text{Position}',[0.8,0.1,0.05,0.4])); \\
\text{set(get(h(}\text{numClasses} + 1\text{)},'YLabel'),'String','Posterior','FontSize',16);} \\
\text{legend(h(1:} \text{numClasses}),'Location',[0.6,0.2,0.1,0.1]);
\]
Fit Optimal Posterior Probability Function Using Holdout Cross-Validation

Estimate the score-to-posterior-probability transformation function after training an SVM classifier. Use cross-validation during the estimation to reduce bias, and compare the run times for 10-fold cross-validation and holdout cross-validation.

Load the ionosphere data set.

load ionosphere

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);

SVMModel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function. Compare the run times from using 10-fold cross-validation (the default) and a 10% holdout test sample.

rng(1); % For reproducibility
tic; % Start the stopwatch
SVMModel_10FCV = fitPosterior(SVMModel);
toc % Stop the stopwatch and display the run time

Elapsed time is 0.935877 seconds.
tic;
SVMModel_HO = fitPosterior(SVMModel,'Holdout',0.10);
toc

Elapsed time is 0.286915 seconds.

Although both run times are short because the data set is relatively small, SVMModel_HO fits the score transformation function much faster than SVMModel_10FCV. You can specify holdout cross-validation (instead of the default 10-fold cross validation) to reduce run time for larger data sets.

**Input Arguments**

**SVMModel** — Full, trained SVM classifier
ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: fitPosterior(SVMModel,'KFold',5) uses five folds in a cross-validated model.

**CVPartition** — Cross-validation partition
[] (default) | cvpartition partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition object as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

The crossval name-value pair argument of fitcsvm splits the data into subsets using cvpartition.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using cvp = cvpartition(500,'KFold',5). Then, you can specify the cross-validated model by using 'CVPartition',cvp.

**Holdout** — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout',0.1

Data Types: double | single

**KFold** — Number of folds
10 (default) | positive integer value greater than 1
Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold',8

Data Types: single | double

**Leaveout — Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'Leaveout','on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout','on'

### Output Arguments

**ScoreSVMModel — Trained SVM classifier**

ClassificationSVM classifier

Trained SVM classifier, returned as a ClassificationSVM classifier. The trained classifier contains the estimated score-to-posterior-probability transformation function.

To estimate posterior probabilities for the training set observations, pass ScoreSVMModel to resubPredict.

To estimate posterior probabilities for new observations, pass the new observations and ScoreSVMModel to predict.

**ScoreTransform — Optimal score-to-posterior-probability transformation function parameters**

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the Type field of ScoreTransform is sigmoid, then ScoreTransform also has these fields:
  - **Slope**: The value of A in the sigmoid function on page 32-2073
  - **Intercept**: The value of B in the sigmoid function

- If the value of the Type field of ScoreTransform is step, then ScoreTransform also has these fields:
  - **PositiveClassProbability**: The value of \( \pi \) in the step function on page 32-2073. This value represents the probability that an observation is in the positive class or the posterior
probability that an observation is in the positive class given that its score is in the interval 
\((\text{LowerBound}, \text{UpperBound})\).

- **LowerBound**: The value \(\max_{y \eta = -1} s_k\) in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class \(\text{PositiveClassProbability}\). Any observation with a score less than \(\text{LowerBound}\) has the posterior probability of being in the positive class equal to 0.

- **UpperBound**: The value \(\min_{y \eta = +1} s_k\) in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class \(\text{PositiveClassProbability}\). Any observation with a score greater than \(\text{UpperBound}\) has the posterior probability of being in the positive class equal to 1.

- If the value of the Type field of \text{ScoreTransform} is **constant**, then \text{ScoreTransform.PredictedClass} contains the name of the class prediction.

This result is the same as \text{SVMModel.ClassNames}. The posterior probability of an observation being in \text{ScoreTransform.PredictedClass} is always 1.

**More About**

**Sigmoid Function**

The sigmoid function that maps score \(s_j\) corresponding to observation \(j\) to the positive class posterior probability is

\[
P(s_j) = \frac{1}{1 + \exp(A s_j + B)}.
\]

If the value of the Type field of \text{ScoreTransform} is **sigmoid**, then parameters \(A\) and \(B\) correspond to the fields \text{Scale} and \text{Intercept} of \text{ScoreTransform}, respectively.

**Step Function**

The step function that maps score \(s_j\) corresponding to observation \(j\) to the positive class posterior probability is

\[
P(s_j) = \begin{cases} 
0; & s < \max_{y \eta = -1} s_k \\
\pi; & \max_{y \eta = -1} s_k \leq s_j \leq \min_{y \eta = +1} s_k, \\
1; & s_j > \min_{y \eta = +1} s_k
\end{cases}
\]

where:

- \(s_j\) is the score of observation \(j\).
- +1 and -1 denote the positive and negative classes, respectively.
- \(\pi\) is the prior probability that an observation is in the positive class.
If the value of the Type field of ScoreTransform is step, then the quantities \( \max_{y_k = -1} s_k \) and \( \min_{y_k = +1} s_k \) correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

- This process describes one way to predict positive class posterior probabilities.

1. Train an SVM classifier by passing the data to fitcsvm. The result is a trained SVM classifier, such as SVMModel, that stores the data. The software sets the score transformation function property (SVMModel.ScoreTransformation) to none.

2. Pass the trained SVM classifier SVMModel to fitSVMPosterior or fitPosterior. The result, such as, ScoreSVMMModel, is the same trained SVM classifier as SVMModel, except the software sets ScoreSVMMModel.ScoreTransformation to the optimal score transformation function.

3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (ScoreSVMMModel) to predict. The second column in the second output argument of predict stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

   If you skip step 2, then predict returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

**Algorithms**

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier SVMModel and by conducting 10-fold cross-validation using the stored predictor data (SVMModel.X) and the class labels (SVMModel.Y), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (SVMModel.Classnames(2)).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2073.
- If the classes are perfectly separable, then the transformation function is the step function on page 32-2073.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2195. The fitPosterior function is not appropriate for one-class learning.
• The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

• Displays a warning
• Resets the original transformation function to 'none' before estimating the new one

**Alternative Functionality**

You can also fit the posterior probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

fitPosterior

Package: classreg.learning.classif

Fit posterior probabilities for compact support vector machine (SVM) classifier

Syntax

ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior(____)

Description

ScoreSVMModel = fitPosterior(SVMModel,TBL,Y) returns a trained support vector machine (SVM) classifier ScoreSVMModel containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 32-2074. If you train SVMModel using a table, then you must use a table as input for fitPosterior.

ScoreSVMModel = fitPosterior(SVMModel,X,Y) returns a trained SVM classifier ScoreSVMModel containing the optimal score-to-posterior-probability transformation function for two-class learning. If you train SVMModel using a matrix, then you must use a matrix as input for fitPosterior.

[ScoreSVMModel,ScoreTransform] = fitPosterior(____) additionally returns the optimal score-to-posterior-probability transformation function parameters (ScoreTransform) for any of the input argument combinations in the previous syntaxes.

Examples

Estimate Posterior Probabilities for Data with Inseparable Classes

Load the ionosphere data set. Reserve 20 random observations of the data, and consider this set new data.

load ionosphere
n = size(X,1);
rng(1); % For reproducibility
indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
The classes of this data set are inseparable.

Train an SVM classifier using the training data. Standardize the data and specify that 'g' is the positive class.

SVMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
                    'Standardize',true);

SVMModel is a ClassificationSVM classifier.
Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as \( g \). For efficiency, make a compact version of SVMModel, and pass it and the new data to fitPosterior.

```matlab
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));

ScoreTransform = ScoreCSVMModel.ScoreTransform
ScoreParameters

ScoreTransform = @(S)sigmoid(S,-1.098922e+00,4.519963e-01)

ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -1.0989
    Intercept: 0.4520
```

ScoreTransform is the optimal score transformation function. ScoreParameters is a structure array with three fields: the score transformation function name (Type), the sigmoid slope (Slope), and the sigmoid intercept estimates (Intercept).

Alternatively, you can pass SVMModel and the new data to fitSVMPosterior, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are in class \( g \).

```matlab
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=20×3 table
    TrueLabel    PredictedLabel    PosteriorProbability
    _______    ______________    ____________________
    {'g'}          {'g'}                 0.78437
    {'b'}          {'b'}                0.024588
    {'g'}          {'g'}                 0.82399
    {'b'}          {'b'}              3.6118e-06
    {'b'}          {'b'}               0.15688
    {'b'}          {'g'}                  0.9622
    {'b'}          {'b'}               6.1348e-09
    {'b'}          {'b'}              0.0019646
    {'g'}          {'g'}                 0.7251
    {'g'}          {'g'}                 0.70263
    {'b'}          {'b'}              0.075298
    {'g'}          {'g'}                 0.90691
    {'g'}          {'g'}                 0.82849
    {'b'}          {'b'}              0.051193
    {'g'}          {'g'}                 0.95331
```
Estimate Posterior Probabilities for Data with Separable Classes

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1);  % For reproducibility
indx1 = 1:numel(species);
indx2 = indx1(classKeep);
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data

gscatter(X(indx,1),X(indx,2),Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. Standardize the data and specify that versicolor is the positive class.
SVMMModel = fitcsvm(X(indx,:),Y(indx),...
    'ClassNames',{'setosa','versicolor'},'Standardize',true);

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as versicolor. For efficiency, make a compact version SVMMModel, and pass it and the new data to fitPosterior.

CompactSVMMModel = compact(SVMMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...
    X(~indx,:),Y(~indx));

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

ScoreTransform = ScoreCSVMModel.ScoreTransform
ScoreTransform = @(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)

fitPosterior displays a warning whenever the classes are separable, and stores the step function in ScoreCSVMModel.ScoreTransform.

Display the score function type and its estimated values.

ScoreParameters
ScoreParameters = struct with fields:
    Type: 'step'
    LowerBound: -1.3385
    UpperBound: 2.0125
    PositiveClassProbability: 0.5333

ScoreParameters is a structure array with four fields:

• Score transformation function type (Type)
• Score corresponding to the negative class boundary (LowerBound)
• Score corresponding to the positive class boundary (UpperBound)
• Positive class probability (PositiveClassProbability)

Alternatively, you can pass SVMMModel and the new data to fitSVMPosterior, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})

ans=10×3 table
     TrueLabel       PredictedLabel    PosteriorProbability
    ______________    ______________    ____________________
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
Because the classes are separable, the step function transforms the positive-class score to:

- 0 if the score is less than `ScoreParameters.LowerBound`
- 1 if the score is greater than `ScoreParameters.UpperBound`
- `ScoreParameters.PositiveClassProbability` if the score is in the interval `[ScoreParameters.LowerBound, ScoreParameters.LowerBound]`

**Input Arguments**

**SVMModel** — Trained, compact SVM classifier
CompactClassificationSVM classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM` model returned by `compact`.

**TBL** — Sample data
`table`

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. `TBL` must contain all of the predictors used to train `SVMModel`. Optionally, `TBL` can contain an additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `Y`. If `TBL` does not include the response variable, then the length of `Y` must be equal to the number of rows in `TBL`.

If the sample data used to train `SVMModel` is a `table`, then you must specify the input data for `fitPosterior` as a `table`.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software fits the transformation function parameter estimates using standardized data.

**X** — Predictor data
`matrix`

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).
The length of \(Y\) and the number of rows in \(X\) must be equal.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software fits the transformation function parameter estimates using standardized data.

Data Types: double | single

**Y — Class labels**
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If \(Y\) is a character array, then each element must correspond to one class label.

The length of \(Y\) and the number of rows in \(X\) must be equal.

Data Types: categorical | char | string | logical | single | double | cell

**Output Arguments**

**ScoreSVMModel — Trained, compact SVM classifier**
CompactClassificationSVM classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a CompactClassificationSVM classifier.

To estimate posterior probabilities for new observations, pass ScoreSVMModel and the new observations to predict.

**ScoreTransform — Optimal score-to-posterior-probability transformation function parameters**
structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the Type field of ScoreTransform is sigmoid, then ScoreTransform also has these fields:
  - **Slope**: The value of \(A\) in the sigmoid function on page 32-2073
  - **Intercept**: The value of \(B\) in the sigmoid function
- If the value of the Type field of ScoreTransform is step, then ScoreTransform also has these fields:
  - **PositiveClassProbability**: The value of \(\pi\) in the step function on page 32-2073. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval \((\text{LowerBound}, \text{UpperBound})\).
  - **LowerBound**: The value \(\max_{y_n = -1} s_n\) in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class **PositiveClassProbability**. Any observation with...
a score less than LowerBound has the posterior probability of being in the positive class equal to 0.

- **UpperBound**: The value $\min_{y_i = +1} s_i$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class $\text{PositiveClassProbability}$. Any observation with a score greater than UpperBound has the posterior probability of being in the positive class equal to 1.

- If the value of the Type field of ScoreTransform is constant, then ScoreTransform.PredictedClass contains the name of the class prediction.

This result is the same as SVMModel.ClassNames. The posterior probability of an observation being in ScoreTransform.PredictedClass is always 1.

**More About**

**Sigmoid Function**

The sigmoid function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$  

If the value of the Type field of ScoreTransform is sigmoid, then parameters $A$ and $B$ correspond to the fields Scale and Intercept of ScoreTransform, respectively.

**Step Function**

The step function that maps score $s_j$ corresponding to observation $j$ to the positive class posterior probability is

$$P(s_j) = \begin{cases} 
0; & s < \max_{y_k = -1} s_k \\
\pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k \\
1; & s_j > \min_{y_k = +1} s_k 
\end{cases}$$

where:

- $s_j$ is the score of observation $j$.
- $+1$ and $-1$ denote the positive and negative classes, respectively.
- $\pi$ is the prior probability that an observation is in the positive class.

If the value of the Type field of ScoreTransform is step, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields LowerBound and UpperBound of ScoreTransform, respectively.

**Constant Function**

The constant function maps all scores in a sample to posterior probabilities 1 or 0.
If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

**Tips**

- This process describes one way to predict positive class posterior probabilities.

1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.

2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

   If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.
